Distilled water has no buffering capacity. Even a tiny bit of some acidic or alkaline material in distilled water will change its pH significantly--including contaminants that might be present on the pH meter. Typically, a probe rinsed in tap water will read well above 7 when placed in distilled water--because of the alkalinity of the tap water.

-) 2) can I expect this thing to be reasonably
-) calibrated just out of the box? Or should I just
-) check to make sure?

Don't trust it. No way. It could be +/- .5 units, or more.

-) 3) Finally is there anything I should look out for?

Cool the samples to <100F before making your measurements. Ideally to <80F. This isn't for the probe's sake, but for the sake of accuracy. The pH changes with temperature.

Subject: DME vs. liquid malt extract

Is there any reason for not using DME only in an extract brew? Is there something in the liquid malt extract that DME has not? As my only source of extract (till I turn grain...) is from abroad I figured DME would give me more extract per kilo (which counts if you have to use over-seas air-mail). So, is my beer going to miss anything?

I just brewed a batch of his "Bruce and Kay's Black Honey Spruce Lager" last month. Fortunately, the owner of my local brewing supplying shop warned me that he had tried to make this several times and recommended that I use only a quarter of the spruce essence that Charlie Papazian states in his recipe. The result was a spruce lager with just the right amount of "spruce-iness" to it. If the store proprietor hadn't warned me I would have ended up with two cases of Pine Sol instead.

From: Andy Kurtz <ak35+@andrew.cmu.edu>
Subject: "candi" sugar

In "Belgian Ale" Rajotte writes:

"Candi sugar is made by the slow crystallization of a highly concentrated hot sugar solution. The sugar solution is cooled in a tank in which cotton strings are hung. The crystals form themselves around the strings. The slower the cooling, the larger the crystals become."

questions:

1. How concentrated is "highly concentrated"?
2. Rajotte says that the taste profile of candi sugar is different from sugar "out of the bag." In what way?
3. This sounds a lot old fashioned "rock candy." Will the results be the same if I try this at home on a micro scale?

Subject: Dark grains at mashout, Freezer

In hbd 1101 Frank Tutzaner referred to references by a local brewmaster and Micah that dark grains should be added at mashout. Forgive me for being a purist, but wasn't the original reason for dark grains, and hence dark beers, pH reduction prior to a good understanding of such matters? Adding dark grains later may add color and sugars, but apart from a slight extra asstringency, what is the problem with conventional mashing getting the benefit of pH reduction? Adding grains late in the mash is a step towards Michelob Dark.

I just purchased a 1950's Jeffrey Dahmer (;-)) chest freezer by International Harvester! They certainly don't make them like they used to. IH may have used the same sheet metal for this that they used for trucks. It has features I have never seen before like a battery powered alarm if the temperature rises and a thermometer in the door - unfortunately it says warm to cold, rather than temperature. This huge heavy beast was moved relatively smoothly and is now in my basement and I do not feel like dragging it back up the stairs! Anyway, now that I have my summer lager I will be very interested in answers to Glenn Raudin's questions in hbd 1101. But I have a few more which refer to lagering. I can probably fit 4 or 5 carboys in the freezer and so can now do long lagering, but what do I do when adding a new beer to the lager? Obviously it would be bad to adjust the temperature upwards from 40 or lower to step down a new addition. I have another small refrigerator that can take a 5 gallon carboy that I use now, and could continue to use for step downs or 32 lagering for those extra special beers. Also, how do people do summer primary fermentations? I wouldn't want to raise the temperature in the freezer even to 48, and because my 7 gallon carboys will not fit in the refrigerator, will I be forced to use a blow off tube and 5 gallon carboys? Any suggestions?

>I think your problem was that you used only 3 tbs of DME. Are you sure
you
>gave the yeast enough to eat?

I guess I have a hard time with measurements like that. For a starter,
you
want 1.020 wort, which roughly translates into 1 oz. for each pint. So
for
1.5 pints you want about 1.5 oz.

3 "heaping" tablespoons might easily be **more** than 1.5 oz. Sometimes I
get more than 1 oz. out of one heaping tablespoon (I weigh for starters)
.
OTOH, 3 "level" tablespoons might easily be **less** than 1 oz.

So, he either put in more DME than needed or less than recommended.

I don't know.

Subject: Re: oat bran in brewing

Has anyone tried using oat bran in an oatmeal stout? As a brewer in the extract/partial mash school, I question the logic of using large quantities of flaked oats as a specialty grain, especially when the starch will obviously not be converted. I would expect the gums and glucans to be concentrated in the bran of the oat -- so why not use just the bran fraction and save the rolled oats for breakfast?

I suppose that I'm assuming here that the major contribution of oats to a stout is the fullness and body provided by the gums.

Can anyone comment on this assumption?
Has anyone tried brewing with oat bran, and with what results?

Subject: pH meter

In HBD 1100 Nick asks:

1) can I just use distilled water to calibrate at
ph7?

No! distilled water is not always at a pH of 7, in fact water will
hardly
ever have a pH of 7. Dissolved gases will cause the pH to vary. Dissolved
carbon dioxide will cause the pH to be around 5.6.

Also I would not trust the calibration on the new instrument. It
probably
is not calibrated at all and the calibration does change with time. Use
a
buffer solution of known pH to calibrate the meter.

Hope this helps.

I use both the temperature controller that William's sells and a Hunter "Air Stat" for different refrigs. The one that William's sells (~\$50) is a very good quality industrial grade unit made by "PENN controls" if I remember right. It is true that it doesn't have a digital display, but who needs one? It would look cool and impress all of your friends, but not really necessary. The Hunter Air Stat I bought at Home Depot for \$19. It does have a digital display for the coolness effect, but has a couple of disadvantages. One is that the user interface was designed for programming room air conditioners to save energy. It is hard to use to just adjust the temp setting and keep it there. The other disadvantage is that it only goes down to 40 or 45 deg F. This is not cold enough for lagering. Its best advantage is price.

As far as refrigs go, I agree that the chest type would be best, although I have not run across one for the right price yet. Most refrigs should not have a lot of trouble getting down to 32 deg F for lagering. I know that none of my three do.

I was under the understanding that the process for malting crystal sort
of
accomplished a pseudo mash. I have never heard how Dextrine/cara-pils is
made. What I do know is that William' Brewing (Bill Moore's company)
sells
Dextrine/cara-pils as something that needs to be mashed, and also sells
L10
light crystal as a non-masher substitute for this. I have used both, but
with otherwise identical brews, so I have no comparison between the two.

Does anybody know how Dextrine/cara-pils is malted? What are the other
opinions and experiences with not mashing it?

Subject: bottle drying rack

With the thread going on about bottle drying racks, I thought I would my \$.02 worth in.

I did not like the idea of something sticking into the neck of my already sanitized bottles, like the commercially available racks do. It seemed that I would have to sanitize the rack also. So, I made my own rack from plastic that I got out of the scrap pile at the local plastics store. It basically looks like a box, about 18"X30"X5" with 60 holes (1.25" I think) drilled in the top. It holds 60 bottles upside down so nothing falls in them, and no part of it goes into the bottle. It sits on the counter top when in use, and is easily stored when not. It can also be moved around with the bottles in it, if one is careful. It is constructed by gluing some 1/4" plastic sheets together, then drilling holes with a hole saw. I don't ASCII graphics are necessary here, unless somebody really wants them.

I suggest using a bigger (I think it's polyester) grain bag. I think
your
process is fine (for extract beers, I suspend the grain bag in cold water
and pull it out when it reaches 170F). Most of the powder when you crush
crystal malt (AND THIS IS IMPORTANT) is the crystalized sugar. Taste it.
It's sweet. The first time I used crystal malt, I shook the grain bag
till the brown powder stopped coming out. I then thought about it (I
had more than an hour to think, you see) and realized that the powder
was probably crystalized sugars. Sure enough, when I tasted it, it was
sweet. Now, if you are pulverizing your grain husks, then part of the
powder will be husk, but the solution is crushing your malt better and
not using a more fine bag. Fix the source of the problem, don't put
a bandaid(tm) on a symptom.

Brian writes:

>experienced growers out there: how far apart your varieties
>are, any problems, speculation on whether I'll get into trouble
>with closer than 6' spacing, etc.

The problem with having the spacing too close is that the hop
plants send runners underground and when they come up, you dont know
which plant they came from. I planted mine 6 feet apart and put
3-foot diameter, rabbit fencing cages around them. This was to keep
the rabbits and the pesky deer away from the young shoots. Any
shoots that come up outside any of the cages, I chop them off with

a vertical chop with a spade. This way, the shoots get cut off at the source, just outside the cage, so they wouldn't eventually creep into the next cage. The fear, in case it's not obvious, is to know what variety you are picking, so you don't dump Chinooks in when you are expecting Saaz. My standard "give each plant 6 gallons of water and as much sun as you can" should also be mentioned.

Frank writes:

This is dependent on your brewing water. In Munich, the dominant style used to be a Dunkel, made with dark grains. This was because the dark grains would acidify the Munich water and dark lagers just came out better than paler ones. If your water is soft, then you may indeed want to only add the dark grains in during mashout.

Jack writes:

> Judging from all the interest in getting that caramel flavor recently

> problem. More importantly, Ken Pachivich at Bader Brau makes an issue of his
> "fire brewed" process to achieve that caramel taste for his award winning
> Pilsner. He brags about how hot the fire must be to achieve caramelization.

Controlled caramelization is quite hard to achieve, especially for us homebrewers. Commercial brewers are better equipped to control the amount of caramelization that occurs. Baderbrau is somewhere between dark blonde and light amber in color, so the caramelization is not very severe. Obviously, Ken has good control over the amount that occurs. For us to add repeatable caramel flavors in our beers, I'd say that crystal malts are our best bet.

With all due respect to you, Jack, and at the risk of bringing an abrupt end to the pleasant demeanor (and humor) you've recently displayed in HBD, I'd like to dispute Ken Pavichevich's claims that Baderbrau is a Pilsener.

We've disagreed on this before and no matter what Ken says or the people who have deemed Baderbrau an award-winning Pilsener say, I contend that it's not a Pilsener. It is too malty in both nose and flavor, slightly fruity and a tiny bit dark to be classified as a pilsener. The caramelly flavor that you say that Ken brags about is out of place in a Pilsener. Pilseners are supposed to be sharply refreshing, their balance should be decidedly towards hops in both flavor and aroma and have a spicy hop nose

(PU uses Saaz). I'd say Baderbrau is a great Munich Helles (albeit at the dark end of the style). I feel it's a great beer, just not a Pilsener.

Subject: Manifold Design and use ??

I have ten feet of 3/8" od soft copper tubing left over from constructing a wort chiller. I have considered using this to construct a slotted copper manifold. Is this diameter adequate? or should I use the Tee and plumbing stock type of pipe.

When using the manifold does one also use a mesh grain bag or does one just add grain to the mash tun with out a screen or mesh bag over the manifold?

Is there any problem using PVC pipe and connectors instead of copper, besides philosophical issues. It is used for hot and cold water plumbing in some new construction so it is able to handle mas/sparge temps.

>Whitbread dry ale yeast. Thanks.

I have had trouble posting (I am not even sure if this will make it, but
...)
but this is what I said at the time:

Well, now that you bring it up, let me ask you a couple of questions,
I just made a couple of batches of cider. They turned out **very** dry,
which is cool, cause that's the way I wanted them. However, they are
a little too dry. I think one of my mistakes was using champagne yeast
(duh!). But other than that, I have a conceptual problem. Let's say
I use ale yeast next time, how do I get a **slightly** (and I do mean
very slightly) sweet AND carbonated cider. Seems like if there is any
residual sugar in there, the yeast will eat it. So you always get a
more carbonated, dry beverage. I know I can add lactose (which
yeast cannot ferment) but that just seems so....."high tech". Any
thing more "natural"?

By the way, my second batch I used apple juice concentrate to boost the
O.G. Don't know if it will work any better, but intuitively one might
think it would contribute more 'apple' flavor. We'll see.

As for your question, you quote an O.G. of 1.054. Did this take into
account the sugar water you added? If not, what was the gravity and
volume (or weight) of sugar water that you did add? Doing a simple-
minded calculation on the figures you give, you (may) have an alcohol
concentration of a little over 8% by volume. This is nearing the
tolerance
of most ale yeast, although I was reading a chart at a homebrew store the
other day that seemed to say that some ale yeast could go up to 12%.

So I guess an answer to your question would depend on how much extra
sugar you treated your yeast to. Although it probably wouldn't hurt
to bottle now. However-- with a whole two batches of cider under my belt
(and the second still in secondary) my advice is probably worth just what
you paid for it. :-)

> Perhaps I am thick but I do not understand this. Which way is up?
```

I probably wasn't too clear on this. The "stem" and arms all lie on the bottom of the pot/cooler, slots face down; then the standpipe comes up the side of the vessel. Here's a side view:

```
      siphon hose ==+
      |<-stand |
      | pipe |<- pot/cooler
      | |
      | arms |
      |/#####|
      |-----|
```

```
>The idea for this one came from McHarry and if you find me pushing a shopping
>cart full of empty cans, you can blame him. He, of course, stole an idea
>from Benjamin but I couldn't understand the latter's drawing so, he beat me
>to it.
```

I wish I could say the standpipe idea is mine, but I stole it from someone else, really. You know what they say... "good artists borrow; great artists steal."

Subject: BOTTLE DRYER

I have seen the plastic bottle drying towers sold in homebrew stores, but I like the one that I built better.

It consists of 2 sheets of 1/2 inch plywood, 15" x 24" separated by six 1 inch dowels, each about 5" long. The top plywood sheet has a 4x6 grid of 2-1/2 inch holes cut into it with a hole saw. The bottom sheet is solid plywood. Below is a side view with a couple of bottles sitting in the holes. This bottle dryer holds 24 bottles, but varying the size of the plywood and holes will change the capacity. You can customize the dimensions to fit your size of bottles. All the wood pieces were painted with several coats of polyurethane prior to assembly to make the entire structure fairly impervious to water damage. As the bottles drain, I prop up one end of the dryer to let any accumulated water run off the bottom sheet of plywood.

I only use 16 oz. Grolsch bottles for my brewing and this handles them nicely even with the ceramic stoppers attached. This drying rack will let the bottles drip-dry upside down and not let any "nasties" fall inside them. It also does not touch the inside of the bottle so there is no need to sterilize the dryer.

After I wash and dry a case of bottles, I just loosely clamp the ceramic stopper in the mouth of the Grolsch bottle to keep out any dust. I store the rubber gaskets separately. When it is time to bottle, I soak a case at a time with a bleach solution, rinse thoroughly and let them drip-dry for a few minutes. The (boiled) gaskets then go on the ceramic stoppers and are lightly closed until each bottle is ready to be filled.

From: ek@chem.UCSD.EDU (Ed Kesicki)
Subject: Recipe: SN Porter Clone

Here is a recipe for a clone of Sierra Nevada Porter. I didn't mean for it to come out that way; in fact, I had never tasted SNP until after I made this one (my 4th all-grain batch).

It is based on Dave Miller's traditional porter recipe:

SIERRA NEVADA PORTER CLONE (5 gal batch):

7 lb2-row pale malt
12 ozBlack patent malt
6 ozBarley flakes
.5 tsp gypsum

Hops: 2 oz Cascades loose hops, 5.5% aa, 60 min boil (= 11 AAU)
0.5 oz English Fuggles plug hops, last 5 min of boil

Yeast: Sierra Nevada Yeast, cultured from two bottles (actually it was the yeast cake from a previous batch)

PROCEDURE:

Mash in: 130 deg. F 9 qts water (San Diego tap water)
Protein rest: 125 deg F 30 min
Mash temp:154-142 deg F 1.5 hr
Mash out: 168 deg F 5 min
Sparge: approx 4-5 gal @ 170 deg F

Total boil time of 1.25 hr, hops additions as noted above, chilled.
Fermented in glass, temp in the low 60's Farenheit, blow-off used.

OG: 50 FG: 17 (but could have gone lower--overcarbonated in bottles)
Total cost: \$1.20 /six pack (not including yeast)

Ed Kesicki

P.S. In an upcoming issue I'll post a recipe for an ale which tastes suspiciously like Bigfoot Ale, but with slightly lower O.G.

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>
Subject: Pub Draught Guinness

I must say that I am surprised at all the enthusiasm for canned Guinness. When I tried it (a 4-pack, shortly after it was introduced) I was totally unimpressed. But, moreover, at a recent CAMRA Ottawa Homebrew Competition, they slipped Pub Draught Guinness into the stout category as a "ringer" in a totally blind tasting, and the judges rated it 12th out of 14 supposedly homebrewed stouts!!

The judge's comments, even before the identities of the brews were announced were (paraphrased): Beautiful head, wonderful nose, no flavour at all. Where's the beef?

Everyone was very amused when this brew was identified as Pub Draught Guinness!!!

Cheers, P.

Subject: Are Zymurgy special issues worth it?

After more than seven years as a homebrewer, i've finally broken down and joined the AHA. The jury is still out on the question of whether it was a wise investment of \$25.

To the point: all of the special issues of Zymurgy from past years can be back ordered, and I'm interested in opinions as to which (if any) are worthwhile for an old dog who's always willing to learn new tricks.

The issues in question:

1985 All-grain 1986 Malt Extract 1987 Troubleshooting
1988 Brewers and their Gadgets 1989 Yeast1990 Hops and Beer
1991 Beer Styles 1992 Gadgets and Equipment

1986 costs \$5 and 1992 costs \$9.5. The others cost \$8.5 and are available as a set for a discount. For the discount to be worth it, one would have to want all 6.

Perhaps replies should be limited to e-mail, but I can't help thinking there are a lot of other HBDers who would be interested in the opinions of those who've read these issues. In particular, sis you learn a lot? Do you still refer to them years later?

Thanks,

Rob (bradley@adx.adelphi.edu)

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: Drs. Balling and Plato

I have two questions about Balling/Plato:

1) Exactly what is the difference between them? Foster (Pale Ale, Porter) says Plato is "a more accurate, revised version of Balling" He also says Balling is calibrated for 17.5C whereas Plato is calibrated for 20C. I presume the 'more accurate revision' is something more than just a temperature adjustment. Was it simply a matter of Dr. Plato (great name!) taking more accurate readings?

It is interesting to note that both triple-scale hydrometers I have owned in my life have had Balling scales, the older, less accurate one. On the other hand, most books (Eckhardt, Foster, Jackson) use Plato, the more accurate one. What gives? Will some entrepreneur out there in HBD-land take up the challenge and produce a Balling/SG hydrometer for us?

2) I understand that the conversion of a degree Plato to 4 points of SG (as in OG 1050 (12.5P)) is only an approximation. A quick look at the Balling scale on my hydrometer shows that $SG \approx 4 \times \text{Balling} - (1 \text{ or } 2)$ in the range of 1030-1060. However $SG 1080 = 20 \text{ Balling}$ and $SG \approx 4 \times \text{Balling} + (1 \text{ or } 2)$ for SGs around 1100. Do I gather that the 1:4 approximation is better when using Plato:SG?

From: G.A.Cooper@qmw.ac.uk (Geoff Cooper)
Subject: OG for starters - a question

Over the time that I have been reading HBD, there have been many articles which have talked about the best gravity of wort to use in a starter. The received wisdom from most postings is that an OG of 1.020 is best, but recent postings have expressed different views.

I recently mentioned the figure of 1.020 to a (knowledgeable) colleague and then realised that I had no hard evidence to support any claims - just HBD hearsay (which I have no doubt is well founded :-)

So what is the best OG for a starter? Is the value different for culturing up from a small amount (say from a slant), from that for growing an existing large colony (say from a packet of dried yeast)? Or, assuming that one might culture from 10ml to 100ml and then to 1lt, should one use the same OG medium for the 2 stages, or might it be better if they were different?

I look forward to your views, but would also appreciate receiving a reference or two that I could follow up - or the results of some experiments that you have carried out.

If I get a lot of info I shall gladly summarise it.

>rate, and I've wondered over the years how much time goes into
>developing each one, and whether he's ever brewed one of them more than
>once (or better yet, more than three times) before publishing them.
>What really struck me was his recipe in the most recent Zymurgy, which
>calls for (not having it in front of me, and whoops, here we go again
>relying on memory) something in the neighborhood of 3.5# of dry malt
>extract and about 3 pounds (maybe a little more) of specialty grains.
>This to produce five gallons of a beer over 1.065. Does anyone else
>think this is unlikely?

Memory can be a dangerous thing.....:-)

I looked at the most recent Papazian recipe for a weizenbock. Actually
the
grain bill is *6* lbs of malted grain (most of it is enzymatic) and 3.5
lb of
dry malt. For a five gallon batch Charlie suggests an OG of ~1.064,
which may
be a little high, though it is reasonable if your sparging efficiency is
good
and you are able to get ~30 points/lb/gallon.

Subject: big brewers brewing ales?

Joe Mulligan recalls a friend of his being on a tasting panel for a "bass-like" product from Miller Brewing. I recently saw a news blurb announcing Miller Special Reserve Amber Ale, and its description fits Joe's. Miller appears to be using the Special Reserve name for specialty or super-premium beers, as it has already brought to market Miller Special Reserve 100% Barley Beer, a blond, all-malt beer. I have not tasted the Amber Ale, and am wondering: is it amber? is it an ale? is it hopped above the taste threshold? In launching the beer, Miller could be responding to Bass and Sam Adams. A spokesperson for Miller said that they believe there is money to be made selling ales, although it is a relatively small market for them and would account for 1% of their sales. It also appears that Heileman's, or someone contracting with them at La Crosse, is brewing Windy City Ale, and Pabst, or someone contracting with them, is brewing Old Tankard.

>At least 30 min steam treatment at 1 bar over pressure after the
equipment
>has heated to 100C is necessary to achieve sterilisation of a
>cleaned piece of equipment."

Yes, for *sterilization*. *Sanitization*, which is sufficient for most
of
homebrewing, is much less rigorous, and more easily achieved. Steam and
boiling water seem to be very good sanitizers.

For anyone interested, I found both Turbinado sugar and Sucanat at the
Granite State Natural Foods store in Concord, NH. The Sucanat was about
\$2.75(!)/lb., the Turbinado was \$1.35/lb. GSNF also has a decent
selection
of homebrew supplies. Most prices are good, but some things (throughout
the
store) are very high. Pay attention, or pay through the nose.

Re. my Chimay clone that had bleach water backwashed up the blow-off
tube:

Well it's fine. No indication of chlorine-induced problems. It's
phenolic,
but no more than would be expected with Chimay yeast. My guess is that
the
amount of chlorine that actually got in was less than what would have
been
there anyway if I didn't boil all the water before starting. Morale:
Relax,
Don't worry.....and don't use bleach in the blow-off bucket.

> add the dark grains in during mashout.

As a datapoint, an award-winning porter I made (the one using Hallertau
hops) did not have any roasted grains added until mash-out, and it
definitely was not anything like Michelob Dark! 10-15 minutes at
typical mash-out temp of 170F or so imparts plenty of color and nice
roasty character. (The water here in Fort Collins tends to be fairly
soft.)

> When using the manifold does one also use a mesh grain bag or
> does one just add grain to the mash tun with out a screen or
> mesh bag over the manifold?

You don't need to use anything other than the manifold; just dump the
grain right on top of it. Just make sure you have the slots facing down
against the bottom of the vessel.

> I have ten feet of 3/8" od soft copper tubing left over from
> constructing a wort chiller. I have considered using this
> to construct a slotted copper manifold. Is this diameter
> adequate?

I don't see why not. The only difference is that you'll get a slower
rate of drainage. This may even be an advantage, since with 1/2"
tubing you have to restrict the flow anyway.

> Is there any problem using PVC pipe and connectors instead of
> copper, besides philosophical issues.

Again, I don't see any reason not to. The only thing you might want
to check is the acid resistance of the PVC, since your wort will be
somewhat more acidic than plain water.

Subject: Flaked barley question

This past friday I brewed a stout, which marked the first time I had ever used flaked barley in a beer. It was an all grain recipe, and the mash went well, but the sparge was terribly slow - by far the slowest I've ever had.

Now according to Papazian and Miller, this is caused by some kind of stuff that's in the flaked barley (beta glucans? who can remember all these names for things in beer, anyway). Miller sais that the way to deal with this is with lager malt and a protein rest (the lager malt has more enzymes of the needed kind for protein breakdown). Papazian mentions the problem, offers no solution, and does no protein rest for his all-grain stout recipe, which does include flaked barley. A quick perusal of the stout/porter section of the Cat's Meow reveals about a 50/50 split of protein rest/no protein rest of people who use flaked barley in all-grain brews.

So what do I do to make it all run smoother next time? Nothing - and live with it? Do a protien rest? With or without lager malt?

Any comments are appreciated.

Just when I thought I knew, I bumped into the "er" at the end in my
newly
acquired, SIGNED COPY of FIX and here we have both spelling in the same
article.

>From: korz@iepubj.att.com

>With all due respect to you, Jack, and at the risk of bringing an
abrupt
end to the pleasant demeanor (and humor) you've recently displayed in
HBD, I'd like to dispute Ken Pavichevich's claims that Baderbrau is a
Pilsener.

Tis not my wont to end pleasant things by propounding on that which I
know
nothing about.

I was simply re-stating claims made by the brewer. The claims (also by
the
brewer) that M.Jackson ageed, seemed to offer some weight but after all,
they
are all in it for one reason and the tendency to offer mutual support
seems
to over ride absolute truth.

Frankly, if what you say is true, it reflects more negatively on Jackson
than
it does on the brewer. If Jackson went around telling brewers they made
lousy beer, he would have to get a real job. He feeds his own
popularity by dropping little jewels around at strategic places so
people can
use them for PR purposes.

I've got three feet of 3/8" copper in a 5 gallon cylindrical Gott cooler and it seems to work just fine. I removed the push button tap and replaced it with a drum tap. There is a stopper at the inside of the drum tap and the copper comes out of it and goes straight across the diameter of the cooler and then circles around the circumference. I've got slots every half inch or so, which is probably overkill.

I would try and get uniform coverage so if you are using a larger rectangular cooler you would need more copper. You might also want to go with a branching manifold with a rectangular cooler to get more uniform drainage.

> When using the manifold does one also use a mesh grain bag or
> does one just add grain to the mash tun with out a screen or

A grain bag probably wouldn't hurt but I haven't found it to be necessary.

I would say that if you can use it for drinking water at sparge temperatures then it should be safe for this purpose. The only caveat on using normal food preparation materials in brewing seems to be related to how they perform in an alkaline environment.

> to handle mas/sparge temps.

I just made a PVC slotted drain manifold for about \$10 that works beautifully. One advantage with PVC is that the lengths of pipe and the connectors fit snugly, forming an airtight seal, without gluing. Thus one can disassemble the whole thing and clean it out after use. Also, by removing the washer from inside the 3/4"threaded-1/2"smooth adapter, I was able to use it in place of the nut on my spigot. Thus it easily adapted to my already existing system, making my bucket-full-of-holes obsolete. (Now I use the former "zapap" inner bucket to carry my brewing supplies up and down the stairs). The PVC resists the heat of sparging without any problem. The only difficulty was getting the glue from the price tags off the connectors :)

My manifold is an almost complete square with a diagonal leading up to the spigot (the spigot was just too high to connect directly, but too low for an elbow and a Tee), with projections from the one side into the middle. Slots are facing down. With this setup the sparge cleared after about 2 Litres of recirc., and all but about 1 cup of liquid was drawn off.

Subject: Clinton E-Mail

Those folks who missed the Mar 22 edition of the Washington Post may want to copy down the following presidential e-mail addresses. Apparently, the prez is a big fan of e-mail and is receiving upwards of 700 messages a day (I'm sure he reads every one!).

Perhaps we should put him on the HBD mailing list. One of our local micros (Oxford Brewing Co) was put under contract to make a special "Inaugurale" for the recent festivities, so someone in the administration takes a liking to quality beer (probably Hilary).

Anyway, here's the addresses:

75300.3115@compuserve.com (via CompuServe)
clintonpz@aol.com (via America Online)
clinton-hq@campaign92.org (via MCI Mail)

Have fun, and let's keep those mailboxes full!

From: Kieran O'Connor <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>
Subject: Fridge Capacities

A note in the HBD indicated a brewer who had difficulty getting his fridge down to 32 degrees. This is so because the fridge's internal thermostat has a range only down to about 38-40. To remedy this, remove the internal thermostat, connect the wires, and rely on the outside (William's or Hunter) thermostat.

My fridge originally only went to 40, but with only the external thermostat, I got it to 28. The problem is that the internal one kicks out before it lets the fridge get down to 32.

Does this make sense? I have an article from our club newsletter, and would be glad to mail it to you--send a message with the subject "fridge" and I'll send it to you.

Subject: Underletting Strike

Subject: Underletting Strike Time:12:58 PM Date:3/22/93
The recently turned pro, Micah Millspaw, once spoke about his method of adding the strike water to his grains by underletting (feeding the liquid into the bottom of the grain bed.

I tried this over the past weekend. I have a slotted copper manifold in the bottom of a 48 quart cooler. I just ran the strike water in thru the manifold and let it fill the cooler where the grain was already in place. This was for a 10 gallon batch so there was 21 lbs of grain and the water used was 1qt/lb.

I cannot report that I was required to do less mixing. Micah felt that the method provided for less dry spots in the grain bed. I stirred for my normal 10 minutes before I was satisfied that the grain was completely wet. The temperature of the grain bed did seem to be more uniform and my target temperature was accurate so the transfer of temperature is the same as my regular method.

The greatest advantage to this method was the reduction in grain dust and the ease of combining the two materials. I normally pour the grain in with one arm and stir with the other as the water pours in from my hot liquor tank. By underletting I was able to have more control over pouring the dry grain into the empty cooler and then just opened the valve from the hot tank and added the strike water. All but the top inch of grain was wet prior to my stirring. I expected the grain to float more than it did.

I like it!

Subject: DRY HOPPING

From: roy.rudebusch@travel.com
Subject: dry-hopping vs. hop nose

DH:>that the way to
DH:>retain good hop aroma is to dry hop in a *sealed* secondary, so the
goodies
DH:>aren't lost thru the air lock. Is that safe in plastic/glass?

Hop nose is achieved by boiling pellet hops for two min. and
loose hops for 5 min.

Dry-hopping seems to contribute mostly to palate flavor.

The best way to achieve maximum hop nose would be to utilize a
"hop cage". Run hot wort through these hops on the way to
a counterflow chiller. This would be "distillation" of the volatile hop
compounds.

Here is Pale Ale I just brewed:

11 Gal 1060
14# U.S. 2-row
4# Munich, Ireks
4# CaraVienne
2# Aromatic

30 HBUs Centennial
finished with 1 1/2 oz Centennial loose hops (boiled 5 min.)
Chilled with immersion chiller
W-1028 repitch.

OBTW, I have also discovered that filtering tends to *improve* the hop
flavor and hop nose of a beer. The beer flavors are cleaned up thus
allowing the hop goodness to shine through.

Brew on.

I seem to remember hearing about various tweaks and modifications to
make it better for malt ---

Jack Scmidling:
JS:>Tighten both nuts that hold the thing together first. No matter
JS:>what anyone tells you, these must be tight. Then adjust the large
JS:>wingnut so that something the thickness of a dime will just barely
JS:>pass between the two plates. You must have a gauge on both sides at
JS:>the same time to do this.

Well said! But I would like to elaborate:

First, disassemble and wash with dishsoap.

Remove and do not replace the inner snap ring. The only purpose for this
ring was to prevent from losing the steel ball when it is disassembled!

To remove the snap ring just turn in the adjustment screw till the
ring is pushed out.

Remove the cotter key from the shaft and adjust the plate so it is more
perpendicular to the shaft. The mobile plate needs to run a parallel
course to the fixed plate. The hub may give some options for refitting.
Also the cotter key may need to be replaced.

File the end of shaft so it smooth and flat.

Crush on!

>lagering for those extra special beers. Also, how do people do
>summer primary fermentations? I wouldn't want to raise the temperature
in
>the freezer even to 48, and because my 7 gallon carboys will not fit in
the
>refrigerator, will I be forced to use a blow off tube and 5 gallon
carboys?
>Any suggestions?

One thing I have seen (in a different context, but fairly valid
anyway) is to keep the freezer as cold as you want the coldest of
your
beers to be, and heat the carboys to the temperature you want. You
can
get flexible heating elements that could be wrapped around a carboy,
and these in conjunction with a thermostat and strategically-placed
temperature probe, could keep a carboy of beer at whatever
temperature
you desired.

The only thing I can see wrong with this is that it is apt to be
expensive.

From: gummitch@techbook.com (Jeff Frane)
Subject: Specialty malts

Specialty Malts -- some info (part I)

In the interests of expanding knowledge about malts -- particularly carapils (dextrine) malt, I'm posting some information drawn from a couple of commercial sources. The first is from an article by Roger C. Briess, of the Briess Malting Co., which originally appeared in *Brewers Digest*, October 1986. The focus of the article was the brewing industry's ability to response to the market threat from imported beers by their duplication through "all-American" ingredients.

The second is from material handed out a few years ago at a presentation to microbrewers at Great Western Malting, in Vancouver, Washington. Shortly before, GW had been taken over by Canada Malting Co., which also owns Hugh Baird, one of Britain's largest malt houses. That information is based on British malts and terminology.

=====
Specialty Malts & Applications in Brewing, Roger Briess

"Basically two groups of malt exist from the maltsters' point of view: kiln dried and roaster dried.

"Kilned malts, such as Pale Brewers or Munich types provide only certain characteristics. The endosperm is generally mealy, providing only limited color and limited flavor; however, few unfermentable components. These malts are relatively inexpensive and easy to produce on conventional equipment.

"Roasted malts, with the exception of Black Malt, have almost completely glassy endosperms, providing non-fermentable components which enhance/impart flavor, body, foam retention and beer stability.

[deleted text, mostly justifying high costs of specialty malts]

"Specific Characters

"Munich type malt increases color to a limited degree in beer with a yellow-golden hue. It does not enhance body, foam retention and beer stability.

"It has reduced enzymatic activity and slightly less extract than standard Brewers Malt.

"Carapils(R) (dextrine) malt has an almost completely "glassy" endosperm, no enzymatic activity and somewhat less extract than standard brewers malt. It greatly improves body, foam retention and beer stability without increasing color or changing beer flavor profile, through non-fermentable components. It is an elegant and inexpensive "natural" alternative to alginates.

"Caramel malt also has an almost completely glassy endosperm, similar to

Carapils. It yields various color intensities in the desirable golden-red hues. Standardized products in the 20 degree, 40d, 60d, 80d and 120d Lovibond colors are readily available. Other variations are custom-made upon request, volume permitting.

"The flavor profile varies with degree of roasting intensity, from a mild caramel to a sharp, pronounced caramel. Fermentation will greatly influence the remaining sweetness in the final beer.

[text deleted]

"One series of tests which were confirmed by brewing university researchers indicates that a substitution of 15% Standard Brewers Malt on an "as-is-basis" with Carapils permits an O.G. reduction from 11.5 d Plato to 10.5 d Plato without detection by a seasoned taste panel. Cost savings and increased drinkability are some of the obvious advantages.

"Specialty malts are easy to use and generally do not require changes in commercial brewing procedures, equipment readjustment, etc."

From: gummitch@techbook.com (Jeff Frane)
Subject: Specialty malts (more)

from Hugh Baird

"Special brewing malts are used to impart, strengthen or balance specific properties of the wort or beer such as color, flavor, body, foam formation, protein stability, aroma and anti-oxident power. Most reference books have little to say about colored malts. Many feel the use of colored malts dates back to the 1600s when a serious fire in a malt house produced a substantial volume of charred grain. It was decided that it could be used in the cheaper beer which was favored by London porters and which was dark in color. By 1842, when the Roasted Maltsters Act was introduced to limit the hours of roasting and control temperatures, a wide variety of colored malts were already in use.

"Today's colored malts are now produced in roasting cylinders. They provide direct heating in which hot, dry air passes through the cylinder and indirect heating, where the grain is heated at a constant moisture level providing a "stewing" effect.

"Colored malts consist of two types:

"Those made from green malt, generally referred to as caramel or crystal.

"Those made from dry material, often called roasted or chocolate.

...

"Carastan: This material is manufactured from germinating grain. The green malt is transferred to a roasting cylinder and heated to 65°C for about one hour. At this temperature and moisture, "stewing" occurs. The interior of the grain is, in effect, "mashed." The starch is hydrolysed and the endosperm liquifies. The temperature is then raised to 150°C for varying periods of time, causing the breakdown products to react according to the maillard reactions. When the malt cools, the liquid interior sets to a pale-brown and caramel-like mass. The result is a malt with a pale brown color and caramel-like taste. Colors are 30-37 ASBC. In addition to their effect on beer flavor and color, they increase mouth feel and head formation.

"Light Carastan: Produced in the same manner as carastan malt only due to the lower color requirements, the roasting is prolonged at a lower temperature. Color: 13-17 ASBC. Provides color without introducing as much caramel flavor.

"Caramel (crystal): Again, the manufacturing method is basically the same as carastan, using the same starting material, only using a longer and higher roasting temperature. The flavors are more intense than carastan, but basically have the same characteristics. The higher colored caramels have a slightly "burnt" note. Colors can range from 50-212 ASBC.

"Amber (brown): Normally kilned pale malt is roasted in a cylinder at temperatures of 138-149°C, resulting in a malt that provides a somewhat bitter flavor. Colors are 55-70 ASBC.

"Chocolate and Roasted Malt: This material is manufactured from kilned malt by roasting at temperatures up to 250°C. Care must be taken not to char the grain. Chocolate malt has a color of 450-500 ASBC and roasted malt 500-550 ASBC.

"Roasted Material: Unsteeped barley is roasted at temperatures up to 250°C. It provides color like roasted malt only has a sharper, more acid flavor.

"Munich Malt: Malt is allowed to "stew" at 50°C, then kilned at temperatures less than 100°C. The high concentration of nitrogenous material and reducing sugars produce high color without introducing the carfamel/crystal flavor. Colros range 5-8 ASBC.

"Vienna Malt: A traditional pale malt produced at higher kilning temperatures. It is characterized by high color and reduced enzyme activity. Typically colors are 4-5 ASBC."

((I deduce from the numbers given above that ASBC colors are essentially the same as those given in Lovibond.))

Subject: Tower System: Part 2

Part 2

Some clarification of the previous diagram:

1. The HOT WATER TANK and the MASH/LAUTER TUN are 58 quart ice chests (58 quart Igloo's can be purchased at SAM'S Wholesale Club for under \$20 each).
2. The cooking KETTLE is a converted 16 gallon stainless steel keg (top cut out and pipe fitting welded in place near bottom).
3. The HIGH TEMPERATURE PUMP is a hot water circulator pump (can be ordered out of Grainger's catalog for about \$75).
4. The PROPANE BURNER is about 170,000 BTU (mine is a King Kooker, purchased at SAM'S for \$50).

The system works by placing grains in the MASH/LAUTER TUN while heating water to mash temperatures in the KETTLE. Once the appropriate temperature has been reached, it is pumped into the MASH/LAUTER TUN. This is done for as many temperatures as required for your recipe.

After all mashing water has been used, sparge water is heated in the KETTLE and then pumped to the HOT WATER TANK.

When ready to sparge, the valves are adjusted so that effluent rate out of MASH/LAUTER TUN is equal to the influent rate from the HOT WATER TANK. The upper and lower manifolds are similar: the upper one is used to distribute hot sparge water evenly over the filter bed; the lower one is used to filter the grain from the wort. This system should allow one to adjust sparging time to as fast or slow as one desires. (I think that I'd try to set my sparge to about 2 hours so that I could leave the system alone while I watched another upset in this years NCAA March Madness!)

You sparge directly into the KETTLE, and you can bring the wort to a boil when you have collected 1 to 2 gallons.

QUESTIONS, COMMENTS AND INSIGHTS (FLAMES?) WILL BE MUCH APPRECIATED!

P.S. I have no connection to Owens or his publisher.

Subject: Drama, Excitement, Surveillance !

This isn't directly related to brewing per se, but I thought the readers of this digest might be interested in a little drama that is unfolding at the Chicago Indoor Garden Supply store, 297 N. Barrington Rd, Streamwood, IL 60107.

I stopped in this past Saturday (3-20-93) to pick up some liquid yeast and the owner asked an unusual question, "Would you like to see a surveillance camera?" At first I thought it was a trick question, but he lead me to the door, shoved a pair of binoculars in my hand, and directed my attention to a utility pole directly across the street. Strange. Power transformers don't usually have little windows on the front and high gain antennas on the top.

The owner went on to allege that the Drug Enforcement Agency placed a camera there to see who visits the store. He claimed that they would send chase cars after the patrons to get the license tag and then in some cases show up at their door step demanding to search their home.

The store not only sells the necessary supplies for making beer, but they also sell supplies for growing spices and herbs in your home. It appears that the DEA assumes all customers of the store are growing marijuana. The disturbing part, the owner alleges, is that the DEA does not have a search warrant when they show up that your door.

It's been a couple of days now and no one has shown up at my door, but I can say for a fact that there was a suspicious looking transformer on the utility pole Saturday afternoon. I wonder if they are monitoring Handy Andy, Franks Nursery, K-mart, etc.

I'm sure if you call the store at 708-885-8282 they will be glad to tell you the latest chapter in this unfolding drama.

The local CBS affiliate, WBBM Channel 2, is going to do a news story tonight (Monday). This could be interesting.

From: 70322.2634@COMPUSERVE.COM (Jim Manda)
Subject: Chill Haze

I'm new to homebrewing and have my sixth batch sitting in the primary as I write. Although I've been very happy with my beer, I've been consistently getting chill haze. I brew from extracts (EEK!) and the only adjunct I've used so far is crystal malt. A typical recipe for 3.5 gallons is:

- 3.3 lbs. John Bull Pale liquid malt extract
- 1 lb. 6 oz. Munton & Fison light DME
- 6 oz. English crystal malt 40lv
- 2 oz. Willamette hop pellets (boiling)
- 1/2 oz. Cascade hops (finishing)
- 1/2 tsp. Irish Moss
- 1 pack Wyeast liquid yeast #1084, Irish ale

My method is pretty straightforward. Crush the crystal malt in a ziploc with my John Bull rolling pin, put it in a grain bag, and place in 1.5 gallons of cold water. Bring to 170 degrees and steep for five minutes. Remove the grains. Add the extracts, bring to boil. Add the boiling hops and let it boil for an hour. I've been adding the Irish Moss during the last 15 minutes of the boil. I force chill the wort by placing it in a couple of sanitized 1 gallon containers and bathing it in very cold water. It gets to pitching temperature within 20-25 minutes.

My thinking is that the crystal malt is somehow responsible for the chill haze. I do a primary and secondary fermentation and the warm beer is very clear. I know the chill haze is not supposed to affect the beer's flavor but I would like to get rid of it.

I've looked around for papain, but the health food stores I've checked don't carry a pure version of it. I've checked with several home brew supply houses for polyclar and their question is usually __What's it used for?__

Thanks in advance for any and all advice. I'm a regular HBD reader and find it instructive and very readable.

-Jim

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>
Subject: HomeBrew Store Staked out by Feds

This story was on WBBM-TV, Channel 2, Chicago's CBS station, on this evening's 10 O'Clock News.

Starting a week ago, the Drug Enforcement Administration has been watching Chicago Indoor Garden Supply of Streamwood, IL, from a camera somewhat ineptly camouflaged as an electric transformer on a utility pole across the street. This store does 70% of its business in homebrewing supplies, and has become one of the favorite suppliers to Chicago area homebrewers. Two homebrewers were interviewed by Channel 2 who had been followed home from the store by the Federalies, and had their homes ransacked for drugs. When Ch.2's news truck parked in front of a nearby storefront the DEA has been using as a staging location, an "interesting" scene unfolded with a Ch.2 reporter not getting very many answers from the Feds, who tried in vain to keep their cover. (Note: Ch.2 did obscure their faces as per standard practice when showing undercover agents.) Then a swarm of Streamwood Police Dept. cars came, sirens and lights going, to try to chase away the Ch.2 news crew.

The whole slant of the story was that this was a case of the DEA going too far in "Operation Green Merchant", where they are going after stores in Suburban Chicago which they suspect are supplying marijuana growers with lights, fertilizer, etc. The presumption is that if they follow enough homebrewers and other purchasers of perfectly legal merchandize home from this store, eventually they'll find drugs in somebody's house, and then they can sieze and close the store. Since they have an officer assigned full-time to follow customers of this store home, they figure the odds are in their favor.

Channel 2 Chicago is to be complimented for broadcasting this story, and for emphasizing several times during it that homebrewing is legal. Watch for further developments - WBBM-TV generally does a good job of following up on stories of this sort.

The place where the hops originally came from is called Hallertau.
I think in german the form 'Hallertau-er' signifies a possession
or origin, so 'Hallertauer' would mean 'from (or of) Hallertau'
(This is only from memory, my last german classes are more than
12 years ago)

I think you'll get closer to the real thing with a partial mash. As I don't have any kind of reference around right now, I'd only say that one hour in 165 F should be enough. But then again, sahti can be brewed with or without rye malt, so depending on how much rye taste you want, (partial)mash, steep or leave it out. Well, that wasn't really much of a help, was it? I guess I'll have to find some reference, an old recipe or something... Anyway (as you perhaps know) there are no strict rules about how sahti has to be made, so go on and just do it!

I think both forms are correct. Hallertau is the name of the region where the hops come from. One of the meanings of the "er" ending in German is "coming from", just like in English: New York is a town, a New Yorker is a person from New York.

In German, the "er" needs to be there in the phrase "Hallertauer Hopfen". In English, it is more customary to leave them off: "Hallertau hops". Take your pick.

From: jwilliam@uhasun.hartford.edu (John Williams)
Subject: Proper use of lager yeast

Hi

I have a question about the proper use of lager yeast. I made three batches from one pack of wyeast #1007 by repitching the dregs; first from the primary and then from the secondary. The first batch was a bock and after sitting in the bottle in the basement (<50 deg) for about 6 weeks was well carbonated and good. The second was double dunkel and after 6 weeks had no head or carbonation. I took a couple of bottles upstairs where the temperature is about 68 deg, shook them when I walked by them and they were carbonated in about three days. Two weeks later, now, the ones in the basement are also carbonated. The last batch has been in the bottle for 5 weeks and shows no sign of carbonation.

Here is the question in all this. What is the proper way to treat the bottles? Should I leave them at room temp for a week to condition the beer in the bottle and then move them down to the basement to clear or should I just move them down to the basement and wait six weeks? What I don't understand is that the beer did the primary ferment down in the basement just fine, it finished in under a week, so why doesn't the yeast carbonate the beer in the bottle in the same time? Are the conditions in the bottle that different then in the carboy?

Thanks for your help.

From: boomer@sylsoft.com (Richard Akerboom)
Subject: Catalog address, phone number

About a year ago in the HBD someone mentioned a restaurant supply catalog that was a good source of homebrewing equipment like pots, tap systems, etc. I think they were located in the midwest, perhaps near Chicago or in Wisconsin. I moved recently and seem to have lost the catalog, and naturally now I need some equipment from them. Any suggestions on the name and telephone number would be appreciated.

Subject: Re:Clinton E-Mail

In HBD 1103 Bill Ridgely provided e-mail addresses for the
Commander-in-Chief (Bill Clinton).

I'm sure that Bill (Ridgely) was using hyperbole when he asserted
that the President reads every one of the 700 e-mail messages
that the White House gets daily. A recent Wall Street Journal
side bar on the subject (my boss gets it and I get hand-me-downs)
indicated that the message traffic doesn't go directly to the
White House but is delivered on disk (the aol.com address is a
contractor's office in Vienna, Va), printed out and then handled
by staffers as normal written correspondence. Replys are only
sent via snail mail so you have to include your postal mailing
address in the e-mail if you expect an answer.

Still it's better than their predecessors as far as access goes
and, Bill, thanks for putting the word out, I should have thought
of it myself.

OFFICE MEMO7 grain beer Date:3/23/93
Jacob Galley <gal2@midway.uchicago.edu> writes:

>Further down on the feasibility scale, I am tantalized by the idea of
>a SEVEN GRAIN BEER. Surely this is not a unique idea. Does anyone >know
>of any previous attempts at this? I'm thinking this would include
>barley (50-60%), wheat, rye, oats, rice (?), corn (?), millet (??). I
>envision this as an amber, steamy lager.

Three years ago I brewed a Kashi Ale. It all started when I saw some
buckwheat
kashi in the bulk grain section of the local alternative grocery. My
wife sees
cereal-I see beer. Next thing I knew, I was brewing. The kashi
contained 5
grains including a majority of buckwheat and some millet. I mashed with
60%
2-row, 37.5% kashi and 12.5% rice to give the 7 grains. I cooked the
kashi in
water before mashing because I didn't know if that was needed or not...
so to be
safe I cooked it. It turned to mush. Interestingly the mush (and rice)
simply
seemed to *vanish* during the mash. I kept the hop rate low to allow
full
flavor evaluation.

The beer was very light in body with an unusual but interesting, almost
smokey
flavor component most certainly due to the buckwheat. Definitely falls
in the
wierd-beer category, but it is worth making again. I would add rye,
eliminate
rice and add some crystal to provide more body and color. I seem to
recall
that high levels of millet is undesirable due to the oil in the grain
(Papazian?).

I can post the recipe if anyone is interested. The basics for 5 gal were
4 lb
malt, 3 lb Kashi and 1 lb rice.

DanMcC

PS. My memory really isn't that good....I was considering making this
again, so
I looked it up just two days ago.

Subject: Re : oat bran in brewing

Jean Hunter writes:

"Has anyone tried using oat bran in an oatmeal stout? As a brewer in the extract/partial mash school, I question the logic of using large quantities of flaked oats as a specialty grain, especially when the starch will obviously not be converted. I would expect the gums and glucans to be concentrated in the bran of the oat -- so why not use just the bran fraction and save the rolled oats for breakfast?"

I cook with oat bran, and it doesn't seem to create much viscosity to me. However, I have made extract stouts which involved a preboiled rolled oats solution, and this definitely has mouthfeel, although zero SG. The best method seems to be to flour the flakes, then add water rather than vice versa in order to stop clumping. The solution throws an incredible amount of sediment, so if you decide to boil the oats along with the malt and hops, forget about racking off the trub, otherwise you will lose too much extract. There's no oil in rolled cereals, so it shouldn't affect yeast metabolism. You can get 30 pts/lb/gall by mashing the oats with either some amylase enzyme or some diastatic malt, and that will reduce the amount of starch sediment.

Subject: German-style Helles Lager

Help requested from successful homebrewers of German or Austrian Helles Lager Bier. After having tried upwards of 40 different recipes and techniques to produce a German style beer rather than an English style beer, I am about to throw in the hop bag and bag it. Can anyone offer some

insight into the problem? Over the years I have purchased brewing materials primarily from Alternate Beverage in Charlotte, NC. The products offered for sale are to a large extent from the U.K. I do not know

if the beers that I have brewed remind me of English beers I had while living in England, because the English Malt extracts are basically produced at higher temperatures and are consequently more bitter than German malts might be or if the yeasts and hops I have used are similarly from the wrong source. Without going into the all the variations of recipes

I have tried and without describing tastes and aromas long forgotten (still

recorded in my log, however), I would appreciate some suggestions for recipes, techniques and sources of ingredients which could be used to produce German or Austrian style Helles Bier.

Thank you

> Let's say I use ale yeast next time, how do I get a *slightly* (and I do mean very slightly) sweet AND carbonated cider. Seems like if there is any residual sugar in there, the yeast will eat it.

The standard trick is to use Campden tablets to stabilize the wine after the desired sweetness is achieved.

I prefer to keep adding sugar till the yeast croaks and then just enough to get the sweetness I want. The key is to do it in small increments when you get close or you will over shoot. The type of yeast you use will determine the alcohol level when finished this way.

In the last stages, I use honey because it ferments more slowly and seems more natural.

>From: G.A.Cooper@qmw.ac.uk (Geoff Cooper)
>Subject: OG for starters - a question

>Over the time that I have been reading HBD, there have been many articles which have talked about the best gravity of wort to use in a starter. The received wisdom from most postings is that an OG of 1.020 is best, but recent postings have expressed different views.

>I recently mentioned the figure of 1.020 to a (knowledgeable) colleague and then realised that I had no hard evidence to support any claims - just HBD hearsay (which I have no doubt is well founded :-)

A MOMILY BUSTER in the bud. I suspect you will find that there are probably sound scientific reasons behind the number but in the real world of home brewing, it really is academic. There are also sound scientific reasons for re-hydrating dry yeast in plain water but the same real world reminder applies.

I find the most practical starter is simply a small amount of the previous batch held back before pitching. I put a pint in the fridge for the next batch and if I feel real scientific, I cut the first pitch with water but I usually just use it as is and as near as I can tell, the yeast loves it.

>So what is the best OG for a starter?

The OG of your last beer :)

> Is the value different for culturing up from a small amount (say from a slant), from that for growing an existing large colony (say from a packet of dried yeast)? Or, assuming that one might culture from 10ml to 100ml and then to 1lt, should one use the same OG medium for the 2 stages, or might it be better if they were different?

I do/have done all of the above and the same reminder applies.

I suspect the best advice would be to lean towards minimum "shock". If the slant is made on 1.020 agar, it could be argued that the starter should be 1.020, but I won't.

For those following the trials and tribulations of the World's Greatest Brewer, I have just started a Wyeast batch. It was given (forced) to (on) me by Tim Norris. So, I am re-culturing it on petri dishes and used the rest to start a starter.

So far, what I dislike the most about it is that it doesn't seem to understand about telephones. After sterilizing the packet, scissors, needle, pipette, flask mouth and removing the air lock, I cut open the packet and the
BLODDY PHONE RANG!

It was a prospective customer wanting to know all about easy mashers and so with the phone on my shoulder and my mind on mashing, I continued to carry on with the yeast. Naturally, it wouldn't pour nice and I slobbered more on the table than in the flask but I got enough to learn what I wanted to learn and converted another plastic bucket brewer to the wave of the future.

Not surprisingly, there is a lot of dead yeast in the packet. Within a few minutes of pouring it in, a significant layer had settled to the bottom of the flask. This is about the amount I would normally have after three days of incubating from a slant. It is now almost 24 hours later and there is only a modest amount of fermentation and thus I assume that it is mostly dead yeast.

From: Richard.Goldstein@EBay.Sun.COM (Richard Goldstein)
Subject: More Manifold Designs

All this talk about manifold designs has got me thinking about a variation, and I would like some feedback. I'm not very mechanically inclined and I don't have a pipe cutter. However, I do have about 10' of copper tubing left over from when I made a wort chiller.

Can I just make a flat coil and put it on the bottom of a cooler, and cut slots (facing down) into it? It would be made with a standpipe.

I understand that most of the other designs allow the cleaning/rinsing of the pieces, or have screens to protect them, but this manifold design doesn't come apart. How important is that? How much gunk gets into the slots of the pipes? Do you think that merely flushing the pipe with water would be sufficient? What other factors or design flaws am I missing?

Thanks.

>(Jeez who dreams up this sheepdip anyway?)

What gets me is the previous Bud commercial where the yuppies are in
the bar with the old guys, and the oldsters are debating what makes
Bud "so great". One says "the hops", another says "the rice".

THE RICE? Geez, that's part of what makes it taste like real beer
filtered
through my kidneys! Seems to me that's a good reason to drink something
else rather than Bud!?!?!

Of course, this is not a slight on (real) rice-based beer, but they're
telling us that they're making a standard pilsner or lager with rice. Does
anybody else find this laughable? I figured they'd play down the rice
content as much as possible, especially with the upswing in popularity of
"real beers" (microbrews, etc).

Then again, why pull a lobe carping about it? The last time I tried Bud
was two years ago and I was offended by it...

David Arnold

P.S. Then there's Killians Irish Red being the "official beer of St.
Patricks
Day"; I wonder what Guinness and Harp thought of this? :-)

Subject: Mashing Crystal, Dextrine Malts. Attenuation of Whitbread yeast

I have been somewhat confused by one of the ongoing threads regarding the mashing of crystal and dextrine malts. I have just recently started doing all-grain batches after three relatively successful partial mashes. In all of my partial and full mashes I have added the crystal malt at the very beginning of the mash. However, I have seen several comments on the HBD over the last few months stating that crystal malts should not be mashed as the mashing has already been done during the kilning stage. What confuses me is that I have not seen this stated (to not mash crystal malt) in either TNCJOHB or in Miller's book (though I haven't finished a thorough cover-to-cover reading of it). I also see no explicit mention of treating crystal malts separately in most all-grain recipes posted to the HBD or in the Cat's Meow from the more experienced contributor's to this forum. Please don't take this as an insult, but I am a little wary of some of the "conventional wisdom" that shows up on the HBD. So, the question is:

Is it bad to mash crystal malts ? More specifically, do the enzymes reduce the desired sugars during the mash or are the sugars derived from crystal untouchable to the starch-converting enzymes ?"

Also regarding the recent thread on cara-pils (dextrine) malt, I forgot to check, but I believe that Papazian EXPLICITLY states that cara-pils MUST be mashed. I have learned to be wary of some of his statements, so once again:

Do the experts believe that cara-pils malt should be mashed ?

One reason I ask these questions is that in my first all-grain batch, I attempted to produce a lower-gravity, lighter colored bitter (target OG 1.035). I was tired of the amber color I found in beers made from extract and the typical extract sweetness that I found inappropriate for some beers.

The grain bill was:

=====

5 1/2# pale malt
1/2 # light crystal (10L I think, it was a very light crystal)
1/2 # dextrine malt

I mashed in at 115 F, raised temp to 122 F for 30 min protein rest, conversion rest at 152 F for 1 hour, mashout at 170 for 10 min., sparged with 3.5 gallons. I obtained 180 pts*gal of extract, but also sparged too long :(. I used a batch of second-generation Wyeast Whitbread Ale for the ferment.

To make the story short, the Whitbread yeast fermented the beer down to 1.005, giving me an exceptionally dry, somewhat over-hopped, and astringent (from over-sparging I assume) beer. Drinkable, but far from what I wanted. I've read about the tendency of Whitbread to become more attenuative over time, but I didn't expect this result in the second generation. I

definitely expected the crystal and dextrine malts to provide more residual sweetness. Though I am skeptical, I cannot rule out breakdown of the sugars during the mash as one reason for the resulting dryness. Thus, the questions above.

Regarding the tendency of Whitbread to become more attenuative with successive generations, is this a result of preferentially selecting the more attenuative of the three strains ? If so, then the difference in behavior between yeast taken from the primary or secondary might be considerable.

Cheers,

Brian Cole

From: Darryl Richman <darrylri@microsoft.com>
Subject: re: Hallertau, Hallertauer

To explain this distinction, one must understand a little bit about the German language (that's about all I understand). If you have a place name, such as Berlin, then someone or something that comes from that place is Berliner. (This explains the oft mentioned "joke" about JFK's "Ich bin ein Berliner" speech; a Berliner is someone who comes from Berlin, but a particularly style of doughnut also originates in Berlin and is often simply known as a Berliner too; hence, the "I am a jelly doughnut" translation.) So, we have Hallertau-Hallertauer, Tett nang-Tett nanger, and Saaz-Saazer. The latter doesn't get much use, perhaps because the official AHA style guide suggests Hallertauer and Tett nanger, but forbids Saazer.

Subject: Carboy cleaning

After racking or bottling I've been adding about 1/2 to 1 cup each of trisodium phosphate TSP and chlorine bleach to my carboys, filling each with water and storing until my next batch. By this time all the nasties from the previous batch have dissolved. I rinse very well and sanitize with idophor (.5 oz./5 gallons). I've never found the need to scrub the inside of the carboys with a brush (sometimes just a quick scrub around the bottle neck). Never had an infected batch since adopting this method.

Aside from the environmental reasons against pouring this much junk down the drain, are there any beery reasons why I should abandon or adjust this cleaning method?

>1991 Beer Styles 1992 Gadgets and Equipment

In my humble opinion (IMHO), these back issues are all quite good or better

and fall into three categories: good, great and indispensable.

I believe the good are the 1986 and 1991, and the great are the 1985, 1988 and the 1992. The indispensable are the 1987, 1989 and the 1990. I literally refer to the 1990 on each batch I brew and refer to the 1987, 1989 and 1991 at least once per month. I should refer to the 1988 and 1992 during the summers (but I don't) when I have the time to build new hardware. Perhaps this summer.

I have this information scattered among files and books, but don't have the time to compile it all into a meaningful, concise answer. However, your mention of dry yeast brings up an important point, the source of which I recall. According to the Lallemand Yeast Newsletter as well as several other sources, DRY YEAST SHOULD BE REHYDRATED IN PLAIN, STERILE (as much as possible) WATER -- NOT WORT. It all has to do with hydrostatic pressure and some other technical stuff, which I didn't store in my head, but the importance of this is generally agreed upon in the literature.

Richard writes:

> Three days ago I made a Trappist ale and used a cultured Chimay for

> Is it time to go to the secondary even though it has only been three

>days? The receipe called for three weeks in the primary and one week in the
the
>secondary.(Cats Meow Ed2 pg. 9-18)

I would omit the secondary. You must have had some very lively yeast or
fermented at a higher temperature than the author of the recipe or
perhaps
aerated better than the author. At this point, now that the beer is
almost
done, going to a secondary would only increase the risk of infection and
an additional racking would aerate the beer more than if you just racked
it into the bottling vessel when the beer is done. I feel that, in this
case, the benefits are not outweighed by the possible problems.

> ^^^^^^^^^^^^^

>Would someone please provide the correct spelling for this word?

Actually, Hallertauer is more correct. The "er" suffix in German
generally
means "of" or "from" therefore, "Hallertauer" are hops with direct
lineage
to the type of hop that was grown in the Hallertau area. "Hallertau" is
kind of correct, but bad grammar. Consider "Boston Lager" versus
"Bostonian Lager."

Perhaps this is true. I've discussed this off-line with Jim Busch, and
have,
with some prodding from George Fix, conceded that Baderbrau is too bitter
and
too dark to be a true Munich Helles but my way of looking at it is as a
over-hopped Helles rather than a too-malty Pilsener. Perhaps, as Jim
suggested in private email, a new category is needed for beers such as
Baderbrau and Samuel(tm) Adams(tm) Boston(tm) Lager(tm).

I propose the name: "Robust American Lager."

From: SWEENERB@memstvx1.memst.edu
Subject: Boiling specialty grains?

I was wondering if anyone holds an intelligent opinion about boiling specialty grains like chocolate malt as opposed to just steeping them in 165-170 degree water which will be added to the boiled wort made from malt extract. Since I have not as yet tried all-grain brewing I still boil in a 4 gallon pot, so I boil half my water first, store it in the carboy then add the wort after a subsequent boil. On my last batch I decided to steep the specialty grains after finishing the initial boil, then strained them out of the water and added boiled wort. Is there a downside to this procedure? That batch, a porter tasted pretty good, a reasonable extract facsimilie of Anchor Porter- yummm, but the vast experiences of the HBD might convince me of the error of my wheys.

Also, Miller's CHofHB recommends aerating the wort at 1hour intervals after racking to the primary, then after 8-12 hours racking again off the hot&cold break. I have tried this a few times and have not been able to tell any difference. Is this worth the trouble? Any comments, observations, etc. would be greatly appreciated.

Subject: Just a reminder

Hi. I know this isn't the kind of message you folks feel like seeing in this digest, but give me a few seconds of your time, could you? About a week ago, my younger brother died in an automobile accident. Alcohol was involved. I don't understand why things had to happen the way they did. Probably never will... but I can't help thinking about how the driver of the other car could have saved my family quite a bit of grief if he had bothered to call a cab or get a friend to drive him home.

I have nothing against homebrewing. To many of us, it's much more than a hobby. It's an art, a science, a tradition, and a way of life all rolled into one. But we often forget the incredible responsibility we have to our safety, and that of those around us. Please don't drink and drive.

From: rak@mayo.EDU (Ron Karwoski)
Subject: Rolled Oats and Judges

All this talk about using oat bran vs rolled oats has reminded me of a problem I had with my last batch of beer. Following TCJOHB2 recipe for Uckleduckfay Oatmeal Stout I did a partial mash using rolled oats (Quaker non-instant breakfast type) and other grains. The resulting beer tastes good, although it is a little thin, probably due to poor extraction. Anyway, the beer is well carbonated but has zero head. A very "loose" head forms when the beer is poured but quickly disappears. I'm not quite sure what the problem is but I am wondering if the rolled oats had anything to do with this. Any ideas?

Also our Club is looking at organizing a homebrew competition for our county fair in August. What we need are judges. Is there a list of registered judges someplace? How does one go about hiring a judge and what are typical costs? Also, anyone know what it takes to become an AHA sanctioned competition and is it worth it?

Thanks.

Subject: Big Brother is Watching

Another incredible tale of the evils of bigger government was played out on the 10 O'Clock news last night. It's another good example of what Big Brother does with our hard earned tax money and why we should refuse him one more cent.

Instead of arresting drug dealers that can be found on thousands of street corners any night (or day) of the week, the FBI choses to hassle homebrewers with our tax money.

They mounted a remote TV camera on a utility pole in front of Alternative Garden Supply in a suburb and monitor everyone who enters and leaves the store. The camera is on a transformer whose top insulator sports a UHF antenna instead of the usual wire running up to the HV line. Not terribly clever but seems to work.

The next thing they did was to open a sting headquarters in a shop in an adjacent shopping center and staff it with a dozen or so agents. They either sit and monitor the tv or watch in patrol cars parked in the parking lot of AGS. When they see someone who fits the "profile" of an evil drug dealer, they follow him/her home and bluff their way into whole house searches including dogs to sniff out the evil weed. Needless to say, so far they have found nothing and have spent millions.

I did my patriotic duty and drove out there and gave the old "vulgar salute" to the camera and had a chat with Dave Itel, the owner. I tried to talk Marilyn into giving the camera a moon but she declined and just waived.

It is truly pathetic and I suggest you all drop a line to the best friend Big Government ever had. He can be reached on line at:

Subject: Coiled tube manifold-fitting in an Igloo cooler

Richard.Goldstein@EBay.Sun.COM described a coiled copper tubing manifold with slots cut into it...

Your description is identical to the one I've been using for two years, and has appeared on HBD before all of the "T" fitting freaks appeared. Have at it.

I'm writing mainly to point out that if you use 3/8 inch tubing, a 3/8 in bulkhead union (tube to tube) will fit snugly in the outlet of an Igloo cooler mashtun.

One supplier: USA Plastics Fax # 419-228-5034 orders 800 537-9724
3/8 in polypropylene bulkhead union #61123, \$1.20 (minimum order \$10)

One difference between your description and mine is the stand tube... I don't really understand why one is desirable (except in a RIMS) All I can see that doing is sucking air into the drain tube, leading to hot side aeration (Gasp!). Why not just let it trickle ad libitum??

have fun...

From: alm@brewery.ht.intel.com (Al Marshall)
Subject: Jeff Frane's Carapils/Dextrine info

> "Carapils(R) (dextrine) malt has an almost completely "glassy"
endosperm,
no enzymatic activity and somewhat less extract than standard brewers
malt.

It greatly improves body, foam retention and beer stability without
increasing color or changing beer flavor profile, through non-
fermentable
components. It is an elegant and inexpensive "natural" alternative to
alginates.

"Caramel malt also has an almost completely glassy endosperm, similar
to
Carapils. It yields various color intensities in the desirable golden-
red
hues. Standardized products in the 20 degree, 40d, 60d, 80d and 120d
Lovibond colors are readily available. Other variations are custom-
made
upon request, volume permitting.

Thanks a lot for this information. I've inferred from your
malt-extract+specialties recipes
that dextrine malt did not need to be mashed with other malts,
and this (and one other
piece I've seen) seems to be confirmation. I'm left to wonder
about various other authorities that confidently state that dextrine malt
needs to be mashed with enzymatic malts. Is there a property of dextrine
malt
that we haven't discussed?

Subject: Towers Time:7:51 AMDate:3/24/93
Sam Atkinson asks for feedback on the Owens-like Tower:

I have a similar tower except I use another converted keg for a hot liquor tank with it's own burner so I don't need the pump. Gravity is certainly the way to go. My only caveat would be the use of Igloo brand coolers. I have a 52 quart Igloo which has made about 22 ten gallon batches. While it is still in use, the interior of the cooler has deformed considerably with time. In fact there were blisters evident after the very first batch. Other brewers who have Igloo coolers report the same results. I still use mine because in spite of the blisters there is no evidence of cracks in the plastic interior. Still, I think that Coleman coolers seem to stand up better to the heat of mashing. I took a survey of cooler users some time ago and the majority used Coleman. I expect I'll replace mine with a Coleman when the time comes.

Subject: Thermostat placement in a freezer

I just bought a new freezer to do my lagering and keg storage which I intend to control using my Hunter Airstat Monitor. I have a question, though, regarding the placement of the thermostat. (That is, the actual remote measuring piece of the thermostat on the end of the black wire.) When I put it on the wall of the freezer, it seemed to give me a false reading as the walls of the freezer are much colder than the actual air in it. I considered hanging it from the lid, but I'm afraid it might catch on the kegs when I lift the lid and tear off the wire. Where do people who use a freezer as their refrigerator place their thermostat?

It is my opinion that this definition (like the one for Munich malt)
does not
apply to the D-K malt from Belgium. Furthermore, I do not understand
the (R)
or the dextrine designation.

I would describe the D-K carapils as hard but chewy endosperm and
anything
but glassy.

It furthermore has a flavor that is easily recognizable and contributes
significantly to the flavor profile and in line with what I taste in an
imported Pilsner.

BTW, another spelling question. Pilsner or Pilsener or?

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: starters

For the record, I've been using the yeast-starting advice given me by a friend who is a great homebrewer. I boil up one cup of DME in a little over a liter of water, ending up with between 750-1,000 ml's after boiling and cooling. I have no idea what S.G. this comes out to, but I do get absolutely great starts.

However, for the sake of simplicity, I think Jack has the best idea - just save a pint from your last batch!! (all together now: "DUHHH!") Anything that saves me time making beer so I can spend more time enjoying the results, I'm in favor of.

Jack, how careful are you about what kind of beer you save for starters? Have you ever used, say, an Imperial Stout for a starter for a Pilsener? Or do you always use less strongly-flavored worts for starters?

Anyone else have experience with this method?

From: Robert Schultz <SCHULTZ@admin1.usask.ca>
Subject: Re: Cider

KILLING YEAST in/for CIDER:

I think a better method to kill off the yeast is Potassium Sorbate, (as apposed to Campden tablets). Use about 1/2 tsp of Potassium Sorbate to 5 gal.

Then adjust sweetness with apple juice if making cider...this kind of falls out of one of the recipes from the Cat's Meow II. If you want carbonation, you must do it with CO2.

My last batch ended with FG 0.994. I added 12.5 oz of McCain frozen concentrate Apple juice and the 'new' FG was 1.000 -- could be a bit sweeter, but a few months of waiting may help ???

As for Jack Schmidling's comment about adding sugar until the yeast dies may not be a good idea... this is how high alcohol content ports are made....by

adding small increments of sugar you are in effect conditioning the yeast (actually I think you kill off the weak cells and continue the ferment with some

of the stronger -- mutants?). The concentration of alcohol changes the taste

(or how one perceives the taste) of the final product.

Hope this helps.

Robert Schultz

Subject: Questions on priming with DME, and Warm climate brewing

Hello all, I'm back with more novice-level questions and comments, looking for guidance & advice from those with the requisite skill level.

In a mid-February posting, I asked for advice about 1.) Using a secondary fermentation vessel, and 2.) Recommendations about priming agents/ amounts, and using a bottling bucket. Thanks to all who responded either here in the HBD or via private e-mail. By sifting through the advice, comments, recommendations, cautions and anecdotes, employing the secondary went off without a hitch, but using a DME/water solution as a priming agent just didn't cut it.

Using the "most recommended" 1.25 cups boiled in water turned my "amber-clear" beer in the carboy into a cloudy mess. Once bottled, it took about 12 days to settle back out, and when I cracked the first bottle this past weekend, only a miniscule 'pffsssst'. The second, third, fourth and bottles were'nt any fizzier. Two and a half cases of nearly flat beer. >:-("Boo, Hiss", no, that should be "Boo, no Hiss". To add insult to injury, I've got the chill-haze blues too (first time ever).

Papazian recommends for that flat beer, adding some dry yeast into each bottle, recapping & re-conditioning. I contend there was enough yeast present based on the activity of the original fermentation, and the sediment in the bottles. His second recommendation (after trying adding more yeast) is un-capping and adding sugar to each bottle. Gee, this was what I was trying to get away from by using another vessel to prime in & bottle from. At any rate, believe me, you can't add very much dry corn sugar to a semi-carbonated liquid! Talk about fluid dynamics!! (;->) I ended up dissolving the sugar into an equal amount of distilled water, boiling for a few seconds, cooling then adding .25 tsp to each of 6 bottles as a test. We'll see what happens in a week or 10 days.

Was I supposed to do the "1-hour rolling-boil/hot-break/cold-break" routine to the DME/H2O priming solution too? Y'all suppose the chill haze came from the priming agent solution or simply because of bad technique while attempting my first syrup/DME batch? Should I attribute the lack of carbonation to a lower-than-expected sugar content of the DME?

Some days I guess you just can't win for losing. Right now I'm gonna go home and mix me a flat homebrew with one that has "character" (Papazian's final recommendation). I just can't bring myself to feed my beer to the wife's Magnolia trees.

A question for all you warm climate brewers out there:

At what temperature do I have to put my toys away for the summer? Here in deepest Dixie, the daily temperatures are getting ready to skyrocket, and I will not be able to use the garage for brewing or conditioning, I suspect in just a couple of weeks or so. This past winter, I fermented everything under the sink in a spare bathroom where the ambient temperatures were fairly constant between, say, 67-72°F. The garage fluctuates too much from day to night, and from day to day to realistically depend on, though I had no qualms using it to cool, age and condition bottled brews.

I customarily maintain the house between 75-82°F in the summer in order to keep the A/C bill within reason, and then crank up the ceiling fans. From what little I have read, I understand that the upper limit of acceptable fermentation temperatures is about 72°F. If I continue to ferment & condition at the higher temps, can I reasonably expect ok results, given the fact I am still a novice extract-er?

Frustrated, disappointed, but still hanging in there.
Noch einmal, bitte!! Mark

Subject: brass,zymurgy,dark grains,chimay clone

Lots of topics...

First, I read in a health newsletter than *brass* fittings, ie. a brass spigot, especially when new, can leach lead into water. What is brass? Copper and ???.

Re. Zymurgy special issues: I refer to the 1991 AHA Beer Styles issue quite a bit. Most articles are well written; not many errors.

Dark grains in mash or mashout? Depends what you're looking for. If you want a hard bite, which I look for in a stout for example, put them in the mash. If you want it smoother, as in a dark lager, put them in the mashout.

Rich S. is concerned about racking his Chimay clone to secondary after only 3 days. What temperature did it ferment at? What was the OG? What is the gravity now? 1 week primary and 3 weeks secondary seem like a longer time than should be necessary. My lastest batch, OG 1.045 fermented

at 65 deg F with Chimay yeast, was ready in half that time. This was also yeast that was cultured from a bottle brought back from Belgium, so it may have been extra fresh and lively. But I'd say treat it as you would any other ale - it should finish in a couple of weeks.

FWIW, a bunch of Bud drinkers had some of mine last night, and they liked it a lot. Go figure.

Subject: Pete's Wicked Clone

Robert Pulliam <pulliam@monty.rand.org>

called for recipes a couple days ago...

>Have any of you successfully cloned "Pete's Wicked Ale"? If so, I would
>love to get your recipe.

Well Robert, try this...

8# domestic 2-row
1# CaraMunich
1# CaraVienne
1# dark German
8 oz CaraPils
6 oz chocolate

Mash-in 4 gallons at 57 C (135F) strike heat.
Falls to 52C (126F). Protein rest 30 minutes.
Raise to 68C (154F),
Sacccrification 2 hours.
No mashout due to brain-cloud. You probably should

Sparge with 6 gallons at 75C (167F)
Got 7-1/2 ~ 7-3/4 gallons. Gravity is 1046.
Extraction = 29.7 points/#/gallon.

Boil 90 minutes.
4.4 aau Fuggles for 60 minutes,
4.4 aau Fuggles for 30 minutes,
5.2 aau Kent Goldings for 2 minutes.

Chill to 25C (75F). OG = 1060.

Pitch Wyeast 1098

If your extraction rates are routinely below mine, add grain accordingly
in your
recipe. Just add to the two-row, don't bother to adjust the specialty
malts,
its just not necessary. My water is fairly soft, and slightly alkaline.
I use
two tsp gypsum in my mash water. Your mileage, of course, may vary. If
you
want a 1055 beer, lose 1# of two-row. But I like mine at 1060. FG was
1018. I
had to add 1/2 gallon water at bottling to bring volume up to 5 gallons.
Let us
know how it comes out...

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Whitbread Warning

The following is my opinion of the situation described in Brian Cole's post in HBD#1104.

Most of the lt. crystal malt I am familiar with has a carbohydrate structure loaded with 1-6 links. These will not be broken in a normal mash, regardless of when they were added. At the ~9% charge Brian reported, he should have gotten a nontrivial dextrin pool.

It is very hard to get a good handle on things based on one batch, however I suspect the culprit may be the Whitbread yeast. The heat dried version is produced in the UK under license from the Whitbread Brewing Co. at a special yeast plant. This plant went out of production in 1991 because of a serious wild yeast infection. Production was just resumed in a new facility in January of this year. These products are only now being distributed to homebrew shops. The versions of the dry yeast available before say Mar. 1, 1993 were the old yeast. Reports that I have seen indicate that 25-35% of the old yeast had unacceptable levels of nonculture strains. The latter were super attenuators, and were reported to leave flavoring like Brian described. The old yeast also also had to be at least 1 1/2- 2 years in age.

I have personally checked the new Whitbread yeast under a contract with Crosby and Baker. There was no pressure to "whitewash" defects, and in fact there was motivation the other way. C+B has a refusal clause with producers whereby they can return any yeast without charge if samples do not meet commercial standards with respect to both infections and viability. To make a long story short, the new Whitbread dry yeast passed with flying colors. My detailed report with plate counts will soon be available from C+B. It should be noted, however, that the "pure" (3 strain) Whitbread yeast will give characteristic tangy, fruity flavor tones. Some like these tones, while others react in a much different way to them.

It looks to me like this is the start of a trend whereby a large number of the producers of dry yeast start to clean up their act. Data as reported in the Cal-Davis study (see Zymurgy's special yeast issue) may become a relic of the past. IMHO we all have the folks at Wyeast to thank for this.

They were to first to set proper standards, which the others are now apparently trying to match.

In a large number of cases when people complain that their beers are too dry and lack sweetness, some sort of infection (low, moderate, or high) seems to have played a part. Certainly the acid forming bacteria will make a beer seem thinner than normal and unpleasantly dry. Yeast like *S. diastolicus* will do this and at the same time leave medicinal/phenolic tones. The wild yeast that occasionally turned up in the old dry Whitbread yeast were apparently not as destructive. Nevertheless, if my conjectures are correct, Brian was done a disservice by the Whitbread folks in the UK.

George Fix

P.S. We were at a Pilsner tasting earlier this week. All the beers were

German, and fresh (a real rarity for Texas). The two favorites were Konig Pils and Veltins. Both were very hoppy (IBU~35-40), and well attenuated with a distinct dry finish. Yet both were very malty and extremely smooth. The net effect was that they were very clean beers with highly attractive flavors. Thus a dry finish is not always undesirable.

Subject: FOOD GRADE PLASTICS

There has been some discussion recently about constructing electric boilers using plastic buckets. Since I only have 120V outlets and do not have access to any area where I could use a propane burner I have been using two Thorne Electric Bims (2 are necessary since I start out with 7 gallons of wort to be boiled). These consist of a heating unit, a thermostat and a plastic bucket with a drum tap (these things are probably very similar to Bruheat boilers). I think the bucket is either polyethylene or polypropylene (Bruheat boilers use polypropylene). The question is this: What plastics are safe to use at boiling temperatures with beer?

As an aside, I was told that people have had problems getting these Bims to even boil water. When I first got mine only one would boil water. I took the back off the thermostat of the one that would not boil water and adjusted the adjusting screw (Do not press down on the screw too hard!). Then I used strips of a foil-backed insulation (see the latest special issue of Zymurgy where Randy Mosher(?) tells how to insulate a lauter-tun) to insulate the buckets. These buckets will bring 3 1/2 gallons of 150 degree wort to a boil in less than half an hour: Not too great but better than nothing. By the way, these units work better if the back plate of the

From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>
Subject: Lager Starers / Starter SG

In HBD 1100 J.Williamson indicated he had a long lag time when he tried to expand his culture from the Wyeast pak.

Using the recommendation from Noonan's "Brewing Lager Beer" of pitching a large population of yeast into fermentation temp wort I took the following steps and had vigorous fermentation in 45F wort in less than 12 hours. The intent of this procedure is twofold 1) produce a large volume of yeast slurry 2) acclimate the yeast to the fermentation temp to minimize shock.

Day 1: Pop Wyeast Bohemian Lager yeast pak at room temp 70F 8:00 AM
Day 2: Pitch the Wyeast pak contents with 12oz of 65F 20sg wort 7:00PM
Day 3: Add an additional 12oz of 60F 20sg wort 7:00PM
Day 4: Pour of 2/3 of liquid, add 24oz of 55F 20sg wort 7:00PM
Day 5:
Day 6: Pour off 2/3 of liquid, add 24oz of 50F 20sg wort 7:00PM
Day 7: Pour off 2/3 of liquid, add 24 oz of 45F 20sg wort 10:00AM

And on the seventh day he brewed.
And when the day was done he looked at his wort and (hoped) it was good.

I pitched all the liquid and the slurry into the 45F wort at about 10PM I checked the brew the next morning and it had a thin milky film over it with bubbles coming out of the S airlock every few seconds.

Notes: Day 1 - 3 the starter bottle was left in my 65F basement wrapped in 2 towels and put inside a cooler. Days 4 - 7 the starter was in my temp controlled refridgerator. By leaving some liquid with each step the temp changes are a bit more gradual also there is a substantial population in the liquid.

I always make starters with 20 - 25sg wort. I produce this starter liquid by half filling 2 gallon bottles with trub from a brewing session. I then fill these bottles with very cold water and let them settle. I rack off the clear liquid from the two jugs and pour it in to 12oz bottles, other people I know use canning jars, I then immerse these bottles in water and heat until the contents of them are 190 - 200F. I maintain this temp for 10 - 15 minutes and cap. This gives me a ready supply of 1/2 gravity wort for starters and I don't feel so bad about leaving stuff behind when I rack off the trub since it gets used. I target a 6 gallon batch so I end up with about 5 gallons going in the keg.

Subject: RE: Petes Wicked Clone

In the last digest, Tom posted a fine recipe for a strong brown ale:

8# domestic 2-row
1# CaraMunich
1# CaraVienne
1# dark German
8 oz CaraPils
6 oz chocolate

Mash-in 4 gallons at 57 C (135F) strike heat.
Falls to 52C (126F). Protein rest 30 minutes.
Raise to 68C (154F),
Saccrification 2 hours.
No mashout due to brain-cloud. You probably should

Sparge with 6 gallons at 75C (167F)
Got 7-1/2 ~ 7-3/4 gallons. Gravity is 1046.
Extraction = 29.7 points/#/gallon.

Boil 90 minutes.
4.4 aau Fuggles for 60 minutes,
4.4 aau Fuggles for 30 minutes,
5.2 aau Kent Goldings for 2 minutes.

Chill to 25C (75F). OG = 1060.

Pitch Wyeast 1098
FG = 1.018

A question: What is Dark German??
Comments: While I think this is a fine recipe, for a Petes Clone, try all Cascade for the hopping. I would also tone down the OG into the 1.052 - 1.055 range (as TOM indicated by suggesting less pale malt). One can also try the Worlds Greatest Yeast (tm): Wyeast 1056/Narragansett/Dominion Ale. You can also make a fine example of this beer with a single step infusion. In fact, the body may go up in the final product when a single step is used due to the rapid conversion of domestic pale malt between 130 and 150F. Tom certainly has plenty of body in his 1.060/1.018 beer, but if you try the Worlds Greatest Yeast (tm), the FG will approach 1.010-1.012. By dropping both OG and FG, you will end up with roughly the same alcohol by volume.

Good brewing,
Jim Busch

PS: Brooklyn Brown Ale is a "Petes Wicked" clone, brewed by FX MAtt, and when fresh , quite delicious.

Subject: Diacetyl, etc.

My most recent lager, that was supposed to be a vienna, but is an Helles, seems to have quite noticable levels of diacetyl. While, this flavor is quite pleasent, and overall the brew has a beautiful malty palate, all that I have read seems to be very concerned about diacetyl levels because they indicate a yeast gone bad. Should I dump all yeasts from that strain and use a fresh lager strain? AHA guidelines seem to indicate that low diacetyl is OK for most lagers. My brew procedure used a 2 week primary at 50F followed by lagering for 4 weeks, the last 2 at 32F, and was bottled with Krausen. The Krausen worked beautifully. I have the most/ beautiful carbonation, and it came quickly. This is with very low sediment levels, but I guess I was fortunate to have brewed a Helles the previous day!

Other points. I just read Eric Warner's Weissbier book. A good book. Well worth the \$9.50 Classic Beer style books cost at the local store. Some points of interest.

He is very unconcerned with oxygen introduction at bottleing because the yeast will use it. This contradcits other writers wh tend to be anal on this point.

Suggests priming with Speise (literally food) and suggests the first runnings, from the lauter tun (with pasteurization). Anyone tried this?

He is, unfortunately, unable to answer the 6 million dollar question - an affordable source of the proper yeast.

To take the 1.020 value somewhat past HBD hearsay:
the directions on Wyeast packs suggest a gravity of 1.020 for stepping-
up
the yeast.

From: tony@spss.com (Tony Babinec)
Subject: canned Guinness/what's a good beer?

Phil Hultin says that Draught Guinness did not fare too well in a blind tasting. Assuming that the Draught Guinness was in good condition -- and this I don't know -- I'll speculate that what we have here is an example of tasters scoring high the beers they like.

To the best of my knowledge, canned Draught Guinness has OG 1.040 - 1.046, which makes it smaller in gravity than the bottled Guinness Extra Stout, OG 1.052 or so. Guinness, being an Irish Stout, is quite sharp and dry, with roasted barley being the signature dark grain. Guinness is therefore dry and not to everyone's taste. And, at its gravity, Draught Guinness doesn't have a lot of body.

In my opinion, when a beer is judged, the major questions ought to be:

- is it clean with no obvious faults?
- is it brewed to style?
- beyond the above, does it delight you?

In fact, in AHA/HBWTA events, judges use detailed point systems. Some score from the bottom up -- x points for malt, y points for hop, z points for appearance -- while others develop a quick overall assessment of the beer, and then use the scoring sheet to aid them in pinpointing the attributes of the beer. If the beer has no obvious faults -- for example, obvious bacterial contamination or a stale, oxidized flavor -- and is brewed to style, then it is a good beer. You may not like it, but it is a good beer. For example, some people don't like the clove-like phenol flavor found in some weizens. If, in addition, the beer delights you, then that might nudge its score higher. If it doesn't delight you, that doesn't make it a bad beer.

The unfortunate reality is that some judges give far too much weight to subjective factors and matters of taste. Probably among the worst things done is to wrongly label a beer as infected. This can happen with spiced beers or belgian beers. Also, it is not uncommon amongst homebrew aficionados to see the hoppiest beer or the biggest-gravity beer be the most preferred. Of course, this taste and preference would not occur amongst the Lite-beer-swilling crowd.

An example of big beers winning is the AHA stout style. Take a look at past issues of Zymurgy. Every year at AHA national, the winner in the stout category is an imperial stout. While the winners were undoubtedly good beers, why hasn't a conventional gravity dry stout ever won? Do better brewers make big beers? Are novice brewers more likely to submit conventional gravity beers? Whatever else is going on, I submit that many homebrewers and homebrew judges are like the musician in Spinal Tap who pointed out that while most guitar amplifiers range from 1 - 10, his went up to 11. In other words, we like our beers with all the dials set on high.

To be a better judge, one should constantly improve knowledge and skills regarding ingredients, process, flavors and faults, styles, national traditions, and commercial examples. For all brewers and

beer enthusiasts, let's recognize that beer has an astounding range of styles and flavor profiles. It is surely much more varied in flavor than the range of wines is, for example. So, instead of abolishing all styles except for BarleyWine, Imperial Stout, and Eisbocks, let's leave some room for the session beers too!

Subject: us versus belgian carapils

Just a reminder: U.S. CaraPils and Belgian Carapils are not the same thing.

U.S. Cara-pils is dextrine malt. As described in Jeff Frane's excerpts, it is hard and glassy, has minimal color, and is used to add body. It contributes dextrines to the beer, which won't be fermented by beer yeast, and therefore will remain in the beer.

Belgian Cara-pils is a light caramel malt/crystal malt, with a color rating of 8L. It can be used in recipes calling for "light crystal malt." It will contribute some color and some caramel sweetness.

Subject: Re: Brass Fittings - Composition

Russ Gelinas asks about the composition of brass, and any concerns about lead.

According to "The Condensed Chemical Dictionary, 9th ed."

Brass is a copper-zinc alloy of varying composition, typically with zinc content ranging from 15% (highly corrosion resistant brass) to 40% (called Muntz metal; used for hot working alloy when cold-forming operations are unnecessary). "Some brasses also contain low percentages of other elements, e.g. manganese, aluminum, silicon, lead and tin)." The Dictionary indicates that the only hazard of brass is that it is "flammable in powder or finely divided form".

The Dictionary does indicate that additional information can be obtained from the Copper and Brass Fabricators Council, 225 Park Avenue, New York (how's that for an address!).

It turns out that children are much more susceptible to lead poisoning than adults. Children may begin to experience symptoms when the level of lead in their blood reaches 40 micrograms per 100 grams of whole blood; the threshold for adults is about 60% to 70% higher. EPA's drinking water standard is 0.05 milligrams per liter. This level was derived assuming that one drinking 4 liters of water per day over an average lifetime with levels of lead lower than the standard will prevent blood level concentrations from reaching levels where symptoms will occur.

We are also exposed to lead in trace amounts in the food that we eat; it is naturally occurring in soil; it is in many pesticides, and it is attached to airborne particles (this is why EPA has banned leaded gasoline). One estimate is that we ingest approximately 130 milligrams of lead each day in our food and drink (ReVelle and ReVelle, 1984 - "The Environment: Issues and Choices for Society").

IMHO, the amount of lead that may be leached out of the few brass fittings that we may use in our brewing gadgets, even under the lower pH levels that brewing creates, would add only a very small increase in the lead we are exposed to. In addition, for every hour we spend brewing, we are reducing the risks of walking across the street and getting hit by a car!

So, I think you can add as many brass fittings as you want to your system (stainless steel would be better, but it's about 10 times more expensive),
,
not worry, relax, and you know....

>I would like to second Phil Hultin's comments. One of the common >complaints about BudMichMiller is the rather thin palate or general >lack of flavor. Well certainly canned Guinness does a bit better but, >hey, it tastes watery to me. I'll stick with the bottled version.

The bottled Guinness Extra Stout commonly available here in the US is considered by many to be a world class beer (including myself,) but this is a completely different product from Draught Guinness (canned or otherwise.) It's sort of an apples to oranges kind of thing. The Guinness Extra Stout is a higher OG product, with a correspondingly higher hopping rate. The draught versions(s) are intended to be much lighter (to use a bad term) and I think more "quaffable". Whereas I don't have any problem drinking multiple pints of Draught Guinness, usually from a real tap at one of several Boulder pubs, I know I would have great difficulty consuming more than a couple of bottles of the Extra Stout in a single sitting.

Now, if I could only finagle a trip to Dublin to try the Real Thing...

Just another point of view...

Subject: Rolled oats

In response to the post about the headless beer made with rolled oats, my Quaker Oats box claims 2 g fat per 1-oz serving (dry) of oats. Yes, this is without adding the milk.

If you added a pound of rolled oats to your mash, you would be adding the equivalent of 32 g, just over an ounce, of lipids. Given that there must be some lipids in barley, and that some folks add baking chocolate (50 to 70% fat) to their specialty brews without complaining of head retention problems, could roughly an ounce of oat lipids be responsible for the beheading of a stout?

Sometimes an oil film on the serving glass can mess up a beer head. Check (with) your dishwasher too.

Subject: Re: Boiling specialty grains?

> I was wondering if anyone holds an intelligent opinion about boiling specialty grains like chocolate malt as opposed to just steeping them in 165-170 degree water which will be added to the boiled wort made from malt extract. Since I have not as yet tried all-grain brewing I still boil in a 4 gallon pot, so I boil half my water first, store it in the carboy then add the wort after a subsequent boil. On my last batch I decided to steep the specialty grains after finishing the initial boil, then strained them out of the water and added boiled wort. Is there a downside to this procedure? That batch, a porter tasted pretty good, a reasonable extract facsimilie of Anchor Porter- yummm, but the vast experiences of the HBD might convince me of the error of my wheys.

After about 5 years of boiling specialty grains, and ending up with beer that tasted much better after a year in the bottle, I stopped boiling my grains and voila! beer that tasted good out of the secondary. As I understand it, higher temperatures will leach tannins out of the husks of the grain. These tannins will add an astringent taste to you finished product. The yeast in each bottle will *eventually* reabsorb the tannins, but it is better to avoid them from the start.

The only doubt I have with your described method is that you don't boil the resulting liquid from the steeping of the grains. Once you have removed the husk material, it is safe to boil the resulting liquid, and may even be beneficial. A boil could kill off residual nasties, although I don't know if anything could live in 170F water for an extended period of time. Boiling might also alter the sugars in the solution.

On the bottom line, if it tastes good, you *must* have done the right thing.

Subject: Re: Culturing Duvel Yeast

> I'm planning to culture the yeast from a bottle of Duvel and I have a
few
> questions:

Where are you located? Fermentation Frenzy in Los Altos, Ca. has slants
of Duvel
yeast that I have used to attempt Duvel clones. I'm pretty sure that
these cultures
would be better to use than the yeast in some poor abused bottle that's
been on the
shelf forever. I don't know the technical profile, but it smells and has
aftertaste
like Duvel. I have done one extract and one all grain attempt at Duvel.
The all
grain came much closer, as I could control the percentage fermentable vs.
percentage
unfermentable sugars in the wort. Normal (tm) extract will have a ratio
balanced
towards normal beer, and Duvel is not normal. It is quite difficult to
get the high
alcohol content without excessive body and residual sweetness. My all
grain batch
included 18lbs of grain and 3 lbs of honey for a 5 gallon batch. I
mashed for several
hours at 148F to try to get maximum fermentable sugars. The Duvel yeast
fermented it
from about ~1.090 to ~1.025 in just over one day! Another week brought
it down to
about 1.015. Truly impressive. It ended up with the nice blond color
and rocky head
of Duvel, but was still a little too sweet. Duvel in Belgium hasd 9.5%
alcohol (not
sure if by weight or volume) and the US version has 5.2%.

If there is interest, I will post the recipe, but I don't want people
to think I
really got it just right.

Subject: Starters, Wine, Brass

>Jack, how careful are you about what kind of beer you save for starters?

Totally reckless. I literally start the next with the last. I really think that a pint out of 7 gallons is in the noise.

>From: Robert Schultz <SCHULTZ@admin1.usask.ca>

> As for Jack Schmidling's comment about adding sugar until the yeast dies may not be a good idea... this is how high alcohol content ports are made....by adding small increments of sugar you are in effect conditioning the yeast (actually I think you kill off the weak cells and continue the ferment with some of the stronger -- mutants?). The concentration of alcohol changes the taste (or how one perceives the taste) of the final product.

Can't argue with the facts but if one uses a low tolerance yeast, you can minimize the problem.

>From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)

> First, I read in a health newsletter than *brass* fittings, ie. a brass spigot, especially when new, can leach lead into water. What is brass? Copper and ???.

Sounds like a case of the media over-reacting to something they know nothing about.

Brass is an alloy of copper and zinc. The amount of either that can leach into beer is probably not measureable and both, in small doses are necessary to human health.

Subject: bad supplier alert

Hi All,

Just curious, anyone else having problems getting orders filled correctly by Northeast Brewers Supply in RI?

I have been (or was) a customer of theirs for about one year. Over the first few months that I did business with them, several orders were shipped either incomplete or with the wrong items. On most of those occasions, the problem was that they did not have the item in stock and had it on backorder. The irritating thing was that they would not tell me this when I placed the order, even though the information was on their computer. I would not discover that the order was incomplete until I received it, one or two days before brewday. Each time this occurred, it put me in the position of scrambling around at the last minute trying to second source the items from other vendors.

After several such incidents, I called and spoke to the owner, a Mr. Kerry Brown. He told me they had just put in a new computer system and hired a lot of new help, and to please bear with them. Being the understanding, easy-going fellow that I am, I was satisfied with that explanation.

Things got a little better for a while, as only the occasional order was screwed up. Two weeks ago, I ordered one pound of Saaz pellets, and 1/4 pound of several other types of hop. After waiting eight days, I called to find out what had happened to my order. After being left on hold for 15 minutes, the person at the store said he was alone, the phones were ringing and the place was full of customers, so he did not have time to look for the shipping log. He could'nt say whether or not the order had been shipped. He did locate my order, but it was totally wrong, they had it as 1 *pound* of each hop.

The next day, as a result of my complaining, I received a phone call from Mr. Brown, ostensibly because he "was interested in my feedback as a customer". I explained the problem with the hop order, and amazingly, he went into the same spiel, new computers, new help, blah blah blah. I reminded him that we had held exactly the same conversation 8 months ago. He then tried a new tack, that "it's hard for any computer to track \$10K a day in inventory". Gee, it's funny how in this age of online transaction processing,

banks can transfer millions of dollars a day across vast distances with no problem, but NE Brewer's computers can't track a few ounces of hops in the backroom. Then it was "banks spend a lot more money for their computers". This is surely earth shattering news to those who use PC driven databases in thier businesses. It became evident that he was interested in neither my feedback or in retaining me as a customer, so the conversation terminated.

In all fairness, NE Brewers does offer very low prices. However, in my opinion, this is made possible because they hire the cheapest, least qualified help they can find, and then understaff, as evidenced by the lone hapless clerk trying to wait on customers and answer the phone concurrently.

The bottom line is, you *can* get good prices from NE Brewer, but you had better have a second source lined up, you may very well need it.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: off-flavor puzzle

Here's one for all you beer - sleuths.

I have been re-using yeast by saving the slurry from the primary and washing it using the sterile-water method. Recently, I decided to pitch a new batch directly onto the yeast cake in the SECONDARY of a previous batch. Both of these batches have developed a similar off-flavor.

I would described this flavor possibly as either "wet cardboard" or "cooked corn" - but since I can't decide which, perhaps it is neither and I'm just groping for terms to describe it from stuff I've read. And incidentally, I don't remember where I read them or what is supposed to cause these particular flavors. Quite a few batches ago I had one that turned out "cidery," and there was absolutely no doubt about how to describe that. The cideriness subsided after a few weeks in the bottle and the beer was not great, but drinkable.

But I digress. The interesting thing is that a third batch of beer made from the same yeast, washed from primary slurry, shows no sign of that flavor defect. The three recipes are completely different except for the yeast. Personally, I suspect that my problem came from reusing yeast from the secondary that had been DRY-HOPPED.

Here's the scenario: Batch one, California Common using Wyeast "California," from package built up in DME starter. Batch two, a porter (?) or at anyrate a dark steam beer, made with California yeast saved from primary of batch one. Bathc three, a cream ale (or cream steam in this case I suppose) made with California yeast from secondary of batch one (which had been dry-hopped). Batch one and batch three have identical flavor defects. Batch two is fine.

And here are my questions: (1) Could the flavor defect in batch one be due to leaving the hops (pellets) in the secondary too long? I thought moving the beer off the slurry in the primary would take avoid the risk of developing off-flavors in case of extended stay in the fermenter, but perhaps the dry-hopping has its own risk in this regard. (2) Should I suspect infection? The hops I used for dry-hopping smell fine in their package, although I doubt I could pick up anything by nose that way. Perhaps the infection was introduced when transferring batch one to secondary, and from there to batch three. (3) What are the chances of bottle conditioning taking care of this?

I should add that the flavor problem is not overwhelming - it sticks out like a sore thumb to me, but my wife guzzles happily and doesn't know what

I'm talking about.

Any thoughts would be greatly appreciated!

Subject: That was gonna be my second guess

The other day I was subjected to a blind tasting at a friends.

"Try this", he said, "It has some flavors that I can't quite place".

"What style is it?", I asked.

"It has some problems but the style should be pretty evident." he said.

So I put on a judge's air and proceeded to dissect the beverage according to the latest AHA guidelines.

Appearance: Very pale, Miller Lite-ish in color. Way over-carbonated. No head retention.

Nose: Perfumy. Fruity, apple-like. No malt nose. No hop nose.

Flavor: Starts out fruity. Finishes dry with some tartness. No body, very thin. Gassy.

After surreptitious evaluation, I decided that it must have been a very bad mead/cyser or an OK sparkling cider. But which? Depending on what I said I could have bruised an ego or given tribute unto Caesar. I loathe those situations. It required tact. Ann Landers, where are you when I need you.

Summoning all of my self-taught guile, I responded: "Well, it certainly is interesting."

"You don't like it?" he asked.

"Um, no, it's not that I don't like it, it's just that it could fall into a number of different categories and I'm having a little trouble deciding which. On one hand it tastes like a very good cider but on the other hand it tastes like a mead or cyser that needs a little more aging." I said as I mentally patted myself on the back.

"Well, truth be told", he said, "it's a French champagne. Perrier-Jouet to be exact, vintage 1983."

(silence)

While trying not to blush too brightly I confidently responded, "I knew that".

From: Phillip Seitz <0004531571@mcimail.com>
Subject: Northeast Brewers' Supply

James Dipalma reports some rather unpleasant experiences with NBS, which I have no reason to doubt. On the other hand, I can report that they have always gotten my orders right, shipped promptly, and charge less for their goods than any full-service dealer I'm aware of. (Hey Al, when's your catalog coming out?)

In fact, NBS is the ONLY supplier I've used that HASN'T screwed up. I don't think this suggests that they're perfect, but rather that much of this is a matter of fate. The fact that they're trying to shave markups to the bone also suggests to me that they're walking a finer line than some suppliers in terms of the resources needed to supply a certain level of service.

I, too, have a minor quibble with their computers. As some may have noticed, they charge less for 15 lbs of grain on a per lb basis than for 5 lbs. Ok, that's fair. As it turns out, a 15 lb order arrives in 5 lb bags. Quirky, but ok if that's how they want it. However, if you want to buy 20 lbs you have to pay a 15 lb price and a 5 lb price. I assume that their computer system is not set up to handle the prices on the basis of total quantity rather than units, but this was a bit irritating.

Finally, my mom says that when she called them before Christmas to order a Corona for me, she also asked if they could supply me with a basement (my chief brewing need). They said no, so I guess they're not FULL service!

Standard disclaimers apply.

Subject: Dark German

Jim Busch (busch@daacdev1.stx.com) asks:

>What is Dark German?

Well, its like this. I **believe** "Dark German" is a toastier version of CaraVienne. I'm actually not sure what distinguishes it from CaraMunich.

I should have said this the other day: my local homebrew supplier (Roy Rudebusch @ IMO in St. Louis) suggested the combination of the three "German" malts instead of the combination of dark and light English crystal malts that I wanted to use in this batch. Roy knew what I was after, and it worked out quite well. My original recipe was formulated with two pounds light English crystal and one pound dark English crystal. Since that isn't what I actually brewed, I didn't post that as "The Recipe". I couldn't tell you what difference this actually makes in the final product. I've noticed that Roy likes to use smaller amounts several "specialty" malts in combination, rather than larger amounts of fewer varieties. Maybe Roy or other experienced all-grain brewers will be inclined to comment on this style of recipe formulation. Can you win a competition this way? Would you really want to? 8-)

What I know about recipe formulation, I learned from Dave Miller (by way of books), and Roy. Roy taught me the practical application. A good homebrew supplier, who actually brews good beer himself, is a fine thing to have in your neighborhood 8-).

> and what are typical costs? Also, anyone know what it takes to become
> an AHA sanctioned competition and is it worth it?

All organizers are encouraged to post competition announcements and requests for beer judges to JudgeNet <judge@synchro.com>.

Most judges charge \$50 per beer judged. I, however, am a bargain. I'll judge for free if you'll cover my expenses and introduce me to a beautiful single adult female biped who owns a brewery or racing team and has bad taste in men.

Seriously, BJCP judges cannot be paid to judge AHA or HWBTA sanctioned competitions. However, a free lunch is considered appropriate, and many competitions offer 'Beds for Brewers' where visiting judges stay at local brewer's homes.

Contact the AHA (phone & address in Zymurgy) for a list of judges and details about becoming a sanctioned competition.

Having a sanctioned competition gets you some advantages:

- BJCP Judges get experience points.
- Competitors may consider it more legitimate (this is debatable).
- Announcement in Zymurgy (if they feel like it).

> this point.

> Suggests priming with Speise (literally food) and suggests the first
runnings,
> from the lauter tun (with pasteurization). Anyone tried this?

Those two suggestions go hand in hand -- *if* you prime with malt sugars,
then you shouldn't worry about a little oxygen in the bottle, since the
yeast will use it. If you prime with corn sugar, however, Miller points
out that the Crabtree effect kicks in, and the oxygen is untouched by the
yeast.

Sometimes I refrigerate the trub after racking into primary -- by
bottling
time this separates, leaving enough wort to prime with. I guess the
first
runnings would work as well, since you'd only have to save a small
amount.
For the homebrewer, though, once you've boiled that small amount and then
separated the hot and cold break, will there be anything left? It might
take a few attempts to get the volume right.

Thanks for the info, Ulick. I've heard a few bad comments about some of
the other books in this series, but so far only good things about this
one. Guess I better go buy it..

Cheers,
Greg

Subject: Ginger Steamer

Salutations all!

I'm an extract brewer that uses spec. grains and starter cultures that just brewed a Steam beer. Anyway, here's the recipe:
Ginger Steamer

6# unhopped Amber liquid extract
1# 120L Carmel Malt
1/2# Victory Malt (25L) (Oven Toasted at 350F for 15 min)
1/2# Double Malt (45L)

1 oz Chinnok 13.6 % (Boil)
1/2 oz Cascade (15 min left)
1/2 oz Cascade (7 min left)
1/2 oz Cascade (2 min steep)
~1 oz fresh Ginger indiscriminatly put in the last few minuets of the boil (15-5 min left)

I will dry hop with 1/2 oz Cascade when I rack to the secondary.

Oh, I am using Wyeast's California yeast, smells GREAT!

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: Dark Grains - Mashout

I've only just started adding the dark grains at mashout, but my initial impressions are:

- 1) It takes a little more, since the extraction time/temp is less.
- 2) It greatly reduces the astringent harshness that comes with high amounts of dark grains.
- 3) It makes chocolate malt more coffee-like and less burned.
- 4) Small amounts of black patent (3 oz.) can add color with no perceptible burned taste.

I haven't tried it with a stout (roast barley) yet, so that's still a mystery to me. I'd like to hear more about other brewers experiences.

Paul.

Subject: Seattle Brew Fest '93

I apologize to everyone for taking up bandwidth with announcements that are only of interest to a small percentage of the readers. Unfortunately, I don't know of any mailing lists for Northwest readers, so here I am. (If there is such a list, put me on it and send me a copy of the list.)

And since I'm talking about Northwest issues: Yes, I did have the Redhook Smoked Scottish Ale. Very drinkable once you got past the first sip, but not exactly my idea of a Scottish Ale. (Never had anything like that on Rose Street!) The current Redhook specialty beer is a Honey Stout. Quite good!

The Washington Association of Small Brewers Presents

SEATTLE BREW FEST '93
at Seattle's Union Station

Opening Gala Evening to Benefit Cancer Lifeline
Thursday, April 8, 6-9pm
Tickets: \$25 in advance, \$30 at the door
(\$50 sponsor and \$100 patron tickets also available)
Admission includes handcrafted beers, souvenir glass and fine local food.
Call 654-4141 to reserve your ticket.

Friday April 9, 3-11pm
Saturday April 10, 12-10pm
Tickets \$5 in advance, \$6 at the door
Admission includes 3 script and souvenir glass
Friday and Saturday tickets available at:
The Trolleyman in Fremont (Redhook)
Big Time Brewery and Alehouse in the University District
or call 365-5812

I recommend the Cancer Lifeline benefit. All the food you want plus all the beer (and cider) you can drink at one low cost, with the proceeds going to benefit a worthwhile charity.

Previous Cancer Lifeline beer have included ALL of the Northwest microbreweries plus some from California (Sierra Nevada and Anchor were there last year) as well as Canada (Big Rock has made the trip from Calgary both of the past benefits). This is a great place to meet and talk with the brewers, and help contribute to a good cause, too.

Hope to see everyone there.

>Subject: Brewing supplies in Europe

>I thought the USA would be a good source for me, but apparently the shipping expences are just too high.

Just for the record, the price I quoted you was for 2nd air shipment of a 20 mill. I refuse to deal with the US Postal Service on this item but I am sure most retailers have no such compuction regarding routine brewing supplies and the cost would be far less than UPS air.
.....

Someone quoted the Wyeast packet as a vindication of the 1.020 starter wort gravity and I only ask, where did THEY get the number? These things have a tendancy to gain a life of their own and rattle around forever.

.....

Here's another GREAT IDEA from the World's Greatest Brewer....

This one is untested but considering the source, it's gotta work.

For the poverty stricken brewer who just knows that kegging is the way to go but has to feed the kids before buying tank and regulator, it has occurred to me that a very simple alternative exists.

Take an empty keg and and drop in a chunk of dry ice. Seal it up and connect it to the keg of beer and the job is done. A few inexpensive refinements would be an air pressure gage to monitor what is going on, a valve or two and even a regualtor if funds allow.

I have no idea how much ice is required to develop what pressures and for how long but, as it's not my problem, I leave the details to those venturesome experimenters who have contributed so much to this hobby in the past.

js

p.s. To protect myself from greedy lawyers, I would not suggest doing this without a pressure gage and close monitoring till we know what to expect. I believe the Cornelius kegs are rated at 150 lbs but I have never and would

never go above 50 lbs with them. I would have been delighted to run these tests but the idea came to me last night will filling the last of my 4 kegs and it will be awhile till I have an empty one.

jjs

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
Subject: Question on sterile wort preparation

Several people have mentioned using a pressure cooker to can sterile wort for the purpose of yeast culturing. This idea appeals to me, since the pressure cooker would sterilize the wort and containers, thereby allowing somewhat relaxed sanitization procedures during wort preparation. However, when it comes time to use the wort, it must be poured out of the canning jars and into the vessel which will be used to culture the yeast, with the associated contamination risks.

It would be nice if the same jar that was used in the pressure cooker could accept an air lock. This way, when it came time to make the starter, one could simply take the jar of sterile wort off the shelf, open it, put in the yeast, and attach a sanitized airlock.

Does anyone know of small-mouthed jars with accompanying small lids and rings, (sort of like a miniature Ball jar), which would accomodate a drilled stopper?

Some may consider this a ridiculous idea, but I feel that anything that simplifies my yeast culturing is worthwhile.

Joel Birkeland

Subject: Re: starters

In HBD #1105, Jonathan Knight writes:

>...

>However, for the sake of simplicity, I think Jack has the best idea -
just

>save a pint from your last batch!! (all together now: "DUHHH!")

Anything

>that saves me time making beer so I can spend more time enjoying the
>results, I'm in favor of.

>

>Jack, how careful are you about what kind of beer you save for starters?

>Have you ever used, say, an Imperial Stout for a starter for a Pilsener?

>Or do you always use less strongly-flavored worts for starters?

Indeed, one should use common sense with regard to the color of the wort
and hopping rate used in the starter and the target beer. Because
starter

wort is usually diluted (see below), you don't have to be too anal about
this.

>

>Anyone else have experience with this method?

I do it all the time. Usually I recover 2-4 pints of wort from the
kettle

trub (filter it through a fine mesh nylon hop bag) and then boil can it
in mason jars. Sometimes I just pitch the cooled wort into the fermenter
(keeps that total extract rate high), sometimes I use it for Krausening
(all natural..) and if I am low on starters I'll dilute the wort to 1.
020

before canning and store those in my beer box. I also use recovered
wort for plating and slants: Just add 2% flaked agar (from the chinese
section of the grocery store) boil to dissolve, strain and boil can in
small mason jars for storage.

A plug for more complicated brewing:

Yeast management is amazingly simple and easy once you get over the
hurdle

of doing it. Just like all grain, it does

involve a little extra effort, but the \$\$ savings over \$5 yeast packets
is considerable. Since recovering wort and canning it is part of my
usual kitchen clean up, after brewing, it doesn't seem to take any extra
time. Building up yeast doesn't take much time either: I just have to
start two days earlier than when using a Wyeast packet.

Cheers!

From: Conn Copas <C.V.Copas@lut.ac.uk>
Subject: Re : oatmeal

Jean's comments on the lipid content of oats prompted me to go looking in the supermarket this weekend. I found that flaked oats, oat bran and wheat bran all contained from 5-10% fat by weight. In the case of the 'brans', that presumably means they are adding back the germ, no? The levels in the flakes varied considerably, presumably depending upon whether whole grain cereals were employed or not. Interestingly, the oat bran contained considerably more carbohydrate than the wheat bran. I made a test mash of oat bran alone today and obtained an extract of around 30/lb/Imp gall, ie, comparable to the flakes. Viscosity, however, seemed less on an informal basis. One thing that has me slightly bemused is that I would expect a 7% lipid content to result in an immiscible layer whenever the substance was boiled in water; yet this does not occur. Adding an additional 7% vegetable oil to the oat bran solution certainly resulted in a visible layer.

I have had more head retention problems using exorbitant quantities of crystal than I have had from using oats. By 'problems' I mean that it may require 3 month's maturation before the brew holds a decent head. A lot of factors are presumably at work here, such as how much lipid is retained in the grain bed (if mashing), how much gets bound up with the trub, how much attaches to any finings which are employed, how much participates in esterification reactions, etc (although George Fix seems to suggest that only saturated fats are significant re ester formation). Following this line of reasoning, I guess that fining can be deleterious to hop aroma?

This was certainly part of the reason tetraethyl-lead was banned. The most important reason, however, was that lead poisons the platinum catalyst in the catalytic converter that breaks down nitrogen oxides. Even a minute amount of lead in the exhaust quickly makes the converter useless...

Subject: Rye Crystal Malt

I read here last week that someone had found a source of rye malt.
I tried getting this myself, but the only source that I could find in
Zymurgy

had gone out of business.

The reason for my interest is that I was thinking of trying to make
crystal

rye malt from it.

Does anyone have a current source, and does anyone know whether soaking
this

stuff to make crystal malt would carry any risk of ergotism?

Maybe I should ask the Pied Piper :-)

I was also looking for a source of quinoa and amaranth to no avail.

I even tried to search the 'Net on the keyword "grain".

Anyone else have any luck, or know the protein/fat contents?

Jack said that he had used mulberries a while back. This was my favorite
berry, but since leaving sunny Australia, I've never seen them again.
Was this a local supply, or would it be possible for me to obtain some
somehow?

Sorry for the wish-list,

Marc Kelly.

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Pilsner Pour

Aside from the SANFU's in my video, probably the most memorable part is the conversation with Ken Pavichavich in the Baderbrau conference room. He would pour a glass of beer with a whipped cream head and it would stay that way till we got tired of looking at it. We were there several hours and one was still 2 inches above the rim of the glass when we left.

The key to this amazing head is a special tap that he got from Europe that has two pour positions. The forward position provides a normal pour with just a trace of head. The back position creates nothing but foam. By combing the two actions, one can get any sort of head desired.

I saw an ad somewhere for one of these and sent for the info (800)-FOAMLESS and was stunned to learn the price was around \$200. It seems the point of these is to save beer (and money) and the rationalization is that it pays for itself quickly in a bar environment.

While thumbing through the Braukunst catalog, I spotted a similar tap for \$46.95 and immediately ordered one. It is directly replaceable with any H-S tap and required only unscrewing the old and screwing on the new.

I was delighted with the results. It does exactly what it is supposed to do and costs only about \$10 more than the standard tap.

For more info on this and other nifty beer gear, you can contact Cliff Tanner, Braukunst at:

Subject: Chocolate

I recently made 5 gal of chocolate porter. I used 24 tablespoons of dark cocoa mixed in with the priming sugar. There was a lot of cocoa left in the bottling bucket and in the bottom of the bottles so I would use about 16 tablespoons next time. You may be able to get more in solution by adding

it to the wort. The taste was just dandy; be careful not to overhop as the

cocoa adds its own bitterness. The 24 came from a recent HBD post, I don't

recall the author.

Subject: Contacts to US and Canadian brew clubs

Hello fellow brewers,

Traffic recently has slowed a bit, so I thought I'd post this.

I maintain a list of email contacts to some 90-100 homebrew clubs around the US and Canada. The point is to help potential members find clubs in their area and to help promote interclub communication.

If you would like the contact information for a club or clubs (or all clubs) below, please send me email. Similarly, if you are a member of a club, either one listed below already or one not listed, and would be willing to be the email contact person for your club, please send me email.

Oh, and if you have any questions, please send me email.....

internet: srussell@msc.cornell.edu or srussell@snoopy.msc.cornell.edu
bitnet: srussell@crnlmsc2.bitnet

PS: I don't have a club contact for a Phoenix area club yet and am very interested because it looks like I'll be moving there in two months.

PPS: it would be nice if someone were willing to take this database off my hands around that time (hint, hint!) -- really not much work any more.

Cheers and here's to great beers,

STEVE

Subject: Questions

Message Creation Date was at 29-MAR-1993 08:15:00

Greetings,

I'm an extract brewer who is quite new to this "homebrew network". I have some questions that I hope won't bore you all. Being new to this network, I don't know whether my concerns have been previously dealt with in excruciating detail.

1. To achieve maximum practical cold-break how quickly and to what temperature must I reduce my wort?

2. I'm intersted in re-using my yeast in order to keep costs down and diminish the time to begin fermentation. How can I efficiently separate the yeast from protein globs and stray vegetable matter in my troob?

3. I was interested in doing some mail order extract purchases. I saw one company offering a Wisconsin barley malt from Briess that was cheaper than what I normally pay for Munton & Fison unhopped extract. Has anyone out there brewed with both of these extracts? I'm interested in how they compare with each other.

4. When sparging in my extract brews, I filter out the hops as well as hot & cold break proteins and plop the gunk onto some cheese-cloth. When I'm finished filtering, I squeeze the cheese-cloth to wring out the last liquid back into my wort. Am I screwing up because my "naked" hand is squeezing out the juices? Am I introducing bacteria as well as skin oils? How should I be doing this?

5. This may be "Politically Incorrect" to ask this, but does anyone out there have serious reservations about any of the mail-order companies from the following list:

Red Bank Brewing Supply, William's Brewing, The Malt Shop, Brew Masters, The Brewers Club, The Brewery, MCC Brewing Supplies, Great Lakes Brew Supply, and Wine Hobby USA

Are there any I should be using instead of these?

Thanks for the help,

Bitch's Brewery

Subject: Hydrometer left in fermenter?

Greetings...I'm a beginning homebrewer, and have a question:

To know when the beer is done fermenting, I gather there are at least two ways to tell: 1, by going by bubbling rate (90 seconds between bubbles being the time to bottle), and 2, by waiting for the gravity to stop changing for 2 or 3 days. On the two batches that I've bottled, these times have coincided, so apparently each is fairly valid.

Is there any reason not to just sanitize the hydrometer and drop it into the secondary? It seems to me that it gives less chance for infection than opening it up every day or two to draw off a sample to test. What I've been doing is just dunking it in there, and reading it once a day or whatever, to keep an eye on it.

Other than needing a hydrometer for each batch you're monitoring (not that expensive, compared to ingredients, and once you buy it you have it forever), can anyone suggest a reason not to do this?

I can see why I wouldn't want it in the primary fermenting carboy, as the krauesen would change the weight of the thing. Getting it out isn't a problem, because it floats out when I rinse the carboy. Anything I haven't thought of? And what is the preferred method for knowing when to bottle, the bubble rate, or the hydrometer reading?

Thanks,
Dave Hinz

Subject: pressure cook/#13 stopper fits pint jar

I recommend using the pressure cooker method to create sterile starter worts. Following Dave Miller's book, add 3 pounds of light dry malt extract to about 2.5 gallons of water to create 3 gallons of wort. Hop lightly if you wish, and boil for 30 minutes. Chill enough to facilitate transfer, and then transfer the wort to 12 Quart Ball jars or 24 Half-Quart Ball jars. I found a 5 or 6 gallon pressure cooker (I don't remember the capacity, but it was the largest one) at a Service Merchandise. It takes two cooking "cycles," as all jars won't fit in the cooker. By cooking at 15 pounds pressure for 20 minutes, you sterilize the wort. Then, whenever you need some wort, you just pop open a jar.

The Half-Quart Ball jar can be fitted with a #13 stopper and airlock, so you can pitch the yeast straight into it if you want.

The pressure cooker also comes in handy should you decide to do yeast culturing.

Subject: Hunters. How not to and how to connect them.

This weekend I wired up my freezer. Not wanting the damage the antique beauty in any way, I mounted the Hunter (heat-cool, round, mechanical model 40005) to a scrap of plywood, and connected it to an extension cable coming in. Anyway, when I turned on the power, she blew. A bright spark and there was no metal left on the thin wires of the mercury trip switch. I then realised that when they said for 15-30V DC low power DC control systems, they meant it. I wondered why I had never heard of any problems wiring these puppies up. Common sense should have told me that the thin wires of the Hunter could not carry a total freezer load. I suspected that I may have been able to connect if across the freezer's regular thermostat circuit. Anti-surge devices and such were mentioned, but guessing that the voltage would still be 115 AC, and the fact that the wires were quite thick, and also the prime directive - not to fuch with the integrity of the freezer, my mind turned to relay.

So off I went back to Builder's Square for a new Hunter and then to Radio Shack for a relay. I got a 12 VDC relay with contacts rated for 15 A at 125 VAC. Overkill maybe but I was taking no chances. I could have got a similar device with a coil that used 120 VAC. It may well have had low enough power to be OK through the hunter, but I was taking no chances. I wired it all up at home. I soldered the relay contacts across the power cord live wire (where the previous Hunter used to be). I connected the + terminal of a 9V battery to the R connector on the Hunter, the Y (cooling) connector to the relay coil, and closed the circuit by connecting the other coil connector to the - terminal on the battery.

But the best point, which I haven't seen made yet is that it is trivial to lower the range of one of these devices. The scale is from 40-90 F, but to be accurate the Hunter must be vertical, because it is based on a mercury trip switch that sits atop a metal coil type thermometer. So I turned my Hunter 1/16 of a turn anti clockwise, and now I get the temperature approximately 10 F below the setting.

It also occurs to me that it should be easy to adapt a heat only thermostat based on the same principle to cooling only by loosening the mercury switch and turning it around. They are usually glued, but the glue connection is easy to break (I discovered this while trying to save my previous one). The heat only ones are ~\$13 as against \$20 or so for the heating/cooling one. The relay cost \$5-\$6 - a standard Potter and Blumfield repacked as Archer, a Radio Shack brand.

Subject: Starters

>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)

>It would be nice if the same jar that was used in the pressure cooker could accept an air lock.

This is getting like the "where can I get a brew kettle cheap?"

Erlenmeyer flasks, which are available at any scientific apparatus supplier, are designed to accommodate rubber stoppers. All you need is a glass air lock (Korz carries them) and you are in business. Bring the wort to a low boil, and attach the empty airlock. The steam will condense into sterile lock water while sterilizing the lock and flask.

>Some may consider this a ridiculous idea, but I feel that anything that simplifies my yeast culturing is worthwhile.

This is certainly a step in that direction.

>From: polstra!larryba@uunet.UU.NET

>Yeast management is amazingly simple and easy once you get over the hurdle of doing it. Just like all grain, it does involve a little extra effort, but the \$\$ savings over \$5 yeast packets is considerable. Since recovering wort and canning it is part of my usual kitchen clean up, after brewing, it doesn't seem to take any extra time. Building up yeast doesn't take much time either: I just have to start two days earlier than when using a Wyeast packet.

Well put and worth elaborating on at the risk of creating a Yeast Snob thread.

Once yeast culturing becomes routine, doing anything else poses the same questions as brewing with extract.

It may very well be a time/money tradeoff for some but in the majority of cases, it is simply fear of the unknown and intimidation by big words and complicated sounding procedures.

I will say no more here but everytime I announce that I have an article on beginning yeast culture, I get inundated with requests which boggle my mail so I will post the article in serial form starting tomorrow.

I have found that small juice jars will reseal once or twice before discarding. We get Mission something or another juices here at work, and I had a few friends save the jars and lids for me. These will accept a #6 stopper. Be sure to use the jars with the pop up top so you can tell if they are contaminated.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)
Subject: re Question on sterile wort preparation

Joel asks:

Does anyone know of small-mouthed jars with accompanying
small lids and rings, (sort of like a miniature Ball jar),
which would accomodate a drilled stopper?

I've had good luck with those hand-sized Veryfine juice bottles. Fill
'em maybe half full of wort, put the lids on so that the threads just
engage, and pressure-cook 'em. When you take 'em out, tighten 'em down
(wear hot-mitts). If the lids pop down when they cool, you got a good
seal, they'll last a long time. They take a regular carboy stopper.

Have a look around the supermarket and/or convenience store,
you'll find something that'll work for you.

Subject: Grain Mills: the Test Drive

Preface:

This is an attempt by an amateur scientist to publish an objective review of two common mills.

----- Test Drive, the final chapter -----

The results of the great Corona Mill VS. MaltMill grain crush are in.

First, an overview of the hardware in the test:

==== Corona ==== Price, as tested: \$39.

The Corona mill is a fairly straightforward design. There is a hopper on top, big enough for about 2 # of pale malt. It is a hand cranked design; the hand crank is about 18 inches long. Once it's going, it's not too hard to keep it going.

The mill itself uses a screw "impeller" to feed grain to the crushing/grinding plates. The plates have a gap, which is adjustable via a wingnut and locknut.

The Corona does require a mount for stability, and could use a mechanism to direct the output of the milled grain.

Nearly all of the Corona's parts are made from cast metal. It'd be fairly hard to break (i.e., it could fall off the brewing table, bounce down the stairs, hit AND kill the cat, and still be functional).

==== MaltMill ==== Price, as tested: \$130

(As tested, this unit had the adjustable gap feature. It did not have the stainless steel rollers.)

This mill has a decent-sized hopper, which uses gravity to feed grain through the rollers. The entire mill is designed to sit atop a bucket.

The MaltMill is a roller-mill design. The rollers and "bearing plates" (for lack of a better term) are made of metal. The rollers themselves are grooved; these were probably used in an industrial application and required a significant cleaning effort before the author felt comfortable about using this device on a food product.

The basic design is manufactured mostly from pressboard, save the name placards and the roller assembly. Structural integrity is provided by a total of 8 bolts; two hold the hopper on, two hold the bottom board on, and there are bolts at each end of the placards.

The rollers have an adjustable gap (on this model). The adjustment is performed by rotating an eccentric cam on which the end of one of the rollers is mounted. The adjustment can be tightened to the point of no gap, or opened to where grain could fall through unmilled. Once adjusted, one must lock down the cam with a wing nut.

On the adjustable model, one of the placard bolts is replaced by the adjustment lock down bolt - which sacrifices whatever structural reinforcement the original bolt had to offer.

If this mill were to fall from 5 feet to a cement floor, there would undoubtedly be irreparable damage.

- - - - -

Pre-test adjustments

The Corona was adjusted to where it left no unbroken kernels, and a minimal amount of husk damage. The adjustment is not hard to perform while milling.

The MaltMill was adjusted to just where it would not allow malt to go through uncrushed. Aside from husk material and flour, the crush was nearly indistinguishable from that of the Corona.

Adjustments had to be made by running a handful of grain through, then loosening the wing nut, adjusting roller separation via twisting the cam, and then tightening the cam. ("lather-rinse-repeat")

The goal with both mills was to adjust for a crush:

- * with minimal flour content
- * minimal uncrushed kernels
- * minimal damage to the husks

- - - - -

The Crush: yields!

The Corona had a very consistent crush. With proper adjustment, one can minimize the damage to the husks and at the same time leave no kernels uncrushed.

The MaltMill has the possibility of passing a few uncrushed kernels through while still producing significant flour.

Quantitative Analysis: procedure

Both mills were adjusted for proper crush. The MaltMill crushed into a grain bag in a bucket. The Corona's output was directed via a sleeve into a grain bag in a bucket.

After milling, the grain was sifted, and the resulting flour was weighed on a counterbalance (accurate to within .02 grams).

Results:

For 2 # Pale Malt, the Corona produced 42.0 grams flour.
the MaltMill produced 49.5 grams flour.

That's a whopping 20% MORE flour with the MaltMill.

This is significant as I've heard theories that flour content can contribute to a stuck sparge; I've also had more sparge problems with high flour content milled malts.

Husks: The husks on the Corona's crush were slightly more damaged than on the MaltMill.

Unmilled kernels: the MaltMill had a higher ratio of unmilled kernels; we did not see any unmilled kernels with the Corona.

If time had allowed, I would have liked to run some deeper analysis on the grain - an actual count of unmilled kernels per 100 ground, etc,

would have been nice to tally.

=====

I leave the reader to interpret the results. Apologies to those whom regard this posting as wasted HBD bandwidth.

Have a homebrew >pffft<,

mike

From: "Jim Ellingson" <jimme@pi28.arc.umn.edu>
Subject: WARNING Re: Almost Free Kegging

Jack suggests using a keg as a pressure vessel and getting pressurized CO2 gas from dry ice. Highly pressurized gas can be very dangerous.

The short answer is: DON'T DO IT!!!!

Let's do a quick BOTEK (Back of the Envelope Calculation) analysis on this. The vapor pressure of liquid CO2 is hundreds of psi (say 500 psi) and is a function of temperature. It's several times the rated operating pressure of a Cornelius keg (120 psi). Clearly there is a potential here for disaster.

Most substances expand about 1000 times upon boiling or sublimating, at a pressure of one atmosphere. So, if we use a pint of dry ice, it will sublimate into 1000 pints of CO2 gas. If we stuff 1000 pints of CO2 into our 40 pint (5 gallon for you non BOTEK alums) keg, what is our pressure? The Ideal Gas Law states that each halving of the volume induces a doubling of the pressure. 25 is roughly 2 to the 5th power, so a pint of dry ice should generate 5 doublings of atmospheric pressure or . . . something on the order of 25 atmospheres or 400 psi.

Using half as much dry ice would half the pressure. So, using a half cup would give us about 100 psi, which is twice Jack's recommended operating pressure. Also, I wouldn't use BOTEK analysis if I wanted a pressure anywhere near the manufacturers rated operating pressure. Using a quarter cup would give a pressure of around 50 psi but I still don't think it's a very good idea.

Pressure vessels are thick, heavy and expensive for a reason. The pressurized gas which they hold contains an enormous amount of potential energy. (That's why they are hydro [water] tested. Compared to gases, fluids are approximately incompressible.)

BTW, thanks to all for keeping the S/N ratio up on the HBD.

Cheers,

--

Subject: Hop Utilization Factors

Message Creation Date was at 29-MAR-1993 14:14:00

Greetings,

Would someone out there please inform me on calculating the difference in the hop utilization factor for whole leaf vs. hop pellets. I read these formulas on calculating the IBUs for a given beer, but I have not seen anything that deals with the form of the hop itself, aside from its Alpha value. It would seem that this would be especially important for hops added near the end of the boil (i.e. for flavor or aroma).

Thanks,

Bitch's Brewery

I would think any glass juice jar with a lined metal lid fits the bill nicely. Just drink the juice and re-use the cap. I use 1-qt jars that take a #7-1/2 or #8 stopper.

I don't use a pressure cooker, but I make starters with normal water-bath canning procedures. After the jar cools, the center of the lid collapses and seals just like a mason jar. I suppose the lid will wear out after a while, but I've used them 3 or 4 times and they still work fine. Their working life may be less when pressure cooked.

Subject: Ithaca Competition

Ithaca Brewers' Union May-Day Ale Competition
AHA Sanctioned Homebrew Competition
Saturday, May 1, 1993

Entry Information:

A. Bottles: three 10-14 oz. bottles are required for each entry. Grolsch-type bottles and bottles with raised lettering or paper labels will not be accepted.

B. Drop-off Sites: entries may be shipped via UPS or delivered in person to Summer Meadow Herb Shop, 319 Eddy Street, Ithaca, NY 14850. In addition, entries from the Syracuse area may be dropped off at E.J. Wren Homebrew, Inc., 209 Oswego Street, Ponderosa Plaza, Liverpool, (315) 457-2282 and those from the Binghamton area dropped off at S & R Homebrewing and Winemaking Supplies, 223 Ridgefield Rd., Endicott, (607) 748-1877. Entries will be accepted from April 10 through April 24, 1993.

C. Entry Fee: \$5 per entry (\$4 per entry if more than 4 are submitted). Please include a check made out to "Ithaca Brewers' Union" and enclose a completed entry form for each homebrew submitted.

D. Styles: all entries will be judged by AHA style definitions, which were listed in the February IBU Newsletter. Fruits, herbs or spices used in speciality beers should be listed and the base style included so that it can be judged appropriately. Note: if a particular category does not receive at least six entries, it will be combined with a similar category for judging and award purposes.

1. Belgian-Style Specialty
 - a. Flanders Brown
 - b. Dubbel
 - c. Trippel
 - d. Belgian Ale
 - e. Belgian Strong Ale
 - f. Lambic

From: SCHREMPPE_MIKE/HP4200_42@pollux.svale.hp.com
Subject: BAA competitor

I just got information on a competitor to Beers Across America. I'm not affiliated... blah, blah,blah.

The company is:

MICROBREW TO YOU
428 E. Campbell Ave
Campbell, CA 95008

Phone: (408) 379-0500
Fax: (408) 379-8837

Their flyer says they will ship two six-packs a month of microbrewery beer and a newsletter about the beer and brewery that produced it. They are a new company, about three weeks old. They say they are starting with californian beers, but will move expand soon.

The monthly cost is:

\$13.95 plus tax, S&H, and Calif deposit.

For those in the Bay area, these guys have a very small store in downtown Campbell that stocks lots of kinds of beer (58 breweries were represented when I stopped in). They are also a source for kegs from many of these breweries.

From: Kirk_Anderson@wheatonma.edu (Kirk Anderson)
Subject: pasteurization, why how and who?

Can someone satisfy my not-overly-technical curiosity about pasteurization of beer? Is there a simple way to tell if a beer is pasteurized (I've been told it's obvious in the head)? Why and how is it detrimental to the flavor? Are all draft beers unpasteurized? Why? Are all imports unpasteurized? Does the cold-filtered process represent a real improvement over pasteurization? What do they filter out anyway that would shorten the shelf-life? What would happen if megabrews were not pasteurized? Who's buried in Grant's tomb?

If this ground has all been covered, excuse me I'm a recent reader. But please tell me where, via e-mail. Otherwise, it's a topic that should interest beer cognoscenti (even though God only knows why anyone would want to do this at home) and might merit some HBD bandwidth.

yours with foam on top,
Kirk

Subject: Re: Question on sterile wort preparation

I've used ball jars in a pressure canner for preparing my sterile wort without worrying too much about dumping the contents into a sanitized container for the starter. The advantages are: you can pour off the wort and leave trub behind; oxygenate the wort while pouring; clean the ball jar thoroughly if it is the wide mouth variety. I haven't had any problems with contamination. (knock knock knock) If you are concerned then maybe you can get your hands on a glass milk bottle. They usually come in 1/4, 1/2 and 1 quart sizes and you'll find that a #6 stopper will fit and you can put these into a pressure canner as well.

Subject: New Supplier in Connecticut

A new homebrew supply store has opened in Monroe, CT:

Maltose Express
391 Main Street (Rte 25)
Monroe, CT 06468
(203)452-7332

They are experienced brewers, and have operated a mail order business for several years.

I tried a Pale Ale that Mark, one of the co-owners made, and it was great !! And it was an extract brew (recipe will be shared if desired).

This is the first supply store to open within a 20 mile radius of Fairfield, CT, where I (and many other homebrewers) live. This is good news !!

CALL BEFORE STOPPING BY; THEY ARE NOT OPENED EVERY DAY !!

Of course, I have no affiliation with this business. I just wanted to share this blessed event with others in the Monroe area.

Subject: Whitbread warning, part I

There have been a number of digest posts in the past few weeks which suggest the quality of dry beer yeasts is improving. The latest post on this was in last Thursday's digest by George Fix. I'd be delighted if these

reports did indeed portend a new beginning for dry yeast, but I remain very skeptical. If I may be allowed to play the devil's advocate, let me first explain why I think the recent reports offer limited encouragement at

best and why I doubt the existing processors of dry yeast are likely to change their ways in the foreseeable future.

Dr. Fix states that the new Whitbread yeast passed his culture tests with flying colors. I presume this means that the bacteria count was low and the viability was high. This indeed is good but it should be noted that Dr.

Fix also suggests that neither of these was the problem with the old Whitbread which he estimates made swill about 1/3 of the time. Dr. Fix further points out that the dryness of these beers might be due to a nonculture (wild) yeast, particularly a *S. diastaticus* which can ferment dextrin. This rather unique property of *S. diastaticus* allows this wild yeast to be detected by a culture method. Basically, *S. diastaticus* will grow on a dextrin or starch agar while the culture yeast will not.

However, I'd like to point out that the majority of nonculture yeasts common to brewing are strains of *S. cerevisiae* for which there are no reliable culture methods of detection. In short, the new Whitbread could be even more contaminated than the old, but with a different wild yeast,

and Dr. Fix's culture methods would not detect it. There are methods which will detect most wild yeasts but these methods are quite sophisticated and would require equipment and expertise found in some microbiology or biochemical laboratories with fluorescence microscopy capabilities.

Although the culture tests conducted by Dr. Fix are indeed useful, particularly for Crosby and Baker, in screening out batches with gross contamination of bacteria, the only reliable and practical test of yeast purity for the homebrewer is simply to test the quality of the beer made with the Whitbread yeast. The only practical way of knowing if wild yeasts are present is to sample the beer and look for off flavors and aromas, poor clarity, low final gravity, etc.

The other reports of improved dry yeast center around the new Lallemand yeasts, Windsor Ale, Nottingham, and Koenig. These yeasts have drawn some attention in part because of the large ads in *Zymurgy*. Some people on the digest have suggested these are also improved dry yeasts. I expressed my doubts about these yeasts some time ago for reasons I'll outline below. GW Kent, the distributor of these, recently indicated that

one of these great new yeasts (sarcasm intended), Konig, has been dropped because of contamination.

Date: Tue, 30 Mar 93 08:38:02 -0600
From: oconnor@ccwf.cc.utexas.edu (donald oconnor)
Subject: whitbread warning, part 2

Their are several factors which suggest that dry yeast processors will not produce improved dry beer yeast. Firstly, dry yeast processors are primarily interested in bread yeast. Bacterial contamination in bread yeast is not nearly as critical as it is in beer yeast. Thus the processors are understandably content with the contamination level of their principle product and not inclined to spend money and time to improve a secondary product.

Secondly, although homebrewing is a recent trend in the US, it has a much longer history in the UK, Australia, and New Zealand. It seems a little unrealistic to think that yeast processors which have been entrenched in making poor yeast for so long are suddenly going to get their act together because of the American market.

Thirdly, culture tests such as those conducted by Dr. Fix for Crosby and Baker have been done before and it's difficult to find any evidence that the results influenced the processors in the slightest. For example, the culture tests conducted by Dr. Michael Lewis et. al. and published in Zymurgy in the '89 special issue indicated some serious problems with amongst others, Whitbread. From Dr. Fix's remarks, we now know that Whitbread only got worse after this, not better.

In spite of the long history of contaminated dry beer yeast, I don't think it is an inherent flaw of the process. I suspect it is simply a lack of adequate quality control. So what is required for adequate quality control? Clearly the entire process must be carried out in a sterile environment. This requires a room with sterile air (special ventilation equipment), sterile packaging materials, sterile glassware and equipment which requires an autoclave. This is indeed what Dave Logsdon at Wyeast has and I suspect at least some of the dry yeast processors have these capabilities. Quality control is really the process of maintaining this sterile environment over time and that is where the dry yeast processors fall short. Quality control requires routinely checking the yeast for contamination by culture methods such as those Dr. Fix runs for Crosby and Baker, routinely checking surfaces of equipment and glassware and even the walls for evidence of contamination. If you take a swab off the wall or an empty flask and it grows on a agar media, you've got a problem. Many breweries routinely make small batches of beer and check for wild yeast contamination by the off-flavors and aromas or appearance (flocculation) of the beer. If processors of dry yeast are truly serious about cleaning up the dry yeast, they would carry out similar procedures.

A history of contaminated yeast suggests an inability to implement

adequate quality control. That is why I am particularly dubious of products from existing processors such as Lallemand in Canada, Distillers in England, Coopers in Australia (also supposedly better according to Dr. Fix as reported by Jeff Frane on rcb), and Red Star (back in production and also improved according to Jeff Frane as reported on rcb) in the US. The reason I was immediately skeptical about the new Lallemand yeasts was that I saw nothing in the ads or information to indicate that Lallemand had improved its quality control. I see nothing in the new information about Coopers and Red Star to suggest that they'll break their pattern of reliably making swill all too often. The most hopeful note in Dr. Fix's post was that a new processor was drying Whitbread yeast. It may well be that the new Whitbread is a good clean dry yeast--for now. After all, if it's a new facility, it's likely to be quite sterile at the outset. But the real test will be in a year or two. Unless this new processor breaks the mold and institutes adequate quality control procedures, I think we can expect the new Whitbread to look very much like the old within a couple of years. Unfortunately, homebrewers won't be seeing any of the new and improved Whitbread for a while; it's only available to brewpubs for the time being. Apparently there is another Australian dry yeast called Mauri Brew (not produced by Coopers) which has appeared in Canada and is thought to be of better quality.

Subject: Belgian Aromatic

CHUCKM writes about Dewolf-Cosyns Aromatic malt. Well, yes, most malts are aromatic, but the Aromatic is especially, uh, aromatic. It has a color rating of about 25 Lovibond, which makes it a bit darker than dark Munich. You know how you'll read a recipe in Charlie's book, and he'll tell you to toast a pound of malt in the oven for 10 minutes. Well, in a way, the manufacturing process for the Aromatic malt has done this for you. Aromatic malt works especially well when used as a substantial fraction of your grain bill for bocks and doppelbocks, and could be used when you want to make any malty amber to dark beer.

Subject: better ginger flavour

I too was very interested in obtaining a strong ginger flavour as I developed a taste for a Jamaican ginger beer (non-alcoholic) last summer which was quite pricey and not too available. So I looked in a text on food

flavouring production and found out that the ginger bite and aroma were extracted very differently. The volatile flavour as Dave Whitman suggested

is volatile and is obtained by distillation but has none of the ginger bite

just the spicy lemon flavour. The ginger bite is obtained by using repeated extraction with a mixture of ethanol and hot water.

We found that the ginger "bite" being much less soluble in pure water can be extracted by grinding fresh ginger to a fine pulp in a little

boiling water. Then letting the mixture simmer for 10 minutes on the stove

in about a litre of water. You can obtain a good extract this way. You then strain it out and repeat this with the pulp twice more.

Most of the spicy lemon flavour came out in the first extraction with a good ginger bite present after the 4th extraction. The flavour of the ginger beer was very strong at first but diminished slightly over time.

This seemed due to some sedimentation as upon tasting it had quite a bite.

Young fresh ginger (the one with the red stalk remnants) is much more fragrant and lemony than mature ginger, I prefer it, use it at 2/3 young and 1/3 mature ginger if you can get it. At the level of 1 lb. ginger per

gallon you'll get lot's of ginger bite unless you're one of those people who eat whole raw jalapeno's. If using only mature ginger try about 8 oz.

to the gallon as it's much stronger. Hope you find this info useful.

Subject: Ale yeast sold by Northeast Brewers Supply

Greetings all HBD readers! I have a question for anyone that may have tried the North American Ale yeast sold by Northeastern Brewers Supply. I brewed up a pale ale with this yeast, and as the beer has aged it has been getting an increasing clove-phenolic flavor that really dominates the taste of this beer. It is not an objectionable, flavor. In fact my SO really loves this batch claiming that its spiciness reminds her of Orval (you have to love a woman that says such things about your beer). Nevertheless, the taste is inappropriate for the style. Last night I popped the first bottle of a stout that was also brewed with this yeast and much to my horror it also has this clove taste that is strong enough to dominate even the pound of roasted barley that I used in this five gallon batch. So, now I'm pretty sure that the yeast is the culprit (I've never encountered this flavor in my beers before). Has anyone out there tried this yeast and have you had similar experiences with it? It is entirely possible that this particular culture that I have is not representative of the yeast sold by NBS. Their catalog describes the yeast as producing a 'clean' profile. When they shipped my order (this is an order I made back in November) they did so during Christmas-New Years time with the result that it was in the hands of UPS for more than a week kept under who knows what temperature. I had to make a number of attempts to culture from their slants before I got one going. So it is possible it could be a freak. Who knows, it might be a great yeast for a wheat beer! But I'll be keeping it out of my stouts.

Subject: Chocolate

Not too long ago, my partner and I created a chocolate wheat beer. We added 3 oz. of chocolate with the boiling hops and another 3 oz. with the finishing hops. This way, we figured we could get an aroma and a good flavor from the chocolate. It seemed to work, because we've got a good beer in the bottle now.

The one piece of advice we got before using the chocolate was that there could be an unusual odor in the carbuoys. We did get soething that was unusual, but there was no infection, and the finished product is rather tasty. From what I understand, you can use less chocolate, anywhere down to around 2 oz. for a more subtle flavor. We wanted a more pronounced one, so we went for [close to] the maximum.

This addition is supposedly valid for just about any beer recipe. Admittedly, I would not find certain combinations palatable to the point that I would want five gallons of it in my kitchen [Chocolate Chili IPA?], but the leeway is there. Enjoy!

Subject: Late Reply to the Brass Question

I figured someone else would have made this piont by now but ...

Not to long ago NPR did a story about possible problems with brass water facuets. It seem some manufacturers of brass faucets still use lead solder in constructing their faucets. The Calf. EPA has been able to measure lead leaching into the water when using these faucet when using very hot water. No numbers were given.

The fellow for the Calf. EPA recomended not using hot water from any faucet for cooking and if you have small children to only use bottled water (how do we know the bottle water is lead free?)

I think the case for how much lead, where it comes from, and who is at greatest risk has been clearly stated here in the HBD so make up your mind on the dangers.

I hope is helps.

Subject: Help!

Help!

I found out today (Tuesday 3/30) that there will be a local homebrew judging on the 16th of April and bottles have to be submitted on the 14th. My dilemma is that I have a carboy full of what I hope is pretty damn good porter, but it is still actively fermenting (about 15 seconds between bubbles) after 6 days. I would really like to enter the contest with this brew, so I figured if I give this batch a couple of more days in the carboy and bottle on the 1st it may be ok by the 16th. Is there anything I can do, however, to speed up the carbonation process and/or help the yeast to drop out of suspension in the meantime to remove the green beer taste? Is there a fining agent which might help? Any suggestions are welcome--tried and true or completely experimental--at this point I'll try anything. Thanks in advance.

Subject: Dead fermentation

Hello all,

Brewed a kit beer with a buddy last Sunday; Monday it was fermenting at a reasonable rate, Tuesday Morning- Nothing. I am a bit disturbed by this.
(not worried, disturbed) We used a full boil, rehydrated the yeast in some of the wort set aside at 70f, for a few hours while the 5 gal of wort cooled. The kit called for 1kg of corn-sugar, we subbed 1 kg light dry m-extract. The original gravity was 1.041, glass primary with blowoff in a 70f room. I guess I should also mention it was a Brew-Pro, Mexican Lager kit. We plan to take a S. G. reading tonight... Is it possible the beer is fermented-out??? As I am convinced that it is not, any suggestions would be appreciated. Please forgive my violation of the "Thou shalt not covet kit-beer" commandment. (it was a gift).

Subject: Belgian aromatic malt/misc questions/

CHUCKM writes:

>and in particular I have seen some mention of Belgium aromatic
>malt. Does anyone know how the 'aromatic' malts differ from
>other non-aromatic malts?

I believe you're refering to the malt that DeWolf-Cosyns makes that they call "Aromatic." Basically, it is like Munich malt in that it is darker than Pilsner or Pale malts but will still mash itself. It is roughly 23-28 degrees Lovibond.

Andy writes:

>1. To achieve maximum practical cold-break how quickly and
>to what temperature must I reduce my wort?

Cold break begins to form at temperatures below 140F. It has been reported and I've verified empirically that the quicker you chill it (the more suddenly the temperature drops) the better the break.

>2. I'm intersted in re-using my yeast in order to keep
>costs down and diminish the time to begin fermentation. How
>can I efficiently separate the yeast from protein globs and
>stray vegetable matter in my troob?

I feel it's better to harvest yeast from the secondary than the primary since the trub, as you mentioned, settles in the primary. I have a big problem with harvesting yeast from the carboys because I dryhop. Instead, I make starters and split them in parallel into several batches. The snag here is that you need to brew several batches from the same yeast in a relatively short period. I have also successfully made starters from the sediment in my own homebrew, but I've had problems with older bottles and only do it for one generation to avoid the pitfalls of mutations.

>3. I was interested in doing some mail order extract

>thin wires of the mercury trip switch.

There's a different Hunter, called the Airstat, which is made to control window air conditioners. That's the one you want. No muss, no fuss and 40F is low enough for me anyway. Any lower and I think there may be a risk of freezing bottles near the walls. The Airstat is digital, has a remote sensing device and you simply plug your freezer/fridge into it.

Mike writes:

>(for lack of a better term) are made of metal. The rollers themselves
>are grooved; these were probably used in an industrial application and
>required a significant cleaning effort before the author felt
>comfortable about using this device on a food product.

These rollers are custom made for this application and the oil on them is to keep them from rusting. Good thinking, you should clean everything before you put food in it, shouldn't you.

>

>The basic design is manufactured mostly from pressboard, save the name
>placards and the roller assembly. Structural integrity is provided by a
>total of 8 bolts; two hold the hopper on, two hold the bottom board on,
>and there are bolts at each end of the placards.

Your tone is not coincident with your impartiality. The "pressboard" is actually synthetic wood made from recycled milk jugs and is IMHO much less likely to break than pressboard, plywood or cast metals.

>

>On the adjustable model, one of the placard bolts is replaced by the
>adjustment lock down bolt - which sacrifices whatever structural
>reinforcement the original bolt had to offer.

Sounds impartial to me... NOT.

>

>Results:

>

>For 2 # Pale Malt, the Corona produced 42.0 grams flour.
>the MaltMill produced 49.5 grams flour.

>

>That's a whopping 20% MORE flour with the MaltMill.

>

>This is significant as I've heard theories that flour content can
>contribute to a stuck sparge; I've also had more sparge problems with
>high flour content milled malts.

You heard wrong. Pulverized husk material is much more likely to cause a stuck sparge than any amount of flour. With proper doughing-in, flour is not a problem -- it will be converted to sugars which are soluble. Flour production should not be an issue when evaluating a mill.

>
>Husks: The husks on the Corona's crush were slightly more damaged than
>on the MaltMill.

I personally feel that this is an understatement, but to me husk damage should have been second only to thorough crushing of the grain as a criterion for evaluation of the products.

>
>I leave the reader to interpret the results. Apologies to those whom
>regard this posting as wasted HBD bandwidth.

>
I don't believe it has been a waste of bandwidth, but also it has not been impartial -- your tone was quite evidently biased against the MaltMill. You should also have researched stuck sparges a bit more before formulating your judgement criteria. On my scorecard, the MaltMill won.

If I sound biased towards the MaltMill, so be it, I feel it deserves to be defended, and if you haven't noticed, I did not preface my comments with a statement of impartiality. I'd like to point out that there have been several reviews of the MaltMill versus the Corona that have come up on the side of the MaltMill. Check the archives... only you and Roy Rudebusch have written negative reviews -- perhaps Roy's bias is due to a hundred Coronas gathering dust in his basement -- I don't know for sure. I can sell either the Corona or the MaltMill. My profit margin is bigger on the Corona, although I've yet to sell a single one. It's designed for making tortilla's for Pete's sake!

Andy writes:

>Would someone out there please inform me on calculating
>the difference in the hop utilization factor for whole leaf
>vs. hop pellets. I read these formulas on calculating the
>IBUs for a given beer, but I have not seen anything that
>deals with the form of the hop itself, aside from its Alpha
>value. It would seem that this would be especially
>important for hops added near the end of the boil (i.e. for
>flavor or aroma).

A recent post (I'm not sure which digest) mentioned 20% less utilization when using whole hops over pellets. The reason for the difference is mostly due to the fact that during pelletization, the lupulin glands are physically ruptured making the Alpha Acids more available.

Kirk writes:

>pasteurization of beer? Is there a simple way to tell if a
>beer is pasteurized (I've been told it's obvious in the head)?

No. There is no way other than to ask or look on the label.

>Why and how is it detrimental to the flavor?

Raising the temperature into the pasteurization range will drive off aromatics which you would like to keep. I've heard some say that it will give the beer a "cooked" flavor, but the only beers that I've tasted before and after pasteurization was Chicago Brewing Company's Legacy Lager and Red Ale. I noticed no categorizable flavor difference. Note that these beers are flash pasteurized while in a piece of stainless

steel tubing, so perhaps there is no loss of aromatics there either.

>Are all draft beers unpasteurized?

I don't think so -- maybe they are and maybe not.

>Why?

Probably because of the rate at which they are consumed.

>Are all imports unpasteurized?

Most are but some are not. Chimay is not.

>Does the cold-filtered process represent a real improvement
>over pasteurization?

I don't think cold filtering is anything but a shortcut to proper
lagering -- it filters out the chill haze.

>What do they filter out anyway that would shorten the shelf-life?

Flavor? Body? No, seriously, sterile filtration filters out bacteria,
but also much of the small proteins that give beer body and head
retention.

>What would happen if megabrews were not pasteurized?

It would not change my buying habits.

>Who's buried in Grant's tomb?

Grant and his wife.

Al.

89 Yeast	8 3	0	0	
90 Hops & Beer	8 1	1	0	
91 Beer Styles	1 2	6	1	
92 Gadgets & Equip't		4 1	5	0

To be fair, "no recommendation" is not as bad as a negative comment. However, if someone has all the issues and just lists the ones he finds useful, that's an implicit criticism of the others. There some guesswork going on here. If he didn't mention whether he owned it or not, I tried to figure it out from context. So take the last two columns as approximate; I stand by their the total of the 2 in each case, but may be off in the particulars. NB the 1989 line adds to 11, the others all to 10. That's because one respondent simply said he thought the Yeast issue was good and offered no other opinion.

There are some clear trends here: Yeast and Hops are pretty much universally liked, Malt Extract and Gadgets '88 are out of the running. Opinion is divided on the others. Once again, the 15% discount deal is on 85 and 87-91 as a set. Maybe this is a ruse by AHA to get rid of their inventory of 88 as a freebie to those who want 85, 87 and 89-91 anyway?

Selected comments

- 85 All-grain: "...a good issue if you're an all-grainer, although a bit of the information seems old now" "...old, more information is available in other books."
- 86 Malt Extract: "Obsolete, for the most part."
- 87 Troubleshooting: "Moderately useful, especially if you're judging." "IMHO the only valuable issues are this, hops and yeast."
- 88 Brewers & Gadgets: "...a real dog...When they sent me the '88 I decided to let my membership lapse."
- 89 Yeast: "A must-have. Top-flight scientific data and advice." "There's good info in there."
- 90 Hops & Beer: "SUPERB! Well worth having!" "indispensable"
- 91 Beer Styles: "Infuriating." "Absolutely the most valuable. A very good reference."

92 Gadgets & Equip't: "Good, especially if you're a gadgeteer."

Subject: what to do with used grain bill

Well, I was wondering, what to do with the spent grain bill... so I was thinking...

What if I were to put the spent grain bill into the primary? any additional sugars that might have been left over can be used for fermentation/taste (depending upon complexity)...

I know that it will probably introduce extra gunk into my beer that might induce chill hazing or whatever, but, in a dark beer? I don't think it'll matter much...

I just hate to see all that grain to down the drain :)

any other ideas? I've heard about making bread out of it, but I don't think that might be feasible for me.. :(but who knows :)

One problem that I can foresee is the soaking up of my beer into the grain????

comments please...

thanks,
-chris

Subject: Flaked barley as a specialty grain.

Thank you for the replys about the question of using flaked barley as a specialty grain. It appears that using flaked barley adds a creamy mouth feel and improves the head. Some people use flaked barley with all beer styles. Recommendations on the amount ranged from 5 ozs to 1/2lb for a 5 gallon batch. It was also stated that flaked barley can be found at food co-ops under "rolled" barley at a significantly lower price than from your local homebrew supplier.

Thank you!

Subject: TEXAS-SHELL COMPETITION

I don't know if this has been posted yet but:

"A homebrewer's dream come true! Almost everyone who has brewed a batch of beer in their kitchen or garage has thought, 'Gee, this beer is so wonderful, wouldn't it be great if I could sell this stuff!' Well homebrewers, here's your big chance!"

So says the intro to this competition sponsored by the August-Schell Brewing Co. in New Ulm, Minnesota. Here's a rundown of the particulars:

What: 1993 Texas-Schell Open Homebrew Competition
Two bottles per entry (Max. 4 per person)
Categories: None (except no 'novelty'/fruit beers)
Entry Fee: None (Schell and C.R. Goodman Co. covers it.)

Ingredients:

"Schell uses domestic grains, so we prefer that you do too. Extract recipes will be converted to all-grain equivalents. Either domestic or import hops ok. If you are brewing an ale, they prefer that you use a dry ale yeast (really!), as they will most likely be using either Windsor or Nottingham ale yeast. If you are making a lager, we suggest Wyeast #2035 which is, co-incidentally, Schell's own strain! Alcoholic content should be a minimum of 4% by weight (5% by vol.) as they wish to bottle the beer in 22 oz. 'big-boys' and in Texas that means that it must be an "ale" or "malt liquor" (ie. over 4%/5%).

Who: Any homebrewer residing in Texas
When: Entry deadline is 4pm Saturday June 5. The contest will be held the following weekend, 1pm Sunday June 13.

Where: Send entries to: Texas-Schell Competition
c/o DeFalco's Home wine & Beer supplies
5611 Morningside Drive
Houston, TX 77005

To be held at: C.R. Goodman Companies
3430 Yale
Houston, TX 77018

They plan to use the winning recipe for an actual commercially produced August Schell beer to be sold nation-wide. Also in the works are plans to fly the winner up to New Ulm for the brewing of the inaugural batch. Sounds a bit like the Pete's Wicked Ale competition eh?

have at it.

Subject: Beer Balls

In 1108, M.Galloway asks about beer balls. I started to get into them several years ago, but abruptly stopped using due to leakage problems. I had the portable type from Fritz in Pottsdam, NY using an EDME tap for CO2 cartridges. The tap leaked like a sieve. The balls were great for a single event, the tap would hold and a cartridge or two would suffice. But any longer just wouldn't cut it.

Randy at Brew Ha-Ha in Pottstown, PA had success with the "regulator" tap system for the balls. He and I both are, however, head-over-heels giddy about 5 liter keggings. You know, those 5 l Dink and other German draft cans. These things are perfect for Non Don Cornelious Keggers. Holds 10 pints of your favorite draft in the kitchen fridge. The key is the CO2 cartridge adjustable pressure bottom-feed tap for these guys. Fits both small and large size CO2 carts.

I do have a question tho... Is there a difference between the ISO CO2 carts and a pack of Crossman CO2 chargers from the Kmart counter? Is this what's termed "Industrial CO2"?

Thanks, and Brew On.

Subject: "Samiclaus" aka strongest beer in world

Hello all,

I just thought I'd let you know what I found out about Samiclaus beer. For those of you who don't know it, It is a high alcohol (14%) lager with a rich malty taste and good hop balance. (I highly recommend anyone to try it once). It is brewed once a year and lagered for a year before sale. Anyway, the interesting thing is that the yeast strain used to manage this feat is under constant development. After fermentation is complete, the surviving yeasts are plated out and reused the following year. What amazed me was that the beer could be so standardized from year to year. It appears that this technique works well for bottom fermenting yeasts, but not ale yeasts. The latter are prone to yeast weakness whereby they revert to an ancestral genetic makeup, thereby spoiling the beer.

The head brewer did say however that sometimes problems present themselves: this year's fermentation started perfectly normally, but then stopped - for THREE months. Just as strangely it then restarted of its own accord, but with serious overattenuation (>30 Plato down to 3, roughly equal to 17% alcohol!).

The moral of this tale is that even the biggest Swiss brewer has trouble with his yeast.

Another thing the brewer mentioned was that they expose their malt to water for 7 seconds before milling to soften the shell (sorry I've forgotten the proper name). This has the effect of crushing the inside while only splitting the husk (knew I'd remember it). This makes for better lautering. We didn't get onto how you expose malt to water for 7 seconds only, but he said they did that because of the delay between milling and mashing (ca.5-10 hours). To wet and the malt would mash itself.

I'll be using some of his malt in my next batch, and will try spraying the malt with one of those plant sprays. Any opinions? Has anyone done this?

Rob.

David C Mackensen <cygnus@unh.edu> writes:

> Well, I was wondering, what to do with the spent grain bill
I toss all the spent grains on to the compost pile in the
back yard. That seems to me to be the best use of the grains.
And adding 10 lbs or so every couple of weeks really adds up to
a lot of compost.

> What if I were to put the spent grain bill into the primary?
> any additional sugars that might have been left over can be used for
> fermentation/taste (depending upon complexity)...

How are you going to sterilize the grains before tossing them in ?
Boil them ? Seems like you'd be asking to extract a pile of
tannins from the husks. Then have the husks in contact with the wort/
green
beer for a week or two ?

Doesn't seem like a good idea to me.

> I know that it will probably introduce extra gunk into my beer that
> might induce chill hazing or whatever, but, in a dark beer? I don't
> think it'll matter much...

Depends on just what you like to drink.

> What does the HBD think about just pouring a can of DARK malt (liquid)
> into the primary before pitching (and of course, mixing it up REALLY
> well)...

Why not add the extract to your boil kettle when you're making the batch
?

I see no reason to do this. What about sterilizing the extract ?
If you want to boost the gravity, add it to the boil.

Tim

Subject: aromatic malt

there are two belgian munich malts, one is called 'munich' and is about 6 lovibond and has a diastatic power of about 50. the other darker munich is called 'aromatic' and is about 21 lovibond and 29 diastatic power.

both malts will convert themselves although 29 dp is really pushing it i suspect.

munich malt is made in the same way as pale ale or pilsener during the initial stages of drying but the last stage is carried out at a higher temperature. the basic process for all kilned malts (pale ale, pilsner, lager, mild ale, vienna, munich) involves drying the green malt which has about 45% moisture at a low temperature until the moisture content reaches about 12-18%. regardless of the type of malt, a higher temperature is needed at this point because this last bit of moisture is more difficult to remove. it is this stage that the each of the kilned malts develops its unique features. the munich is dried at the highest temperature and thus has darker color and less catalyts (enzymes).

by the way, contrary to what has been reported here, this process is basically the same the world over. i.e., european and american munich malts are made in the same way.

You know, I wonder if this reflects the dichotomy between those who try to brew true to style (for competition or otherwise), and those who just brew what they like. One member of our club hates competitions because of the focus on style -- he says "... this is a good beer, I don't care if it's too/not enough (hoppy, malty, fruity, whatever) for style X/Y/Z. I like it."

Subject: spent grain in primary?/how about malt syrup?

I wouldn't put spent grain in the primary! The grain is contaminated. Some brewers exploit this by doing sour mashing, but the mashing is done in a vessel, and is followed by a boil. So, throw the spent grains on the compost heap, or make a bread out of them.

I also wouldn't add malt syrup directly to the primary. Again, you want to boil the malt syrup for sanitation, and the boil does other things such as help the clarity of the resulting beer.

Date: Wed, 31 Mar 93 09:21 CST
From: arf@genesis.mcs.com (Jack Schmidling)
Subject: YEAST CULTURE, one

JACK SCHMIDLING ON YEAST CULTURE

Part one

Objective

The objective of culturing yeast is to isolate a single cell from a beer or culture that has the characteristics desired and encourage this cell to reproduce enough offspring to start a new batch of beer.

This is easier said than done but with reasonable care, luck and modest investment, can be accomplished by the serious home brewer.

General Program

The general program is to dilute the original culture and spread it over the surface of a growth medium in a petri dish so that individual cells are far enough apart to allow them to grow into visible colonies without touching each other.

A sample from one of these typical colonies is transferred to a test tube containing a growth medium. When this colony is actively growing, it is considered a pure culture and can be refrigerated for later use or started by covering with beer wort. When this starter is actively fermenting, it is poured into a larger amount of wort which, when active, is pitched into the beer.

Basic Assumptions

The procedure makes a number of assumptions which are correct, often enough to allow it to work well enough, to satisfy most requirements.

The first assumption is that one can select the desired strain by looking at colonies on a petri dish. This is more or less true because the overwhelming majority will be the same, i.e. the dominant strain. Bacteria, molds and many wild yeasts are obvious and recognizable to the naked eye.

The second assumption is that, while still very small, all round colonies are the progeny of single cells.

The third assumption is that all such colonies, at least in the center are mono clonal or at least mono-cultures and otherwise sterile.

To do the job right, one would have to study the original diluted culture under high magnification and do a presort at that level. This is revealing and fun. It also gives an indication of any bacterial contamination in the culture but the rub is marking individual cells and finding them later when they grow into colonies. This is done using a calibrated X-Y stage on the microscope and making careful notes. Fortunately, however, I do not believe that it is really necessary for the home brewer, although a must for the lab selling selected strains.

Details

There are many growth media available for the purpose and no doubt someone can recommend a source or recipe for the ideal but for my experiments, I mixed two packets (16 gr) of Knox gelatin with one cup of 1.020 wort. After heating and dissolving, this is poured into petri dishes and test tubes and sterilized in a pressure cooker for 15 min at 15 lb.

It should be noted that a pressure cooker is the preferred method of sterilization but for our purposes, one could probably get by with steaming in any pot with a lid and a half inch of water. Set the dishes or slants in or on a cup or some other support to keep them out of the water.

The petri dishes are turned upside down after solidifying and cultured this way to prevent water of condensation from falling on the medium. The test tubes are cooled on a slant to allow the water to settle on the bottom when vertical. They are also stuffed with cotton before going into the pc. You can also use tubes with plastic screwcaps and avoid the cotton.

It should be noted that gelatin melts around 75 F so its use in summer is precarious. The better alternative to gelatin is agar agar. This is available at oriental food stores in stick form. Half a stick (about 4 inches) in a cup of wort will get you through the hottest weather.

From: "Dean Roy" <DEAN@alpha.uwindsor.ca>
Subject: Yeast Labs yeast cultures

I recently purchased some liquid yeast cultures from my local homebrew supplier. Unfortunately he no longer has Wyeast cultures but he said the Yeast Labs cultures he had in stock (distributed by G.W. Kent) were just as good.

I have the following questions about these cultures:

(1) Are these the same yeasts as Wyeast? I purchased a California Lager and an American Ale (is this 1056)?

(2) The fermentation temperature suggested for both of the above is in the 70 degree range. Is this correct for the lager yeast?

(3) The cultures come in clear plastic tubes. No inner pouch or anything similiar to burst. Do I simply dump the contents of the tube into a starter?

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Dry Yeast

I have personally reviewed the Whitbread production procedures for dry yeast. Not only are they using a new facility, but their procedures are new with a strong accent on downstream quality control, the point of the process that caused problems in the past. For the record, our analysis of this yeast did include Rodney Morris' incremental actidione method for detecting wild yeast. This showed less than 1 nonculture cell per 10 million viable yeast cells. Crosby and Baker is currently distributing this yeast to both commercial customers and home brew shops.

Crosby and Baker is also distributing the Mauri yeast from Australia. I have tested this yeast as well, and it too meet specs. C+B has my report, which contains the detailed plate counts.

The Red Star products from Universal Foods have not as yet been tested. I have had several discussions with Dr. Foy, the QC biologist at Universal.

They have not made beer yeast for over a year, and will be introducing entirely new production procedures for their new yeast. Whether this leads to improved product quality remains to be seen. But it very definitely is not business as usual.

I hope this and my previous post are not seen as an endorsement of dry yeast.

Each of these strains have their own personality, which may or may not be to a particular brewer's taste. For example, the Mauri strain is a "pure" version of a well known Australian yeast. The test brews we did with this yeast indicated a clean but relatively bland finish, whereas the "impure" version was awash in flavors of all sort. This yeast IMHO is a good strain

for beginners who are just starting to develop their techniques. What is discernibly true is that the dry yeast of 1993 and in the future are and will be produced with much more rigorous QC standards than at any point in the past.

As I noted in my first post, Wyeast gets credit for this as they were the one who set the proper standards.

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: YEAST CULTURE, two

JACK SCHMIDLING ON YEAST CULTURE

Part two

Isolating Cells

The first step is to inoculate the petri dish with as diluted a mixture as possible. The books are full of procedures for doing this but I find the simplest is just as good. Take a copper wire or thin glass rod and heat several inches in a flame to sterilize. Dip this, when cool, into a working beer or yeast culture. If starting with dry yeast, dissolve one granule of yeast in a test tube with about one inch of sterile water. Gently drag the inoculated wire across the gelatin in the petri dish, trying not to break the surface. Next, draw the wire across this line at several points, to further dilute the sample. Turn the dish over onto the cover and "incubate" at room temp for several days. Do this on several dishes just for insurance and as controls.

Pure Culture

The next step is to visually inspect the surface of the petri dish under low magnification (hand lens or naked eye will do) to pick out a "typical" colony that appears to have come from a single cell. All colonies should be rejected that are any shape other than perfectly round and differ in any way from the majority.

Flame your wire again and after cooling, remove a small sample from the center of the selected colony and poke this into the surface of the medium in a "slant" test tube. You can do this to several slants, with the same sample, to assure all slants are the same or flame the wire and take a new sample from a different colony. You can make as many slants as you will need for several months and throw away the petri culture.

You now "incubate" the slants until 25% or more of the surface is covered with the pure colony and then refrigerate them till needed.

Starting

When needed for use, cover the slant with sterile wort and pitch when ready, i.e fermenting. For best results, this starter should be used to pitch about a pint of wort, a day or so before brew day.

This process can be used on anything from a packet of Red Star to a bottle of your favorite beer and will produce a pure culture. There is no guarantee however, that the strain will remain the same for ever because of natural mutation. As it is my experience that the most common and objectionable contaminants of dry yeast are bacteria and mold, this process will guarantee at least, to eliminate these most serious problems.

SIMPLIFIED PROCEDURE

An even simpler process can be used if one is not interested in isolating single cells and has confidence that the starting culture is pure.

This procedure skips the petri dish part and assumes one is starting with a packet of liquid yeast or a culture slant obtained from a reliable source.

After preparing the agar/wort medium and a convenient number of slant culture tubes, they are simply inoculated directly from the culture.

Using the sterile procedure outlined above, just dip into the packet of liquid yeast with the transfer wire and poke this into the agar in the sterile slants. One dip is enough to inoculate several tubes. You can use the rest of the yeast in the packet to start the next batch but the slants can be saved for a year or more.

If you use a purchased culture slant, the same procedure applies. Poke the wire into the yeast culture and then poke this into the slants. Save the original for future iterations. If you started with a liquid yeast packet, save the last slant to start a new group.

Using this simple approach, one can go several years without spending a penny on yeast and possibly forever once you get into the "yeast swapping" mode. I have yet to buy any yeast since I stopped using dry.

While this is not necessarily music to the ears of yeast suppliers, it is good news to the homebrewer. That \$'s for yeast in the bill of materials becomes zero to the yeast culturer. Yeast suppliers (like extract suppliers) will no doubt always be with us and in the case of yeast, we need them to

maintain pure strains when ours go south. But to keep buying the stuff
for
routine use is strictly for the affluent and laz.... naw, I won't do
that
again.

Don, goes on to explain why he is still skeptical of dry yeasts. With
all due respect, Don, how much of your data is concrete and how much is
conjecture? I'm willing to accept your arguments, but have you visited
the plants that make these yeasts? Have you talked to the manufacturers?
I don't mean to flame you -- I think you make some good points, but I
just
want to know if this is based on concrete evidence.

>and Dr. Fix's culture methods would not detect it. There are methods
>which will detect most wild yeasts but these methods are quite
>sophisticated and would require equipment and expertise found in some
>microbiology or biochemical laboratories with fluorescence microscopy
>capabilities.

Are you familiar with all the equipment George has at his disposal? I am
aware of the fact that he has some pretty heavy-duty equipment available,
and would not doubt that there's quite a bit more that I don't know
about.

Mark wrote about a kit beer made with dry yeast rehydrated in 70F wort
with
an original gravity of 1041, which stopped fermenting after about two
days.
I would have quoted his text, but MARK FAILED TO USE CARRIAGE RETURNS,
WHICH
MADE A MESS ON MY TERMINAL WHEN I TRIED TO INSERT A ">" AT THE BEGINNING
OF
EACH LINE.

I recommend that you not use wort to rehydrate dry yeast -- you are not
only
stressing the yeast, but tempting the remaining live ones to produce off
flavors. Secondly, if you fermented at around 70 to 72F, a 1041 wort
could
easily have fermented out in two days. It would have helped to know the
temperature of the surroundings and if there were any sudden temperature
changes that could have knocked the yeast out. If there were no sudden
temperature changes and you fermented above 68F, I'd suspect that it's
done.
If your SG turns out to be below 1010, I'd say it fermented out. Give it
a

few more days and then bottle. If the SG is well above 1010, then I'd say something happened to the yeast. You could try making up a starter of fresh yeast and pitching it after it finishes fermenting out (to ensure that you are not adding additional oxygen to your main wort).

Chris writes:

>Well, I was wondering, what to do with the spent grain bill... so I >was thinking...

>

>What if I were to put the spent grain bill into the primary? >any additional sugars that might have been left over can be used for >fermentation/taste (depending upon complexity)...

I have no hard data on this, but my gut feeling is that I would recommend against it. Actually, it would make something like Ninkasi --if memory serves correctly, the "beer" of ancient Babylonia did not have the grains removed -- talk about liquid bread!

I'm raising squirrels the size of pit bulls with my spent grains. I just dump them in the yard -- I think the deer like the hops and the squirrels like the grains.

>What does the HBD think about just pouring a can of DARK malt (liquid) >into the primary before pitching (and of course, mixing it up REALLY >well)...

It's sanitary, and I assume you are adding it to water, so it will, er..

work..., I guess, but you still want to sanitize the water and would *like* to boil the wort to get the proteins to coagulate, but technically it would make beer.

Chris (another one) writes:

>Thank you for the replys about the question of using flaked >barley as a specialty grain. It appears that using flaked >barley adds a creamy mouth feel and improves the head. Some >people use flaked barley with all beer styles. Recommendations >on the amount ranged from 5 ozs to 1/2lb for a 5 gallon batch.

You can get away with not mashing it (using it as a specialty grain) in dark beers, but it will make light-colored beers cloudy if you don't mash it.

Subject: MaltMill review

hi all,

after reading in the last two issues, i remember i owe a review on the
maltmill
i bought - yes off jack - last fall. i have the adjustable one and after
hearing a war story from a fellow brewer (commercial - both of us) i am
glad
i do. mine has worked very well in crushes of malted wheat, crystal and
2 row
pale (both MF and canada malting). thruput is so far fair (but them i
ask a
lot). i can easily got thru 10lbs in a few minutes (with var speed drill)
.
i have yet to grind a full 100lbs+/- in it tho i do not forsee a problem,
provided the spinning of the rollers is not to slow nor to fast.

(anyone got any hints at the correct rpm for the rollers - max thruput
and
least hassels)

on the other hand - this fellow brewer - had a hell of a time. again
this
was with the non-adjustable roller model. the bill called for pale malt
(MF)
crystal malt (MF) and choc malt (MF). i was not there when the problems
came
up - but the crystal ended up to fine, the pale did not feed properly
and the guy had to rush out to get a corona. now mind you this is a
motorized
(probably too fast) with hoppers above and below. the total grain bill
was on
order of around 100lbs (+/- 20 - i don't ask what he puts in his beers)
. the
first 20lbs or so of the pale did run ok. he is going ot order the
adjustment
kit and upgrade.

anyway from my experience and his, if you get one get the adjustable one.

standard discalimer from a commercial user.

Subject: WYEAST contamination?

There has been a thread recently about contamination of dry yeasts, but what about liquid? From what I can make out, one form of contamination, apparently somewhat prevalent in the old Whitbread, is by a wild yeast which can ferment dextrine, giving excessively dry and bland beer. This is just what happened to me with a batch of 1056!

My first brew went from 1.036 down to 1.006, as measured with a hydrometer. I've never had such a low reading, and the beer sure is bland. I can hardly taste anything in it.

The second batch used the slurry from the secondary of the above, and went from 1.044 down to 1.008. I would normally expect 1.012 minimum for this type of beer. This, too, is somewhat bland.

Both the above had some crystal malt, although I forget how much without my notes.

My latest use of another pack of 1056 went from 1.044 to 1.013, much more expected.

Has anyone else had WYEAST problems like this?

>think it'll matter much...

>

I would strongly advise against this course of action. From what I have read grain is highly contaminated with bacteria (lactobacillus, I think). If you put your spent grain directly in your primary, you are risking a serious infection. If you boil the grain to sanitize it, you will end up extracting tanins from the husks. This would probably (sheer guess, here) be detectable even in a dark beer.

>I just hate to see all that grain to down the drain :)

>

>any other ideas? I've heard about making bread out of it, but I don't
>think that might be feasible for me.. :(but who knows :)

Here's a few: I have heard of some people using it to supplement their pet's food. Also, do you have a compost heap? Maybe you could dry it and make your own granola? I've never done it, but it sounds easier than bread.

Hey, maybe you could make bread with it, then add the bread to your next batch in the mash. For that good ol' summerian taste!

Just a thought.

Subject: Plastic tubing questions

I have a difficult time cleaning the plastic tubing I use for siphoning and blow-off. For this reason, I end up going through a lot of tubing, and probably wasting a lot of money. This causes me to ask the following questions:

Grainger stocks vinyl and polyethylene tubing which "conforms to FDA standards", although they state that the vinyl product exhibits a "slight" taste and odor. They sell this stuff pretty cheaply. Can I use this for siphoning?

(For some reason, Home Depot does not carry the I.D. tube that fits my bottle filler.)

In grad school, we used plastic tube called Tygon, which I believe was autoclavable. Can this be used for beer?

Finally, does anyone know where I can get 1" ID blow-off tube?

Thanks for all of your help.

Subject: MM review

Hi All,

I recently purchased a Maltmill with the roller adjustment, and would like to share my experiences with it. I would like to preface my remarks by stating that I used a corona for about two years before getting a Maltmill.

It arrived in good shape, and required just a few minutes to assemble.

There are two bolts that fasten the roller assembly to the baseboard, and one other to fasten the crank. I set it up, ground a pound of malt, and used an old toothbrush to clean up the rollers.

Upon reading the enclosed instructions, it only took a few minutes to adjust it properly for two row. I dropped a few grains onto the rollers,

none of it fell through. I ground a handful of malt on this setting, the

grain chunks were a little large, so I tweaked the adjustment just a bit tighter. I ran a pound through at that setting, each kernel was broken into several small pieces and the husks were virtually intact. There

were

a few grains that *looked* whole, but when I picked them up it turned out

that they were crushed so gently that they just didn't separate from the husks. I've never gotten that good a crush out of a corona, despite doing

all the modifications to it that have been posted in HBD.

The throughput of the MM is very impressive, in fact, if I had a complaint with the mill, it would be that it grinds a pound so fast that I had to keep stopping to refill the hopper. I solved this by notching the bottom of a 4 gallon food grade bucket so that it fit snugly inside the hopper. The bucket holds 8 pounds of grain easily, I only needed to stop to refill once, so I was able to grind 10 pounds of grain for a batch in under 10 minutes. This used to take 30-40 minutes with the corona.

The mill itself is designed to sit on a bucket, so that the output from the mill is easily collected. I had seen a demonstration of an early version of the MM that required a shallow pan to catch the crushed grain, which had to be emptied every couple of pounds. The newer version

is a distinct improvement, the 5 gallon food grade bucket I placed under the mill easily contained all the grist.

My extraction did not go up, but I really didn't expect it to. I get 30 pts/lb/gal with infusion and 33 with decoction mashing. The biggest difference in brewing with grain crushed with the MM was how incredibly fast the runoff from my lauter tun cleared. With the corona, by the time I adjusted it to produce small enough chunks of grain to get decent extraction, the husks were pretty well trashed and there was a lot of flour. This meant I used to have to recirculate 1-2 gallons of runoff before it cleared, with all of the associated problems of heat loss and HSA. With the MM, there was very little flour and the husks were virtually intact, providing good filtration, so the runoff cleared after 1 quart! I was quite literally *stunned* how fast it cleared. Scarcely believing my eyes, I recirculated a second quart, which ran crystal clear. I don't think this was really necessary, I could easily have gotten away with recirculating just the one quart.

In all fairness, the corona was *intended* to produce flour for

making tortillas. If one goes to the trouble of removing the snap ring, filing the end of the impeller shaft flat, replacing the cotter pin that retains the movable plate to minimize wobble, and gaps the plates correctly, the corona will do an adequate job at something it was never designed to do, i.e., crush malt. I took each of these steps, and they all helped produce a better crush, but IMHO, for quality of crush, throughput, and ease of collection of the grist, the Maltmill is far superior.

I, for one, am a very satisfied customer. Congratulations on a fine product, Jack.

Cheers,
Jim

Subject: hop utilization

The discussion of a 20% loss in hops utilization in going from pellets to whole hops made me realize why one of my recent beers was surprisingly over-bitter. First let me say that I always use whole hops. Usually I pull some of them open to expose more of the lupulin glands, but a lot of the cones are still intact even after the boil. What was unique about this "Bitter Steam" was that, rather than manually pull the hops apart, I put them into a coffee grinder and gave it a few spins. They chopped up very nicely. I now believe that this chopping exposed virtually *all* of the lupulin glands, resulting in a greatly increased utilization.

In fact, what are pellets if not chopped up whole hops?

Date: Wed, 31 Mar 93 19:27:58 EST
From: Ulick Stafford <ulick@bernini.helios.nd.edu>
Subject: Hunter update, spent grain

I would like to update my Hunter post in 1107. I have been informed that a Hunter Airstat is what is normally used. Its main use is controlling window air conditioners and so can easily handle Freezer loads. It is simply plugged in and the freezer plugged into it. I don't know how available they are. I didn't see one in any hardware stores but now that the seasons are changing they may become available.

BUT to update my description of how to use the regular heat/cool home thermostat. I found the 9V battery to be useless for running the relay. It seemed to go flat in a day (and I thought relay loads were low!). I replaced it with an old 9V power supply that I had lying around. 6V will also do it, and maybe there would be no problem with a 120VAC relay.

Otherwise I am now very pleased with the performance. I like the simple way of adjusting the range. I have been informed that a method for modifying the thermistor based airstat with a resistor was posted a while back, and this would seem to be a less complicated approach than mine. But hey, if you can't get an airstat, this is an alternative.

David Mackensen asked about spent grain. The best thing is to feed it to livestock, if you know a farmer nearby. You can use a little in bread, but it usually ends up a little solid. Or do what I do, compost it. It makes a fine mulchy compost, especially if you forget about it and leave it rotting in your cooler for a week before dumping it :-)

Andy, if there is anything true about homebrewers it is that we all have our own ways of doing things and the ultimate test of our practices is the quality of the beer we make. However, having never tasted your beers, I would object to this practice of yours on two grounds. The first

is certainly the increased chance of contamination that you bring up. I hope you at least sterilize the cheese cloth by boiling. The second objection I would make is that once you've gone through all the trouble to filter trub out of your wort, you want it to stay out! The couple of ounces of extra wort that you can obtain by pressing the trub is probably not worth introducing trub into your fermenter. My advice is to not do it at all!

From: Mike Rego <MREG01@vax.clarku.edu>
Subject: Whitbread yeast

The recent discussion concerning Whitbread yeast has caught my interest. At the end of February I brewed a porter using dry Whitbread Ale yeast. It was a 12 gram packet with a serial number of 020412 stamped on the back. I bought it along with my other ingredients the day before brewing.

I did not have any trouble with this yeast during the ferment, and the resulting brew is lovely.

Still being new to this, I have not yet tried a liquid yeast. Almost everything I've read talks of Wyeast. How is that name pronounced, and is it the best?

By the way, I just finished a bottle of Sam Adams Cream Stout. It has a distinct flavor that is hard to describe. A slight suggestion of burned popcorn? After a few bottles it becomes a familiar signature - kind of like the Guinness sour tang.

From: RADAMSON@delphi.com
Subject: 5 liter Kegs

I received several inquiries regarding the 5 liter metal keg setups.
Here's
what I know:

The problem with getting the Dink, et.al. cans from the stores is that
the tap
they sell you for \$2.00 is a gravity tap that you insert in bung, flop
the keg
upside down and 'can-open' a hole in what was the bottom (and now on top)
. .
Certainly makes the vessel non-recyclable.

The solution is these bottom-feed CO2 cartridge taps made by Beer*King in
Germany. I originally got my tap(s) from Hoster Brewery (brewpub) in
Columbus, OH - but they no longer 'keg' into 5 liter cans (and,
therefore,
don't sell the taps anymore). Dock Street Brewery in Philly kegs into 5
liter
cans, but I'm not sure about the type of tap they sell. Stoudt's in
Adamstown, PA likewise.

A source that I do know of (and have no affiliation with) for both taps
and
empty kegs is:

Randy Martin, Proprieter
Brew Ha Ha, Ltd.
209 High St
Pottstown, PA 19464
800-243-2620 (orders)
215-326-2620 (Dr. Brew)

Randy picked up a bunch of kegs from the now defunct State College
Brewery
(Penn State) and could probably set you up.

The tap has a central stem the height of the can which feeds brew from
the
bottom. There may be a small yeast burst in the first couple ounces of
brew/foam when first tapping, but none whatsoever afterwards. The tap
also
has an adjustable CO2 valve that I "tweak-up" a little at a time to
intro-
duce more gas - you can hear it enter and build up a bit, then back it
off
to zero. I put more gas on for overnight storage, haven't had any
leaking.

As far as keging these guys go, I have usually filled a couple 3 kegs
along with a couple dozen bottles. And to keep it simple, I still bulk
prime with either DME (.50 cup) or Corn Sugar (.75 cup) and just fill
them
as I go along. Use your own standard priming rate, mine are low-to-fair
carbonation level (British Ales, mostly). Since the volume is larger
than

that of each bottle, the maturation time is increased (takes longer to reach carbonation), but is well worth it. Handling and storage is the same as if they were bottles. The 5 liter is equivalent to about 14 12oz bottles

- but it goes in the fridge better.

For Sanitizing, I just drop a few tbls of Bbrite in, fill and soak for a couple hours prior to keggling. So far the hardest part about these is forcing the bung in after I fill the keg. I think I've been filling to high - I'm going to be leaving about a 1" head space next time.

Subject: "Samiclaus" aka strongest beer in world, for now?

Recently I toured the brewery of the Boston Beer Company, the makers of Sam Adams. It was not terribly interesting, but it was cheap, a \$1 donation, and the beer was fresh and free. Basically, I would highly recommend it.

During the tour, they bragged about being in the process of developing a "Triple Bock", apparently it is Jim Koch's goal to get the world record for the highest alcohol content in a commercialized "malt beverage".

Subject: Test Drive

>From: Mike Deliman <miked@wrs.com>

Just a few comments on this review...

> The rollers themselves are grooved; these were probably used in an industrial application and required a significant cleaning effort before the author felt comfortable about using this device on a food product.

The rollers were designed by me and custom fabricated for use in MALTMILLS.

They are brand new and any oil or other foreign matter is a result of the manufacturing process. They are vigorously wiped before assembly but a film of oil remains as a rust preservative and some lint from the rag might also remain..

>On the adjustable model, one of the placard bolts is replaced by the adjustment lock down bolt - which sacrifices whatever structural reinforcement the original bolt had to offer.

Nothing is sacrificed as the screw's only purpose is to hold the panel in place.

>If this mill were to fall from 5 feet to a cement floor, there would undoubtedly be irreparable damage.

Damage, possibly, but not likely irreparable. The most probable damage would be to the easily replaceable particle board base.

>The MaltMill was adjusted to just where it would not allow malt to go through uncrushed. Aside from husk material and flour, the crush was nearly indistinguishable from that of the Corona.

That is not hard to understand because it is not the correct way to set up a roller mill. The MM is designed to be operated with a nominal roller spacing of .055" and the adjustable models are shipped set, at that spacing.

What you did to it was to make sure it could not possible produce a proper crush. The adjustable feature is there only for very minor changes required to optimize feeding when motorized.

>The MaltMill has the possibility of passing a few uncrushed kernels through while still producing significant flour.

With the current model (yours) it is impossible to pass grain uncrushed through the rollers if properly set up or with the standard spacing. Unless,

of course, you have malt less than .055" in thickness. On earlier models, it was possible for some to get around the rollers but this has been corrected.

Furthermore, your statements contradict each other. If you "adjusted to just where it would not allow malt to go through uncrushed" then by definition, you would not be "passing a few uncrushed kernels through". You have the procedure right, you just didn't follow it.

Secondly, as has been pointed out by several users, the benign nature of a roller mill frequently crushes the grain but leaves the husk so entirely intact that it appears to be uncrushed. However, upon teasing apart, is found to be thoroughly crushed.

>After milling, the grain was sifted, and the resulting flour was weighed on a counterbalance (accurate to within .02 grams).

The key here is, the nature of the "sifted". That may sound like a nice general term but in brewing science it is meaningless unless we know the mesh size.

According to Noonan, "flour" is defined as that which passes through a 100 mesh screen. I received no response when I asked you what mesh you used.

Furthermore, for up to about 10% of the total grist, flour so defined is considered beneficial. Beyond 10%, it COULD be a problem but that depends on the lauter system used and most importantly on the amount of husk material in the grist.

I hate to sound like a broken record, but the flour phobia derives from the problems created by grinding malt in mills like the Corona. It is a simple fact of physics and chemistry that the finer the crush, the more efficient will be the starch conversion and sugar extraction.

The problem with grinders, i.e. devices with a moving surface working against a fixed surface, is that they damage the husk to the extent that the effectiveness of the filter bed can be seriously weakened. This can be compensated for by a coarse grind but it is a compromise, the price of which is overall efficiency.

As a roller mill only squeezes the malt, the impact on the husk material is trivial, resulting in the ability to mash and sparge with far larger proportions of fine grist, including flour.

It just so happens that expensive commercial mills, with multiple rollers and sieving devices can create more fine grist than the MM. But the MM is also a compromise, to keep the cost within the range of homebrewers' budgets.

>That's a whopping 20% MORE flour with the MaltMill.

Thank you but let's not confuse that with percentage of total grist.

>Husks: The husks on the Corona's crush were slightly more damaged than on the MaltMill.

That is probably enough to make the previous statement good news. However, the problem here is that you can only compare the husks that are left large enough to see. The ones that are pulverized and turned into dust by the Corona are not obvious to a casual inspection. You have to microscopically examine the fine grist to see it. This is not an easy thing to quantify and even I gave up trying. I just sort of rest on the intuitive notion that squeezing has got to be better than grinding.

>Unmilled kernels: the MaltMill had a higher ratio of unmilled kernels; we did not see any unmilled kernels with the Corona.

Again, the MM was improperly set up and I would be most interested in hearing from you after you try it again. The adjustment is only on one side, so if you set it so the rollers look parallel, you will be close enough. You can also use a dime as a gauge that is pretty close to the nominal. You can also set it so that it almost touches on the adjustable side and more closely simulate the .020" spacing of multi-roller commercial mills. However, you may have some trouble turning the crank.

Or you can return the mill and your money will be cheerfully refunded.

Subject: Re:immersion cooler length

>Does anyone know about the minimum length of copper tubing that
>can be used as an immersion wort cooler? Successfully.

The longer the better. Many of them are 20', some are 25', mine is a 50'
double helix (homemade). It all depends how fast you want to cool and
how
cool your tap water is, and how much water you want to use. Maybe one of
the thermo-scientists out there can come up with a cool cooling equation
relating $d(\text{temp})/d(\text{time})$ to length, tubing size, flow rate and tap water
temp. Of course some heat is disipated out the side of the pot, so
cooling
will be faster than this equtation says.

Subject: Subject: ICE BEER is here

Sounds basically the same as Eisenboch which translates into an "Ice Bock."

The beer is frozen as so that the water can be removed thus leaving a more potent liquid behind. Typically Eisenbochs are much higher in alcohol content than what Labatt is producing.

I have, in need of a quick chilling process, placed beers in the freezer and, inadvertantly, created a ice brew. HMMMMM, maybe I should trademark my process!!

Subject: YEAST CULTURES

I read Jack Schmidling's posts re subject and had some questions.

I've been culturing my own yeasty beasties for a few months now. Generally following procedures similar to those outlined by Jack. So far things have worked well but I live in fear of mutations and/or wild yeast contaminations. Questions are:

I don't get isolated colonies on my plates, rather one big long smear of yeast where I've dragged the inoculating loop. How can I inoculate

so I get isolated colonies? I suppose I could dilute by yeast source (usu bottle dregs or secondary dregs) but that add just another contamination risk.

I understand some yeast cultures are actually combinations of several strains (eg whitbread). Will I see all three of the whitbread strains as different looking colonies? Do I have to culture each of the strains

seperately? What about yeast from Trappist ale which I understand actually contain some bacteria important to the flavor produced?

I've heard that even if I get a good pure culture on a slant it will mutate and I can only use yeast from a given slant for a few months? Is this true? Is there a way to identify mutataants besides brewing a batch an looking for strange behavior such as low final s.g?

Finally, I'd to take a look at these marvelous little creatures who work so hard to ferment my wort for me. (Kinda like to say hi.) I've got a pretty decent optical microscope if I can figure out what box it's

in. Any suggestions on preparing a sample for viewing? Reflected light,

transmitted light? What power do I need to see these folks? Can I recognize mutations this way?

Subject: Legality of Mailing Homebrew

Eric Wade <ericwade@CLASS.ORG> says:

>Section 124.42 of the U.S. Postal Service Domestic Mail Manual prohibits
>the mailing of taxable alcoholic beverages. However, homebrew, up to
>certain quantities is not taxable. Authority 27 CFR sections 25.195 -
>25.207, 26 USC 5053.

I don't doubt this is true, but there must be more to it than that. One
of
the gifts I got for my wedding was a membership in a wine club. Every
month
two bottles of wine arrived in the mail. Wine is certainly taxable
(oh, BTW, this was commercial wine I was receiveing). Now, I do not
remember whether I got it by US Postal or by UPS or what. Would this
make
a difference?

In addition, I understand there is an analogous club for beer. How do we
reconcile these seeming disparities?

> competitions because of the focus on style -- he says "... this is a
> good beer, I don't care if it's too/not enough (hoppy, malty, fruity,
> whatever) for style X/Y/Z. I like it."

Normally, Spencer, I'd be inclined to agree. We have the same disagreements in my club, and they occur here and in other electronic fora with some regularity, but in this instance I think the cause is a bit different. I may have been the one to offer the "infuriating" comment, and I'm about as committed to styles as anyone you're likely to meet. My criticism of that issue is not of its premise, but of its content. Some of the sections are quite good. Some are not. And no apparent attempt was made to reconcile the style descriptions in that issue with those of the AHA Nationals, an appalling oversight which has been a freaking pain to deal with, I'll tell you! Contestants and judges like get in wrangles over which set of criteria to use, since both are published by the AHA. The Official Answer, of course, is that if it's the Nationals, then ignore Zymurgy and go with the style descriptors published along with the contest rules, also in Zymurgy (confusingly enough). I'm still surprised that this was allowed to happen. In my view, the value of the material presented wasn't commensurate with the trouble it's caused. Just my opinion ...

Subject: Using Sulphites

I have used a solution of potassium metabisulfite to sanitize all of my brewing equipment for many years. I recently read that it is ineffective, that it does not release enough SO₂ to do the job. Considering the pain inflicted on my nasal passages by this stuff, I find it hard to believe that any microbe could withstand such an onslaught.

Is there any scientific proof for the claim that sulfites don't work? The enormous advantage of using sulfites is that no rinsing is required. It seems to me that re-contaminating something with rinse water, after you sanitize it, totally defeats the purpose of sanitation!

Chlorine and iodine must be rinsed out because they will impart bad flavors to the beer, but sulfites are essentially tasteless. (Otherwise people would have stopped drinking wine long ago -- the stuff is full of it.) Sulfites protect beer from oxidation to some degree. Commercial yeasts are usually bred to have some sulfite tolerance. (Which I encourage by exposing them to it from day one.)

I don't like the idea of baking bottles because of the thermal stress to the glass. (They're not even Pyrex, and they get repeatedly pressurized and depressurized.)

I have a plastic bottle tree with a squirter attachment that is fast and convenient for sanitizing bottles. Because of the way that the bottles drain, it leaves a white residue under the bottle caps, though. Maybe if I lowered the sulfite concentration to 1% . . .

1993 AHA NATIONAL HOMEBREW COMPETITION

-----> FIRST ROUND - EASTERN REGION <-----

JUDGE AND STEWARD REGISTRATION

June 5th & 6th - Kingston, New York

Dear Fellow Beer Enthusiast,

The 1993 AHA National Homebrew Competition is right around the corner. Preparations are already under way to make this a successful event, but we need your help. This year we anticipate over 800 entries from the New England/Mid-Atlantic region. This means that we need a lot of help unpacking and registering entries, and more importantly judging them.

This year the judging will be held at the Woodstock Brewing Company in Kingston, New York thanks to the graciousness of Nat Collins, Owner and Brewmaster. Dates for unpacking are May 15, 16 and 22. Judging will be on June 5 and 6, with two sessions on the 5th and one on the 6th.

In planning this event we realize that many judges need to drive a distance in order to participate. Therefore, we have made arrangements for local hotel accommodations and a festive party featuring regional microbrewed and homebrewed beer, snacks, raffles and door prizes on Saturday night, June 5th.

To receive a registration form and further information please send mail to Bob Gorman <bob@rsi.com> which a subject of 'Kingston'. The registration deadline is Saturday, May 1st (National Homebrew Day).

Anyone already enrolled in the BJCP will receive a us-mailing later next week, you need not reply to this message. If you are new to the BJCP or not in the program then this is your official notice. I look forward to your replies.

Cheers!

Subject: maple beer

>>>> John Edens <johne@sa-htn.valmet.com> writes:

John> Has anyone out there made a beer using maple syrup as an
John> adjunct like Papazian describes? If so, how did it come out
John> and how much did you use?

Well, I've got a batch in the secondary (6.25lbs M&F amber malt,
** 3 LBS ** grade B maple syrup (gotten at a local food co-op, approx \$3/
lb
so comparable to malt), probably too much hops). I was going to report
on
it after bottling, tasting, but thought I'd comment now. The one problem
with my batch is hops. Chinook, for that matter. I've tended just to
try
new things arbitrarily (if I want to drink what I expect, I'll head to
the
local pub or beer store, THANK YOU.) and this might be my first major
mistake. Maple doesn't seem to bitter well (i.e. take to strong hopping)
very well at a young age. Of course, cutting back on the hops, or using
a
normal amount of hops would probably result in a taste of maple, malt and
hops.

Last I checked (during transfer to the secondary) it smelled like 1/2
beer,
1/2 pancake breakfast, tasted like beer with a taste (not just a hint) of
maple, especially once you knew what to taste for (I missed it on the
first
sip, and wondered how that happened on the later sips). The aftertaste
was
something to be missed, though, and that had to do with the hops.

Well, maybe next time...

-tony

Subject: Re: 5 liter kegs

R. Adamson (delphi.com) mentions using 5 liter kegs for home brewing.

I have 2 questions for him:

1) What do you do with the original bung that gets pushed inside the keg when it is tapped? Do you leave it there? Can you get it out? Will it affect the taste of the beer?

2) Where do you get new bungs to seal the kegs for home brewing? Can a rubber stopper be used? What holds it in place after the CO2 pressure starts to build up? If you use exact replacements, won't the keg start to fill up with used bungs each time it is tapped?

I have a foreign-made 5 liter tapper that uses a hand pump on top for pressure. It works very well for this type of keg. If I were to use it for home brew, I might cut the central stem 1/2" to 1" short so it wouldn't go all the way to the bottom and suck up yeast sediment.

>Many many brewpubs making ales require 11 days from brewday to the
>first tapping. I have tasted many 11 day beers that were fine.
>
>Jim Busch

The brewer at the Cambridge Brewing Co. (Cambridge, MA) has told me that
some
of their ales go from the grain to the glass in 7 days. This is
partially due
to lack of storage capacity as well as robust sales. It is amazing what
a
healthy fermentation, filtration, and forced carbonation can do!

Although one could argue that more aging may be beneficial to the final
product, the CBC's beers are quite drinkable.

FROM: Dennis B. Lewis<dblewis@jscprofs.nasa.gov>
SUBJECT: Decoction mashing

I've noticed that I'm not the only person confused by decoction mashing. It seems like a lot of screwing around just to increase yield. Personally, I'd rather just add another pound or so of grist and not worry about it. Are there other benefits to decoction mashing? Clearer wort/green beer/finish product?

Noonan says to remove "the heaviest third" of the mash. I suppose that does not include any grains since you will eventually boil it. This is really hard to do for those of us who mash in a pot on the stove instead of in a Gott cooler. Anyway, his directions are "marginal" (I'm being nice) in the decoction specifics.

At any rate, I'm very happy with multi-rest infusion mashes and the decoction stuff is simply a curiosity. Maybe I'll try it if I have an entire Saturday to blow on it.

Subject: Legality of Mailing Homebrew, etc.

Troy Howard <troy@scubed.com> questions how his wine club and BOTM clubs can mail "taxable" products given the postal regs I quoted. (Sorry all, I am a bit novice at this and know not how to include just the portion of the HBD I wish to respond to w/o including the whole HBD in my reply, advice by e-mail would be appreciated).

My suspicion is that these clubs probably pay their taxes before mailing, once paid, the product is no longer subject to taxation and should therefore pass the postal service's scrutiny. BTW, the entry instructions for the AHA Nationals state that mailing homebrew IS illegal and that other shippers (e.g. UPS) may refuse to ship if they know that you are shipping alcohol. I had an experience with UPS with my very first order of supplies from Great Fermentations of Santa Rosa, The Beverage People. UPS had no problem carrying the shipment but wouldn't leave it since I was not home. They explained that they can't leave alcoholic beverages on the doorstep. I convinced them it was only supplies and not alcohol (yet), and I've since had all my supplies shipped to my work address.

So, the upshot of all this? If you wan't to battle the postal service in light of AHA's warning and others' experiences, I've given you the results of my research. Me? I'll probably use UPS or find out if I can deliver personally to Anchor since I work in SF.

Found in "The Monthly", an East Bay advertising freebie, in an article on local beery spots: Why is American beer (lets assume Schludwillers) like making love in a canoe? Because they're both f*ck*ng close to water:-)>

Streak a third of the plate, flame the loop, streak the second third of
the plate after dragging through the path on the first third, flame again
and repeat on the final third, dragging through the second third.

I don't know about the Whitbread, but only one Trappist ale I that I know
of has a bacterial component and that's Orval -- you may be thinking of
Lambiks which indeed contain a long list of microbes.

Thomas writes:

>the bottom of the bottle. I used to use a primary and secondary

>sediment on the bottom of the bottle?

If you let the beer sit in the fermenters longer, more of the yeast will
sink to the bottom. (You should go back to using a secondary if you
plan to let it sit in the fermenter for over 2 or 3 weeks.) This will
minimize the sediment in the bottle, but not eliminate it.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: off-flavor puzzle/yeast wierdness/blowoff tube/succanat

Thanks to the folks who responded to my queries about off-flavors in two out of three batches made with the same yeast. I'm going to assume that I picked up an infection while racking batch one to secondary, which was then perpetuated when reusing the yeast from the secondary for batch three. I don't suspect my plastic tubing at this point because batch two, made with yeast from batch one primary, is fine - and the same tubing would have been used to rack, bottle, etc. Bottle conditioning seems to be improving things, however. Regarding plastic tubing, how often do people replace it? I'm assuming once a year is fine, but does anyone replace more often?

Now on to my next adventure. I'm making a pale ale (actually it's making itself right now) with some Wyeast 1056 "American" right out of the packet via a DME starter solution. On the sixth day it was still bubbling at about three per minute, but as the krausen had subsided I racked to secondary anyway, and tossed in the dry-hopping pellets. Within a day or two, what did to my wondering eyes appear but a KRAUSEN in the secondary! Coming up on two weeks now, it's still bubbling between one and two per minute. I have made ales this year with American, British, Irish, and London, and I have never had yeast behave in this manner (including a previous "American" two batches)!! My basement has been around 60-62 F. all winter, but this is the first time I have had such a slow fermentation. What should I do (besides of course RDWHAH)?

Joel Birkland asked about 1" I.D. plastic tubing. I got mine at True Value. They'll cut it to size and it doesn't cost much. While we're on the subject of blowoff tubes, I've seen several posts regarding the difficulty of cleaning them. My question is, what's the big deal? The only beer that comes in contact with it is what's being "blown off" - so as long as the tube is dry, that is, nothing dripping into your beer when you first attach the tube, why should it matter that you didn't get it squeaky clean after the last batch?

Finally, for any Eastern Iowa brewers who were as interested as was I in the recent thread on brown sugar alternatives, I can report that I found "Succanat" at the New Pioneer Co-op in Iowa City. It's a little pricey at five & change for a two-pound can (they also have Turbinado for <\$1/lb.) but

I plan to try it out. If I like it a lot, would anyone in New England be willing to mail me a bunch "in bulk" from Bread and Circus?

OK, this one isn't a major "aha!", but...

When you're pouring all that sanitizing solution out of the carboy, if you shove the racking tube in there, air can enter through it and the stuff just pours right out instead of glug-glug-glugging and splashing all over the place.

Just one of those things that dawned on me after an evening of bottling and RDWHAHB'ing...

Subject: Brewing to style, Malt Mill, Chillers

Brewing to Style:

Having been a brewer for 3 years I recently have paid more attention to "brewing to style" and have migrated away from "nikebrau", Just Brew It. This switch in brewing philosophy coincides with a change in method, partial mash to all grain [insert flames and name calling here]. My feeling is in order for me to produce beers with flavor profiles that I would like I must be able to control my process. A good way to validate my process is to attempt to brew to a certain benchmark/style and have my results reviewed by certified tasters which generally means some sort of competition. One of the finest homebrews I have had was an attempt at one style, a Bier de Garde, which turned out to be an excellent Extra Special Bitter. The color was too dark, the hopping was incorrect and it lacked the body and sweetness of a Bier de Garde. It still was a great beer.

Malt Mill: I would concur with Jim Dipalma on his review. Having participated in its use my observations: Cleaning- grind a couple pounds of grain, then brush off the rollers 3 minutes max. Adjust for proper crush about 5 minutes. We ground, excuse me , crushed 10 lbs of grain in about 5 minutes. I too had the fastest clearing, clearest run off of any batch I brewed. The unit is not fragile. It is well designed, place it over a 5 gallon bucket and crush. I want to sell my Corona, Email if interested lmenegon@necis.ma.nec.com

Immersion wort chillers: I would be more concerned about how long I could make it. Mine is made from 3/8" OD soft copper tubing which I wrapped around a soda keg to make a coil. I Used about 35 feet of tubing. I filled my brew pot with 6 gallons of water, measured the height and coiled until I exceeded that height. I allowed for the in an out tubing to rise out and over the pot to a point 6" below the top to prevent water getting in the wort in the event of a leak. 50 feet of 3/8' soft copper was \$22 the 3/8 to hose male connection was about \$3. I clamped old plastic tubing on the output end total, cost \$25. With the extra tubing I am making a manifold for my lauter tun.

> to get the world record for the highest alcohol content in a
> commercialized "malt beverage".

I had some of this at the Sunset Grill in Boston. It is very strong and I thought nicely done. The bartender (normally very well informed at the sunset) claimed 14% alcohol. I found it hard to believe that Sam had brewed something stronger than Samiclaus and figured that 14% was by volume. I don't have my Jackson's Pocket Guide here, but Samiclaus is 13.x% alcohol by weight, so it would be more than 14% by volume.

I would be interested in hearing from anyone who had some concrete knowledge about the Sam Triple Bock, such as original and final gravity and the alcohol content (and whether is by wt. or vol.).

>Using a quarter cup would give a pressure of around 50 psi but I still don't think it's a very good idea.

>Pressure vessels are thick, heavy and expensive for a reason. The pressurized gas which they hold contains an enormous amount of potential energy.

Thanks for the envelop engineering. In spite of your cautions, it still seems that it is a workable system if one is careful and does not work in the blind, i.e. monitor the pressure with a gauge. If a quarter cup produces 50 psi in an empty keg, it would seem to be enough to carbonate a 5 gallon batch and dispense it with pressure to spare. Once the beer is carbonated, the pressure could be relieved down to working pressure and I assume there would be enough to dispense an equal volume of beer.

It would seem prudent, however to add a pressure relief valve in case things don't work out as planned.

>Subject: Yeast Labs yeast cultures

> (3) The cultures come in clear plastic tubes. No inner pouch or anything similar to burst. Do I simply dump the contents of the tube into a starter?

Have no idea about the rest of your questions but there are two ways to use the tube cultures. Come to think of it, you did not say whether they are on agar or just in a liquid medium.

If the latter, they are probably intended to be poured into a starter wort for one time use.

If on agar, you can use them to start new cultures on slants and keep the original as your pure culture. If you just want to start a batch with it, the best way is to pour enough sterile wort in the tube to cover the yeast and incubate it for 24 hours than use this liquid to start your starter.

The article I just posted on yeast culture details how you can turn one of those tubes in a lifetime supply of yeast.

>From: korz@iepubj.att.com
>I recommend that you not use wort to rehydrate dry yeast -- you are not only stressing the yeast, but tempting the remaining live ones to produce off flavors.

I have accepted the above on faith but have just read Fix's "Principles of Brewing Science", (a most humbling experience) and I now wonder if we are on the wrong tack. If George could review the following paragraph and comment on whether or not it has any relevance to rehydrating dry yeast....

From P 170.....

"As a general rule, yeast stored for any length of time should be "fed" with fresh sterile wort to ensure that the storage medium has adequate yeast-assimilable sugars and amino acids. Storage under a water cover should be avoided not only because water lacks nutrients, but because of the adverse osmotic pressures it would create."

I presume that dried yeast includes whatever is left of the "yeast-assimilable sugars and amino acids" at the time of drying. I also presume that they would be in a depleted state and adding only water would create the adverse osmotic pressure above referred to. Whereas, re-hydrating it with a wort of comparable SG would not.

What say, George?

Subject: Milling, Yeast

>From: Joe Rolfe <jdr@wang.com>
>Subject: MaltMill review

>(anyone got any hints at the correct rpm for the rollers - max thruput
and
least hassels)

>on the other hand - this fellow brewer - had a hell of a time.

Not knowing who your friend is, I can not comment intellegently but to
answer
the first question in an indirect way and wondering if it might be the
same
person.....

I received a call from someone several weeks ago who was having problems
with
a motorized mill. It was throwing grain all over and chewing up orings.
When I asked him what speed he was running at, he said he really didn't
know
but there was a 2 in pulley on the motor and a 2 in pulley on the mill.
If
its a typical 1750 rpm motor, the problem is obvious. On my personal
mill, I
use a 10 in pulley on the mill and a 2 in on an 800 rpm motor. That
gets it
around 160 rpm and crushes about 5 lbs/min with little dust, noise or
other
problems.

> i was not there when the problems came up - but the crystal ended up
to
fine, the pale did not feed properly and the guy had to rush out to get
a
corona. now mind you this is a motorized (probably too fast) with
hoppers
above and below.

Sounds suspicious. Why don't you have him get in touch with me? There
has
got to be a better solution than what he did :)

Having said that, I started receiving malt from Minnesota Malting a few
months ago that would not feed properly on the fixed mill which was
designed
using the same malt and I was totally frustrated till I had a few
conversations with the maltster.

Turns out that the lot was one that did not meet commercial specs for
size
and they put it aside for homebrewers assuming we would not care. He
said
that there was less than a 5% chance of this kind of stuff getting out
normally, whatever that was supposed to mean.

When I asked why mega brewers care, with fancy adjustable mills and he said because they do not want to adjust them. They just want to run forever.

It is interesting to note that the Belgian malt is even larger than the MM malt but feeds without difficulty. It appears to me that the real problem is not just the size but the finish or texture of the husk. The MM stuff was very smooth and shiny while the Belgian is coarse and rough. As the mill relies on the grooves in the roller to grab the grain, the smoother the husk the more likely the grain will roll around for a while.

On a motorized mill, if enough of them roll around, they will fill up the space and nothing gets done. With a hand crank, this is rarely a problem because of the randomness of starting and stopping plus the ability to back up a bit to clear jams.

The only other problem I know of is someone who came up with some Engl. ... sorry British malt that was so small, it passed right through. After running this one down, it also turned out to be reject malt.

> anyway from my experience and his, if you get one get the adjustable one.

IF you have thoughts of motorizing it.

>From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>
>Subject: YEAST CULTURES

> I don't get isolated colonies on my plates, rather one big long smear of yeast where I've dragged the inoculating loop. How can I inoculate so I get isolated colonies?

The key is more dilution. After you think it is dilute enough, give it another 10:1. Here is a standard streaking sequence....

```
  1.....2.....3.....4.....5.....>
| | | |
  6.....>
| | | |
  7.....>
| | | |
  8.....>
| | | |
//////// //
```

After inoculating your wire, you start at 1 and by the time you get to the end of 8 you should have some single colonies if you start with a dilute enough sample.

To give you an idea of how little you need, I recently did a Wyeast and I

dipped my wire into the packet and followed the above on two petri dishes in sequence and only got three isolated colonies on the second one.

When I have done dry yeast, I would drop one granule into a test tube of sterile water and got about the right dilution.

> I understand some yeast cultures are actually combinations of several strains (eg whitbread). Will I see all three of the whitbread strains as different looking colonies?

I tried Whitbread dry about 6 months ago and found no clue as to what was what. It all looked the same and concluded that either it was all the same or telling the difference was beyond my patience. I didn't particularly like the beer it made but that could be because I don't like it or because one or more of the necessary strains were missing.

> I've heard that even if I get a good pure culture on a slant it will mutate and I can only use yeast from a given slant for a few months? Is this true?

If you only use the original slant to inoculate others, it should be good for years or until you contaminate it in the process.

> Is there a way to identify mutants besides brewing a batch and looking for strange behavior such as low final s.g?

That's about it.

> got a pretty decent optical microscope if I can figure out what box it's in. Any suggestions on preparing a sample for viewing?

Put a dilute drop of yeast on a slide, add a cover slip and work your way up to the highest magnification you have. You need 1000X, oil emersion to see any detail.

>Can I recognize mutations this way?

No chance. You will be able to identify certain wild yeasts and bacteria and have a lot of fun but won't solve any real problems in the process. Unfortunately, Peterson hasn't come out with a "Field Guide to Yeast" for pretty obvious reasons.

From: JLIDDIL@AZCC.Arizona.EDU (Jim Liddil)
Subject: Failure of first All grain

Made a beer today with the following ingredients

3lbs belgain pilsner malt

4 pounds belgian pale ale malt

8 ounces caravienne

Mashed in 2 gallons of distilled water at ~154 for 1.25 hours at which time the iodine test was negative. The pH of mash was around 5.2. Used a Zapap type lauter tun with grain bag. Recirculated about 0.5 gallons. Used distilled water for sparging. Placed a pie plate on top of grain bed and added water at about 165. Also mashed out at 170. Sparged till gravity was 1.008 .Ph of run off was still around 5.5. Collected about 7 gallons of wort. Gravity after boiling down to about 6 gallons was only 1.028. Where did I go wrong? If the answer is perfectly obviuos please e-mail me rather than waste bandwidth here.

End of HOMEBREW Digest #1112, 04/05/93

Date: Mon, 5 Apr 93 10:16:35 MET DST
From: THOMASR@EZRZ1.vmsmail.ethz.ch
Subject: Mac Thread, Decoction

Hello all,

Nir Navot asked if there was a thread for Macs out there somewhere. There is a Hypercard stack at Sierra.stanford.edu (pub/homebrew...) which will read in mail lists and then allow you to manipulate them in Macintosh point and click fashion. If my hard disk space weren't limited I'd add all the mail lists to it for the complete brewing reference text. As it is they stay on the vax. Also, Dennis Lewis asked about decoction mashing and why people do it. Well, I now do it for a combination of reasons:

1. I can only get lager malt (here in Switzerland) which is really high in protein --> requires a protein rest at 50 deg.C;
2. I mash in a picnic cooler, and haven't got a pan big enough to do a full stepped infusion;

I think (he says, sticking his neck out) that there is little difference in the end result whether you do a stepped infusion or a decoction over the same temperatures.

By the way, the "thickest third" does include the grains. If you take out only the liquid and boil, possibly repeating a number of times, you will quickly run out of enzymes, since they are mostly in solution. The object of the decoction is to raise the temperature of the mash in a stepwise manner without having to heat the mash tun. I've not had problems with tannin extraction etc because I only just bring the thick third to the boil before replacing it. A longer boil (involving the grains) would have the effect of gelatinising the starch, and hence (apparently) of making it more available.... I don't know, I get about 28-29 pts/lb/gall(US) most of the time.

- - - - -

finally, Chris Lyons asked about when to add sugar. Although I'm only going on my experience here, I find that for normal gravity beers I see no difference, but for high og (>1080) I see alot of caramelisation (although is this bad, since you're adding brown sugar for the caramel anyway?). I brewed Dave Line's ESB using exactly his recipe, and although it didn't taste exactly like draught ESB, it was certainly very pleasant.

Anyway that's quite enough of my opinions.
Rob Thomas.

I have in front of me one of those sheets of marketing material that is typically placed in the plastic thingies at restaurant tables. This one is from the Boston Beer Company and was lifted from Doyle's in Jamaica Plains (South Boston). Unfortunately, I wasn't the one who lifted it, so I can't give first hand impressions of Triple Bock. I can however type in what Jim Koch says about his new beer.

"We offer this strong, malty bock beer in the best tradition of warming winter brews. Our Triple Bock begins with a recipe calling for over three times as much malt as our Boston Lager. A long, slow fermentation produces the rich, complex flavor notes and an extraordinarily high alcohol level of 12%. This strength is comparable to a fine wine and is almost three times the level of ordinary beer. In addition, this brew is carefully aged for four months at extremely cold temperatures. This traditional German technique develops the remarkable smoothness of our beer. At this strength, our Triple Bock is ideally sipped slowly from a 5 ounce serving, enabling the true beer lover to savor and appreciate its enormous character. We present our unique ice-conditioned beer this winter as a great way to take the chill off the cold weather."

Subject: re:yeast storage & mutations

JS writes about yeast culturing in the last digest:
<If you only use the original slant to inoculate others, it should be good
<for years or until you contaminate it in the process.

This is why you should make a working stock slant from your original slant. Only culture yeast from the working slant. Go back to the original slant to make new working slants. Plating from the working slant is a better way to ensure what you are brewing with. There is an increased risk associated with "dipping" a loop into a slant repeatedly. I would advise restreaking to a single cell at least once a year. In theory it can last for years, but why risk it? If you are already culturing yeasts, then what is the extra plate and slant once a year to ensure clean yeast? A very important issue is for the brewer to constantly question the performance of one's yeast, is it flocculating like it used to? Any slight change in flavors or lag time or aromas of the fermenter?

Good brewing,
Jim Busch

Subject: Duration of a botled beer

Rafael Busto asks:

> As a beginner I'd like to ask a probably FAQ. Once the beer is
> bottled, How many weeks can I keep the beer (no preservatives, no
> pasteurization) before it gets undrinkable?

A long time, if you did a good job making it. I've had beers that have been in bottle for 10 years. At that point, they're kind of "old" tasting, but still drinkable. Only strong, highly hopped beers will last that long, but you should be able to keep your beer for a year, easily.

Things that can reduce its keeping power:

1. Insufficient sanitation. An low-level infection can take a long time to take hold. If you drink your beer up in a month or so, you'd never notice it. If you keep it for a year, you might.
2. Oxidation. Again, this is something that takes a while to show up. The damage may be done at any point in the brewing process, from mashing through to bottling. The key is to minimize splashing at all times, EXCEPT just before pitching the yeast, when you need lots of oxygen in the wort so the yeast can grow and reproduce.
3. Light. Can cause skunking and other staling reactions. Keep your beer in the dark.
4. Heat. Keep the beer in a cool place, preferably below 60F (i.e., in a cellar), but not where the temperature goes above 80F, for sure. Temperature swings are bad, too.

Subject: Yeast Lab yeast

You should have gotten an instruction sheet. It suggests two ways to use the yeast:

1. Make a starter.
2. Just dump it into your wort.

The first way works better -- quicker start, less chance of infection, but the second way does work.

Subject: rehydrating yeast

Jack asks:

> I presume that dried yeast includes whatever is left of the
> "yeast-assimilable sugars and amino acids" at the time of drying. I
also
> presume that they would be in a depleted state and adding only water
would
> create the adverse osmotic pressure above referred to. Whereas,
> re-hydrating it with a wort of comparable SG would not.

If I may be so bold as to jump in here, dried yeast have much of
the water removed from the cytoplasm, and need that water replaced before
they can behave normally. A hypotonic solution (ie water) will cause the
yeast to swell up and soak up the necessary water nice and quickly. A
hypertonic solution (ie wort) will be soaked up much more slowly. In
order
to re-hydrate the yeast, water is best, but don't keep them there too
long,
or they may start to suffer osmotic lysing, or at least malnutrition. Boy
is that a run-on sentence

As for brewing to style versus brewing to taste, I would have to
say a good brewer should be capable of both. Having a style guideline to
shoot for gives the brewer knowledge, experience and skill. If you can
brew a Sam Smith's clone, a Pilsner Urquell clone, and a Duvel clone, you
know what ingredients and protocols produce what results, and by all
means

brew a beer you like, because you can know ahead of time what the result
will be. If you just brew for fun, it's a great ride and the end product
is invariably good, but frequently a bit of a surprise. Having style
categories in competition does two things: it shows a brewer's skill at
producing the intended product, and it provides guidelines for the
judges,
so they don't have to decide if the dry stout is better than the malty
helles. Someone long ago on this forum (or maybe it was r.c.b) was
lamenting that they had lost a competition because their Pilsner was too
dark (or some such breach of category), but that if that same beer was
produced commercially it would be a "dark pilsner" and a category in
itself. Sure. And Pete's Wicked Ale won at the GABF, but could it fit
into any AHA category? The point is these are not the only possible ways
to make beer, but target styles for homebrewers to emulate in order to
demonstrate their skill.

Subject: Sanitation Using Spent Grains

David C Mackensen (HBD 1109) asked

> What if I were to put the spent grain bill into the primary? any additional sugars that might have been left over can be used for fermentation/taste (depending upon complexity)...

In the HBDs following, Mr. Mackensen got somewhat jumped on. Timothy Dalton asked

> How are you going to sterilize the grains before tossing them in ? Boil them ? Seems like you'd be asking to extract a pile of tannins from the husks. Then have the husks in contact with the wort/green beer for a week or two?

and Tony Babinec said

> I wouldn't put spent grain in the primary! The grain is contaminated. home brewers exploit this by doing sour mashing, but the mashing is done in a vessel, and is followed by a boil. So, throw the spent grains on the compost heap, or make a bread out of them.

and so on. While I agree with the concerns about tannins, I have to question the contamination potential. Think of the process so far. Mash at 150 to 160 for an hour or more, then optionally mash out at about 170 degrees. Maybe I'm wrong, but it's hard to believe that the grains aren't pasturized after that. Yes, some people use malt to start sour mashes, but they use raw grains, not spent grains.

I admit that I remain dubious about how worthwhile the attempt would be, but hey, we're only talking beer here. I know that most of the sugars and starches are gone, but maybe the grains can add interesting proteins. I don't know, but I'd be interested in learning.

Subject: AHA First Round Regional, Chicago

1993 AHA NATIONAL HOMEBREW COMPETITION
FIRST ROUND - MIDWEST REGIONAL
JUNE 11-13, CHICAGO, ILLINOIS

CALL FOR JUDGES, STEWARDS, AND PARTICIPANTS

As you already know from other posts to this forum, the first-round regionals of the AHA National Homebrew Competition will take place in early June. The Midwest Regional will be over the weekend of June 11-13, at the Goose Island brewpub in Chicago. Last year's regional was a great success, due in part to an excellent turnout of judges and stewards. While we fully expect the same this year, we're leaving nothing to chance. We've added some special activities to the schedule that you won't want to miss.

After the second judging session on Saturday afternoon, there will be a seminar conducted by Chicago's own Siebel Institute. From there, we'll move on to dinner and the First Midwest Invitational Brewoff, an event that might attract you to Chicago even if you couldn't pick up those judging points.

Last month, we invited 10 of the region's best homebrewers to brew five gallons using the same set of ingredients. A number of the area's homebrew supply stores donated the raw materials, which were recently packed and delivered to the participants. The brewers can use some or all of the ingredients, plus they can select their own yeast. The beers will be judged in a blind but informal judging at Saturday's dinner, and the champion brewer will receive an attractive trophy.

Think you can brew as well as the invitees? Well, everyone else is welcome to participate in the Open Brewoff. To enter, you can purchase an ingredients kit (by the way, we're making everyone make an extract beer with specialty grains) from one of our sponsoring suppliers and bring the result to the event. We'll have balloting in the Open category as well, and that winner will be automatically eligible for next year's Invitational. Sponsoring suppliers are: Evanston First, Sheaf and Vine, Chicago Indoor Garden Supply, and Tim's Homebrew Thing. You only pay for the ingredients. There's no competition

entry fee.

The Midwest Invitational/Dinner will be open to all interested comers, but space will definitely be limited. To help defray the costs of the event (and pay for the food, of course), there will be a \$25 fee to attend. Early interest is high, so we expect there will be a lot of great beer to consume.

Of course, we need plenty of qualified judges and stewards. A mailing with registration form will be sent soon to all area BJCP judges, but those not in the program or not in the area should feel free to contact me directly (e-mail or phone).

Look forward to seeing you in Chicago.

I have dry hopped about 4 batches, and always have observed this same
thing. It is a real pain when using whole hops, because they try to to
push themselves out of the air lock. It seems that there was a thread
about this on HBD about 6 mo. ago. Then I went out of town and never
caught a conclusion about what was really going on. Was there a
conclusion? Does anybody have an explanation for this?

Subject: silly question on kegging

Could anybody give me any insight on why NOT to carbonate a keg naturally, like in bottling, instead of using carbonated water and all the works needed to do kegging. My reasoning is simple; kegging didn't used to be done the way it is today. So, what are the pros and cons to throwing in priming sugars in a keg and cork it? I would appreciate any HELPFUL suggestions.

I have to agree with Jim on this. You really should try this yourself
and
gather some empirical data before suggesting it to people who might not
know
better. I have a lot of experience with forced carbonation of water,
wine,
beer and soft drinks, and if you've ever tried gassing beer up to 50psi,
you'll
find that its difficult to even vent the pressure down to dispensing
level
without it blowing out your venting tube. If you do get it bled down to
tapping pressure, the resulting brew would dispense as incredible gusher
of
foam as the brew tried to outgas. The idea of it retaining enough
pressure to
dispense itself means that as it goes from wildy overcarbonated to flat
it will
be able to push itself out of the keg, but you'll only get a small amout
out of
the tapper, then the brew will have to outgas enough to built up pressure
to
tap more, this might work for a few brews in between the gushers and it
being
so flat it cannot dispense, but it seems like a lot of sacrifice.

At a nice cellar temperature, adding a constant 16lbs or so of CO2 and
agitating the brew for about 5-10 min. will result in nice carbonation.
If you
dissolve too much CO2 in it, you'll have to 'burp' the keg down to a
reasonable

carbonation level before it will be usable. I've found that 35 LBS of CO2 is way too much (check Byron Burches CO2 chart and read his article in one of the Beer and Brewing Journals - its the one from Oakland). I've gassed champagne up to the level you are talking about (in an appropriate container) and its a horrible mess to dispense through a tap (even with an adjustable flow tap like a guinness with the turbulence baffles removed from the tip).

The only way I can see to dispense beer thats been gassed up to 50psi would be to slowly bleed it down to ambient atmospheric pressure (wipe the beer from the ceiling:), remove the lid from the cornelius and pour it into pitchers. I had to do this about 10 years ago when I was just beginning to do forced carbonation.

What might work would be to put a regulator on the keg such that anything over 16psi gets bled off, add your CO2, and agitate while it dissolves, wait a few days, then put CO2 on it at about 10-12 lbs and dispense.

50'
>double helix (homemade). It all depends how fast you want to cool and
how
>cool your tap water is, and how much water you want to use.

Aha! A personal pet peeve, that I know nothing about. Spout-off
warning!

My own personal theory is that the shorter the better, until you get to a
reasonable minimum length.

Why?

Let me interject personal observation from my 15 ft. copper coil.
Probably
more than a foot is outside the wort, say one foot on each end, making 13
ft. in the wort. I think that is too long. Why? Because the water
comes
out boiling hot at the other end. [I placed my quick-reading thermometer
in a cup which got the outflow from the wort-chiller, and it quickly
jumped
to 210 or so.]

OK, what good does boiling-hot water do in your wort chiller? I submit
it
does no good at all. So if I had another ten feet of copper in there, it
would be another ten feet carrying boiling hot water, doing no good.

So, the question is:

How long does water traveling through 3/8" copper tubing (it can only
flow
so fast) take to reach equilibrium with the wort?

I suspect we are talking about 6-8 feet here, just from WAG speculation.

Anyone who really knows what they are talking about willing to resolve
this
issue? Are there completely overlooked issues, such as increased
efficiency with longer tubing as wort and source water temperatures get
closer? [So I just made this up and don't think it likely. Sue me.]

Of course the temperature of the water used, the rate of water flow
(dependent at least in part on the tubing ID), and maybe other items are
involved. Is there maybe a chart already made up for us to use by
experts
in the field?

OK, I ranted enough. Now I feel better. Thanks and apologies to all.

Subject: Wine and Oxidation, Grain Bags

We all know what evils to expect of beer that gets oxidized after fermenting and the need for quiet racking and transfer. However, wine drinkers also know that good red wine needs to "breathe", which of course is, a snob word for oxidize.

I have also seen several references to the fact that one of the reasons for racking wine at regular intervals is to promote oxidation. Clearly, we have a conflict here and my Fall Wine is now in the aging stage and it would be nice to know if I should intentionally splash it around while racking or use the usual beer cautions.

Anyone out there know?

>From:(Jim Liddil)
>Subject: Failure of first All grain

>3lbs belgain pilsner malt
>4 pounds belgian pale ale malt
>8 ounces caravienne

>Mashed in 2 gallons of distilled water at ~154 for 1.25 hours at which time the iodine test was negative. The pH of mash was around 5.2. Used a Zapap type lauter tun with grain bag. Recirculated about 0.5 gallons. Used distilled water for sparging. Placed a pie plate on top of grain bed and added water at about 165. Also mashed out at 170. Sparged till gravity was 1.008 .Ph of run off was still around 5.5. Collected about 7 gallons of wort. Gravity after boiling down to about 6 gallons was only 1.028. Where did I go wrong?

First of all there is nothing "wrong", you just made a lighter beer than you expected.

The procedure reads like a textbook and aside from possible measurement error, and the need for more water in the mash, the only thing that sticks out is the Zapap with a grain bag.

I do not wish to start another snob thread but it is my opinion that of all the lauter systems out there, the grain bag represents the one with the highest probability of failure. Having said that, I realize that many people

use them and swear by them but until a beginner at all grain learns their tricks of the trade, I would think low yield would not be unusual.

First of all, if your Zapap has a false bottom, it is not clear why you use the bag. The purpose of the false bottom is to prevent the grain from clogging the outflow while establishing a filterbed. Once the bed is established, the grain itself acts as the filter and a grain bag is only overkill and a source of trouble. I know of no commercial brewers that use grain bags so maybe there is a message in there for homebrewers.

One sure test would have been to just dump the contents of the grain bag into the Zapap and stir it around with some more hot water. My guess is the gravity of the next runoff would have shot way up.

My suggestion is to try it without the grain bag next time and if that fails, build an easymasher or manifold lauter tun. The advantage of the easymasher is that you can stir the mash at intervals during the sparge without upsetting the filter bed and scavenge every last bit of sugar out of the mash.

Subject: Using Sanitizers of Various Sorts

>From: mikel@netlink.cts.com (Mike Lemons)

>Is there any scientific proof for the claim that sulfites don't
>work? The enormous advantage of using sulfites is that no rinsing
>is required. It seems to me that re-contaminating something with
>rinse water, after you sanitize it, totally defeats the purpose of
>sanitation!

>Chlorine and iodine must be rinsed out because they will impart bad
>flavors to the beer, but sulfites are essentially tasteless.

I personally don't use sulfites because of relatives who are allergic, so
I
don't want to risk anything. This may or may not be relevant to you.

But mainly, I can't imagine why someone would rinse after using chlorine
or
iodine. After all, if you use the recommended amounts of each in your 5
gallons of water (or however much it takes to fill your sink or
fermenter),
simple air drying after draining out all the water leaves so little of
either chlorine or iodine as to be practically immeasurable.

The main problem seems to be that many people think that if the
recommendation is to use X ounces, then 10*X ounces must be 10 times
better, and 100*X ounces 100 times better.

Subject: Dry hopping

I tried dry hopping on my last batch for the first time. Encountered a few difficulties. I used hop pellets. When added to secondary, the pellets hydrated nicely then floated to the top and stayed there for the duration of secondary fermentation (~ 1 week). When I started racking the beer into my bottling bucket this hop head got broken up and started sedimenting--a fair amount got siphoned into the bottling bucket. I let it settle in the bucket for ~1/2 hr before bottling but still got a fair amount of hop particles in the bottles, particularly the last few bottles.

Questions:

What are pros & cons of pelletized vs whole hops when dry hopping?
Any advice on removing hops when preparing to bottle?
Alternatives to dry hopping that will give good hop nose?

From: adiron!scott@uunet.UU.NET (Scott Barrett)
Subject: More stupid carboy tricks

In HBD #1112, Andy Rowan (rowan@ocean.rutgers.edu) provided a tip for emptying a carboy more quickly by using a racking tube to break the suction. "Strike while the mash water's hot" I always say, so here's another way to do it.

Begin to swirl the contents of your (still upright) carboy until you get a good whirlpool going. Invert the carboy quickly and swirl it strongly 2 or 3 more times. The whirlpool effect should continue as the liquid drains out and air will enter the carboy through the open center of the vortex. When the carboy gets near empty, the remaining liquid will be swirling pretty fast and will hang on the inside of the carboy's shoulders (like the ball on a roulette wheel) rather than draining out. Simply tilt the inverted carboy a bit off vertical and the remaining liquid will quit its tail-chasing and drain through the neck.

With this technique you can keep both hands on the wet carboy and don't have to stick anything inside it. It's also kind of fun having a white tornado inside your draining carboy.

Yours in brewing,
Scott Barrett

Subject: Ale Grist Part I

Ale Grist, Part I

After I posted some information a while back from HL Hind's textbook on British brewing, from the 1930s, several people requested that I post his data on ale grists. My copy of volume II finally surfaced, so here's the information. In order to follow it, though, there are a few things you need to know.

A quarter of malt = 336 lb.
A British barrel = 43.2 American gallons

The numbers given under Malt. No. refer to a list of malts available at the time Hind was writing. The numbers 1, 4, 6, and 13 refer to British 2-row ale malt; colors are, respectively, 4.5, 6.0, 6.0 and 4.0. Number 14 is Moravian 2-row, color 6.5. Nos. 19 & 20 are "Californian" 6-row, colors 6.0 and 4.0. No. 26 is Syrian six-row, color 5.5.

Grist for Pale Ales (100 British barrels)

Malt. No. Quarters % of Total OG
Extract

=====

All-malt pale ale
1 16 85.1 1.055
20 3 14.9

Pale Ale with sugar and maize
6 7 37.7 1.050
14 6 32.3
26 3 14.8
Maize 1 5.5
Malt extract .5 1.9
Sugar 2 7.8

Light pale ale for bottling
4 4 27.7 1.040
13 4 27.4
19 3 19.4
Enzymic .5 3.3
Maize 1 7.0
Sugar 3 15.2

"The use of flaked maize, rice or grits and sugar depends on the character of the beer. Sugars add sweetness and, like flakes, reduce the tendency to early haze formation in filtered beers, particularly if the malt is at all under-modified. The sugars must be pale in colour and carefully selected in accordance with the flavor required in the beer. No. 1 and No. 2 inverts and other sugars of somewhat similar character are suitable. The percentage of adjuncts used varies with the type of beer, and may provide 10-25% of the total extract."

Ale Grist, Part III

There is a different list of malts for the dark ales. Number 3 is English, color 5.5; No. 5 is Scotch, color 6.5. Nos. 7-9 are English, colors are 7.0, 8.0, and 7.5, respectively. 19 is Californian, color 6.0.
24 is Chilean (or similar 6-row), color 6.0.

"There are a number of distinct types of stout and porter, for which different blends of materials are used. On the one hand, are the stouts brewed from malt only or from malt and roasted barley. On the other, are the sweeter stouts, for which a fairly high percentage of sugar is employed. The basis of the grists is a mixture of pale malt, not too fully modified, but with a moderate diastatic activity, and either roasted malt or roasted barley to give the requisite colour and flavour. Roasted barley gives a drier flavour than roasted malt and is preferred by many. Crystal and amber malts are commonly blended with these in the sweeter stouts. A proportion of six-rowed malt and of maize is also frequently used, as in mild ales. A limited percentage of oat malt or oat flakes is included in the grists for oat malt and oatmeal stouts. Milk stouts generally derive their name from the lactose or milk sugar added, with cane or other fermentable sugar, in the form of primings. The copper sugars are generally full flavoured and dark coloured. Good raw cane sugar, No. 3 invert and various mixed sugars are suitable, a sweet caramel being added if it is desired to increase the colour without the special flavour and aroma of roasted malt or barley.

Subject: Ale Grist Part III
Subject: Malt Mill

I wholeheartedly concur with James Dipalma's analysis of Jack's malt mill. I was also impressed with Jack's own measured and thoughtful response to the negative review of his mill. Here I simply wish to throw in some data that was obtained from the comparison of Jack's mill and a commercial mill.

I received Jack's mill in Jan., 1992. Shortly thereafter it was taken to the Dallas Brewing Co. (DBC) for the test. The latter was done with a standard and well established screen sieving procedure. This is described for example in DeClerck, Vol. 2, pages 321-323. It in effect consists weighing out the grain fractions that are retained on screen meshes of diminishing width. The following is what we measured:

ASBCscreengrains retained, % by wt.			
screen no.	width, mm.	MM	DBC Mill

For those interested in details, the malt crushed was a Canadian 2-row from Prairie Malting. The mill at DBC was made by Mangel, Scheuermann, Oeters, Inc. of Huntingdon Valley, Pa. It costs around \$6500. It is a "BMW" as far as mills go for micros. A more common mill is the one made by California Grain Milling, which costs around \$2500. Those who have visited Dave Miller's brewpub in St. Louis will have seen one. It is the monster setting on the second floor in his grain room. Screen tests with these mills have given similar results. It has also been my experience that if roller mill spacing is appropriately adjusted, then this type of crush can be obtained for any type of grain.

The commercial mills have been constructed so they can process 100 to 1000 lbs. of grain in minutes. Jack's mill can not touch that sort of throughput. Nevertheless, the data shows that the same type of crush is achieved.

I concluded my original review of Jack's mill by congratulating him for producing such a good mill. I also observed it was very much worth the price he was asking. Nothing I have seen or heard since then has altered this opinion.

Subject: That Damned Maltmill

Through a series of strange coincidences, I came into possession of a MaltMill(TM). As those who have been around awhile will attest, I have had my differences(TM) with the MaltMill's builder so I determined to submit it to the sort of rigorous and fair testing only a true HBDer could provide.

My first problem arose with the box the MaltMill was shipped in. There was so much tape on it that it required an Xacto knife to get into the box. Once in, I discovered the MM was crammed in with tightly-crumpled balls of newspaper -- the Chicago Tribune -- which were rendered unreadable by this process. This reduced my co-worker, who hails from Chicago, to tears. Another strike.

Once I had dragged the MM home (not easy, given its weight) and assembled it (requiring the use of a crescent wrench!) it was clear that if I had been able to carry the thing to the roof of my house and throw it off, the MM would have been rendered unusable -- unlike my Corona, which for the last several months has been propping up the rear end of a Dodge power van in the back yard.

Having assembled the MM according to instructions and placed it on a five-gallon bucket, I discovered that the device required me to use my left hand to operate, even though I am right handed! However, after some examination, it seemed possible to Turn The Bucket Around, so that the crank was on the right. Why this was not explained in the instructions, I do not know, but even more diabolical was the fact that when I started cranking some malt through the MM, the malt refused to grind and in fact mostly sprayed around the kitchen. Once again, I discovered -- only through superior intelligence -- that by cranking the other direction I was able to achieve a crush.

Further deceptions: although I had been told that I could expect to crush enough malt for 5 gallons in 10 minutes, in real terms it took seven! Ha!

Conclusions: the crush was excellent, the crush took 7 minutes rather than the usual 30-40, and anyone who feels a need to motorize this thing in order to do small batches of beer needs to spend a little more time away from the computer lifting things heavier than their fingers.

One real problem: the bolt holding the wooden handle on the crank seems to be threaded in such a way that it inevitably comes unscrewed while cranking. The first time it happened took me by surprise and the handle came off; after that, I kept an eye on the bolt and tightened it as needed.

It also looks as though I'll need to put rubber feet on my bucket, so it doesn't slide and hop around while I'm cranking the mill.

product?

The dococtions do caramelize a bit and I'll bet that there would be a slightly different flavor with a decoction mashed batch as opposed to an infusion mashed batch with the same ingredients. Probably not too big a difference. I've read somewhere that decoction mashing was primarily a way to get consistent temperatures before the advent of the thermometer (think about it), but the "modern" breweries that still use the decoction method, like the brewers of Pilsner Urquell, use (I believe) a less modified malt which would require triple decoction for reasonable yields.

No, the heaviest third DOES include grain. A few months ago, Darryl Richman finally cleared up the reason that the decoctions did not extract gobs of tannins: its the pH! Indeed, the decoction mashing method would work much better in a cooler than a kettle.

I'd recommend against it. Many suggestions in those older homebrewing books from England are full of errors. Naturally, boiling anything will tend to diminish aromatics (consider hops), and perhaps it would be best to add the brown sugar in the last 5 minutes of the boil --

just long enough to sanitize, but minimizing any loss of aromatics.

Rafael writes:

> As a beginner I'd like to ask a probably FAQ. Once the beer is

No, it's not that frequently asked... actually. The answer is, depends.

On average, I'd say a homebrewed, unfiltered beer, stored at 65F would be perfect for two months and then slowly begin to decline in quality. Unless infected, most homebrew would be drinkable for more than a year. The following factors *increase* storagablity:

high alcohol,
high hop rate,
cold,
oxygen-scavenging bottlcaps (PureSeal(tm), aka Smartcaps(tm)),
small headspace in the bottle, and
stable yeast strain.

The following factors *decrease* storagablity:

bacterial infection,
wild yeast infection,
aeration during bottling,
large headspace in the bottle,
heat,
light, and
unstable yeast strain.

Wyeast #1056 tends to be slow in general and, although it has been reported to ferment down to 55F, I've heard that it should be fermented well above 60F. I proved this with a recent batch. As the fermentation temperature approaches 60F, the yeast slows down to a crawl. I suggest you find a way to warm it up to about 65F. 1056 also tends to lose all its "ale" character in the low 60s.

>Where did I go wrong?

I would suspect two areas of problems: 1) a very bad crush, or 2) channelling

in your lauter tun. Was the "grain bag" the kind with cloth sides and a mesh bottom (the right kind) or the kind that's mesh-all-over. The mesh-all-over type have a tendency to allow all the sparge water to head immediately to the sides of the bucket and the channelling at the sides pulls all the sparge water along the wall of the bucket and not through the grain.

Subject: Unusual recipies

I posted this request to rec.crafts.brewing on the network and due to lack of response decided to widen the call.

When I got started in the wonderful world of homebrewing 18 months and 18 batches ago I quickly found myself making some, for the lack of a better word, unusual beers. Not at all the beers I envisioned myself creating when I started.

I figured I could buy just about any style of beer I wanted and the main reason for me to homebrew was to create something not commercially available.

I started with the wheat beers, whose light palette lends themselves to an easy bastardization. Cherry and raspberry batches were not very adventurous so the great watermelon experiment was performed. From there spruce and chocolate, whit and kriek. Molasses, honey and maple syrup. Yes it was enough to make a beer purist shudder. Rhienhosptgiet, why I don't even know how to spell it.

To make a somewhat long story somewhat shorter, my last batch has some of my friends questioning my hold on reality. Captain Crunch Crunchberries and strawberry poptart ale.

Here is call for all you would be gross-out artists to brag.

I would like to receive a description of all of your most adventurous, innovative or just plain wacky experiments. They don't have to be tasty; for by our failures we learn as much, if not more, as by our successes. Extra points for leaving the vegetarian nature of brewing.

I will compile and post.

Subject: eternal ferment

Hello Brew Sages:

A few weeks ago, I asked you what you thought about my 'nonstop fermentation' and the concensus was that I should not throw the stuff out but check the airlock and the S.G. I won't print the recipe again. Suffice to say it's an extract brew with half a pound of maple syrup and 2 oz of apricot flavoring intended for wines, and Edme dry yeast.

Update: now after eight weeks, it ain't over. The airlock is still giving a feeble 'glug' once every 70 seconds. The color got noticeably darker. No off flavors to suggest contamination. Specific gravity down to about 1.009 (I think).

Question: can I bottle this now? I'd really like to get on to my next batch and only have one carboy. But I'd hate to ruin this one just because I got impatient. If I do bottle, should I decrease priming sugar from the standard 3/4 cup?

As long as I've got your collective ear: I just enjoyed some Catamount porter. Is this a good example of the style?

Hell, someone's got to ask all the questions around here.

specific
>keyword? Thanks in advance. Nir.

I use Super Boomerang. This program is included in the Now Utilities
package
from Now Software. It has a Find command which will scan every file on a
disk
(hard or floppy) for a keyword. The name of every file with the keyword
is
displayed. You can then choose one of the files and the program will
display a
three line section containing the keyword to see how it is used in
context.
This is helpful if you use the keyword "hops" to look for posts on
growing
hops as opposed to using hops in brewing beer. If the keyword is used
more
than once in a file you can view each occurrence in context. After you
are
done looking through a file you can select another file from the list
displayed.

Subject: Fridge defrosting

Hi All..

I recently came into an old Beermeister; a little 'fridge with a standard and tap mounted on the top. It needed a little modification to take the 5 gallon soda kegs - a bit too tall. It works great, and I'm really happy, except that the cooling element (?) gets a bunch of frost buildup on it. The cooling mechanism in this device looks very primitive. I was wondering if I hooked a Hunter AirStat up to it, could I program it in some way that might let it have a "defrost" phase? Does anyone else have any experience with this? Should I just learn to live with it and throw it out on the back porch for a few days every six months?

On another note, how long should I expect my 20lb CO2 tank to last? I got it last summer and have made at least 10 batches of beer since then. I also use it to push the sterilizer out of the keg when cleaning it. The pressure gauge for the high side hasn't really moved.

Any ideas???

Subject: Re: Heading Agent

My local homebrew shop also sells small packets of off-white "heading agent." I didn't ask the manufacturer's name, but I did ask about the contents: "ground bark of the gum acacia tree" I was told. It's pupose is to reduce surface tension. I use it all the time by adding it to my priming sugar before adding water and boiling. It's probably not necessary if you have very clean utensils and beer glasses, but it helps fight off detergents, oils, and other head killers that tend to creep into the brews we less careful brewers produce. Anyway, at 1/2 tsp per 5 gals, it goes a long way. Back when I brewed only extract I noticed a definite improvement using it. I suspect I don't need it now that I brew all grain, but I'm in the habit.

Decoction is technique that provides other benefits besides additional
extract. It coagulates more proteins and therefore produces a clearer,
more stable product. It also aids in melanoidin formation, which can
increase the perception of the malty character of your beer, as well as
adding some color. It gains the extra extract by completely
solubilizing all of the starch from the malt, which can also lead to
clearer, more stable beer. It tends to remove more of the DMS
character that will come from lightly kilned malts, and makes the wort
more compatible with sulfury hops and/or yeast that accentuate sulfur
character.

No, the heaviest third does include malt solids. You do actually boil
the malt, husks and all. (The next question is always "Why doesn't
this extract tannins from the husks?"; I believe that the pH controls
this extraction, and since the pH of the decoct is in the low 5's, none
is extracted. Hot water above pH 6 will extract tannins.) For a first
try at decoction, I would recommend pulling more than 1/3 -- perhaps
40% -- since many variables are at work in determining whether your
rest temperature is achieved (amount of cooling in transport of decoct
back into the mash tun, how much the decoct cools as you add it back,
etc.) By returning the decoct slowly, you can observe the temperature
rise; if you have too much, you can cool the remaining decoct after
the rest temperature is achieved with cold water.

> At any rate, I'm very happy with multi-rest infusion mashes and the
decoction
> stuff is simply a curiosity. Maybe I'll try it if I have an entire
Saturday
> to blow on it.

I did spend all day with my first decoction. Part of that was due to
it going from a planned two decoction mash to a four decoction, because
I was far short of my temperature marks. But having got beyond that,
decoction requires less equipment than a step infusion, and I believe,
produces a different spectrum of flavors and aromas.

From: alm@brewery.ht.intel.com (Al Marshall)
Subject: Carbonation in bottle-primed beer

Can someone recommend a technique for making bottle carbonation a little more predictable without investing in counterpressure filling? By predictable, I mean time to condition, and carbonation level. Does anyone have experience with pitching fresh yeast when priming, and how exactly do you do it?

By way of example, I have 5 gallons of porter in bottles which are absolutely flat (and no yeast sediment) after 1 week from priming with 1 pt water and 1/2 cup corn sugar and conditioning at 65F. Although this period is a little brief, my experience would indicate that I am in for a long wait for carbonation if there is no carbonation at all at this point. I've noticed this problem in moderately (1055) to very (109X) big beers which spent a long time in secondary.

If I get any attractive ideas, I'll implement them on the other half of the batch. Unfortunately, the experiment will not be very scientific, as the in-bottle half is Wyeast 1028 whereas the in-secondary half is bottle-cultured Sierra Nevada.

By the way, I think there is some kind of natural law that makes these problems occur on beer that is absolutely delicious :-).

Thanks in advance...

Subject: Miles of dense surface troooob

I brewed a scotch ale last night, and noticed today a curious thing. On the bottom of the carboy lies a thick (4-5 inches) layer of trub. The fermentation is going full speed (no noticeable blowoff though in it's 19th hour of fermentation) but the yeast seems to be collecting on top of this layer of dense fermentables rather than eating into it. I used Irish moss with this batch, and haven't done so in months. Is this normal for beers brewed with the stuff? I'm gonna give it a few days yet to see what happens, but the separation in both color and consistency between the top and bottom is remarkable. For those out there interested in this mystery: I used pellets not whole hops and partial mash with 3#syrup/3#dry extract and 1#munich/1#crystal/ 1/2# roasted. Any comments/ helpful words of wisdom?

> out and air will enter the carboy through the open center of the
vortex.

I also use this technique with my bottles to drain them of washing,
rinsing
or sterilizing water before using my faucet bottle rinser. With the
bottle
inverted, 2 or 3 swirls drains them in about 1/3 the time it would
normally
take them to gurgle empty. When doing this with 40 bottles, it saves a
lot
of time.

Subject: beer from Brussels/Antwerp - BBrite effectiveness

A buddy of mine will be spending the next 5 months working in Brussels and Antwerp and has offered to bring me back some beer. Any suggestions on local brews to bring back? I like all types of beer (except those that taste watered down).

On sanitation, I have brewing 4 years now and use partial mashes. I did have one gusher my first year but haven't had any real problems since. I use BBrite soaks and cleaning for 5 - 10 minutes followed by a little rinsing by tapwater on my brewing equipment and soak my bottles in bleach solution overnight. I now plan on storing some beer in bottles longer than the 4 or so months they last now to maybe 8 months. I usually don't brew from May to August and would like to store a variety of beers styles (I usually have 5 or 6 at any time during my "brew season") over the summer in my basement (~68 degrees). However, I have been wondering if BBrite soaks and cleaning for 5-10 minutes is sufficient. Since any batch doesn't last past 4 months, I don't know for sure that there haven't been slight infections that are not apparent after 4 months but that could be a problem at 8 months.

To summarize: how effective is BBrite used in short (5-10 min) durations as a sanitizer?

What was the pH of the sparge water ?
I've found that acidifying it (pH 5.5 or so) helps my extraction rates.

How good was the filter action ? Did the sparge water run completely through the grain bed, or was some/most of it channeled though, without contacting the grain ?

Subject: RE: decoction, first all grain

Hi All,

In HBD#1112, Dennis B. Lewis writes:

>I've noticed that I'm not the only person confused by decoction mashing.
It
>seems like a lot of screwing around just to increase yield. Personally,
I'd
>rather just add another pound or so of grist and not worry about it. Are
there
>other benefits to decoction mashing? Clearer wort/green beer/finish
product?

Higher yield is just one benefit of decoction mashing. The
gelatinization
of insoluble starch and reduction of high molecular weight proteins that
occurs during decoction mashing produce a wonderfully clear, clean-
tasting
finished product.

There are also certain styles that benefit greatly from decoction
mashing.

I use this type of mashing for wheat beers, because of the proteins, and
for Bohemian pilsners and any German lagers that require a malty
character.

IMHO, decoction mashing produces an incredible malt character, in both
the
nose and the flavor of a beer. I have never been able to produce the
same
effect with infusion mashing, regardless of ingredients used or how high
the saccharification rest temperature was held.

>Noonan says to remove "the heaviest third" of the mash. I suppose that
does
>not include any grains since you will eventually boil it.

Removing the "heaviest third" of the mash is also called a thick
decoction, and involves removing mostly grain and very little liquid.
I assume your concern is that boiling the grain will extract tannins
from the husks, and cause astringency in the final product. Due to the
low pH of the mash being boiled, this does not occur.

>This is really hard
>to do for those of us who mash in a pot on the stove instead of in a
Gott

When I use decoction mashing, I do the first saccharification rest
using exactly this method, by heating the thick decoction to 152F-155F
and holding that temperature for 30 minutes, essentially doing stove
top mashing.

>Maybe I'll try it if I have an entire Saturday
>to blow on it.

The decoction procedure I use requires 2 - 2.5 hours for mashing, or
about
one hour longer than it takes me to do a single infusion mash. I've done

about 20 batches using decoction mashing, it has never taken all day.

**

Also in HBD#1112, Jim Liddil writes of his first all grain batch:

>boiling down to about 6 gallons was only 1.028. Where did I go wrong?

I'd like to commend you on where you went right. You seem to have the basics of sparging down, recirculating the initial runoff, sparging with water at a reasonable temperature, sparging for a reasonable duration, monitoring the pH of the mash and of the wort going to the boiler. Actually, you did many things "right".

I'm assuming your concern is with your extraction rate, let's see:

28 * 6 / 7.25lbs means your sparge extraction was around 24pts/lb/gal, bearing in mind that the gravity was measured after the boil, which will lower the gravity somewhat. This is not terrible extraction, especially for a first effort. It's a little difficult to offer suggestions to improve your extraction without more details of your process, but I can mention some things to look out for that do impact extraction.

What was your crush like? Ideally, each kernel should be broken into several small pieces, and the husks left intact. If you had large chunks of kernel or uncrushed grains in your crush, this will reduce your extraction. Try grinding as fine as possible without pulverizing the husks.

How fast did you sparge? While there has been no consensus in this forum on what the "correct" runoff rate is, my experience was that my extraction dropped when I tried to run the wort off faster than 1 gallon per 8 minutes, or about 45 minutes to collect 6 gallons. I use the Zapap system as well. If you completed sparging in less than 45 minutes, try running off the wort a little more slowly.

Not directly related to extraction, this is more of a recipe design issue, but a little over 7 pounds of grain sounds a little light for a 6 gallon brew length. This is, of course, dependant on what your target OG was, and the efficiency of your specific system. This latter point is key to recipe design, you must know what level of extraction your system will consistently produce in order to figure out the grain bill. If you want a

higher gravity brew, try boiling down to 5 gallons, or if you're brewing a 6 gallon batch, use another 1-2 pounds of base malt.

I'm not sure about the use of distilled water either, everything I've read suggests that this is not a good idea. I can't quite recall why, something to do with lack of necessary ions in the water. Maybe someone with a chemistry background can jump in here.

Cheers,
Jim

From: Phillip Seitz <0004531571@mcimail.com>
Subject: All-grain troubles

Jim Liddil recently described his problems with an all-grain batch using 7 lbs of pale malts and 1/2 lb of crystal. He got something on the order of 6 gallons of wort at 1.028, and asked what he could have done better.

First, there was nothing wrong with your technique or equipment. I used equipment almost identical to yours, including a piece of window screen in the base of my Zapap (almost equivalent to your grain bag). In fact, my last batch had a grain bill almost identical to yours--7 lbs pale malt, 1 lb crystal. Here are some observations.

1) What were you trying to make? This is an excellent grain bill for a British bitter (I ended at OG 1.037), but if you were shooting higher you'd need more malt. Assume for the time being that you'll be able to raise the OG of one gallon by 25 points for every pound of malt you use. As your technique gets better you will get more.

2) If things don't work out well, there are some things you can do. In no special order:

a. Add some extract. This has the advantage of allowing you to finish at any volume you want, regardless of the amount of sugar you have (or have not) obtained from your grain. The amount you add is likely to be trivial in comparison to the grain, so don't get hyper about purity.

b. Boil more. You ended up with 6 gallons from a 7 gallon sparge. For instance, I started with 6.15 gallons that I boiled down to 4.5 or so, then topped up to 5.3 with tap water to get the desired gravity. You could have continued boiling to about 4.5 gallons and have been on target for a bitter. You'd have to boil a long time to get to 1.055, though.

c. Boil less. This is appropriate if you get MORE sugar from you grain than expected. In effect, you're increasing the dilution.

Several issues back there was a good article on hitting target gravities in Zymurgy (the mead issue), which included a chart for converting gravities depending on the temperature of the sample. You'll need it. The rule in all-grain brewing is not to base your brewing expectations on the amount of finished beer you want, as this will constantly vary somewhat depending on your extraction. I'm on my fourth all-grainer; the first three left me with 4.3-4.5 gallons at the end of fermentation, but this last one will probably leave me with well over 5 gallons, as I was able to pull more sugar out.

My procedure, in line with the above-mentioned article, is to do my sparge to 1.008, then mix the wort well and take a gravity reading and figure out how much wort I have. For instance (from memory) I had 6.15 gallons at 1.033 before boiling on the bitter. Since boiling vents off liquid but very little sugar, I could estimate a final yield of 5.5 gallons at 1.037. (My apologies if these numbers don't add up exactly--I leave

my brain at home when I come to work). Basically, you just fiddle with the

volume and gravity until you get the match you want.

For those who use those 32 qt. seafood cookers like mine, I've found that 3 cm of liquid depth (measured at the center of the pot) equals one gallon of liquid. I just stick a spoon into the center, then measure the liquid level by marking the spoon. This gets trickier when the liquid is boiling, but that's life. Anyway, I knew I had 6.15 gallons because the liquid was 18.5 cm deep.

Hope this helps.

Subject: my diatribe on styles

Howdy folks, once again questions of validity on judging to style have once again popped up here. The following is an article I posted to rec.crafts.brewing in the past on this issue. It was also reprinted in the Wort Processors Newsletter, and Pat Baker (of Crosby and Baker and the HWBTA representative to the Beer Judge Certification Program) expressed an interest in possibly using it for future BJCP materials. Since it has been well received I figured I'd post it here in the hopes of better explaining why styles are useful and where they fall short.

JaH

Q: I have a hard time with style definitions and judges' comments since I often look at certain flavor profiles as "defects." Can you help me?

A: Defect is a harsh word. There are a lot of flavors present in beer. These arise from a variety of sources and vary widely with the style and the process. Often characteristic flavors are strongly related to traditional processes used to produce a certain style of beer. As George Fix has indicated one can not divorce the flavor of a particular style from its history.

So characteristics that are a desirable flavor in one beer are indeed considered a defect in another, but this is not a random designation. This arises from an understanding of the history, ingredients, and process in which that beer is made. For most of the styles used in competitions there is a reasonable consensus as to what the characteristics of that style are. The styles are not defined in a vacuum, rather they arise from a cross section of commercial beers that designate themselves to be of those styles as well as what I mentioned above (history, etc.).

Homebrewing is a hobby/art/science whereby a brewer tries to create a product that expresses themselves, pleases their taste (and their friends tastes), and possibly also to create an existing recipe/style. If a particular brewer considers the presence of a certain flavor as desirable that others may find offensive, that is OK. The brewer is suiting their taste. It has been said that there are as many styles as there are beers being brewed and in a sense that is true. But that also makes it impossible to try to impose any objectivity on the judging process, a process that by its very nature is subjective. In order to

have any means for comparison that tries to impose some level of objectivity, the concept of styles has arisen. This concept is not unique to beer. Wine has this concept as well and this concept also serves marketing purposes in that it can promote (as well as confuse, i.e. Cranberry Lambic sic....) competition by presenting a brewer's offerings to be in a range of flavor characteristics that includes that brewer's competitors.

Styles exist as a mark by which those seeking competition can judge themselves. An old friend used to offer up beers to me for my advice on his recipe concoction. He would ask me what to do to his recipe. I would ask him what style he was trying for, or at least in his mind what he wanted the beer to taste like. He would get a little irritated since he previously was adamant about styles not mattering. I then posed the parable to him that he was like a lost person asking directions without knowing where he was trying to go.

To finally beat this point to death I'd use a cooking comparison. If you wanted to make chocolate chip cookies you'd want a recipe. While there is variation among this style of cookie from household to household, and manufacturer to manufacturer, people can still tell chocolate chip cookies from sugar cookies, etc. If you were to set out to make them you'd want some guidelines as to what the recipe might include and what the final product should taste like.

With regard to beer I think most judges would agree that there are only a few flavors that would universally be classified as defects. Most others are characteristic flavors which may or may not be suitable for style.

I hope this explains a little more about style and judging.

> We all know what evils to expect of beer that gets oxidized after fermenting
> and the need for quiet racking and transfer. However, wine drinkers also
> know that good red wine needs to "breathe", which of course is, a snob word
> for oxidize.

I beg to differ. From my experience in wine making and my limited qualities as a wine connoisseur I believe that what is commonly referred to as "breathing" has nothing to do with oxidation. Usually when you pour a red wine from the bottle (i.e. decant it) you don't drink it immediately. Instead, you let it `breath' in a caraffe for some time (half an hour to one hour or so). The rationale is to let it develop its bouquet. Some volatile substances in the wine evaporate and saturate the air immediately above the wine (that's also, by the way, one of the reasons why you should serve red wine in big, wide glasses; so as to retain the `aromatic air', i.e, the bouquet). There is no oxidation involved (to my knowledge). That would take much longer.

There is a commonly recognized off-taste in wine which is caused by oxidation. Usually everyone strives hard to avoid it.

On the other hand, there is also a specific category of wines which get their distinctive flavor from this particular oxidation off-taste: Sherry. One goes through great pains to ensure that Sherry wines get enough air to develop this flavor. I don't know that this is known as `brething'.

Subject: culturing belgian yeast from bottles (?)

I would like to culture the yeast from Duvel and Steendonk (a Wit) in order to produce a strong belgian ale and a wit, respectively. My questions are:
is the bottle conditioning yeast the same as the fermentation yeast? Does the high alcohol content of Duvel (or Maredsous for that matter) harm the yeast? Has anyone had any luck brewing beer from yeast cultured from Duvel or Steendonk? Can you plate the yeast directly, or should you (I) make a starter by adding fresh wort to the bottle dregs?
thanks

13
>ft. in the wort. I think that is too long. Why? Because the water
comes
>out boiling hot at the other end.

You could say this tubing is too long; on the other hand, it is equally accurate to say your flow rate is too low. Increasing the flow rate would result in cooler water coming out, and more (quicker) cooling of the wort. Also, this tubing may be too long during the initial stages of cooling, when cooling is very efficient due to the high temperature differential, but it may still be inadequate during the latter stages of cooling, when the temperature differential is much lower. How long does it take you to cool your wort?

>Anyone who really knows what they are talking about willing to resolve
this
>issue? Are there completely overlooked issues, such as increased
>efficiency with longer tubing as wort and source water temperatures get
>closer? [So I just made this up and don't think it likely. Sue me.]

Trained as a chemical engineer, I can affirm that the calculations involved here are indeed complex, involving not only aspects of the flow inside the tubing (water temp, flow rate, tube diameter, thickness and age of the tube, etc.) but also effects outside the tube, in your pot (geometry of the coil, pot, amount of stirring, etc.). It would be very difficult to come up with a formula that takes all of these factors into account for the wide variety of setups that HB'ers use. (Of course, having said this, some upstart will soon do just that, if only to make me look foolish :)).

As an aside, try this: when your cooling water outflow begins to drop in temperature, try gently stirring the hot wort. The temperature of the outflow water should immediately shoot back up to almost boiling! This indicates the effect of pot convection/stirring on the heat transfer rate.

My own cooler is about 30 feet of 3/8" copper tubing, wrapped in a 12" (?) diameter coil. I connect this to my house cold water line, and can force enough cold water through it to keep the outflow warm (as opposed to John's boiling hot). Thus, with my combination of tubing and water, 30 feet is not too long, and I can cool my wort to 65F in about 15 minutes.

So, the length of tubing you will need depends on, among other things, your cooling water temperature and flow rate, and just how fast you need to cool your wort.

End of HOMEBREW Digest #1114, 04/07/93

Date: Tue, 06 Apr 93 11:28 CDT
From: XLPSJGN%LUCCPUA.BITNET@UICVM.UIC.EDU
Subject: Warp-speed Fermentation (?)

Dear Brewers,

Last Friday night, I brewed up a 5-gal. batch of ale with the following ingrediants:

- 6.6 # M&F Light Malt extract syrup (unhopped)
- 1# crystal malt
- 1 oz. cascade for boil
- 1/2 oz Northern Brewer for finish
- 1/2 oz Northern Brewer for aroma

Wyeast liquid British Ale yeast, made with a starter last Wed.

I followed a typical Papezian-type method of steeping the specialty grains before boiling the hops and extract for an hour and cooling. No sparging, as I used pellets. Unfortunately, I neglected to get an original gravity reading (it was quite late). However, I racked last night to the 5-gal. carboy (I didn't use the blow-off method that Papezian advocates), took a hydrometer reading and tasted the brew. So here's my question: the reading was at 1.010, and the flavor and aroma then was quite good, but it needed clarification. Is it possible that all of the fermentables could have been fermented out within that short of time? I'm estimating, given the ingrediants and amount of water, that the original gravity was somewhere around 1.040 or slightly higher (?). If indeed the fermentation's finished - rather than stuck (drag!) - is it better to let it clarify in the carboy or the bottles?

Thanx in advance for any responses and directions. And thanks in response to all who answered my query about brew clubs in the Atlanta area; my brother's brewin' just fine!

Cheers!

John

Subject: Yeast, Kegging

>From: Jim Busch <busch@daacdev1.stx.com>

>There is an increased risk associated with "dipping" a loop into a slant repeatedly. I would advise restreaking to a single cell at least once a year. In theory it can last for years, but why risk it? If you are already culturing yeasts, then what is the extra plate and slant once a year to ensure clean yeast?....

I guess I am more concerned about the risk of making it sound so complicated that people are intimidated. For the person who has never done any of this before, the simpler the better and if he has to buy a new slant every year is still way ahead of buying new yeast for every batch.

Turning that liquid yeast packet into ten or so slants directly would be my choice as the way to get one's feet wet. I think I tried to get too much into that "beginner's" article on yeast culture. The petri dish streaking can be ignored till the easy part becomes routine.

>Subject: silly question on kegging

>Could anybody give me any insight on why NOT to carbonate a keg naturally, like in bottling, instead of using carbonated water and all the works needed to do kegging.

Not sure what you mean by carbonated water but the two basic reasons most of us force carbonate are:

1. Although it improves with time, you can drink the beer within an hour of kegging.
2. It creates no additional sediment as natural carbonation does.

>From: "John L. Isenhour" <isenhour@lambic.fnal.gov>
>Subject: Dry Ice carbonating in keg

>I have to agree with Jim on this. You really should try this yourself and gather some empirical data before suggesting it to people who might not know better.

All my kegs were full at the time and I just had to lay out the idea. I got the answer I was looking for and presume anyone who tried it would have sense

enough to use a pressure gage and keep an eye on things. However, that is not what makes lawyer's rich and your point is well taken.

.....DISCLAIMER.....

IF YOU PUT DRY ICE IN A CLOSED KEG, SUE GOD IF IT BLOWS UP.

> I have a lot of experience with forced carbonation of water, wine, beer and soft drinks, and if you've ever tried gassing beer up to 50psi, you'll find that its difficult to even vent the pressure down to dispensing level without it blowing out your venting tube.

Here we are going to disagree. You may be interested to know that I carbonate all my beer at 50 psi.

Why?

1. My beer is always at basement temp.

2. I have found that some kegs don't seal properly at low pressure and must be raised high enough to seal. This is actually why I quit naturally carbonating them. It seemed to take forever till I found out what was going on.

3. It's a lot faster.

Having said all that, the important issue is the volume of CO2 absorbed not the pressure it is done at. One could use 500 psi if the keg would take it and get it done real quickly. The key is knowing when to quit.

Here is the way I do it: I purge the keg several times to get all the air out then crank the pressure up to 50 psi and start shaking. The pressure drops in 10 lb leaps for several minutes. When it starts slowing down significantly, I turn off the CO2 and shake it down to about 30 psi and turn the gas back on. If it continues to flow while shaking, I continue to shake.

If not, I turn off the gas and let it sit for awhile. If it has not dropped or I can not shake it down to dispensing pressure after an hour or so, I bleed of the pressure to 20 psi and call it done.

For the record, I dispense through a cold plate with ice on it so my pressure is a little higher than normal but the bottom line is, I have no problem dispensing my beer (in fact I recently bought a Pilsner tap to create foam) and the one thing no one has yet complained about is the carbonation level of my beer.

>From: gummitch@techbook.com (Jeff Frane)
>Subject: That Damned Maltmill

>One real problem: the bolt holding the wooden handle on the crank seems to be threaded in such a way that it inevitably comes unscrewed while cranking.

All MMs are shipped with one defect just to generate hateful commentary on the Digest to keep me humble.

Seriously, this could be done my email but as there are 700 of them out there, you may not be the only one with this problem.

The thread on the inside of the crank is bunged up with a special tool so that when the knob/handle is screwed in, it can only go so far before tightening in the thread. I may have been sipping when I did yours but you can mush up the end of the treaded hole a bit with a screwdriver and a hammer. Just be sure to do the right/correct end (inside).

>It also looks as though I'll need to put rubber feet on my bucket, so it doesn't slide and hop around while I'm cranking the mill.

Doing it on the bucket looks a lot easier than it is and depending on the floor surface, it can be like wrestling with an aligator. I think most people eventually conclude that it works best clamped to a table with the business end hanging over the edge so the grain can fall into a bucket.

Thanks for your humor.

Subject: contamination

hello,

I am a relatively novice homebrewer (about a year) and I have just recently noticed some trouble with an extract/specialty grain beer. I used crystal malt (1/2 lb) biscuit malt (1/2 lb) and Alexander's pale ale (6? lbs.). The problem: the beer sat fermented in the primary until the fermentation was nearly done (i.e. more than 90 seconds between bubbles). I racked(?) to the secondary and everything looked fine for about a day. Yesterday I noticed that the secondary was bubbling about once every 45 seconds. There is also a light foam forming on top of the beer -- basically a thin airy head. The gas escaping from the lock doesn't smell like the usual gas so I am suspicious. Does it sound like I have a contaminant yeast. If so is there anything I can do? I thank everyone in advance. My address is ADCMR@UTXDP.DP. UTEXAS.EDU

Subject: Roller Mill, Rev. 1

Well, I've done it. OK, OK, my father-in-law has done it, but he's done it to my specifications. My roller mill, rev. 1 is complete and working. This thing is a dandy. It is motorized, with a 1/3 horse washing machine motor, and uses four pulleys to gear down the speed. The rollers are reworked iron pipe (3.5 inch diameter, I believe). It is sort of a scaled-down version of the one presented by RW and (??) in the latest Zymurgy gadgets special issue.

He is a tinkerer from way back, but the only special tools used were a welder and a table-mounted belt sander. The total cost of supplies was around \$75. I will give more info if there is interest, but I'm very busy right now and if I have to choose between brewing a batch of beer and writing a legible report on this mill, well, you can guess what'll happen. I can say without a doubt that the price of Jack's mill is very reasonable, considering the labor put into this one. I expect the two mills to produce roughly similar crushes, BTW, although I probably will never have the chance to do a direct comparison.

Cheers,
Norm

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: Dry Hopping

>From HBD 1113 Sherman Gregory comments on dry hopping. I dry hopped for the first time a week ago and both observed and expected this behavior. I threw hop pellets into the secondary before siphoning from the primary. Sure enough a "krauesen" developed and even though I didn't fill it right up, I still ended up with this green, hoppy froth bubbling out the neck. Next time I'm going to fill it even less and put the remainder into another container, to transfer into the secondary after the action subsides. I think I'll put the hops into a hop bag also to keep them in one place. Does this work as well as putting them in loose?

The cause seems obvious enough. There is lots of dissolved CO2 in the beer after fermentation and the hops act as nucleation sites causing loads of gas to be released. This gas continues to escape slowly (even without dry hopping) and looks like fermentation but isn't.

Peter

Not a silly question at all... this is what distinguishes British Real Ales from processed "keg" beers. The cask conditioning is what adds the subtleties to the flavor of the beer. If you pump your beer full of gas, you are "killing" it because this will prevent any further fermentation taking place.

> Could anybody give me any insight on why NOT to carbonate a keg naturally,

Well, it's quicker and requires less skill...

> My reasoning is simple; kegging didn't used to be
> done the way it is today. So, what are the pros and cons to throwing
> in
> priming sugars in a keg and cork it?

It's a bit more complicated, because you don't want the pressure to build up too much or it will have the same effect as artificially carbonating it.

> I would appreciate any HELPFUL suggestions.

Hopefully, I am being partially HELPFUL, if a little provocative... ;^)

Interestingly, the April edition of What's Brewing, the monthly newspaper of Britain's Campaign for Real Ale, has a two page feature on the preliminary results of some research they have been doing into whether brewers are cheating by minimizing the cask conditioning of their beers. They have been measuring the drop in gravity of beer delivered to beer festivals (and in some cases to "friendly" pubs) and also the quantity of yeast present. They have been able to confirm that many beers are sufficiently cask conditioned, but they can't prove when this isn't so (due to factors such as the beer having completed its secondary fermentation before they got their hands on it). Reading between the lines, they are particularly suspicious of Courage (Foster's) Directors' Bitter. However, they do conclude that the Campaign is right to place so much emphasis on the benefits of cask conditioning in its definition of the term "Real Ale".

>-- End of excerpt from C05705DA@WUVMD.Wustl.Edu

P.S. The same issue of What's Brewing has an article by Michael Jackson on the topic of German double bocks, including Paulaner's Salvator, recently the subject of some discussion on HBD.

Subject: Re: why blowoff?/Goose deliveries/Length of chiller/dryhopping

Gerald asks, why use the blowoff method?

It's merits have been argued in the HBD, but I believe it makes the beer taste better, so I continue to use it. Papazian says that the kraeusen contains fusel oils (I've seen fusel alcohols elsewhere) which some say contribute to hangovers. The most graphic proof I have for using the blowoff method is to challenge anyone to drink a glass of blowoff. YUK! Just sniffing it is enough to guarantee my continued support of this procedure.

The arguments against using the blowoff method (just to be fair) are that you lose beer and that you lose some of the bittering you just but in with the hops. One of the test batches that I made was severely underhopped.

It turns out in this case that the non-blowoff half tasted better than the blowoff half albeit the bitterness was a bit harsh.

If you are going to use the blowoff method, I suggest you go and get some 1.25" tubing and just stuff it into the top of the carboy. Stick the other end in a bucket or jug with a little water in it. Don't use a thin tube and a one-hole stopper as it will eventually clog and really make a mess (especially likely when fermenting with fruit -- I know firsthand).

Kevin asks:

The AHA won't know and won't care, the only people who might would be the organizers of the Midwestern 1st-round judging and Goose Island itself. Last year they accepted my entries hand-delivered, so I assume they will accept them this year too.

John then goes on to theorize that length may be important when the wort approaches the temperature of the water.

I think you're wrong in the first assertion and right about the second one -- as the wort cools, the length of the chiller becomes more and more of an issue... you need a longer chiller. My chiller is 50' of 1/4" copper tubing (immersion) and it chills the wort from boiling to 70F in about 15 minutes during Chicago winters when my tapwater is about 45F.

William writes:

Questions:

What are pros & cons of pelletized vs whole hops when dry hopping?

I've found that when I use whole hops, they simply float and I siphon out from under them -- no hops in the bottling vessel or bottles.

Any advice on removing hops when preparing to bottle?

If you use pellets, you can put a copper scrubbing pad over the end of the siphon hose followed by a mesh bag (this idea was originally introduced by Al Taylor (I think it was Taylor...) and then independently by Kinney Baughman).

Alternatives to dry hopping that will give good hop nose?

See Kinney Baughman's article on a sort of hop-back in the Gadgets and Equipment special issue of Zymurgy.

Subject: Thanks ...and more...

I would like to thank everyone who responded to my recent inquiries about getting started. I have purchased a couple of the recommended books and I have located a homebrew shop in the area. They offer a class plus a discount on supplies to those who take the class. Now all I need are the supplies to get started and the nerve to begin....

Next, what is the best source for bottles? Are bottles bottles, or are some better than others? Should I stay away from bottles all together?

Also, does anyone know if the Frankenmeuth (sp?) brewery gives tours and if they do, do you know the hours of the brewery?

One more...I will be in Atlanta, GA in May. Are there any brewpubs or microbreweries to worth going to?

Thanks for everyones help. I wish I had something to contribute.

Subject: Rehydrating dry yeast?

The recent thread about rehydrating dry yeast before pitching drove me to make my first submission to HBD. (Loud clapping and cheering can be heard from audience.)

As a relatively new brewer, this is the first I've heard of rehydrating dry yeast before pitching. For the few batches that I've made, I pitched the dry yeast directly into the primary, with no noticable bad effects (i.e., it fermented just fine, and the beer tasted the way it was supposed to taste).

Is there any advantage to rehydrating the dry yeast? Is there any disadvantage to tossing the dry stuff directly into the primary?

Subject: Immersion Chiller Length

John Decarlo <jad@pegasus.mitre.org> suggests that a shorter cooling coil might be better than a longer one, down to some minimum. What he has noticed is that there may be an inflection point in the time vs. temperature curve on this heat exchanger. He's right. There's no point in making a coil so long that no additional heat is picked-up by the cooling water during some portion of its travel. Not that I could reproduce the work today, but this was a problem on a physics assignment I did maybe 12 years ago. It has to do with the modulus of heat transfer in materials. Essentially, heat takes time to "travel" in a material, and the speed with which it "flows" depends on the temperature difference. A bigger difference in temperature causes faster heat-flow.

So when you get to the point that a new, incoming volume of water is picking up heat faster than some number of volumes of water already inside the tube, your exchanger is too long. What does this mean in practical terms? Gee, any physics students out there who'd like to take a shot at finding the optimal heat exchanger length vs diameter vs flow vs tap-water temp for cooling wort? Could be fun... Or maybe we can do a net-wide emperical data collection experiment. If anyone's interested in the latter approach, send me e-mail.

Oh -- mine's 50 feet of 3/8" copper, fwiw.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: dry hopping/fermentation in secondary

I'd like to hear more from people who have dry-hopped and had their fermentation re-start in secondary. I have dru hopped with pellets 3 or 4 times, and with whole hops once, and this is the first time I've had my beer jump-start on me.

Specifically: when do I know when to bottle? I've still got a krausen sitting on top, although the bubbling is very slow now. I hate musking around in the beer to get gravity readings, but I suppose that's the obvious answer.

Also: I had thought that next time I dry-hop I might try whole hops in a muslin bag, weighted down with a couple sanitized marbles. Will this be more or less likely to cause the same renewed fermentation?

And finally: should one perhaps not rack until the beer is within a point or two of final gravity if one is going to dry-hop? My gravity was still in the high teens when I racked this time, and I'm thinking this may have contributed to the jump-starting effect.

Thanks in advance.

It is true that for the first minute or so that the output is nearly at boiling temp, but after that it is far less. After that, hotter the water coming out indicates more efficient cooling. The idea here is to remove as much heat from the wort as fast as possible. The temperature delta times the cooling water volume is proportional to the heat removed. With a longer tube, the output temp will be closer to the wort temp meaning more heat removed. I see two measures of efficiency here. One is cooling rate. The other is temp change/water volume (important in waterless So. CA). Both of these will be improved with a longer chiller. I know that this is not linear with chiller length, but more length always helps.

So much for flaming and counter flaming! It is so much fun!

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: Immersion cooler design

Sherman has asked about immersion cooler design, what length and diameter is appropriate, etc. John DeCarlo sez short is good enough.

I'm sorry, John, but you are right and wrong. It is correct that short coolers put out very hot water initially, but longer is better. Here's why--

Heat flow is proportional to temperature differential. The rate of temperature drop is fast at first, but slows down as the wort cools. If your cooler is smaller, it will take a lot longer to cool down below 90 degrees. My water temperature varies from 45F (winter) to 55F summer. The final 10 degrees of temperature drop takes a lot longer in the summer than in the winter, due to the smaller differential.

All other things being equal (now there's a simplifying assumption!), the greater the mass of copper tubing, the faster your cooler will chill that brew. I'm talking about using 1/4" - 1/2" i.d. soft copper tubing in the longest length you, your brewpot and wallet feel comfortable with. I have been using 20 ft of 1/4" i.d. and just got 50' of 3/8" i.d. cause bending over the pot for so long makes my back hurt.

BTW, there was a long (3 month) thread last summer on immersion and counterflow coolers. I have extracted the messages into one BIG file, and will gladly send it to anyone who wants one. If the demand is too much for me to easily accomodate, I'll see about posting it to the sierra.stanford.edu FTP site.

see ya in Portland,
Paul.

Subject: Grain during fermentation?

Following up on the recent thread of adding grain during fermentation ... In Dave Line's book (BBLTYB) he gives an extract recipe for a brown ale (Brown Jack Best Brown Ale) in which he uses crushed roasted barley in both the pre-boil and in the primary fermentation (pitched with yeast) stages. I haven't considered this before, but wonder if anyone has any comments on it. Also, since many have found that an ideal time to add hops, fruit, peppers, spices, or any miscellaneous flavorings is during the secondary, it seems that this would be a better time to add the roasted barley. Has anyone experimented with the addition of speciality grains during secondary fermentation? Thoughts?

Subject: Corrections on Samichlaus

Well, I spoke from memory which is always a mistake.

Samichlaus (note spelling) beer from Huerlimann in Zuerich, Switzerland is, according to Jackson's Pocket Guide, Third Edition, brewed with a original gravity of 27.6 Plato (about 1.110) and ferments out to 11.1-11.2 % alcohol by weight, which is 13.7-14 by volume.

OK, now that we have that correct, I am still interested if anyone knows the real story on Sam Adams Triple Bock.

Historical Recipes by F Accum 1821
translated by Rob Thomas.
All recipes are adjusted to give 4 UK gallons
of beer at fermentation (i.e. 5 US gallons).
All measurements are UK units (same as US, except
gallon US = 0.8 gallon UK)

PART 1

Brown Stout Porter.

Ingredients.
13.99 lb malt, 1/5 pale, 1/5 amber, 3/5 brown
5.3 oz. hops.

Mashing.
Mash 1: 2.375 gall of water at 165 F, 1.5 hours.
Mash 2: 1.875 gall of water at 160 F, 1.5 hours.
Mash 3: 1.938 gall of water at 186 F, 3/4 hours.

Boiling.
mash 1 boiled with the hops for 1.5 hours.
mash 2 boiled with the used hops for 1.75 hours.
mash 3 boiled with the used hops for 2.5 hours.

Produces 4 gall at 1071.
fg. 1024.

London Ale.

Ingredients.
25.45 lb pale malt
9.29 oz. hops.

Mashing.
Mash 1: 1.820 gall of water at 175 F, 0.5 hours,
then add a further 0.91 gall at 175 F, 2 hours.
Mash 2: 2.180 gall of water at 180 F, 1.75 hours.
Mash 3: 1.270 gall of water at 150 F, 1.25 hours.
Mash 4: 1.270 gall of water at 150 F, 1.25 hours.

Boiling.
mash 1 boiled with the hops for 1.5 hours.
mash 2+3+4 boiled with the used hops for 3 hours.

Produces 4 gall at 1068.
fg. 1026.

Table Beer.

Ingredients.

10.1 lb pale malt

1.92 oz. hops.

Mashing.

Mash 1: 2.880 gall of water at 160 F, 0.75 hours,
then add a further 1.71 gall at 160 F, 1.5 hours.

Mash 2: 2.700 gall of water at 180 F, 1.25 hours.

Mash 3: 1.980 gall of water at 185 F, 1.25 hours.

Boiling.

mash 1 + 1/2 mash 2 boiled with the hops for 1 hour.

rest of mash 2 + mash 3 boiled with the used hops for 2 hours.

Produces 4 gall at 1035.

fg. 1012.5.

From: envkas@sn370.utica.ge.com (Karl A. Sweitzer)
Subject: vortex drain strength, and coriolis acceleration

I have found that the best vortex drains are formed when you swirl the bottle or carboy in a counterclockwise direction (when viewed from above, in the northern hemisphere of our spaceship earth). The reason is the coriolis acceleration vector caused by the counterclockwise rotation of the earth. When you rotate the bottle in the same direction as the earth rotation the coriolis acceleration vectors constructively add, forming a greater force on the liquid molecules. The coriolis acceleration vector tends to force the liquid to the outside of the rotation circle leaving room in the middle of the bottle for air to enter and replace the exiting liquid. This air path is more efficient than "gurgling" air entering the bottle as periodic bubbles. (note, for those of you in the southern hemisphere, rotate the bottle in the clockwise direction. For those at the equator, rotate in either direction.) Some say that the coriolis accel. vector makes pigs tails curl (no kidding!). I have seen pictures of pigs from Equador with straight tails!

I have also found that you can drain a full carboy quickly by inserting an air tube into the neck and extending to the bottom. The air tube allows air to enter while the liquid exits. Another trick is to cut an air hole in the top corner of the handle of plastic gallon jugs. I have several jugs like this that I have marked in quart divisions that are handy for measuring and pouring large quantities of liquid.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: decoction

I had heard from a reasonably reliable source (at least, he *claims* to be reliable :) that decoction was classically performed by thrusting a bucket into the top of the mash to make a well, and collecting any liquid that collected there. The decocted material then contained mostly liquid, with a small quantity of grain (maybe 5-10% by weight). When I mentioned the line about taking a quantity of grain and leaving the liquid behind he thought I was looney. Anyway, his suggestion was to use a picnic cooler/lauter tun and drain liquid only off the bottom, boil it, and dump it in on top. So I set up my slotted manifold and tried just that. I did a protein rest, and then a rest at 149-145 F, and another at 159-155 F. I had to decoct and boil several times to accomplish this. All I can say is whoever claimed that drawing off the liquid and boiling it would seriously reduce the enzyme content should have watched the mash clear during the last rest. You could literally watch it clear it happened so fast; from cloudy starchy muddy water to crystal clear wort in about 15 min. I don't know, maybe this is a decoction-infusion hybrid if I don't boil any grain, but it sure worked well.

Subject: Decoction Mashing

>From: Darryl Richman <darrylri@microsoft.com>

>I did spend all day with my first decoction. Part of that was due to it going from a planned two decoction mash to a four decoction, because I was far short of my temperature marks. But having got beyond that, decoction requires less equipment than a step infusion, and I believe, produces a different spectrum of flavors and aromas.

There is a simple alternative method I use that makes the first step a lot easier and totally predicatble along with cutting the time down to about the same as a "normal" kettle mash.

I use the stove to bring the mash to the low end of the saccharification range and just use decoctions to maintain the temperture. I scoop out several quarts of mash and bring this to a boil in a separate kettle. By the time this is boiling the main mash has cooled enough to need the decoc to maintian the proper temp. Several gallons are boiled (during a one hour mash) in this manner and although far from a "real" decoction, it is a compromise that is easy and probably provides some measure of "a different spectrum of flavors and aromas" as noted above.

Subject: Yeast, Kegging

>From: Jim Busch <busch@daacdev1.stx.com>

>There is an increased risk associated with "dipping" a loop into a slant repeatedly. I would advise restreaking to a single cell at least once a year. In theory it can last for years, but why risk it? If you are already culturing yeasts, then what is the extra plate and slant once a year to ensure clean yeast?....

I guess I am more concerned about the risk of making it sound so complicated that people are intimidated. For the person who has never done any of this before, the simpler the better and if he has to buy a new slant every year is still way ahead of buying new yeast for every batch.

Turning that liquid yeast packet into ten or so slants directly would be my choice as the way to get one's feet wet. I think I tried to get too much into that "beginner's" article on yeast culture. The petri dish streaking can be ignored till the easy part becomes routine.

>From: C05705DA@WUVMD.Wustl.Edu
>Subject: silly question on kegging

>Could anybody give me any insight on why NOT to carbonate a keg naturally, like in bottling, instead of using carbonated water and all the works needed to do kegging.

Not sure what you mean by carbonated water but the two basic reasons most of us force carbonate are:

1. Although it improves with time, you can drink the beer within an hour of kegging.
2. It creates no additional sediment as natural carbonation does.

>From: "John L. Isenhour" <isenhour@lambic.fnal.gov>
>Subject: Dry Ice carbonating in keg

>I have to agree with Jim on this. You really should try this yourself and gather some empirical data before suggesting it to people who might not know better.

All my kegs were full at the time and I just had to lay out the idea. I got the answer I was looking for and presume anyone who tried it would have sense

enough to use a pressure gage and keep an eye on things. However, that is not what makes lawyer's rich and your point is well taken.

.....DISCLAIMER.....

IF YOU PUT DRY ICE IN A CLOSED KEG, SUE GOD IF IT BLOWS UP.

> I have a lot of experience with forced carbonation of water, wine, beer and soft drinks, and if you've ever tried gassing beer up to 50psi, you'll find that its difficult to even vent the pressure down to dispensing level without it blowing out your venting tube.

Here we are going to disagree. You may be interested to know that I carbonate all my beer at 50 psi.

Why?

1. My beer is always at basement temp.

2. I have found that some kegs don't seal properly at low pressure and must raised high enough to seal. This is actually why I quit naturally carbonating them. It seemed to take forever till I found out what was going on.

3. It's a lot faster.

Having said all that, the important issue is the volume of CO2 absorbed not the pressure it is done at. One could use 500 psi if the keg would take it and get it done real quickly. The key is knowing when to quit.

Here is the way I do it: I purge the keg several times to get all the air out then crank the pressure up to 50 psi and start shaking. The pressure drops in 10 lb leaps for several minutes. When it starts slowing down significantly, I turn off the CO2 and shake it down to about 30 psi and turn the gas back on. If it continues to flow while shaking, I continue to shake.

If not, I turn off the gas and let it sit for awhile. If it has not dropped or I can not shake it down to dispensing pressure after an hour or so, I bleed of the pressure to 20 psi and call it done.

For the record, I dispense through a cold plate with ice on it so my pressure is a little higher than normal but the bottom line is, I have no problem dispensing my beer (in fact I recently bought a Pilsner tap to create foam) and the one thing no one has yet complained about is the carbonation level of my beer.

>From: gummitch@techbook.com (Jeff Frane)
>Subject: That Damned Maltmill

>One real problem: the bolt holding the wooden handle on the crank seems to be threaded in such a way that it inevitably comes unscrewed while cranking.

All MMs are shipped with one defect just to generate hateful commentary on the Digest to keep me humble.

Seriously, this could be done my email but as there are 700 of them out there, you may not be the only one with this problem.

The thread on the inside of the crank is bunged up with a special tool so that when the knob/handle is screwed in, it can only go so far before tightening in the thread. I may have been sipping when I did yours but you can mush up the end of the treaded hole a bit with a screwdriver and a hammer. Just be sure to do the right end (inside).

>It also looks as though I'll need to put rubber feet on my bucket, so it doesn't slide and hop around while I'm cranking the mill.

Doing it on the bucket looks a lot easier than it is and depending on the floor surface, it can be like wrestling with an aligator. I think most people eventually conclude that it works best clamped to a table with the business end hanging over the edge so the grain can fall into a bucket.

Thanks for your humor.

Date: Wed, 7 Apr 93 9:20:34 CDT
From: tony@spss.com (Tony Babinec)
Subject: boiling concentrates the wort

Keep in mind that in all-grain brewing you collect sweet wort which is boiled down to 5 gallons typically. That is, one of the functions of boiling is to concentrate the wort. In a 90-minute or so boil, you'll be evaporating the water in the wort. As an example, a beer which would have SG of 1.050 at 5 gallons will give a gravity reading of 1.042 at 6 gallons and 1.036 at 7 gallons. At 7 gallons, the wort is dilute, and when boiled down to 5 gallons, the more or less same amount of sugars and stuff give the beer a gravity of 1.050. So, if you collect 7 gallons of wort and take a gravity reading of 1.036, you'll have a 1.050 beer provided you achieve a vigorous and sustained boil and boil the beer down to 5 gallons. One last point: the gravity reading done on the 7 gallon beer should either be done at 60 degrees F (typically) or should be adjusted for the temperature of the wort. An uncorrected gravity reading on hot wort will understate the specific gravity of the beer.

From: tony@spss.com (Tony Babinec)
Subject: diastatic power of some malts

Here are some numbers on some of the DeWolf-Cosyns malts:

Malt	color	diastatic power
U.S 2-row (Schreier)	1.78L	131.0
Belgian pilsner	1.8	105
Belgian pale ale	3.260	
Munich	7.850	
Aromatic	25	29

Any of these malts is capable of conversion by itself, including the Aromatic. Notice that the Schreier has the highest diastatic power. Keep in mind that mega-brewers like to use adjuncts such as corn in their mash, and are therefore interested in a base malt with high diastatic power. The homebrewer can use any of these malts alone or in combination. A typical pale ale malt can be mashed alone and need not be mashed with a malt of higher diastatic power.

From: u4imdmre@cpc41.cpc.usace.army.mil (Markham R. Elliott)
Subject: Help, I boiled away the hops

Hello again fellow brewers!

I've returned with a deal you can't refuse....I will continue to call myself a novice until I've got 2 years of hands-on homebrew experience, but I get to continue to ask the dumb-s**t novice, extract-brewer questions. OK? Knew you couldn't pass it up. :-)

I have been taking in all the advice I can read, and have taken much of it at face value, few questions asked, but alas, silly me, I should have known better without thinking things through.

Case in point, then an urgent request for opinions.

My beers have dramatically improved since that first fateful batch. Reduced, then eliminated the use of sugar. Then came the use of a secondary fermenter. Then the use of DME, and finally the failed attempt at using DME as a priming agent. Longer boils...longer boils...longer boils. No one reminded me that when using a hopped extract, the longer you boil, the more you remove what the hops were put in there for. No one to blame but myself, should have seen it coming. Knew better. Dealt with essential oils in Organic Chemistry those many years ago. Faithfully read the HBD daily, and see cautions about not boiling away the "hop nose", etc, etc.

Now the plea for help.

Should have guessed why everyone said "not bad, but not bitter enough". Now that I've screwed up another batch (now 3 days in the primary), is there a way to salvage what I'm sure will be another "bland", hop-lacking brew? The flavor of the past few batches has been ok; rich, sort of sweet, but kinda watery and again, missing a lot of what the hops were there for to begin with.

I have read with increasing interest over the past couple of weeks about "dry hopping" in the secondary. Would me adding some high alpha hop pellets to the secondary be worth the try to put back in what I boiled away? Any other suggestions (other than throwing it out) will be welcome. BTW, no more hopped kits for this kid, gonna take another step toward what many seem to feel is the

only way to brew.

Noch einmal, bitte!! Mark

From: tima@wv.MENTORG.COM (Tim Anderson)
Subject: Re: Immersion cooler length

I made a change to my immersion chiller that made a noticeable difference. Like many others I made mine by attaching hose fittings to 25 ft of 3/8 in. copper tubing and coiling it into a helix (like a fat spring) which I just set into the boiling wort. While waiting for the magic occur, I entertained myself by probing various parts of the wort with my thermometer. There were huge temperature differences. The top middle was the hottest by far.

Well, it seemed to me that the chiller is doing the most good where the wort is hottest, so for the next batch I recoiled the tubing into a spiral (like the burner on an electric range). I suspend this maybe an inch below the surface of the wort. Since I use a big wide canning kettle, there's lots of room. Chilling is much faster. I can stand there and watch the cold break material form and fall between the coils to the bottom. In fact I have to stand there, because I haven't found a way to suspend it other than by holding it. Admittedly a pain, but the faster chilling is easily worth it.

Subject: Problems with tab characters

Sorry to waste bandwidth with small stuff, but I have to mention about people's use of tabs. Please remember that your tab stops may not be mine.

In HBD 1113, for example, Jeff Frane included big tables of recipies, using lots of tabs. Well, his tabs don't match mine, and I had to work on his table extensively to make it readable. This is the case with almost everyone's articles that use tabs, signatures, etc.

This is rather like the problem with articles over 80 columns wide. They look good to the sender, but suffer in translation.

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: Copper tubing sizes

Since it looks like we may be in for more interesting explorations of thermohydrodynamics (wort chillers), please be aware that there is a lot of potential for confusion about pipe (hard) and tubing (soft) sizes.

Soft copper tubing, like we use in most of our chillers, is usually measured, sold and fitted by o.d. (outside diameter). Hard pipe, that has threaded or soldered fittings is measured by i.d. (inside diameter).

To add to the confusion, soft tubing used in refrigeration is sometimes measured one way and sometimes another. Also, many chain stores use both i.d. and o.d. for soft tubing. This may be a marketing ploy to get hapless do-it-yourselfers to purchase the wrong fittings to clutter up their junk drawers :-)

Rounding sizes to nearest 1/8", for soft copper tubing:

O.D.	=	I.D.
1/4"		1/8"
3/8"		1/4"
1/2"		3/8"

Now *I've* probably added to the confusion,

Paul.

SUBJECT: Thanks for the decoction info.

Thanks to all who posted info on decoction mashing. I made an American pilsener last weekend (my first attempt at an all grain) and got pretty mediocre extraction--2lppg using temp-controlled mashing on Klages malt. I'll try the same recipe (tastes good from the fermenter) using a decoction mash and post the taste test results (it may take a month). Anyway, someone wrote that some of the big breweries like Pilsener Urquell still use decoction mashing. How on earth do they remove the grains from the mash tun? They must have to boil hundreds of pounds of grain. Anybody taken a tour?

From: "Steve Kurka" <kurka@bmcw.com>
Subject: Questions

I have a few questions:

This may be an insignificant question, but so what:

I would like to upgrade to a glass carboy soon, but don't know whether to go with a 5 gallon or 6.5-7 gallon carboy. What are the advantages of each size?

(Ex: - no blowoff tubes needed to large sizes

- no blowoff tubes on large size to blowoff stuff (but what stuff?))

Does anyone have more info on sulfites not killing bacteria?

Does anyone have simple ideas on cheap filtration methods?

I would also like to thank all who sent me lists of San Fransisco brewpubs recently, the trip was a success (good beer).

Thanks, Steve kurka@bmcw.com

From: brewmstr@genesis.mcs.com (Jim Bayer)
Subject: Runaway Ferment... HELP!!!

I've been brewing for about 2 years now and just did my first all-grain batch 2 weeks ago. Until now I've never seen a ferment go so strongly and so long.

My grain bill is as follows:

6lb 2 row Klages
2lb Special Roast
1lb German Light crystal
1lb Cara-pils

I used Wyeast Irish Ale (forget the number), Northern Brewer, Cascade and Hallertau hops.

Since it was my first all-grain batch, I expected it to take me longer, and it did. My sparge ran about 2.5 hours (trouble with the Listermann system) and I ended up with some (very little) grain in the brewpot. The edges of the false bottom did not seal very well for me.

I tasted the output from the sparge and it seemed ok. I boiled it for about 1.5 hours and added the Irish moss 10 minutes before turning off the heat. I used a submersion chiller for the first time and got the temp down to about 65°F in 20 minutes. I pitched the yeast (no starter alas) and waited.

As a preamble, I should say I cleaned and soaked everything I used, spoon, primary bucket, hoses, etc. in bleach solution. I made it a little too strong (used about 1 to 1.5 cups to 5 gallons) so I rinsed everything before use. I soaked it all for 15 to 30 minutes before the rinse.

I filled the primary, stirred vigorously for aeration and pitched, closed the lid, sealed it tight and set up the air lock.

After 3 days of fermenting (took 36 hrs to start), I raked to the secondary and thought it would finish in a few days. To my surprise, it went to full kreausen AGAIN and is still giving me 1 blip per second after 10 days. I checked it last night and the secondary is still at full boil.

Am I infected? Is it the yeast? What is going on??

I did notice that the wort was REALLY REALLY SWEET. Never tasted one so sweet before. could it be the yeast are still feasting? OG was 1.040

Any input will be greatly appreciated

Jim

>a feeble 'glug' once every 70 seconds. The color got noticeably darker.
>No off flavors to suggest contamination. Specific gravity down to about 1.009
>(I think).

Recently, I had, what appeared to be headed for a record-breaking ferment.

It was a simple 1048 English Ale using Wyeast #1028 "London Ale." Well, the problem started when I got married. No, don't get me wrong, my wife is wonderful and very supportive of my brewing and related endeavors. However, when she got a look at one of our gas bills, she suggested we lower our thermostat, from 72F to 68F. I agreed.

I started my batch as usual with a 500ml starter and pitched the 70F starter into well-aerated, 70F wort. I put it in the fermentation room just like I used to and proceeded to not worry. Well, I had forgotten about my wife's cost-saving measures and failed to look at the 9" diameter thermometer in the fermentation room. It said 61F!

Two days and no kraeusen. That's when the temperature dawned on me. I brought the fementer up into the study (68F), closed the shades and covered the fermenter with a couple of dark brown plastic garbage bags to prevent light damage. The next morning, although the fermentation had started, I still thought it was too bright in there and closed the door. Guess what, the closet is not insulated and the temperature dropped to 60F by that evening. Fermentation back to a standstill. I opened the door and put some cardboard around the fermenter.

10 days later, it was still fermenting slowly at about 30 seconds between glubs. 20 days from the start of the ferment, it had gotten down to a minute between glubs, so I added the dryhops (1oz of Goldings plugs).

10 days of dryhopping, still 1 glub/min. 14 days of dryhopping, still 1 glub/min. Hmmm? Is this yeast brain-damaged or what?

Then, I thought, perhaps a lot of the yeast had gone dormant thanks to the cold and had not awakened from simply warming the wort. I rocked the carboy around-and-around to swirl the yeast up from the bottom. Naturally, lots of CO2 started escaping through the blowoff tube. 8 hours later, the ferment was going at a good pace, perhaps 1 glub per 30 seconds.

24 hours after swirling, the glubs were 2.5 minutes apart -- ready to bottle!

I came up with this thought to rouse the yeast from what I've read about yeast rousing used in some very strong beers (Thomas Hardy's may be one, I'm not sure). Next time a ferment is taking longer than you expected, try rousing the yeast (without aeration, of course -- I just swirled my airlocked carboy).

Chris writes:

>On another note, how long should I expect my 20lb CO2 tank to last? I got
>it last summer and have made at least 10 batches of beer since then. I
>also use it to push the sterilizer out of the keg when cleaning it. The
>pressure gauge for the high side hasn't really moved.

I have a 20# tank, but it hasn't run out yet since I got the leaks fixed. The first filling only lasted perhaps 10 kegs, but the second is well over

20 and still going. It's very important to change that washer between the

valve and the regulator with each filling -- it's a common source for leaks. Regarding the high-pressure side gauge, I'll stick my neck out and

say I think it's useless. It won't begin to drop till all the liquid CO2 has run out and has turned to gas. Then it will drop to zero in one or two days. That's not my idea of warning you that it's about to run out!

I plan to weigh my tank the next time it runs out and use its weight as an approximation for when I should go get it refilled. It should weigh, well... 20# more when full (for a "20#" tank).

Subject: Follow-up: Tower System

I promised a posting of comments made on the Tower System, and am glad to do so! Thanks to everyone who showed interest. My initial impression is that the Tower System is a good idea because there were no flames. However, it may be because of the limited experience that people have with this system. I'm still putting my system together (working on limited funds, you know) and will let everyone know what I think after its up and running and the little kinks have been worked out. So some of the replies:

1. Stuart Galt suggested that I build a welded steel rack with wheels to house the tower so that it could be moved around for brewing and storage. Sound like a great idea, but since I have a hammer and saw, but not a welder, I built my rack out of 2 by 4's and 3/4 inch plywood. I used Simpson Strong-Tie (TM) connectors to make sure that there was plenty of strength to hold 10 gallons of hot sparge water and mash (if you haven't seen these connectors, they are great for building work tables and shelves - ask your hardware store about them). Also, by planning for my glass 6.5 gallon fermentor to sit on the ground and allowing the kettle to gravity drain into it, the mash/lauder tun to drain into the kettle, and the hot water tank to drain into the mash/lauder tun, I designed the rack so that nothing with hot water ever has to be lifted (other than pumping from the kettle up to the hot water tank). Thus, my rack has a working surface 45 inches above the ground for the mash/lauder tun to sit on, and a shelf 20 inches higher (a total of 65 inches above the ground) for the hot water tank to sit on. This allows me to slide the mash/lauder tun underneath the hot water tank when I'm not brewing so that I've got a work bench. However, since my mash/lauder tun is 16" tall (a 58 quart Igloo cooler), and it sits on top of a 45" high shelf, it is a too tall for even my 6'2" body to work with. Therefore, I built a 10" platform that I can stand on when stirring the mash. This platform simply slides underneath the rack when not in use.

My rack, from the side, looks something like the sketch below.

2. Rich Lenihan had several comments and suggestions.

a. Rich suggested that I put a rolled screen/tube inside the kettle (like the EasyMasher (TM)) to filter out hops and trub. An excellent idea that I have included.

b. Rich also was concerned about heat loss along the way, and that perhaps by preheating the system prior to mashing, this problem might be eliminated. I checked with several people and using a picnic cooler for the hot water tank will hold the temperature to less than a couple of degrees heat loss over the few hours necessary. Thus, preheating should probably not be necessary. Also, Rich reminded me that Papazian has a grain bill/water temperature/water volume chart so that I can use that for a guideline. I looked, and sure enough, it will be usefull!

3. Bob Hodge suggested that instead of two manifolds in the mash/lauter tun, that only the lower one be used, and that mash water can be introduced from the bottom (underletting) like a recent thread had suggested. I like this idea, and will implement it, but I still will need the upper manifold for sparging.

A few people had questions about what I was going to use for high temperature hose, what kind of fittings I was going to use, etc. I mentioned Grainger's and McMaster's supply catalogs for sources.

Finally, this post was originally to the Home Brew Digest, and not rec.crafts.brewing. So now, I am posting both the original and this follow-up post to rec.crafts.brewing to see if there are any other suggestions.

Thanks to all for the ideas!

Sam Atkinson

>Klages to get quicker conversion? Thanks in advance.

Sure, it's 60 degrees Lintner. I don't think you would get much of a increase in conversion -- you certainly would not *NEED* to add anything. By the way, Klages hasn't been grown in the US for (I believe) two seasons -- Harrington is what most (all?) of the brewing barley growers are producing. If your supplier is advertising Klages, either they don't know what they are selling or are selling very old malt.

Subject: kiwi wine

Here is an experimental recipe I came across and it actually worked.
This is for all you wine lovers.
This recipe need not be followed exactly and even if you do I doubt
you'll
get the same result twice.
Get a 1 gallon jug, empty milk jugs work great. Be sure to clean it good
otherwise you'll end up with vinegar, not wine.
Clean the jug with a tablespoon of bleach and 3 cups water. Swish it
around
for a few minutes.
Take about 2 1/2 lbs. of fresh kiwi and put it through a juicer. If you
don't
have a juicer just smash it up and use the pulp and all. In this case
you'll
need to avoid the lower 1/3 of your wine when you drain the wine from the
container.
Put the kiwi juice, or pulp, into the container. Add 2-3 cups of sugar
and 1
tablespoon of yeast. fill the jug almost full with distilled water.
Regular
water will work but it increases the chance of having a bacteria which
will
produce vinegar.
Cover container lightly, it must be able to "breathe" but not have stuff
fall
into it. Leave sit in a semi-cool place and wait a)1 month for harsh
wine,
or b)2-3 months for a smooth wine your freinds will love you for!!!!
Any questions about kiwi wine a317-475@edu-utah-bus-lab

Where
>did I go wrong?

I'm not sure you did anything wrong. SG is a function of
temperature. So if you read an SG of 1.028 at 212F, that would
be equivalent to an SG of 1.068 at 60F (which sounds great to
me). Its common practice to record the temperature and SG
simultaneously, and then correct the SG for a temperature of 60F
(actually I normalize to 59F).

To this I can but say: Horse poop. The coriolis force on the
liquid in a carboy 30cm or so in diameter is virtually nil. Swirl it any
way you please, there will be no difference. The friction of the side of
the jug is far greater than any coriolis effects on the water. As for
the
pigs, they can poop too.

Subject: boiling exploitation

Hi,

How much does boiling change the malt... i.e. I know that you should boil the malt for a little bit to sanitize it, but...

what if I were just to have plain water in my boil with the hops and then add the malt into said boil long enough to sanitize it at the end... of course adding the appropriate irish moss or whatever...then cool and pitch like normal...

would this affect the taste of my bier (mackensen extra stout:)?

thanks,
-chris

for
>racking wine at regular intervals is to promote oxidation. Clearly, we
have
>a conflict here and my Fall Wine is now in the aging stage and it would
be
>nice to know if I should intentionally splash it around while racking or
use
>the usual beer cautions.

First, there is a difference (if only semantically) between breathing,
which refers to the exposure of wine to air immediately before
consuming, and aging, which is done either in bulk or in bottle, but
before uncorking.

As to breathing: There is no general agreement on why (or even
whether!) breathing is beneficial. Some feel it releases the aroma of
the wine, or helps dispel volatile compounds (such as SO₂) which may
mask aroma and flavor. Others feel it is desirable to oxidize a
certain portion of the phenols (e.g., tannins), especially if the wine
is big and young.

As far as aging goes, oxidation is definitely involved. However, slow,
controlled oxidation is what we want, as it tends to oxidize metallic
ions, phenols, etc., improving the wine. It is generally believed that
too rapid oxidation (as may result from splashing, etc) will tend to
oxidize other components instead, such as alcohols, leading to
undesirable byproducts such as aldehydes, etc.

Remember that as a home winemaker, your wine is already getting much
more oxygen than commercial wines, due to the much higher surface
area/volume ratio present in small scale operations. IMHO, your wine
will be oxidized enough just by such things as airspace in your carboy
or bottle, normal exposure to air during gentle racking, etc. Any
intentional splashing may be overkill.

Disclaimer: Little is really known (or agreed upon) about the mechanism
of oxidation, aging, breathing, etc. In the end, your own experience
and evaluations will have to guide you.

Hope this helps,

Kelly Jones <k-jones@ee.utah.edu>

Subject: hard cider brewing

Dear Homebrewers:

Having once lived in the south of England and fell in love with English
cider (hard cider), I want to find out if anyone else out there has tried to
brew their own. I'm looking for good recipes for "dry" English-style cider, not
the sweet overly-carbonated [I think] stuff like the Vermont Woodchuck cider.
So, if anyone is interested in the idea, I can offer a few suggestions, but so
far I have stuck to brewing from a Boots Country Cider kit -- which is very
good, by the way, but only available in England.
Please send any info to me at BCULLIN@auvm.american.edu. Thanks. Bridget

I've seen several posts re; dry-hopping. I always get krauesen in the
2ndary
when dry-hopping and have come to accept it as normal. I've also taken
to
using hop plugs. They provide the advantage of pellets in terms of
convenience
and of whole hops in that I seem to get better aroma from them (as I seem
to
with whole hops) with none of that ubiquitous green sludge clogging the
carboy
neck. Only problem is, they're slightly too large to fit thru the neck
so I
end up cutting them in half with a steak knife. I put them in a boiled
hop
bag with marbles. This usually prevents it from rising to the top and
clogging
things up.

On another topic... keg-conditioning, I always keg-condition my beer,
and by
trial and error, have found that 1/2 the normal priming sugar recommended
for
bottling works best.

above, in
>the northern hemisphere of our spaceship earth).

OK, I haven't tried this but, I assume that when you start swirling the
water
in the carboy, that the carboy is already inverted (and over the sink/
lawn).

If you get up a good swirl and then try to invert the carboy, you would
really
goof up your swirl when the carboy gets horizontal. Plus the rotational
inertia of 3+ gallons of water spinning fast enough to hug the sides
would be
impressive when you tried to flip it around. I think it just needed to be
said.

Subject: **Bottle Sources**

Dan deRegnier asked for sources for bottles, which has been a common request.

The usual source is from beer distributors. I've gotten cases of returnable beer bottles (longnecks) for little more than the cost of the deposit (and an occasional promise to bring them a sample of the resulting beer). That kept me in beer bottles for several years, but I was still having problems finding wine or champagne bottles.

For the last few years, though, I've done my bottle shopping at the local recycling center. I don't know if you have any in your area, but there's a recycling center near me (near the University of Maryland, for anyone local) that accepts aluminum, paper, some plastics, tin cans, and (the most important for me) glass, separated into clear, green and brown 55 gallon drums.

While everyone else was depositing their stuff, I'd be withdrawing. You want to talk about some strange looks. I'm one of the few people who leave with more stuff than I brought. I have to weed through a lot of junk, but there are some fascinating bottles there.

It's the best recycling I can think of.

Subject: Chiller Study?

In HBD #1115, Tom Leith has a *great idea* for collecting data for an empirical chiller design study. Does anyone have the time and stats pack to do the regression analysis? I know the theory, but don't have much practical experience or time, since my job is being shut down in June due to budget cuts.... [Our motto: "Leading the Way in Deficit Reduction."]

Anyway, Thanks to Mike Hall, [hi Mike] the necessary parameters are:

tubing length, ID & OD, flow rate (may I suggest seconds needed to fill a 5 gal. carboy), water in/out temps (actually in temp would be sufficient, but will increase the number of data points needed)

,
final temp of wort and time to reach that temp, wort stirred or not (Y/N).

Additional temp readings at various times of water out and wort will speed the process and reduce the number of data sets needed.

All the other things are more or less equal for all of us: wort SG doesn't alter specific heats much, water pressure is difficult to measure and flow rate is really what counts. Copper tubing is pretty standard in terms of wall thickness and conductivity. A yes/no datapoint should be sufficient on stirring, since it will be hard to standardize measuring stir rates. I heartily recommend stirring anyway, since wort is a very poor conductor of heat and the delta_t around the chiller doesn't generate very strong convection.

There's a Nobel prize (or at least a lot of HBD fame and gratitude) here for someone who wants to do the work. It will probably take a month or more to get an adequate number of data sets....

Free Beer in Portland this Summer,
Paul.

Subject: Re: why blowoff? dryhopping

>Gerald asks, why use the blowoff method?

>It's merits have been argued in the HBD, but I believe it makes the beer taste better, so I continue to use it. Papazian says that the kraeusen contains fusel oils (I've seen fusel alcohols elsewhere) which some say contribute to hangovers. The most graphic proof I have for using the blowoff method is to challenge anyone to drink a glass of blowoff. YUK! Just sniffing it is enough to guarantee my continued support of this procedure.

>The arguments against using the blowoff method (just to be fair) are that you lose beer and that you lose some of the bittering you just but in with the hops.

The above arguments seem to be based on only two possibilities:

1. Blow-off
2. Do Nothing

Based on this, it would seem that blow-off is the preferred method.

The third possibility is to ferment in an "open" container and skim the bitter crud floating among the foam.

I put "open" in quotes because by this, homebrewers mean a large container with an opening large enough to get in to skim and a lid to keep out contaminants while fermenting.

This usually is the "standard" 7 gal plastic fermenter universally available in retail shops. In my case, I use my 10 gal ss mash kettle for a fermenter.

So, once we agree (ha ha) on the need to get rid of the crud, the discussion becomes... skimming vs. blowoff.

As Al mentioned, little or no beer is lost by skimming. I wait till the foam is just about gone and only skim the brown crud that floats because that is what is bitter. The foam is just wort puffed up with CO2 and it turns back into wort when the fermentation subsides.

On the negative side is the risk of contamination every time the fermenter is opened to skim but reasonable precautions can reduce this to the noise level.

I don't think anyone will argue about the ease of cleaning an open fermenter vs. a carboy and associated tubing.

.....

>If you use pellets, you can put a copper scrubbing pad over the end of the siphon hose followed by a mesh bag (this idea was originally introduced by Al Taylor (I think it was Taylor...) and then independently by Kinney Baughman).

First of all, whatever happened to Kinney? I still see his ads but he has not posted here for months. I am sure it is just a coincidence but it seems that he vanished about the time Jay Hirsh started his censored, politically cleansed, alternative forum.

Well, anyway the pot scrubber is a nifty idea but in a recent experiment with dry hopping, I found a new use for the easy masher. It just so happens (ha ha) that the ID of the strainer tube is 3/8" and fits snugly over the end of the "standard" siphon tube. You can slide it up or down to expose as much or as little of the strainer as you like and keep it whatever distance off the bottom you wish.

BTW, the experiment was interesting in that I prefer the normally hopped beer to the dry hopped but the gang at CBS has exactly the opposite view. Guess I will abandon all plans to become the World's Greatest Beer Judge. Not liking hops could be considered a restrictive bias.

.....

Someone recently posted an article on diluting Michelob Dark with various amounts of water to make color calibrators. I know have the beer and can't find the article.

Subject: Hop Alpha Acid rating

A fellow brewer and I were talking about ingredients recently and made the following observation:
The European hops we have been getting pellets and plugs have been steadily declining in Alpha Acid rating each year. My current Saaz pellets are 2.1%
What is the cause of this. Is it due to economics, fixed supply of hops going into an expanding market and homebrewers getting what mega brewers do not purchase. Or is it that that the hops actually are becoming less acidic.
Or are have the measurement methods changed. Is it cyclic or seasonal. Reviewing the original Papazian CJHB and its list of hops and alpha acid ratings what I am getting now are almost 50% less than listed then.

>malt (1/2 lb) biscuit malt (1/2 lb) and Alexander's pale ale (6? lbs.).
The

DeWolf-Cosyns Biscuit (if that's what you used), although it is a roasted
malt (like very pale chocolate malt) still has LOTS of starch in it and
should be mashed. Given the pale-ness of your beer (judging from your
ingredients), I suspect that you'll have a starch haze.

>problem: the beer sat fermented in the primary until the fermentation
was

The
>gas escaping from the lock doesn't smell like the usual gas so I am
suspicious.
>Does it sound like I have a contaminant yeast. If so is there anything
I
>can do?

I suspect that you have roused the yeast which may have indeed caused a
little bit more fermentation or perhaps simply provided nucleation sites
for dissolved CO2 to form bubbles and come out of solution. A day is
much
too short a time for a wild yeast or bacteria to begin releasing any gas.

Subject: Are bottles, just bottles? PLUS: Question for Charlie Papazian

Dan writes:

>Next, what is the best source for bottles? Are bottles bottles, or
>are some better than others? Should I stay away from bottles all
>together?

The best bottles, in my opinion, are, what we call here, "bar bottles." They are the thick, brown longnecks that require a deposit and are often so scratched up you can't see through them. You can really mishandle these bottles and still not break them. On the down-side, they do tend to have chipped-up lips (which can result in a bad seal) and are pretty ugly. I've heard that they are as scarce as hen's teeth in the West. Around here, several small, old Wisconsin breweries, such as Huber, use them as well as AB, Miller and Heileman's. Go find a bar that uses them or a big liquor store that stocks beer in them -- you can buy them for the deposit and you get a nice waxed cardboard case free!

The reason I say these bottles are the best is because they are competition-ready... you can use them for competitions. Besides having no raised lettering, I would be willing to bet that of all the broken bottles that arrive at competitions, less than 1% are "bar bottles" just because they are so durable.

My two other favorite bottles are much harder to get: Orval and the *old* Whitbread (and Mackeson's) bottles. Alas, they have raised lettering so are not usable for AHA-sanctioned competitions. They are really thick, brown glass and usually are not re-used by the breweries so they are in much better shape than "bar bottles."

The general rule is the thicker the glass and the darker brown they are, the better the bottle. Also, if you have your choice, you might as well get bottles that are usable for competitions. I need to make sure that I have enough competition bottles of each batch. It would be a shame to have best beer ever just at its peak, right in time for the Nationals and then find out you've only got Bass, Youngs, Fullers and Orval bottles left. Oh yeah... generally, only (approximately) 12 ounce bottles are acceptable for competitions, so don't bottle the whole batch in Weiss, Xingu and other jumbo bottles if you plan to enter some competitions. Actually, if you only want comments on your beer, any bottle will do -- it will be judged, but will probably be disqualified if it doesn't meet the bottle requirements.

Now, I have a question for Charlie: "What about the bottles that have raised glass codes or "NO DEPOSIT" on the bottom edge of the bottle, like McEwan's Scotch Ale or Samuel(tm) Adams(tm) Boston(tm) Lager(tm)?" Last year, at the 1st round judging, we were told to accept such bottles and disqualify only bottles with raised brand names such as "Bass," "FULLERS" and "ORVAL." I complied, but feared that the 2nd-round Nationals may be more demanding on bottle requirements. What's the official word?

Subject: Re: Rehydrating dry yeast?

Rich writes:

>As a relatively new brewer, this is the first I've heard of
>rehydrating dry yeast before pitching. For the few batches that I've
>made, I pitched the dry yeast directly into the primary, with no
>noticeable bad effects (i.e., it fermented just fine, and the beer
>tasted the way it was supposed to taste).

You could have excellent sanitation and study yeast or just good luck.

>Is there any advantage to rehydrating the dry yeast? Is there any
>disadvantage to tossing the dry stuff directly into the primary?

From Paul Farnsworth's article in the Yeast Special Issue of Zymurgy:
"The latest data from Intek, an Australian dried-yeast producer who is just entering the U.S. market, are as follows: Rehydrate the dried yeast in one-half cup of water. Clean water between 95 degrees F and 104 degrees F (35 and 40 degrees C) should be used. City water supplies containing high concentrations of chlorine will inactivate dried yeast during rehydration. Chlorine can be removed [and any live bacteria killed - Al] by boiling. Cold water will significantly decrease the viability of dried yeast during rehydration. It is advisable to not rehydrate yeast in wort because compounds extracted from hops are antiseptic and can decrease yeast viability while the yeast is being rehydrated."

Also, the Lallemand Newsletter has very similar recommendations (alas, I don't have it here to quote), but mention that the osmotic pressure difference rehydrating in wort can cause the yeast to produce off-flavors when it later switches to fermentation.

I have a personal experience with a two three-quarter-gallon test batches using Lallemand Nottingham yeast. The 1048 wort was cooled to 80F, aerated and the yeast was pitched. In batch 1, the dry yeast was simply sprinkled on top of the wort. In batch 2, the dry yeast was rehydrated in 104F water for 15 minutes and then pitched. Both batches were kept in a 65F room. Batch 2 was actively fermenting in about 8 hours, whereas Batch 1 took over 72 hours to begin fermentation. Fermentation in Batch 2 appeared normal and healthy and was complete in about 5 days, whereas the fermentation of Batch 1 was sluggish and took much longer.

Time and other projects prevented me from completing this experiment, i. e. taking FG readings and tasting (in fact Batch 1 is still sitting there in my fermentation room between pseudo-Kriek#2 and pseudo-Gueuze#1), but the importance of rehydration was clearly shown.

Al.

gak
Richard Stueven, Castro Valley CA

Item 12.

Which Way Will my Bathtub Drain? updated 11-May-1192 by SIC
----- original by Matthew R. Feinsein

Question: Does my bathtub drain differently depending on whether I live in the northern or southern hemisphere?

Answer: No. There is a real effect, but it is far too small to be relevant when you pull the plug in your bathtub.

Because the earth rotates, a fluid that flows along the earth's surface feels a "Coriolis" acceleration perpendicular to its velocity. In the northern hemisphere high pressure storm systems spin clockwise. In the southern hemisphere, they spin counterclockwise because the direction of the Coriolis acceleration is reversed. This effect leads to the speculation that the bathtub vortex that you see when you pull the plug from the drain spins one way in the north and the other way in the south.

But this acceleration is VERY weak for bathtub-scale fluid motions. The order of magnitude of the Coriolis acceleration can be estimated from size of the "Rossby number". Coriolis accelerations are significant when the Rossby number is SMALL.

So, suppose we want a Rossby number of 0.1 and a bathtub-vortex length scale of 0.1 meter. Since the earth's rotation rate is about 10^{-4} /second, the fluid velocity should be less than or equal to $2 \cdot 10^{-6}$ meters/second. This is a very small velocity. How small is it? Well, we can take the analysis a step further and calculate another, more famous dimensionless parameter, the Reynolds number.

The Reynolds number is $= L \cdot U \cdot \text{density} / \text{viscosity}$

Assuming that physicists bathe in hot water the viscosity will be about 0.005 poise and the density will be about 1.0, so the Reynolds Number is about $4 \cdot 10^{-2}$.

Now, life at low Reynolds numbers is different from life at high Reynolds numbers. In particular, at low Reynolds numbers, fluid physics is dominated by friction and diffusion, rather than by inertia: the time it would take for a particle of fluid to move a significant distance due to an acceleration is greater than the time it takes for the particle to break up due to diffusion.

Therefore the effect of the Coriolis acceleration on your bathtub vortex is SMALL. To detect its effect on your bathtub, you would have to get out and wait until the motion in the water is far less than one

rotation per day. This would require removing thermal currents, vibration, and any other sources of noise. Under such conditions, never occurring in the typical home, you WOULD see an effect. To see what trouble it takes to actually see the effect, see the reference below. Experiments have been done in both the northern and southern hemispheres to verify that under carefully controlled conditions, bathtubs drain in opposite directions due to the Coriolis acceleration from the Earth's rotation.

The same effect has been accused of responsibility for the direction water circulates when you flush a toilet. This is surely nonsense. In this case, the water rotates in the direction which the pipe points which carries the water from the tank to the bowl.

From: Scott Lord (CompuCom) <v-ccsl@microsoft.com>
Subject: RIMS AND Immersion Heater Length?

I just picked up a two stainless steel vessel double wall insulate with copper coil that runs between the two walls. It was made for A&W rootbeer . Freon was pumped in the coil to keep it cold. It came with four pumps two for pumping the rootbeer and two as a Freon compressor . It holds 48 gals. and has a lid and a bottom drain with a stainless steel screen that rises 1 inch off the bottom and a stainless steel valve. I am going to use one for a fermentor and the other as a hot water vessel used for sparging and rims. Now I want to set up a rims system and to heat the mash I will pump wort out of the bottom of the mash tun through some copper coils that is placed in side the hot water vessel to boost the mash temp. Now I will use a pump to transfer hot water from my boiler kettle to the hot water vessel. The pump has a max flow rate of 5 gals. a minute but I have built a pump speed control. I will keep the temp. of the hot water vessel at 80 degree C. . My mash tun is a converted 15 gal. keg that has 6 inches of that spray in foam around it and my wort boiler is a 15 gal. converted keg also with a hop back.

1.) So what size and what length should I use to get a 1 degree C. rise in temp. ?

2.) What should I use to seal the lid of the fermentor down to keep the air out ?

Yes and No. Yes: the coriolis force does exist and is in the direction
you
indicate. No: the size of this force is negligible compared to the
other
forces acting during the process, e.g. the forces you exert by swirling
the
carboy, and the viscous and frictional forces of the water and carboy. I
have not done a calculation, but I would bet the coriolis force is even
smaller than the surface tension of the water.

My \$0.02: whether you get a better vortex CW or CCW will most strongly
depend on whether you are right handed or left handed.

Also (I hate to quibble, but...) it is the CENTRIFUGAL acceleration
(not coriolis) that forces the liquid to the outside when it is rotating.

No flame intended. Just wanted to put my degree to *some* use :-)

With all the frothing that the hop pellets cause in the secondary I would think that all the air would have been purged out and the beer was sitting under a layer of CO2. This being the case, what's wrong with causing some splashing as long as the airlock is left on?

Subject: Lab Equip. Resources

Does anyone know of reasonably priced mail order resources for lab equipment and supplies? Specifically looking for the full range of slant tubes, petri dishes, erlenmeyer flasks, stoppers, agar, and the like for yeast culturing. I know that a couple of brew supply stores have put together "kits" but the reviews suggest that additional material would probably be required and I'd like to compare buying my supplies directly from a lab supplier vs. the kit price as well as having access to other material.

If you don't know of any mail order suppliers, I live in Oakland and work in SF, so Bay Area stores would be appreciated as well. Reply by e-mail please unless you think the community would like to know about the mail order places.

And, since I seem to be in the information gathering mood, what about Bay Area liquor (or other) stores that have a good range of Belgian beer products that you would trust to be well handled. I recently bought a bottle of Chimay that was a couple of years old (didn't know it until I pulled the cork).

BTW, Norm Pyle posts of a homemade roller mill:
>...sort of a scaled down version of
>the one presented by RW and (??) in the latest Zymurgy gadgets special issue.

(??) is Wayne Greenway and its a beautiful mill, my extract rating soared after switching from buying precrushed to using this mill. I'll miss having it in the neighborhood when he moves.

> It's merits have been argued in the HBD, but I believe it makes the
> beer taste better, so I continue to use it. Papazian says that
> the kraeusen contains fusel oils (I've seen fusel alcohols elsewhere)
> which some say contribute to hangovers.

"Fusel oil" is the oily byproduct of ethanol distillation consisting of mainly long-chain alcohols: propanols, butanols, etc. The terms "fusels," "fusel oils" and "fusel alcohols" are synonymous so far as I know. I don't know whether the term applies to aromatic as well as aliphatic alcohols; since I don't hear phenols grouped in with fusels, I assume that it doesn't.

Fusel alcohols are an important flavor component. The shorter ones have medicinal/disinfectant flavors (e.g. isopropyl). The longer ones are pungent and have a kind of fruity-citrusy-medicinal character that is unmistakable. I've had quite a few homebrewed pale ales where the octanol (orange-sweet-medicinal) was quite prominent.

In fact, the last Liberty Ale I drank smelled and tasted strongly of octanol or something similar. I was a bit surprised by it and intend to try another bottle from a separate source, since I consider it a defect. The last bottle of Liberty Ale I had was a few years and quite a bit of palate training back, so I don't remember what it used to be like.

A professional brewer who was drinking with me (at the Brickskellar) at the time said that it seemed "old." I'm not so sure; I've never seen beer change in flavor this way in a bottle. (Anyone care to comment on the Liberty Ale profile?)

Some people claim fusels contribute a "clinging bitterness" to beer. Bitter though they may be, they are so pungent that the flavor of the beer will be negatively affected long before the finish, at least in my opinion.

As far as hangovers go, long chain alcohols may well be a factor. They become increasingly toxic and intoxicating as the chain of carbons grows, to a point, anyway. Many many other fermentation byproducts are also mildly toxic. I would bet that the aldehydes, ketones and esters contribute unpleasant metabolic byproducts.

Finally, fusel alcohols are quite soluble in alcohol, and can not be removed by blowoff. The unpleasant substances in blowoff residue are tannins, unisomerized hop resins, etc. They are largely insoluble, even in a weak alcohol solution, and are not going to be a primary source of bitterness or astringency in your beer once it has cleared.

Subject: malt extract for priming; exploding bottles

I'm a beginning extract brewer, and would appreciate any comments on a couple of questions about bottle conditioning...

(1) On my first (and so far, only) batch of beer (a brown ale), I used 1.25 cups of malt extract for priming instead of 0.75 cups of corn sugar. Papazian mentions parenthetically that this can be done, and I thought, why add sugar to my beer? I was happy with the results... does anyone know why corn sugar seems to be the standard method?

(2) I had a bottle explode while I was out of the house (4 weeks after bottling). What would be a common reason for this? I wonder if I left too little air-space, or whether it might have to do with using malt extract for priming.

kindawatery and
>again, missing a lot of what the hops were there for to begin with.

If I read your note correctly, you've been using hopped extract kits and
boiling away. A long boil will indeed destroy any hop aroma that was in
the
beer. You can still use hopped extract kits, but make sure you add some
flavor
hops in the last 20 min of the boil and/or aroma hops in the last 5 min.
Keep
in mind that there are styles that do not typically have appreciable hop
aroma
or flavor--like stouts and most german lagers.

If you want to add bitterness, see if you can find pre-isomerized hop
extract.
This is essentially what you get when you boil hops for bitterness.
Keeping in
mind that your beer probably already has some bitterness, follow the
directions for adding LESS than the full amount. This stuff is
concentrated
and a little goes a long way. Remember, you can always add more. It will
also
add some hop flavor. You could add it to the secondary or to a malt
extract
primer at bottling time.

If you want some hop flavor or aroma, there are two things you can do.
(1) Dry
hop with pellets if you have no head space in your secondary or use leaf
if
you have room. (2) Add hops when you bottle using the "coffee-pot
method."This
was discussed on HBD a couple months ago.

>From what I understand, `Breathing' of wine *is* to let it oxidize.

In wines, tannins are very important to the the aging of wine, but do
produce a somewhat undesirable taste. I am pretty sure that the
`Breathing' period is so the oxygen can react with the tanins and sort
of `surround' them to mellow their taste.

I do agree however that oxidation of whine before it gets to the bottle
and ages is a bad thing...

I hope I'm not way off on this...

Subject: Re: vortex drain strength, and coriolis acceleration, wort chillers.

Karl writes:

- - - -

I have found that the best vortex drains are formed when you swirl the bottle or carboy in a counterclockwise direction (when viewed from above, in the northern hemisphere of our spaceship earth). The reason is the coriolis acceleration vector caused by the counterclockwise rotation of the earth. When you rotate the bottle in the same direction as the earth rotation the coriolis acceleration vectors constructively add, forming a greater force on the liquid molecules.

- - - -

A couple of terms spring to mind here...."unmeasurable", "negligable", and "insignificant" spring to mind.

The amount of force you are imparting into the molecules is, I would guess, on the order of thousands or millions of times stronger than that of the coriolis effect. Yes it exists, yes it is measurable, but your swirling a carboy full of water gives you a heck of a lot more force than the earth's rotation, neutrino bombardment, specific gravity of your tap water, or the color of the paint in your kitchen.

- - - - -

About wort chiller length (oh no, not more!).....

I've got a 50 foot, 3'8" chiller I made, by wrapping it around a 5-gallon bucket, then laced up the sides in 3 places with copper wiring wire. It chills the wort to pitching temperature in a rather rapid time (guessing 15 minutes, I can look at my records to tell you for sure). The water comes out boiling (steam, actually) for a few seconds, then comes out progressively cooler. Stirring with a sanitized spoon speeds up the heat transfer, and the lacing keeps the coils far apart enough so that the wort can circulate pretty freely.

I, personally, can't see any benefit to a shorter length, at all. You want to give the water as much opportunity to absorb the heat of the wort. I would think the following are involved:

>Coil surface area (not mass, as someone else mentioned???)
>flow rate of water passing through coil
>temperature differential between wort & water.

So, let's try this: We bring our cold water into the hot wort. Should we bring it in the top, or bottom? The wort is probably warmer at the top, so we should put the cold water in at the top so the temperature differential is highest, or maybe not. Any ideas?

Now, how about flow rate? Slower flow would give the water more time to absorb the heat, but I think the extra length does the same. I dunno, I'm asking. I suppose you could adjust the flow from the faucet for maximum outlet temp in your chilling water, which would indicate maximum heat transfer. It will change as the temperature delta changes, however, I THINK.

What about tubing diameter? Surface area goes up, flow rate goes up, but restriction, and therefore time in the chiller, goes down. Where is the optimal point, extrapolated across all temperature differentials?

There are probably a thousand more variables. I like the idea that someone proposed here, to do an empirical study of what we are using, and decide which coil construction works best. I propose we look at the following variables:

- 1> water going in at top or bottom of chiller coil
- 1A> Coil rotation direction (for the hell of it, can't think of an effect but who knows...maybe a coriolis thing after all!)
- 2> diameter of tubing & length of tubing
- 3> flow rate used (how long to fill a quart bottle from the outlet of the chiller coil?)
- 4> temperature of your tap water (just for reference, not really something you can change all that easily)
- 5> amount of time to chill the wort to, say, 75 degrees F.

Can't think of anything else to measure offhand, any ideas? Someone else mentioned they'd tabulate results, I'd be willing to do so also or help. Of course, it would mean that we'd all have to brew a batch of homebrew to tabulate the results....sorry for the inconvenience ;-)))

> have to boil hundreds of pounds of grain. Anybody taken a tour?

Umm, yeah, I have taken a tour. Most of the info was published in a
Zymurgy article about 3 years ago. (Sorry I can't tell you the issue
right off hand, my collection is at home.)

But to answer your question, a tour of nearly any of the German
breweries would do, since they almost all practice decoction mashing.
The usual arrangement is a 4 vessel brewhouse: a mash tun
(maischebottich), mash cooker (maischepfanne), lauter tun
(lauterbottich), and a kettle (wuerzefanne). The process involves
doughing in in the mash tun, and then pumping from a bottom outlet to
the mash cooker the decoct. That's how a "thick mash" is obtained for
boiling. This decoct is eventually returned to the "rest mash" to
raise the whole to the next temperature plateau. When the decoction
mash is finish, this outlet is used again to pump the entire mash to
the lauter tun. During lautering, the bed will compact, and lautering
is stopped while an arrangement of "mash knives" is run around the tun
to loosen the bed. When lautering is complete, the knives can be
turned sideways to form a moving wall, and this pushes the spent grist
into an outlet that leads to a holding tank or a farmers truck. A
final wash is required, of course, to get the last recalcitrant husks to
leave.

The reason for a 4 vessel system, rather than a two vessel system
(kettle and lauter tun) is that the commercial breweries can get a
significant overlap of successive batches on the equipment. This is
important if your mash and boil process takes 11 hours to complete and
you want to make more than a million barrels of beer each year, as it
does at Pilsner Urquell.

From: Ulick Stafford <ulick@bernini.helios.nd.edu>
Subject: cooling

Tim Anderson posted an adjustment he made to his chiller to improve cooling. I have been considering a simple change - reversing the flow. At present cold water enters at the bottom of the coil and exits at the top. That combined with water's tendency to stratify in layers causes the wort to be still, stratified and hot near the top. A reverse in flow would chill the top stuff first and it would then sink setting up convection currents that may aid coagulation and heat transfer. The reason I haven't until now is worry about air pockets being trapped in the coil, but given high flow rates that is probably a foolish concern, and an actual desire not disturb the hop pellets so much so I could rack off them quicker. However I usually have to rack wort twice anyway before pitching so this is of less concern. Comments?

Also related peripherally to cooling, Al's post interested me. I have roused yeast since the first batch I did when I was a whelp, thought everybody did it, and thought it was essential for beers brewed with bottom fermenting yeast (not Al's beer of course). But the temperature thread intrigued me. 72 or 68 is much too warm for a house I have to heat, but then 60 is what I am used to. In Ireland I usually had to put the ferments in a warm place. But 60 is too cool for my SO's guinea pigs and bird. So their room is heated to 68-70. This means that for nice temperature steps I can start at 68 in the rodent room, rack to secondary and move to the kitchen (60) and then put it in the basement 50-55 to clarify prior to bottling. If only lager temperature steps were so easy.

Another ale comment is that I have gone back to my plastic bucket for ale primaries. I never used to skim, but now I have decided after reading Warner that I should collect yeast from the top. I did so on my last ale. The yeast is quite the foulest stuff I have ever tasted due to the hop resins and other lovely scum. It doesn't seem to be contaminated in that I can't taste anything off but that could be due to masking by the hop resin. I have decided that I should rinse and, to be sure, acid wash the yeast prior to reuse. Comments?

Subject: Wyeast reuse/stretching

Howdy all,

Well, after all this talk about dry yeast contamination (notwithstanding the recent posts concerning the improvements at Whitbred) I have finally decided to take the liquid yeast plunge.

!*SPLASH*!

Ok, so I shelled out \$4 for Wyeast Belgian Ale yeast. FOUR BUCKS! For microscopic fungus! It boggles the mind. In HBD #1103, Philip J Difalco <sxupjd@fnma.COM> reposted an article by Rick Cavasin on stretching Wyeast by making a 1/2 gallon starter, fermenting to completion, bottling the results in 5-6 bottles, and using the bottles to make starters for pitching into your wort. In the post, Philip asks for comments from the yeast-gurus out there.

I have not seen any replies posted, so I thought I would ask again; with a slightly different slant (no pun intended).

I have followed Rick's instructions and I now have a 1/2 gallon starter fermenting away. This should yield ~6 bottles of yeast. However, for my next brew, Belgian may not be appropriate. So I'll go out, get another packet of Wyeast (say, London Ale), and do the same thing for it. Then, I'll have 5 bottles of Belgian and 5 bottles of London in the fridge.

So now I forsee obtaining my own collection of Wyeast, all bottled in 12 oz. beer bottles and stored in the fridge. I might only have to buy yeast once a year (once my collection is established).

This seems like a very cheap, very easy form of yeast management.

Is it?
Are there draw backs (like problems with autolysis, or the yeast just dying)?
Am I wasting my time?

Rick mentions he has had bottled yeast last 6 months. Will they last longer?
Are those 6 mo. old yeast just as good as those from a new Wyeast packet?

Please, please, please, send me guidance.

Lost in the terrifying world of expensive microscopic organisms,

Troy

Mark, In my opinion most hopped extracts are way underhopped. You didn't
give us a recipe to work with but I suspect that if you are relying on
the

extract to give you your hops, that could be your problem.
I would recommend using unhopped extract and adding your own hops.
There are many advantages: it is more fun, you become more familiar with
recipe formulation (after all, you may want to brew all grain some day),
and your flavor will drastically improve. You also have much more
freedom
to brew what you want.

If you use your own hops, remember - you cannot boil away bitterness!
A vigorous 1-hour boil is just what you need to extract bitterness from
hops.

You will lose some of the more volatile flavor components but thats ok
because you can add hops near the end of the boil to give you flavor and
aroma. The amount to add and when to add it really depends on the style
you're after. Find a homebrewer with a beer you like and get the recipe!
Then stick to it (just once anyway).

As far as the batch you have in the carboy, I know that hop extracts
are available. Some are for bitterness, some for aroma. I've never used
them. Ask your supplier and make sure you get the right kind (or both?)

Good luck!

OK, I'll give this one a try. I am not sure I am right, so if any of you
out there know better, please feel free to gently correct me.

Hop essence and hop bittering are two very different things.
You are certainly right that boiling for any significant period will
almost
completely eliminate hop aroma. However, my understanding is (and this is
the
part I am not really sure about) that the alpha and beta acids which are
responsible for hop bitterness are not really all that volatile. So they
should not easily boil away.

Also, as I understand it, hopped extracts don't really have that much hop aroma to begin with.

If I understand you correctly, you did not add any hops to the boil, and just relied on the hopped extract.

So my suggestions depend on what you want:

1. If you want more bitterness, try boiling some hop pellets for 30 minutes in a ~pint of watter, and add this to your secondary. [I have never tried this.

It seems like it should work. Any one know any better?]

2. If you want more hop aroma, try dry hopping in the secondary.

3. If you want both, try 1 AND 2.

In the future, add your own hops. It's as easy as falling down, and it opens up a whole new dimension to your brews.

Troy

FROM: Dennis B. Lewis <InterNet:dblewis@jscprofs.nasa.gov>
SUBJECT: Bucket Sealer

I recently acquired a couple of 20 liter plastic buckets. The bucket and the lid are both made from HDPE (which is food grade). The bucket is white and the lid is deep red. They used to contain laundry detergent. So far I've only used the buckets to soak-sterilize bottles. I would like to use them to ferment because if I put 19 liters (5 gal) in them the kraeusen will push the goop to the top of the bucket and stick it to the lid (Budweiser does this with their fermenters; it eliminates the need for a blow off hose, although I'll have to change the airlock a couple times.) I have a couple of questions regarding these buckets:

1.) Is there any hazard associated with detergent that may have seeped into the bucket walls? They have been cleaned, soaked in bleach water and in hot tap water (160F). The buckets no longer have any perfumy smell whatsoever.

2.) The lid does not seal well. Is there any food grade cheap sealant that I could use to caulk up the lid? How about some sort of gasket? Regular lids from other buckets don't fit.

It's true that boiling boils-away hop aromatics, thereby removing hop bouquet and flavor, but boiling does not boil-away hop bitterness. What I think your problem may be is that you added some DME to an already underhopped kit but did not add some hops to make up for the increased malt. The Extract Special Issue of Zymurgy has a useful, albeit somewhat outdated, table of commercial malt extracts which gives, among other things, Homebrew Bittering Units (HBU) per can and HBU per pound for the hopped extracts. I've switched over to IBUs long ago since they are much more universal, especially given that not everyone does full boils (using IBUs and Jackie Rager's formulas from the Hops Special Issue of Zymurgy, you can compensate for partial boils and get consistent bittering).

>only way to brew.

It's okay to use hopped extracts, as long as you use quality brands and know how many IBUs have been added (in converting from HBUs to IBUs, 25% utilization is often what's used). To save this batch, what you can do is to buy some isomerized hop oil and add that at bottling time. Another alternative, is to make a hop "tea" by boiling some hops in water for an hour (and while

you're at it, you can add flavor hops 15 minutes before the end of the boil and finishing hops 5 minutes before the end of the boil), strain out the hops and add this "tea" to your batch at bottling. Try to minimize splashing so you don't oxidize the hop oils. Get the Hops Special Issue of Zymurgy to figure out how much hops to boil up in the "tea" for whatever IBU level you want your "tea" to have -- use 5 gallons for volume, since that's what it's going into, even though it's not what your "tea" boil volume was.

Greg Noonan's book, *Brewing Lager Beer*, is probably the best modern discussion of the decoction mashing method that I know of. Greg also has an article in the All-grain Special Issue of *Zymurgy*, which has a condensed version of the decoction process -- I don't recall if it was enough info to actually do a mash.

> Regarding the high-pressure side gauge, I'll stick my neck out and say I think it's useless. It won't begin to drop till all the liquid CO2 has run out and has turned to gas. Then it will drop to zero in one or two days. That's not my idea of warning you that it's about to run out!

That confirms my suspicions. I inherited an antique single gage regulator from my father who used CO2 for his airbrush in his art studio. He's long gone and it has a lot of sentimental value but I always wondered what I was missing. When I moved into this house, strangely enough, there was another one in a drawer in the basement just like my father's. I put that on my 2.5 lb cylinder for traveling.

>I plan to weigh my tank the next time it runs out and use it's weight as an approximation for when I should go get it refilled. It should weigh, well... 20# more when full (for a "20#" tank).

I did that for the last two tanks and it leaves little doubt. If you look carefully, you will find the tare (empty) weight of the cylinder stamped on it somewhere. So if you forget to weigh it empty, all is not lost. This is important for those of us who just swap tanks instead of waiting around for refilling.

It is also a good idea just to be able to keep the gas man honest.

The last time I swapped tanks, it seemed a bit light and when I got home it weighed in at 39 lbs. The tank weighs 31 lbs so I got 8 lbs of gas instead of 20. He cheerfully gave me a different one but it was a pain never the less.

The final count on the previous tank was 40, 5 gal kegs carbonated and dispensed along with a lot of miscellaneous squiriting around.

Subject: HOP ALPHA ACID

A Proposed Method for Determining Hop Alpha Acid Content

The following methodology is based on empirical measurement and experiments. It may be seriously flawed but as the end results seem to achieve the goal desired, it is worth further experiments by anyone who cares to replicate the results.

My pH meter arrived late last week and I must confess that I spent most of the time since then playing with it. Although I suspect it will not have much impact on my beer, I bought it mainly to learn whether pH could be used to determine Alpha Acid content of hops.

The instrument I purchased is made by Oakton and is the pH Tester 2. Claimed accuracy and resolution is .1 pH unit. After calibrating the unit with pH 7 and pH 4 buffer solutions, I proceeded to test just about everything in the house. The biggest surprise was to learn that tea, as we drink it, has a pH of 6.9. I always thought that the astringency of tea was a result of tannic acid. I also found that to test tap water accurately takes about 9 minutes to reach a stable value. Boiled tap water reaches stability within a few seconds. I presume it has something to do with dissolved gas.

My hypothesis on hops Alpha Acid was that a high AA hop should produce a tea with a lower pH than a low AA hop under controlled conditions.

To test the hypothesis I proceeded as follows:

Tea #1 3 grs Chinook (AA 12%) in 250 ml water.

Tea #2 3 grs Saaz (AA 2.9%) in 250 ml water.

The teas were brought to a boil for 5 minutes and poured through coffee filters.

The quantity of 3 grs was selected because that is 1/10 the amount of Chinook I normally use to hop a 7 gallon batch and it would make the math easier later on.

After cooling the teas to room temperature, the following pH measurements were obtained:

Tea #1 Chinook pH 6.2

Tea #2 SaazpH 6.6

The delta is .4 pH which I believe works out to a factor of 4 in the real world and nicely matches the delta of the AA in the hops.

Although, measuring at different times sometimes provided different numbers, the spread was always the same and I attributed the problem to lack of understanding of how to use the instrument.

The only significant anomaly was that on the third day, the pH of both teas dropped to 5.7. They had been left uncovered throughout the period but something significant happened overnight of the third day.

In conclusion, if the results are the product of Alpha Acid in the hops then it should be possible to work out formulae to determine the approximate AA of hops or at least determine how much of an unknown hop is required to achieve the same pH of a known hop.

Subject: Boulevard Brewing Co.

While on a recent trip through the mid-west, I picked up some micro brews (I assume) made by the Boulevard Brewing Co. in Kansas City,MO. I carried back some Bully Porter, and some Irish Red ale. Both of these beers seem to have a metallic after-taste, very noticeable in the Irish, less so in the Bully, because of the extra malt/hops flavor. What I am wondering is if any locals, or anybody else who has tried these beers has tasted something similar. Rather than criticizing their beers, I am trying to educate my taste buds. Is this taste from high metal ion concentrations as Miller suggests? Or is this what phenolic tastes like, perhaps from high chlorine content of the water? Or maybe the beer was stale - the label suggested drinking by April, so maybe I was catching the beer at the end of it's preferred life cycle. The two were tasted at room temp (Probably in the mid 60's F). If anybody has any input, I'd love to hear it.

Subject: Dry Hopping

I have seen a lot of converstion about dry hopping lately. I have tried dry hopping a number of times, with limited results. I have tried enough that I do feel qualified to shoot my mouth off a bit. (I have only worked with pellets).

1. Several people have reported "gushing" upon the first addition of pellets. I have reduced and reduced the amount of pellets I add, to try and reduce the amount of gushing. The last amount I tried was one pellet about 1/8" long. The beer still gushed, although not quite as violently. I added the rest of the hops about a day later, with no gushing.

The beer was at about 68F, and virtually done fermenting. Apparently, there are several factors involved:

- A. The slow release of CO2 by the yeast has caused the cool beer to become super-saturated with CO2.
- B. The hops particles are nucleation sites for CO2 release.
- C. The hop oils support head (foam) retention.
- D. The "shock" of the initial CO2 release triggers a much larger release from the super-saturated fluid.

2. I have frequently seen a re-start in fermentation a few days after the addition of the dry-hops. Several others have also reported this effect to me. It is easily observable by charting the "seconds per bubble" count of the airlock. Usually, a nice foamy head rises for a couple of days. Normally, there are no off-flavors associated with this renewed fermentation, but I have detected contamination flavors if the dry hopping was performed when the gravity is too high. I also pitched from a dry hopped batch, and the resulting beer was badly contaminated.

Why? I don't know.

3. I have occasionally tasted a very bitter component after dry hopping. My feeling is that these are hop particles that have not settled out yet. Usually this "rough" flavor disappears in time.

Subject: My Belgian rock collection

I have taken up rock collecting. And not just any rocks either. I collect only the finest. I collect Belgian rocks.

Oh sure. I know what you're thinking. The answer is no. I'm not on drugs. And yes, I still think that rock collecting in general is still up there with bird watching, golfing and other ectomorphic endeavors.

It's all come about innocently enough. I'm an avid user of Belgian malts. On top of that I don't buy it in no stinkin' five-pound bags neither. Only bulk flips my skirt up. If there's no risk of a hernia, why bother?

Mixed in with the malt is a strange collection of unidentified malted objects. Most are easy to figure out. A tangled clump of barley rootlets, an odd twig or a mangled piece of wire. But every now and then I'll find a rock. And while all of the objects warrant inspection, to me the rocks are keepers.

To date my collection numbers four. They all appear to be similar in appearance. All are bluish-grey, flat and layered. It's hard to tell whether they've been malted. I'd like to think that they have as I don't know of anyone who collects malted rocks. At least the authoritative source on the achievements of western civilization, The Guinness World Book of Records, doesn't seem to have a category for it.

I look at the rock and try to imagine it's voyage. I try to picture where the rock came from and how it got mixed in with the malt. Where was the farm located? The malting company? What does the local terrain look like and how close is it to the coast? Considering the region's history, has this rock ever been tread on by a Roman sandal or the track of an armored vehicle? Only the imagination can provide such answers.

When I go under I'll probably donate my collection to the Smithsonian. After all, when you consider what the Hursts, Rockefellers, and Carnegies of the world have donated, a Belgian Malted Rock Collection is far more interesting than a bunch of stupid paintings any old day. At least I think so.

Subject: proposed beer tax increase

I've just seen a memo from the Small Brewers Coalition which contained the following information:

Senator Daniel Inouye (D-Hawaii) has introduced Senate Bill 684, titled "National Health Care Act of 1993", which proposes to raise the excise tax on beer a whopping 450 percent, as follows:

Large brewers: currently \$18.00/barrel, proposed \$81.00/barrel
small brewers: currently \$ 7.00/barrel, proposed \$31.50/barrel

Increases in taxes for distilled spirits and wine are 215 percent and 20-30 percent, respectively.

Apparently, Sen. Inouye has it in his mind that beer is the root of all health problems in the US!

Based on what I've seen of production figures for the last year or two, A-B's taxes alone will go from about \$1.5 billion to \$6.5 billion.

Micro's would have to raise their prices to the point that some may not survive.

If you feel as I do, write or call your senators and representatives and let them know. Taxes are one thing, highway robbery is an entirely different matter.

-- Paul Edwards

PS - If the bill passes, be **real** glad you know how to brew your own.

It may be the only way to afford a beer.

Subject: Fermenting Apple Cider & Filtering Cold Break

The following attachments were included with this message:

TYPE: FILE
NAME: ANDY

Greetings,

I had a friend over last night to help me with a Steam beer I was making. He had with him a gallon bottle of apple juice he had picked up for his son. He decided to experiment with the apple juice by re-hydrating an extra packet of dry yeast I gave him, pitching it into the apple juice bottle, and putting a cork with an airlock on top. This morning I got up and it's bubbling vigorously (I wish my beers fermented that quickly!).

My questions:

1. Does anyone know how this "cider" will turn out?
2. I never measured OG, so does anyone know how much alcohol should be created?
3. It may be too late, but is there anything that can be done now to make this concoction more palatable?

With regard to the beer I made last night, I have a question. After the boil was over, I chilled the wort down to about 70 degrees and strained it into my carboy. I let it sit for about a half hour and watched as the cold break gently settled down to the bottom 1/4 of the carboy. I then poured the carboy's contents through 2 separate funnels with strainers into another carboy. I was attempting to filter out the cold-break. Apparently, it is too fine to be trapped by the normal strainers which come with a brew shop's funnel. Almost all the cold-break passed through both filters into my second carboy. My question is, aside from siphoning off the clear wort from the cold-break sediment, is there any practical way to filter out the cold-break? If a finer filter is the answer, then how fine should it be and where do I procure one? (And yes, I realize that by all this filtering between carboys I am increasing my risk of contaminating my newborn beer!)

Thanks,

Andy A

Subject: more comments on bottles / European system

I also agree that genuine bar bottles are the best for bottling. I've heard horror stories of Sam Adams (tm) bottles breaking during the capping phase after so many uses, although, I personally have not had this problem yet! Has anyone seen this yet?

Bar bottles are noticeably heavier than standard returnable bottles, such as Sad Adams(tm); the glass is much thicker, and hence, more durable.

Another bottle type I like is the 16oz standard european bottle. these are pretty heavy, and, then have 4oz more capacity than the bar bottle types widely used in the states.

When I was in Austria this past fall, we went on a tour of the Zipfer Brewery. It was completely in german, hence, I did not understand much, but I could guide myself through the tour with my nose! At any rate, they've really got their s&t down in Europe. Most of the brew sold in bottles there comes in a standard 16oz bottle (I think it is 16oz?!). So, on the bottle input side of the bottling room at the Zipfer brewery, you'll see returned bottles in standard returnable crates (much like milk crates) from all sorts of breweries. They all use the same standard bottle, they make it easy to return them to just about anyone, and just about any brewery can fill the bottles. Green ones, brown ones, etc. Being an environmentally concious person, I really liked what I saw. The US of A is so caught up in making \$\$\$ as quickly as possible that we'll probably never see anything like that...

Interesting hypothesis but I doubt you've have ACTUALLY testing it (the
coriolis effects on the water that is). I have and I can say that
getting
the water swirling in EITHER a 5 gallon glass carboy or a 12 oz. bottle
will
indeed get the liquid to drain faster. I have been using this trick for
quite
some time but I'm sorry I didn't try to prove it on paper first.

While I will not comment on the actual forces involved (we all really
known
there is not true coriolis 'force') or their magnitudes, the technique
does
indeed work.

Dennis B. Lewis writes:

would be
> impressive when you tried to flip it around. I think it just needed to
be said.

Yes, start dumping the water and then begin to swirl it about. As soon
as
the water starts to clear out of the mouth (and air can be drawn up) the
carboy will quickly drain. You do not need to continue to swirl the
carboy
after the water starts draining quickly.

Believe me the inertia is NOTHING to be concerned about in comparison to
a
gripping a wet, glass carboy containing somewhere between 16 and 32
pounds
of water.

John Adams

From: Kelly Jones <k-jones@ee.utah.edu>
Subject: Re: Chiller Study

I'd love to see someone perform this study, although one could probably get equally valid results by running a simulation, with less time/material expended. However, as I indicated in my last post on this subject, there are two important heat transfer coefficients at work here: one inside the tube, and one outside the tube. It would make little sense to accurately quantify conditions inside the tube in terms of ID, flow rate, etc. and then simply characterize conditions outside the tube as "stirred" or "unstirred". One should include parameters such as chiller diameter, spacing between coils, diameter of pot, height of coil, velocity of stirring, etc., etc. A compounding problem is that the inside convective heat transfer coefficient is highly dependent upon the "scale factor": a new, shiny tube will conduct much better than an old, crusty one... Not a simple problem at all, unfortunately.

PS: gak writes:

>Got this from the sci.physics FAQ...

>Summary: the Coriolis force is real, but irrelevant at the bathtub (or carboy) scale.

(followed by technical explanation of fluid dynamics involved in the coriolis effect)

FROM: Dennis B. Lewis <InterNet:dblewis@jscprofs.nasa.gov>
SUBJECT: Yeast pitching rates

I have a question about how the yeast pitching rates affect the flavor/
quality
of the finished beer. I have been guilty of dumping in a puffed up pack
of
yeast directly into the fermenter. But lately, I've been brewing by
racking
cooled wort onto sediment from the primary of a previous batch. The
results
are like night and day. The resulting explosive fermentation is very
satisfying to watch and commences withing a few hours :-).

Anyway, here's to point: when I pitch the small packet of yeast into the
wort,
it makes copies of itself until it hits the terminal concentration (50 M
cells/ml(?)), THEN it goes into the fermentation cycle. If you pitch
about the
teminal concentration, then there is very little reproduction and all
fermentation. It seems to me that this method would leave a lot of
proteins in
the beer because they weren't used to make other yeast and more alcohol
for
the same reason. Is the taste noticable? Do the extra proteins increase
head
retention/taste? I haven't had enough experience doing this to tell the
difference.

One other point: one common thread I've noticed regarding yeast
culturing is
how many generations the yeast are good for. Since I'm only using one
generation(!?) for a couple batches... (N.B. I remove most of the trub
so I
don't think there is much of a problem with accumulated crud on the
bottom of
the fermenter.)

I may be nuts. If so the phaser me directly and save the bandwidth for
more
important things like Coriolis force physics lessons.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)
Subject: Immersion Chiller Efficiency

There seems to be a confusion in this discussion of IC efficiency between time, water, copper, and dollar efficiency.

To Improve Time Efficiency:

A larger, colder surface will cool the wort faster than a smaller, warmer one. Use as long a chiller as you can manage, and run lots of really cold water through it. The cooler the water exiting the chiller the faster the wort will be cooled. When cool water is exiting it indicates that there is an appreciable temperature differential between the cooling water and the wort for the entire length of the chiller tubing, therefor more heat energy is being extracted from the wort than if the exit water were warm or hot. Simply put: The more cold water you run through the chiller the cooler your wort will get, the faster you do it, the faster it will get cool. Especially if you stir the wort. Use the chiller to stir with.

To Improve Water Efficiency:

This is a whole other question, one best answered by a thermodynamacist, which I'm not, but I'll take a shot at a simple answer anyway. Regulate the flow so that the output of the chiller is at the temperature you want the wort to be. This will take longer. Theoretically, I guess it would take forever because you would always be approaching the target temperature, but the flow would become infinitesimal in an hour or two and you could get on with your brewing. I don't think the length of the chiller matters in this case.

To Improve Copper Efficiency:

Make the chiller very short. It will take a long time to cool the wort by either method but you won't be using much copper to do it.

To Improve Dollar Efficiency:

Borrow someone else's chiller.

The Real Question:

What's important to you?

Carl

Subject: kegging using a beer chiller

I have a question for you keggers out there. I have the opportunity to buy several used Cornelius (sic) kegs and connections for what seems like a reasonable price (\$10/keg with connections). I do not however have an extra fridge and probably won't for the near future. Is it possible to use these kegs by connecting up a beer chiller like the one displayed in the recent Gadgets issue of zymurgy--basically a copper tube running through an ice bucket through which the beer flows? I was wondering, beyond the obvious pain of having to fill the bucket with ice periodically, what are the disadvantages of this system? Any advice would be appreciated.

Your friend and mine,
Bob

> the cold and had not awakened from simply warming the wort. I rocked
> the carboy around-and-around to swirl the yeast up from the bottom.
> Naturally, lots of CO2 started escaping through the blowoff tube. 8
hours
> later, the ferment was going at a good pace, perhaps 1 glub per 30
seconds.
> 24 hours after swirling, the glubs were 2.5 minutes apart -- ready to
bottle!

Are you sure the yeast were really roused into fermenting? I offer the
theory that the 1 glub/min was due purely to escaping CO2 and not
fermentation, so the swirling just released a lot more gas (as evidenced
by
increased bubbling). After this had died down the release rate would
decrease. The lower temperatures that you'd been fermenting at would
allow
more CO2 to dissolve which would explain why it took longer to escape.

I'm convinced I'm right, but feel free to flame away at my ignorance.

Peter

First of all, thanks for the very informative post -- I'd like to sit down with a few Pale Ales and do some palate training together -- how about Portland, say, late July?

I've had very little chemistry, so I can't disagree with you regarding what actually gets blown-off, but I have some beers done in split batches blowoff versus non-blowoff and the difference was stunning. I can't begin to explain it in chemical terms, but there definately was a big difference in bitterness and astringency between the two sub-batches. Perhaps its not the fusel alcohols or the tannins or the unisomerized hop resins, but the difference in flavor was unmistakable.

Over the weekend, I bottled an Imperial Stout which I fermented using the blowoff method. I would like to suggest an additional effect of using the blowoff method (although it seems quite negative and does little to reinforce my continued support of this method) -- loss of head retention. It's not so much that I've noticed a reduction in head retention with the blowoff-method beers, rather that the brown foam that oozed out of the blowoff vessel and onto the floor during high kraeusen, HAD DRIED AND STILL RETAINED IT'S SHAPE TWO WEEKS AFTER IT HAD FORMED! Do you follow me on this one? The blowoff filled the gallon jug which was supposed to catch it all and foamed out of the top of it, onto the floor. When this happened, I cleaned up most of it but some was back between the carboy and jug. This weekend, that stuff was solid and looked like brown styrofoam. Could this be some of the small proteins and big dextrans that give you good head retention? Could I have lost something useful, besides the quart and a half of beer? Or are the proteins and dextrans distributed throughout the beer and I'll just be able to do parlor tricks with this beer? [By the way, OG 1120, FG 1050 (approximately 9.2% Alcohol by volume) -- more attenuative yeast needed next time (very sweet).]

Subject: All Grain technique questions

From: Ed Moore
Subject: All grain method?

I'm an extract brewer, interested in all grain. The logistics of all grain (bigger pot, chiller, heating up 6 gallons of wort) have so far kept me from trying all grain. My brother-in-law (Greg) told me of his method this weekend and I'm posting this note to see if others have used it (and with what success). FYI, Greg has been brewing for several years and makes a good brew.

OK, this is what Greg does which I found interesting.

- 1) Prepare mash in a pot with 'warm' water.
- 2) Put pot with mash into the oven, with the oven set to "warm". Leave it for an hour or two. (As Greg says 'no fuss, no muss'.)
- 3) Transfer mash to lauter tun.
- 4) Run 2 or 3 gallons of hot (170F) water into lauter to sparge.
- 5) Boil the wort (2-3 gallons) with hops.
- 6) Run 2-3 gallons of cold (tap) water into lauter to complete sparge.
- 7) Combine cold sparge/wort with boiled wort to make a complete batch AND to obtain cold break.

This is his tried and true technique. He does not seem to have any contamination problems and as I have said, makes a good brew. Has anyone else used this partial boil, cold sparge, method?

Subject: Bigfoot in NJ?

While we here in New England see most of Sierra Nevada's fine products, for some reason two of their most interesting brews--the Maibock and the Bigfoot Ale--aren't distributed here. Rumor has it, though, that they can be found in New Jersey, where I'm going in a few weeks to visit the in-laws. Can some Garden State reader of the Digest help me find them?

I'll be getting on the Parkway at its northern terminus, right off the Tappan Zee, and driving it to south of Asbury Park. While my wife does like beer and is willing to put up with my interest in it, she doesn't have much patience for driving around aimlessly for very long, so I'd like to know of a store within a few minute's drive off the Parkway.

Send me private e-mail (eric@synchro.com), or even call me (old style: 617-536-9500 w; 617-965-0573 h).
Thanx.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>
Subject: Oops, bottle bombs???

I recently made a batch of wheat ale (Wit style) with a new yeast (supposed to be Hoegaarden strain). It started slow, but built up a big krauesen -- needed a blow-off tube for a week. Eventually it slowed, and 3 weeks later was putting out one bubble every 45 seconds, roughly. I figured it was time to bottle. Racked onto priming solution in a second carboy, and took S.G. 1.020... Hmm... Initial gravity 1.040... Hmm... Tastes ok... Not too sweet... Late night decision -- let's go for it.
Bottled 2 cases.

But then, I got worried. Talked to the friend who gave me the yeast. He didn't think it should stop so soon. Talked to another friend who had used the same yeast in a similar recipe. His went from 1.047 to 1.014. Hmm... One major difference: my fermenter was in the cellar, at 56F, his was at 65F. Maybe this yeast doesn't like to be cold. Hmm...

Ok, brought a bottle up from the cellar, shook it well, and fitted a fermentation lock. Couple days later, it's still going nicely. Hmm... Haven't taken an S.G. on this one yet, but it's looking like I blew it, and mistook a stuck fermentation for a finished fermentation.

Now, I could chill the he** out of these bottles, and drink them up quickly, or I could try to relieve the pressure, or something. I'm not wild about pouring 2 cases of bottles back into a carboy (not to mention the inevitable aeration that would take place). I could see lifting and resealing (or replacing) the caps a couple of times. Or, I could chill the h*** out of it...

Any advice?

And, a hard scientific question: How many volumes of CO2 should I expect to get from a .001 drop in S.G.? Haul out the old envelope. Let's say that 3/4c corn sugar produces 2 volumes in 5 gal. That's 3/8 lb, at 40pts/lb/gal is 12/5 pts, so maybe I get 1 volume/gravity pt. So, if my test bottle keeps going down to 1.014, I'm going to get about 6 volumes! Bottle bombs for sure! But I could relieve the pressure a couple of times (if I do it at the right time!) and be ok, ... maybe ... Hmm....

Subject: Cheap Carboys!!

I finally got around to looking for a 5 gal. carboy for a secondary and went to talk to my lab professor in the Chem E. department and guess what!! I got two 5 gallon carboys for \$5. They were really dusty, but didnt smell like any noxious chemicals and weren't stained or anything. So, if you have a university you might want to check out the Chem E or Ag department to see if there are any old carboys around.

BTW, one of the carboys is made of the old blue tinted glass and has the date 1932 stamped on the bottom!! I wonder if it's worth any money :-)

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Wyeast Bohemian Lager yeast

In an effort to make a Pilsner Urquell type lager, I used the Wyeast 2124, Bohemian Lager, as per recommendations on the net. A friend also used the same strain, and his beer came out, well, bad. I chalked it up to an infection or some such. But I tasted my lager yesterday (still in secondary, clearing slowly) and it tastes the same as his. Quite phenolic, a little estery, and lots of dry sulfury compounds. In short, it tastes like a mediocre Lambik. Admittedly there was a long lag time when I pitched the yeast (the pack hadn't quite swelled up, so it took about 3 days to get going). But the fact that I have not once had an infection since my first batch (followed the instructions on the can on that one), and that my friend has yet to have an infection, and both of us brew with 2124 and it tastes the same in each case seems to indicate that either 2124 isn't the yeast for making PU clones, or these packs were contaminated. Anyone else out there with similar experiences?

Actually, all brown 12 oz. returnable bottles in the U.S. are a standard
shape and size. Any brewery can use these bottles no matter what
brewery previously used them. Open thine eyes and ye shall see.

Dennis B. Lewis writes:

Each time a beer ferments out and the yeast is re-used for another
batch, this is considered a new generation. The multiple "life cycles"
and alcohol environment the yeast work in can cause mutations.

Scott,

I've been a member of CAMRA for several years, mostly just to get the
Good Beer Guide, but it also to help me in planning my trips to the UK.
Their newsletter is good, and keeps me up-to-date on the dates and
locations
of Beer Festivals (to which CAMRA members are admitted free).

If you travel to the UK often, CAMRA membership is well worth the price.
While passing through an area, I can always rely on the pubs in the Guide
to give good service, beer, and usually food.

Keep in mind, however, that omission from the GBG does not imply a lower-
quality pub. Indeed, many of my favorites are not listed. If you're in
a town for more than a day, don't depend solely on the GBG - ask the
locals
about good pubs.

Subject: Screen Tests

I received some e-mail from people asking for more detail regarding the sieving tests to evaluate grain milling. Apparently there are a few people who would like to build their own apparatus for doing this. I think this would be a terrific project for a homebrew club.

The best model that comes to mind for getting ideas for designing a screen sieving device is the Pfungstadt plansifter described by DeClerck (p. 321, Vol.2). Here the screens are in parallel, and placed in order of decreasing screen width.

One will note that the device is not large. Indeed, it is traditional to do tests on only 100 gram samples. This of course raises the practical problem of avoiding sampling errors. The usual rules regarding small sample sizes apply. It is often a good idea to run several tests on samples taken from a particular crush to make sure the measured results are robust.

There is strong agitation during sieving. DeClerck reports that the screens on the Pfungstadt plansifter are rotated ~300 times per minute for 5 minutes. It has been my experience that this is *****very***** important. As Jim noted in his post, the MM will leave over half of the kernels in a state where they look as if they were not crushed. Without the proper agitation they will be artificially captured on the coarser screens. This will result in very large errors (up to a factor of 2) in the measured results. With proper agitation, on the other hand, they will fall apart just as they do when we rub them in our hands.

The major application of a sieving device is in the determination of the proper roller spacing. This can be used not only for a MM, but for any other mill, and indeed even a Corona. It has been my experience that the best spacing will vary with the type of malt that is to be milled.

I hope that anyone who who starts a project along these lines will keep me abreast of their progress. I bet the whole affair turns out to be a lot of fun.

Subject: Fermentable sugars in honey

Message Creation Date was at 13-APR-1993 09:36:00

Greetings,

I was interested in using greater quantities of honey in some of my "Speciality" (or "Peculiar") Beers. In my attempt to calculate how much hops to use as well as body characteristics, I need to know how much fermentable sugars are in a unit weight of honey. I realize that there is no simple answer to this, given the fact that honeys can vary greatly depending on the flower and the regional conditions. However, that caveat being stated, any insight would be greatly appreciated.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re measuring alpha acids with pH meter

One problem with the assumptions and one with the results:

Tannic "astringency" doesn't have much to do with pH. Examples: colas are in the range of pH 2-3 (/very/ rough, but certainly more acid than your tea---the acid in colas is as much a problem for your teeth as the sugar) and nobody calls them astringent; typical vinegar at 5% acetic acid is something like pH 3 (it's been a /long/ time since I had to work from Kdiss to pH), ditto. There are many organic acids which have a very modest effect on the pH of water. I don't know the mechanism of astringency but I would guess it's some other reaction completely; try tanning leather with a random acid and see where it doesn't get you....

pH is a log10 measurement. .3 decrease in pH is 2x acidity, .47 is 3x, .6 is 4x, .7 is 5x. According to bc (UNIX calculator program), $e^{(.4 * \ln(10))}$ is 2.5, so your result actually doesn't agree with expectation--

--
EXCEPT that weak acids don't affect pH in proportion to their concentration. Crudely put, the acid has to break into H+ and (remainder) -, to change the pH; this is a balancing act in which the more acid you have, the less of it actually dissociates. What's the average Kdiss for hop acids? Damfino---George Fix or Steve Stroud might have numbers.

I also don't know how "utilization" (amount of acid extracted) varies with acid content---I would expect the % utilization to be lower for the same mass of high-alpha hops compared to low-alpha (since you're trying to make a more concentrated solution) but have no figures on /how/ /much/ of a difference this is. To eliminate this factor you might need a Soxhlet (sp?) extractor, which is fun to watch but not cheap.

Subject: Oregon Homebrew Festival
Full-Name: Ted Manahan

ANNOUNCING

THE ELEVENTH ANNUAL

OREGON HOMEBREW COMPETITION AND FESTIVAL

On Saturday, May 8, 1993 at 12 noon.
Benton County Fairgrounds - 110 SW 53rd Street, Corvallis, Oregon.

The Capitol Brewers, Cascade Brewers Society, Heart of the Valley Homebrewers, Mary's Peak Lagers, and the Oregon Brew Crew invite you to participate in the ELEVENTH annual homebrew competition and festival, the longest-running event of its kind in Oregon. The focus of the event will be a judging of homebrewed beer sanctioned by the American Homebrewer's Association (AHA). In addition, the Club will host a festival to promote awareness and knowledge of various beer styles, provide opportunities to share information about the homebrewing craft, and encourage interaction of homebrewers in a social atmosphere.

ENTRY REQUIREMENTS FOR THE COMPETITION:

Anyone 21 years of age or older may enter. All entries must be personally homemade by the entrant. No entrant can enter more than two entries in any one category. Entries must be registered for judging by 11 AM on Saturday May 8, 1993. Festival organizers will not assure registration or judging of entries received after this time. To help avoid a log jam of registrations the morning of the competition, entrants are encouraged to send or bring their entries to: Oregon Homebrew Competition and Festival, c/o Freshops, 36180 Kings Valley Highway, Philomath, OR 97370 by 5 PM Friday, May 7th for entry registration. All reasonable efforts will be made to transport, store, and serve each entry in the best possible manner. Entries that are mailed should be shipped via UPS as non-perishable food in appropriate protective packaging. As shipping may resuspend sedimented material, shipped entries should arrive with sufficient time for settling to allow the best appearance.

Three bottles of at least 10 fluid ounces each are required for judging (one each for first round judging, potential second round judging, and potential best of show). Each entry (not bottle) must be accompanied by a sheet of paper specifying the following information: Brewer's name and address, category to be judged in (note: brewers should specify style within category to assist judges in evaluation; e.g. Light Lager - Continental Pilsner), recipe, and a \$5.00 entry fee (checks must be made payable to Ted Manahan, not Heart of the Valley Homebrewers; the entry fee is used to cover expenses for hall rental and ribbons). Efforts will be made to allow entrants at the festival to reclaim unused entries and empties; however, festival organizers makes no guarantees in this regard.

Qualified judging of all entries is the primary goal of the event. Three judges will evaluate and score each entry using the American Homebrewer's Association (AHA) 50 point system. The average of the three scores will rank each entry in its category. The Master of Ceremonies or other qualified person will review elements of beer categories and styles with each panel prior to judging. The Best of Show will be

determined by the best average score in a second judging of the highest average scoring entry in each category. A club competition will also result from the outcome of the judging. Brewers associated with any homebrewing club will receive points for their winning entries credited toward a club total. Club members should include their club name on their entry form. Points scored in this competition count toward NORTHWEST Homebrewer of the Year. The descriptions and standards used by the AHA at the National Homebrew Festival and Competition will be used in judging. Judging will be conducted in a controlled environment (separate room) away from the hubris of the festival.

Entries will be received for judging in the seven following categories:

- 1) Light Lager (includes American and Continental styles)
- 2) Dark Lager (includes bock)
- 3) Stout and Porter
- 4) Light / Pale Ale (includes IPA)
- 5) Dark Ale (includes Brown Ale)
- 6) Specialty (includes wheat, fruit/herb beers, steam beer)
- 7) Strong Beer (includes dopplebocks, barleywines, and imperial stouts)

Festival organizers reserves the right to judge an entry in an alternate category if, after registration is completed, it is found to be entered in a category having fewer than four entries. Ribbons and prizes will be awarded to First and Second place in each category as well as for Best of Show.

We are looking forward to a highly enjoyable festival with a relaxing atmosphere, several displays, food concessions, music, a raffle and the opportunity to interact with masters and luminaries of the brewing craft. Judging and award presentations should be completed by 5 PM.

Any questions regarding the festival can be directed to Ted Manahan at 503/926-6228, internet address tedm@hp-pcd.cv.hp.com

>run through the chiller the cooler your wort will get, the faster you
>do it, the faster it will get cool. Especially if you stir the wort.
>Use the chiller to stir with.

This isn't really right...A larger colder surface will cool faster
because of more surface area and with a larger tube diameter you would
want a
high flow rate so that there would be turbulent flow instead of laminar(
If it
was laminar flow, there would be a warm boundary layer of water near the
walls
of the coil and the water towards the middle would not be doing any
cooling).
However, I think you would want the exiting water to be warmer for a
given
length of tubing. The amount of heat removed from the wort should be:
 $(\Delta q) = m \cdot Cp \cdot (\Delta T)$
where m =mass flow rate of water
 Cp =heat capacity
 (ΔT) =temperature difference= $T_{out} - T_{in}$
So, if the flow rate increases, the heat removed increases, and if the
temperature difference increases, the heat removed increases.
(I'm sure there is a bit more analysis of this that can be done...It's be
a
couple years since I had heat transfer and I didn't like that class
anyway:-)

I exclusively use Sam (tm) Adams (tm) Bottles (tm?). These seem to be
good
bottles to me. I had one break on about my third batch, but that was a
homebrew virgin bottle (as opposed to many uses). I think that I was
getting overly aggressive with the capper, so I have never considered
that
the bottles fault. But maybe I am wrong. I have had no other problems.
Has anyone else?

Sherman

Why not add some English rocks to your collection? I buy large quantities of Hugh Baird malt, and have noticed similar looking rocks in my grain. I usually discover them when the handle of my mill suddenly ceases to turn, so they're a little chipped around the edges and are therefore probably not museum quality.

Does anybody know if these rocks serve some mysterious purpose in the maltster's arcane art? Or are they merely slip-ups in the quality control department somewhere?

Subject: Krausening/Mashing

KRAUSENING

I remember a recent thread regarding krausening and I am considering trying it soon. My question is this - in order to achieve the same carbonation as using 3/4 cup corn sugar I need to calculate the Degrees of Extract available in the corn sugar. Then, based on the SG of the wort for krausening add enough to create the same Degrees of Extract. Is the above statement correct.

MASHING

What is the proper mash temperature during sparging?? I would assume it to be very close to mashout temp (170deg F). I have noticed that the temperature of my runoff during sparging has been 150F. I typically heat my sparge water to 170-175 about fifteen minutes before I start my sparging procedure. Is this reducing my YIELD??????????

Next time I will heat the sparge water to the proper temp. immediately prior to using it.

As well as further discussion! Jack, I heartily applaud your experiments. I did have some comments on your interpretation that seemed worth posting, but I think your efforts were worthwhile.

Or another explanation involves the cantankerous nature of pH meters. In general, they will respond much more rapidly if they are used to measure similar samples consecutively. For example, if you calibrate the meter using the commercial buffers, then put the electrode in a solution with comparatively little dissolved solids (like water) it may take the electrode a while to settle down in its new environment. Once stabilized, the next water sample you measure should equilibrate much more rapidly. Try it!

> The delta is .4 pH which I believe works out to a factor of
> 4 in the real world and nicely matches the delta of the AA
> in the hops.

Keep in mind the logarithmic nature of the pH scale. In the 'real world' this difference in pH amounts to:

$(10^{-6.2}) / (10^{-6.6}) = 2.5$ times the amount of free H in the Chinook tea

> Although, measuring at different times sometimes provided
> different numbers, the spread was always the same and I
> attributed the problem to lack of understanding of how to
> use the instrument.

The changes over time could be due to either temperature changes (although not in this case since you waited for the samples to cool) or they could be due to re-equilibration with atmospheric gasses (most notably CO₂) after the sample was degassed by boiling.

> The only significant anomaly was that on the third day, the
> pH of both teas dropped to 5.7. They had been left
> uncovered throughout the period but something significant
> happened overnight of the third day.

Distilled water in equilibrium with atmospheric CO₂ has a pH of 5.6!

Microbial action is also a possibility if the pH change was sudden.

You may have something there, but I wonder what other types of acids might be present in hops that produce no flavor components. Ultimately we don't want to know the total acidity that the hops can produce in our beers, but the specific quantities of a particular class of acidic compounds.

Subject: More on Immersion Chillers

After seeing all of the discussion on immersion wort chillers, I could not resist throwing in my paltry 2 cents.

Before I started to brew, I saw a friend of mine do a batch. He had a wort chiller, and so I thought it was a great idea. So, I went to the hardware store, got 50' of 3/8 O.D.flexible copper tubing and a compression fitting. The coil is fit so that there is about 2 inches of space between the coil and the side of the container for the wort. The outer coil just spirals down from the compression fitting [where the water comes in], then I made a much smaller coil inside the outer one which spirals up and out, where the water flows out.

This chiller will cool wort which is fresh from the stove in about 15 minutes. Usually, I notice when the temp is at around 80 degrees [F] walk into the next room to tell my partner that it's just about ready, toss a dart or two, then come in to the 65 degree wort, all ready to pitch.

All I can say is I have no complaints. It works for me.

Subject: rotten egg smell

Last weekend I brewed up a batch of wheat beer using Alexander's 60/40 wheat extract, a 1.5 lb 100% wheat kicker, and various grains and hops. I used Yeastlab Bavarian wheat liquid yeast. Prior to brewing I made up a starter using 5 tbsp DME. After 24 hours in the starter there was quite a bit of activity as well as a good deal of sediment but minimal kreusen. I pitched into the primary and vigorous fermentation began within 18 hours. Once fermentation started, I began to notice a sour sulphur odor. Now that fermentation has stopped and I've racked to the secondary, the odor isn't as distinct but it's still there. Questions:

- 1: Has anyone had this experience using Yeastlab yeast. This is my first experience with it. I've always used Wyeast before this batch.
- 2: Will the odor disappear with time.
- 3: Is there a chance that I have a contaminated batch.

Any feedback will be appreciated
Thanks.

I've been a member of CAMRA, the Campaign for Real Ale, since 1978. When I moved to the US, I brought my membership with me, and I certainly find it a good way to keep up with the UK beer, pub and brewing scene.

It costs 14 UK pounds (approx US\$21) for "overseas membership". I believe

CAMRA will accept credit card orders over the phone (they will for book orders, like for the Good Beer Guide). Their number is 011+44-727-867201.

They keep regular office hours, so remember to call early enough in the day

(before approx 12noon Eastern, 9am Pacific). Or write for details to CAMRA,

34 Alma Road, St Albans, England, AL1 3BW.

Membership includes a subscription to What's Brewing, their monthly newspaper. This is 32 tabloid-format pages of news about British pubs, breweries and beers, a column on homebrewing, a full page of beer hunting from Michael Jackson (April issue: German Bocks and Doppelbocks), various industry news (what's Anheuser Busch up to in Europe?), listings of beer festivals, etc, etc.

Subject: growing hops

Hello fellow homebrewers,

I am a little new to this forum as well as homebrewing itself. I am sure this has been talked about before, but I could use some information. I would like to grow my own hops. It doesn't look too tough. I have a supply that can give me rhizomes for Hallertau, Cascade, and one other I can't remember. The only info I have is out of Papizanian's (sp?) book. Can anyone give me maybe a little more insight, tips, etc.? Everything would be appreciated.

Thanks in advance,
Jim

Subject: SF Brews (That's Santa Fe - the original SF :-)

There are no brew pubs in Santa Fe. Embudo Station (on the way up to Taos) is the closest. It's probably about a 45 min drive but very pretty and worth going. Santa Fe Pale Ale is brewed at the Galisto Brewing Company just south-east of Santa Fe. It's not a brew pub but they will give you a tour (I think just on the weekends unless you arrange otherwise). If you just want to try the beers you can get any that are available at The Royal Buck on Galisto Street in Santa Fe. They have a pretty good selection of beer and they carry "Santa Fe" beers from the Galisto Brewery which are not available in bottles anywhere but at the brewery. Of course there are good beer drinking establishments in Albuquerque too.

Subject: Guinness in cans

Does anyone have any word with regard to Guinness draught in cans making its way to more locations in the US? Currently, I've heard they are available in Wash DC, San Fran, and one other place. I live in the Boston area and I've been relying on my Irish comrades to supply me - I'm really surprised that Boston was not chosen as a "test" site for the canned draught Guinness, which, IMO, is very authentic.

I've heard that this summer we may see more of these. Anyone else know more about them? I wouldn't mind seeing the Murphey's in cans here as well 'cuz they too are quite yummy!

From: tims@ssl.Berkeley.EDU
Subject: tips gleaned from Anchor brewing tour

Dear Folks,

I promised a while ago to report on some of the things I learned during my recent trip to the Anchor brewery. The folks there are very nice about giving tours and information, and most of all free samples of their various beers, all of which add up to a great visit if you have the chance to go.

Since they are in the business to sell beer, I hope you will patronize their products even as you attempt to duplicate them using the information below.

Here are some random notes, scribbled hastily during the tour. I can't guarantee the accuracy, but this is to the best of my knowlege and scribbling.

- their Steam beer is mashed at three separate temperatures
- steam beer uses both pale and crystal malts, while the Liberty Ale is 100% pale
- their wheat beer is 70% wheat malt

- The steam beer boil is 1.5 hours, with hops added throughout the boil. It gets a 2 hour sparge.
- Steam and porter both use lager yeast, and are fermented at 60 F.
- they reuse yeast after washing it.

- They use iodophor to santize their fermenting vessels
- Liberty Ale is dry hopped
- their steam beer is aged (lagered) at 50 F.

That's it. For you steam lovers like myself, the above info and the net-lore that steam uses 100% Northern Brewers hops should be able to come up with a pretty good match to the beer, if you are the mashing type.

Good luck, Tim Sasseen

Subject: RE: PH METER FOR AA%

Jack Schmidling is attempting to use a pH meter to measure hop alpha acids.

I had asked this question of some hop experts and always got the reply that the alpha acids were too weak to show up on a pH meter. Jack, can you try this: Dilute the Chinnok tea with distilled water by an amount intended to match the Saaz? tea's AA and see if the pH matches the Saaz tea. That should tell us if you are measuring the AAs or something else. I am also skeptical that only a 5 minute boil got any AAs in the tea at all. I would repeat the experiment with more water (say 1 litre) and do a 60 minute boil. This will give iso alpha acids, but should be proportional. You might also try a methanol extraction rather than water. This is a more common practice in the hop world.

Subject: Reuse of bottles in USA

Subject: Reuse of bottles in USA Time:11:27 AM Date:4/13/93
>They all use the same standard bottle, they make it easy to
>return them to just about anyone, and just about any brewery
>can fill the bottles. Green ones, brown ones, etc. Being an >
environmentally
conscious person, I really liked what I saw.
>The US of A is so caught up in making \$\$\$ as quickly as possible
>that we'll probably never see anything like that...

In fact that used to be the way everybody did things. Well, almost. As
little
as 20 years ago I was able to purchase bottled beer in cases of
returnable
bottles. The beer came from Bartells in PA (I lived in NJ at that time)
it was
around \$3.50 a case plus \$0.03 deposit per bottle. I also recall buying
soda by
the case right from the plant in a refillable quart bottle around the
same
time. All glass containers for beverages were at one time returnable for
the
purpose of refilling. All milk was sold this way when I was a kid. While
we
never saw a standardized bottle which could be used by any brewery, the
principle was certainly there.

I suspect that the practice was abandoned when the range of sales for any
given
producer extended beyond where it was cost effective to reclaim the
bottles.
For the big breweries this was not such an issue (hence the continued
existence
of the "bar bottle") but for small regional or local brewers (or other
beverage
producers) if you wanted to get a bigger market share you had to figure
on the
loss of the container. Also one way to reduce or maintain the cost of a
product
is to reduce the cost of the package. Cans also contributed to the
elimination
of re-use containers.

Standardization of glass containers would go a long way toward
facilitating the
re-use ethic. Alas there would be no end to the cries of "foul" if such a
suggestion were made. The idea of cross-use between industries alone
would be
enough to get the neo-pros out of joint. "What?! Use the same bottle for
milk,
soda, water, AND BEER, WINE, or WORSE!?!"

Don't expect it in our timelines. We can't even get the world to agree on
a
measuring system! I can hear the Ayn Rand-ites coming for me now...

Subject: Zima Review & Thanks

Hey, folks:

I had my first taste of Zima this weekend, and thought I would post a short review.

First, Relax. Beer it definately AINT. It calls itself a "clear malt beverage". While I cannot testify on it being malt, it was a beverage and certainly was clear.

COLOR: none
HEAD: none
HOPS: none
AROMA: sweet and slightly citrusy
TASTE: exactly like a vodka-seven (that's vodka and seven-up)

If you like 7-up, you'll love this drink. It was a little too sweet to be refreshing, even on a hot day.

I won't buy any more. If I want something that tastes like Zima, I'll mix up a vodka-7 myself. It'll be WAY cheaper.

Many thanks to all of you who responded to my plea for help on yeast culturing. Your suggestions/advice/experience were very timely and helpful.

Cheers,

Troy

From: ek@chem.UCSD.EDU (Ed Kesicki)
Subject: Recipe: Bigfoot Jr.

Here is a recipe for a beer similar in flavor to SN Bigfoot Ale, although it is not quite as high in alcohol content. (OG of 70 compared to 95 for the real bigfoot according to M. Jackson). Let's say it's Bigfoot Jr. I wasn't attempting to make a clone, it just came out that way--maybe not surprising since I used the SN yeast. In fact, I had never tasted SN Bigfoot until after I had made this one, and I found the flavor very similar.

SIERRA NEVADA BIGFOOT JR (4.5 gal batch):

10 lb2-row pale malt
8 ozDextrin malt
1 lbAmber crystal malt (40 deg L)
.25 cup Chocolate malt
2 tsp gypsum

Hops: 1.5 oz Northern Brewer loose hops, 5.7% aa, 60 min boil.
1.0 oz Cascades loose hops, 5.5% aa, 60 min boil
(total of 14 AAU bittering)
0.5 oz Hallertauer pellets, last 5 min of boil
0.5 oz " " , end of boil, sat 10 min before chilling

Yeast: Sierra Nevada Yeast, cultured from two bottles

PROCEDURE:

Mash in: 130 deg. F 12 qts water (San Diego tap water, boiled+cooled)
Protein rest: 125 deg F 30 min
Mash temp:155-146 deg F 1.25 hr
Mash out: 170 deg F 5 min
Sparge: approx 4-5 gal @ ~ 170 deg F

Total boil time of 1.5 hr, hops additions as noted above, chilled,
racked off trub
Final volume was 4.5 gal
Fermented in glass, temp in the low 60's Farenheit, used primary+
secondary.
Two week fermentation

OG: 71 FG: 15

Primed with 1/2 cup corn sugar, bottled 2.5 gallons like this, which became the Bigfoot Jr. The remailing 2 gal. was diluted up to 3 gal with water, then bottled after adding a little more corn sugar (~1or2 tbsp). This produced a very very good pale ale (Not at all bigfoot-like!) with a more civilized alcohol content.

Please try it and let me know how it turns out.

Ed Kesicki

Subject: Mashing temps for De Cosyns Belgian malts?

Went to a presentation by Dr. Michael Lewis from U.C. Davis a few weeks ago where he said that a temp. step mash was absolutely essential to give best extract yeilds and fermentability when using American lager malt (aka "klages" in this neck of the woods). He also said that with British Pale Ale malt, a single temp infusion mash was best. I get the idea that the mash temp profile really depends on what your malt was designed for.

I have some Belgian Pilsner malt and Pale Ale malt from De Cosyns maltings. Does anyone have info on the proper mash temps for these two fine malts? (If I had to guess, I'd do a single temp 150F infusion mash with the Pale Ale, and a temp step/ramp from 122F-142F-158F for the Pilsner malt.)

Subject: How not to filter beer

Ok, so I've been asking around and reading up on how to filter homebrew and I went by and looked at some whole house water filters. It seemed that they contained an awful lot of liquid for filtering five gallon batches and might be wasteful. So I notice these cute little 'icemaker' filters by Pollenex that are clear tubes about 1.5" in diameter and about a foot long. These are filled with carbon but they have a threaded cap and an O ring seal on one end. I found one of these for \$5.00 and also a 5.0 micron string filter (two for \$5.00) so I figure I'll just pour out the carbon and stuff the wound string filter in the cartridge and see what happens.

BTW,

I've looked all over and I cannot find the 3.0 micron filters I think George Fix was talking about, if anyone knows where I can find one of those let me know. (the filter store says ??)

Anyway, I'm working on the little filter cartridge and found that the plastic connectors that come with it - that thread into each end of the cartridge, have outer threads that fit cornelius keg threads (ball lock type at least - I dont have pin lock), I added a compression ring (a little brass ring that looks like a double of the normal cornelius plastic compression washers i.e. "<>" rather than ">") to get a good seal.

Then I try to unscrew the O ring cap off the cartridge. It is stuck on really tight, so tight I thought I'd break it if I tried any harder (I had the hex-head cap in a vise and was using 2 pipe wrenches on the body of it). I thought I remembered testing one of them and it unscrewed, so I ran to Kmart but they were all beyond hand tight. So I went back home and heated the cap in real hot water... finally put some ignited propane on it. After about a half hour of heating and twisting and cursing, I got the cap off.

Ok, so now I pour out the carbon and take the poly wound filter cartridge and open it up and find the end of the string. I roll the string up in a tight little ball estimated to simulate what would pass through the poly string filter if I hadnt grossly mutilated it. I didnt want to filter it too much (gad! barley wine 'in' and Coors extra light 'out' red alert).

(CO2 purging, fixing leaks etc mercifully omitted)

I diverted a sample:) on the way out of the fermenter into tank#1 which I used to compare against the filtered stuff going into tank #2 (I was using CO2 to push the brew rather than a pump).

The glass I diverted after the filter looked exactly the same (clarity wize etc) as the stuff right outta the fermenter:-)

I disassemble the whole deal, stuff the little housing with as much filter string as seems sane, and repete procedure. same results.

So, I think that a small cartridge filter that would be disposable or reusable with a small amount waste is still a good idea. I think I could fabricate a smaller less wasteful housing if I could find the right media. FWIW, the Filter Store told me today that pleated filters were much more effecient and poly string filters were only

about 65% effecient at their rated effectiveness.

Now I've got a bunch of barley wine samples that I'm not about to waste and its getting late!

I guess this is going around. My last batch was very similar to this; in particular, I also used the Yeast Bavarian Wheat Liquid Yeast (from a starter). The fermentation went on for nearly a week. And, it gave off a distinct "rotten egg" smell (my wife was the first to complain; I don't need to give her any more reasons to object to my brewing in the house). I called my local brew shop. The proprietor suggested leaving the beer on the yeast for four days after the krausen had fallen; by that time the smell should have dissipated. He was right! At this point I didn't see any reason to go to a secondary, so I went ahead and bottled the beer. My taste tests at that point indicated no ill effects; we'll have to wait until this weekend to test the finished product. My only complaint was that there were some fairly ugly remnants from the krausen floating on top of the beer when I started bottling. Some of it made its way to the last few bottles; I guess I can expect some puzzled looks from unsuspecting guests.

Subject: Yeast Propagation

Message Creation Date was at 14-APR-1993 07:26:00

Greetings,
I've a question about starter cultures and their OG's. I remember reading several items on hbd recently concerning whether an OG of 1.020 was appropriate or just a piece of folklore handed down over time. I've read that when a fermentation reaches full yeast saturation, there are supposedly 50 million yeast cells per milliliter of solution. Is this irrespective of the Gravity of the wort? Does a unit volume of 1.020 wort create the same number of yeast cells as 1.080 wort? If the OG of the wort does make a difference in the final quantity of yeast cells, is there some sort of mathematical relationship I can use to determine final number of yeast cells for a given volume of wort at a set OG? It seems to me that if the OG has no bearing in the final saturation number of yeast cells, and saturation will always be 50 Mill/ml, then why not just decrease the DME, increase the water, end up with an OG of 1.010, but because of a greater volume have a greater number of yeast cells.

Help!! I see yeast in all my dreams!

Subject: Milling nightmare

I recently brewed a Brown Ale. One of the malts in the recipe is English crystal malt. This stuff really makes a brown ale. I usually put it in the mashout to minimize some of it's harshness. I will mill the crystal malt separately from the pale malt. Well all was going well with the pale malt. I then started to crush the crystal malt. The mill started making funny bumping noises. I looked at the cracked grain and it didn't look cracked, more of a mashed look. Well I tasted the malt and it was like gum. Well I figured I would pass the malt through the mill one more time to better crack/mash it. The mill stopped! The malt gum/goo/sticky crab stuck to the mill rollers and clogged the mill! It took me about two hours to clean the rollers up. Not an easy task if you don't want to use water for fear of rusting the rollers. I think what happened here is the malt was in a room where the humidity was very high and it sucked up all the moisture to make bubble gum malt. Under my house flooded during the winter and created this high humidity. The lesson here is I will taste test all malt before they go through the mill and I am considering some sort of moisture tight bag around the malt to prevent this from happening again. Grooved rollers on a mill are a definite disadvantage in this circumstance.

Subject: Wort Chillers

It's been a while since I got on my soapbox (so as not to get too tiresome on the subject), but having used both immersion chillers and counterflow chillers (former first, latter second), I believe that there is nothing like a counterflow chiller.

- 1) Because the wort and cooling water are going in opposite directions, you get a very efficient heat exchange.
- 2) The bulk of the wort in the boiling pot stays hot enough to discourage assorted bugs.
- 3) The wort is chilled in complete sterility and then dumped out at pitching temperature right into your sterile (I hope) carboy. I usually pitch the starter culture into the carboy and then dump the wort on top of it.
- 4) You get (depending on the temperature of your cold water) a really good cold break during the chilling process.

The big dread that most people consider is cleaning it. This is actually not too bad. First I run hot water through it, then a solution of chlorinated TSP and hot water and let that sit for 10 minutes. Then another two minutes of hot water flow and cap both ends and leave it sit with water in it. The chlorinated solution must NOT sit in it long term, it will corrode the copper. Then I always rinse for two or three minutes with hot water prior to use.

If anyone wants a drawing with detailed instructions, email me for my home address and then send me a self addressed stamped envelope for the drawing itself.

Subject: re: Lab equip

>I would like to second that request for Lab equip supply places. Also
> does anyone have the number for Aldritch and know if they sell to
> individuals?

The toll free Customer service for Aldrich is 800-558-9160.
They sell non-chemicals to individuals but if you want
chemicals (agar included) you must order through a business.
I recently bought some Pyrex Petri dishes from them.
Theirs was the only catalog I found with Pyrex dishes, which they
sell in different sizes, namely,

o.d.XH(mm)	Cat. No.	Each	Pkg/12	Case
58X15	Z13,973-4	\$6.05	\$47.80	\$258.75/72
98X10	Z13,974-2	5.40	39.80	214.60/72
100X15	Z13,975-0	5.40	39.80	214.60/72
98X20	Z13,976-9	5.40	39.80	214.60/72

(100X15 seems to be the standard size).
They also added on a \$10.00 shipping charge to the order.

As far as other supplies for yeast culturing go

test tubes - The minimum order in the catalogs I've seen
is 144 for over \$100, so your best bet is
probably a local hobby shop.

agar - I took Jack Schmidling's advice and found it
both in stick and powdered form in a local Chinese
market. The powdered form seems most convenient
but the instructions were in Burmese (I think).

For some of the other items
J&H Berge, Inc. of 4111 So. Clinton Ave., So. Plainfield,NJ
(I don't have their phone number handy) have a more limited selection
of supplies than Aldrich, but at generally lower prices.

From: 14-Apr-1993 1341 <macneal@pate.enet.dec.com>
Subject: Equations for wort chiller and immersion heater length

All of this talk about proper wort chiller length and length of immersion heaters made me dig out my copy of Perry's Chemical Engineers' Handbook (5th edition, pp. 10-36 and 10-37). Here are some formulas that may be of help.

First, let's define some terms. This will be a little tricky since I can't sub and superscript easily. I'll use an * to signify multiplication.

A, area in sq. ft.; Ab, of tank bottom; Ac, of coil; Ae, equivalent; As, of sides; At, of top; A1, equivalent area receiving heat from external coils; A2, equivalent area not covered with external coils; Dt, diameter of tank, ft.; F, design (safety) factor; h, film coefficient, B.t.u./(hr.)(sq.ft.)(OF); ha, of ambient air; hc, of coil; hh, of heating medium; hi, of liquid phase of tank contents, or tube-side coefficient referred to outside of coil; hz, of insulation; k, thermal conductivity, B.t.u./(hr.)(sq.ft.)(OF/ft.); kg, of ground below tank; M, weight of tank contents, when full, lb.; t, temperature, OF; ta, of ambient air; td, of dead-air space; tf, of contents at end of heating; tg, of ground below tank; th, of heating medium; to, of contents at beginning of heating; U, over-all coefficient, B.t.u./(hr.)(sq.ft.)(OF); Ub, at tank bottom; Uc, of coil; Ud, of dead air to the tank contents; Ui, through insulation; Us, at sides; Ut, at top; U2, at area A2.

Case 1: Tank Maintained at Temperature with Internal Coil

For steady state: $q = U_s * A_e * (t - t')$

for a tank on legs: $A_e = (U_t / U_s) * A_t + (U_b / U_s) * A_b + A_s$

for a flat-bottomed tank on the ground:

$A_e = A_s + (U_t / U_s) * A_t + [(2 * D_t * k_g / U_s) * (t - t_g)] / (t - t')$

The coil area is: $A_c = (q * F) / U_c * (t_h - t)_m$

The safety factor, F, is a matter of judgment based on confidence in the design. A value of 1.10 is normally not considered excessive.

For a flat-bottomed tank indoors, not insulated, using water as a fluid, $U_s = 1.8$, and $A_s = 0.35 * A_t + A_s + 0.9 * D_t$. For an uninsulated tank on legs indoors, $U_s = 1.8$, and $A_s = 0.35 * A_t + A_b + A_s$.

Case 2: Heating with an Internal Coil from Initial Temperature for Specified

Time (wort chiller length for desired chilling time)

$$Q = Wc \cdot (t_f - t_o)$$

$$Ac = [Q / \theta_{h} + U_s \cdot A_e \cdot ((t_f + t_o) / 2) - t'] \cdot [1 / U_c \cdot (t_h - (t_f + t_o) / 2)] \cdot F$$

where θ_{h} is length of heating period.

Over-all heat transfer coefficient for copper coil with cold water flowing through it and immersed in hot water with no agitation is 105-180 B.t.u./ (hr.) (sq.ft.) (0F).

Good luck!

Subject: dry-hopping, pitching rates

Brewing Comrades,

I have a couple remarks on postings in HBD#1118.

First, Carl Eidbo's remarks on dry-hopping problems remind me very much of what I have been through with a recent batch. I have only gotten a few comments on my trials and tribulations from digest contributors (I'm afraid my postings had to compete with that very lively thread on swirling) but enough to point me in this direction for future dry-hopping:

>>>when dry-hopping, I will (1) wait until the gravity is within a couple points of finishing, and (2) use leaf hops rather than pellets, probably sunk in a muslin bag weighted down with sanitized marbles.

Comments, anyone?

Second, regarding Dennis Lewis's post on pitching rates, I seem to recall a year or two ago there was this fellow identifying himself as "Father Barleywine" who claimed to be brewing multiple batches re-using the yeast cake over and over, just dumping the new beer on top each time. I was intrigued by this and tried it a couple of times, but the results were really not very pleasant. Papazian says that the phenomenon known as "yeast bite" can be associated with high pitching rates (and I also recall he says something like "there is no scientific explanation for this") and I think this was my problem - my yeasts were biting me!

However, thanks to the wisdom of the digest I no longer dump onto yeast cakes and I also plan to give up washing my yeast for re-use in favor of the "parallel propagation method" described herein recently, in which one lets a starter solution ferment to completion, then splits it up into several bottles fitted with airlocks and stores them in the fridge until brewing time.

Subject: Beer Chillers

In HB#1119 Bob Sweeney asks about the use of beer chillers comprising a coil of copper tubing, a bucket, and ice. He expressed some concern about possible negative aspects of this device. When I was very young (right after prohibition) such coolers were built right into the bar in all the neighborhood saloons. We had one in our summer house which was used during fund-raising picnics attended by large crowds (hundreds of people). They'd go through about a dozen half-barrels of brew. The beer was delivered cold but would get pretty warm towards the end of the day. The chiller worked great. It had about fifty feet of half inch copper tubing in an insulated box about two feet by one foot by one foot deep. The ice was delivered in large blocks about the same size as the cooler. It was chopped into smaller (fist-sized) chunks using an icepick.

The only problem I ever observed during the forty years I knew this gadget occurred late one hot afternoon when the bartender (who had been busily replacing his electrolytes) decided to save time in replenishing the ice by putting in large chunks and chopping it up in the cooler.

After a short period of furious chopping, the level of the ice began to rise. Then it became surrounded foam and finally beer began pouring over the sides.

This shouldn't be a problem with today's technology where the ice comes pre-chopped.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: dry hopping versus hop tea

In HBD 1118 Al talks about adding hop tea prior to bottling:

> to make a hop "tea" by boiling some hops in water for an hour (and
while
> you're at it, you can add flavor hops 15 minutes before the end of the
boil
> and finishing hops 5 minutes before the end of the boil)

How does this compare with dry hopping for the same effect? I would
think
that 1/2 oz hops sitting for a week in a secondary would have more effect
than the same quantity boiled for 5 or 15 minutes in water. Also, how
does
the volume of boiled water effect the extraction? It all has SG=1.0
which
implies it's independent of volume???

It would seem to be much easier to boil hops to make tea which is added
at
the last minute than to mess around with dry hopping.

From: mikel@netlink.cts.com (Mike Lemons)
Subject: Guinness Stout (Imperial) Recipe

There has been some discussion lately about the difference between different types of Guinness Stout. Here are some statistics from The Essentials of Beer Style by Fred Eckhardt:

	Original Gravity	Alcohol ww/vv	Final Gravity	Hops ibu
Guinness Extra Stout	1052	4.4/5.51	1011	50
1901 Guinness Extra Stout (In Ireland)	1075	6.3/7.91	1014	90

The numbers for the Irish Guinness are quite similar to those for Grant's Russian Imperial Stout. (So the truly Irish Guinness is really Russian! -- go figure.)

The book also states: "Pale 2-row ale malt, plus 9% each of flaked barley and very dark roast barley, in a two-step infusion mash (1-hour at 148-151 F/64.5-66 C). Bullion bittering and Golding aromatic hops to 50 i.b.u." (This is for Export Guinness)

I would like to brew a beer in the style of Irish Guinness, but with more body. I also like the molasses flavor of Mackeson Stout. So I came up with this all-extract recipe:

Ingredients:

- 6 pounds, William's English Dark liquid malt extract
- 3 pounds, Australian Dark dry malt extract
- 1 pound, dry weizenmalt (60% wheat)
- 1 pound, crystal malt (40L)
- 1 pound, roasted barley (540L)
- 1 pound, chocolate malt (400L)
- 1/2 pound, black patent malt (500L)
- 1 cup, molasses
- 2.34 ounces, Bullion pellets (8.8% alpha), boil 60 minutes
- .78 ounce, whole Kent Golding (7.8% alpha), boil 10 minutes
- Wyeast Irish ale #1084

Leave out this ingredient, since it requires mashing:
1 pound, flaked barley

Any comments? Do you think the yeast will handle the high gravity or will I need to re-pitch with champagne yeast? Should I throw something else in to increase the body? (I would like it as thick as possible. Maybe I should make my first attempt at mashing with flaked barley and carapils.) Should I reduce the hops because the roasted barley will add some bitterness? How many i.b.u. worth? Does anyone think that lactic acid should be added?

End of HOMEBREW Digest #1120, 04/15/93

Date: Thu, 15 Apr 93 01:46:01 -0500
From: oconnor@ccwf.cc.utexas.edu (donald oconnor)
Subject: whitbread warning, part 3

There seems to be some confusion regarding the availability of the new Whitbread dry yeast. George Fix mistakenly believes Crosby and Baker is presently distributing the new Whitbread to homebrew shops. They are not but hope to make it available in 2 or 3 months. Additionally, Crosby and Baker is not currently distributing the Australian yeast, Mauri.

George reports the use of an actidione test to check for wild yeast. The basis of this culture test is the same as all culture tests; to prepare a medium on which the culture yeast cannot grow but contaminating yeasts can. Like all other culture methods it's limitation lies in the fact that many wild yeast contaminants common to breweries are quite similar to the culture yeast. If you inhibit the culture yeast, you often inhibit the wild yeast. In the actidione test, the wild yeasts are broken into 2 subsets - those that are more resistant to actidione and those that are less resistant. George apparently drew the line as fine as possible by using the minimal ('incremental') amount of actidione. This approach has been in the literature for at least a quarter of a century. George reports wild yeast counts are less than 1 in 10 million culture cells. A more accurate statement would be that wild yeasts which are more resistant to actidione than the culture yeast are less than 1 in 10 million. It's impossible to say what the overall level of wild yeast contamination is based on this test alone.

For those interested, there was an article in Journal of the Am Soc Brewing Chemists a few issues ago in which the relative merits of the culture tests were compared. Each of the culture methods individually misses many wild yeasts.

George Fix suggests the old Whitbread might be contaminated, perhaps by a dextrin consuming yeast, *S. diastaticus*. *S. diastaticus* may well be a common contaminant of dry yeast because it is a pastry yeast and as far as I know every dry yeast processor makes oodles more bread and pastry yeast than brewers yeast. There is a culture test for *S. diastaticus* but the easiest method of determining if it is NOT there is simply to make some beer. *S. diastaticus* and many other wild yeasts make beer with the characteristic 'medicinal' taste. The compound responsible for this flavor can be easily detected by running the beer through a gas chromatograph and also, as we all know, by merely sniffing the beer. This is just one example of the value of sensory tests. Sensory tests are not only easier and practical but often more reliable than culture tests, particularly limited culture methods. It would seem that George Fix is also of this opinion based on the following quote from his book. "Perhaps the best way to detect yeast disorders is by examining their by-products and the

resulting alteration of beer flavors." George may have only been referring to respiratory-deficient mutants at this point which is yet another common problem of dry yeasts. There is a reasonable hypothesis that respiratory deficient mutants (aka petite mutants) are an inherent problem of large scale commercial production.

The value of any test is diminished by distance and time from the brewery, in this case the homebrewery. The viability of dry yeast is one area where this can be easily recognized. It's not surprising that freshly dried yeast is still viable. The far more pertinent issue for the homebrewer is the viability in 6 months, a year or 2 years. Of course the history of the yeast packet has a lot to do with answering this question, but a dated package would surely help the homebrewer.

Since the new Whitbread is not even available yet to homebrewers, it's impossible to perform the culture tests and sensory evaluations on packets of the yeast directly relevant to homebrewers. It may well turn out that the new Whitbread is an improvement over the old and also a good clean yeast, but George's data is simply too limited and too removed from the point at which the yeast will be used by homebrewers to reach that conclusion now.

Finally, I have heard that the new Whitbread is in fact not the old Whitbread at all. The old Whitbread was a mix of three strains. The rumor is that the new Whitbread is a single strain. Perhaps George or someone else can confirm or refute this.

you dispense it with several gadgets, including the one you mentioned.
The
cooler the keg is kept, the longer it will last but in typical basement
temps, the keg will be long gone before it spoils from the heat alone.

There is however a far better device for home use than the coil type
chiller.
First of all, I would not use copper for the coil and all the commercial
producers use stainless tubing to keep the greedy lawyers at bay.

The device of choice is called a cold plate. It consists of a
serpentine of
very narrow ss tubing, imbeded in a cast aluminum plate with in and out
fittings.

The plate is placed in a dish pan and hooked up between the keg and the
tap.
Ice cubes are dumped on the plate and voila, cold beer. Two cups of ice
will
chill several glasses of beer, depending on the ambient temp.

I have mine hooked up so that I can direct it to my counter-flow bottle
filler and it does a great job.

The major advantage of the plate over the coil job is that it only holds
about an ounce of beer and requires far less ice. You would typically
purge
the beer from the line between periods of non usage and the coils can
hold a
lot of beer.

On the other hand, for a picnic or large party the coil configuration
would
be more efficient.

For more information on cold plates and other beer type gadgets, you can
get
a free catalog from Superior Products by calling 800 328 9800.

>Subject: RE: HOP ALPHA ACID

<Keep in mind the logarithmic nature of the pH scale. In the 'real world' this difference in pH amounts to:

$(10^{-6.2})/(10^{-6.6}) = 2.5$ times the amount of free H in the Chinook tea

I can't find my old slide rule nor a log table and it does seem a bit simple minded to assume that if 1 unit equals ten then .4 must equal 4. Thank you.

- > The only significant anomaly was that on the third day, the
- > pH of both teas dropped to 5.7. They had been left
- > uncovered throughout the period but something significant
- > happened overnight of the third day.

<Distilled water in equilibrium with atmospheric CO2 has a pH of 5.6! Microbial action is also a possibility if the pH change was sudden.

Sounds like I am reinventing the wheel.

- > In conclusion, if the results are the product of Alpha Acid
- > in the hops then it should be possible to work out formulae
- > to determine the approximate AA of hops or at least
- > determine how much of an unknown hop is required to achieve
- > the same pH of a known hop.

<You may have something there, but I wonder what other types of acids might be present in hops that produce no flavor components. Ultimately we don't want to know the total acidity that the hops can produce in our beers, but the specific quantities of a particular class of acidic compounds.

Maybe we should redefine what I was trying to learn. As I recall, the whole notion of AAU and bittering units is a fiction created to help duplicate a given bitterness so as to make consistent beer. It produces a formula to guide the brewer in knowing how much hops to put in the kettle and what that number is based on is of little interest to the brewer as long as he gets an accurate number from the supplier to plug into his formula.

If another set of guidelines, that give the same results but based on a totally unscientific use of a pH meter, that anyone can purchase, it would be a boon.

I doubt that we could keep the producers honest by faulting the numbers on their packages but I am thinking more along the lines of helping the grower of hops who hasn't a clue.

Subject: chilling wort

I think I might be missing something in the discussion. I have a wort chiller made of about 15 to 20 ft of copper tubing that I run cold water through to cool the approximately two gallons of wort in my brewpot.

I have always assumed that since I am going to dilute the wort with cold water to bring the volume up to five gallons, I only need cool the wort to 100 degrees F, or 40 degrees C for our European and Canadian readers. I haven't noticed any bad results from this. My standard procedure is to siphon the wort out. What would happen if I just poured the cooled wort from the brewpot into the primary, skipping the siphon. I know that a lot of the leftover clumps of protein and hop residue would get in that would otherwise be left behind. Anything else?

John

Subject: Re: Immersion chiller

Andy says:

>I think you would want the exiting water to be warmer for a given
>length of tubing. The amount of heat removed from the wort should be:
> $(\Delta q) = m \cdot C_p \cdot (\Delta T)$
>where m =mass flow rate of water
> C_p =heat capacity
> (ΔT) =temperature difference= $T_{out} - T_{in}$
>So, if the flow rate increases, the heat removed increases, and if the
>temperature difference increases, the heat removed increases.

You're OK until you define ΔT , the ΔT that is important here
is $T_{wort} - T_{water}$ at each point along the chiller.

To keep this ΔT high you need to keep T_{water} as low as possible,
if T_{out} is high then the ΔT through the wall of the copper tubing
is low for the last part of the chiller, wasting cooling potential.

If you want to cool the wort as quickly as possible, you want the chiller
to be as cold as possible for as much of its length as possible, the way
to do that is to run as much water through it as possible, starting as
cold
as possible.

Stirring helps. On both sides of the copper. It might help to install a
wiggly wire through the length of the chiller to cut down on laminar flow
through the tubing.

I believe the whole problem is really quite simple, it's alot like
putting
ice into a glass of soda, more ice cools it faster.

Subject: Hard (Lager) Cider?

GOAL:
To make a Hard Cider?

PLAN:
I made a 1 quart yeast starter from Wyeast #2112, a California Steam Beer Lager Yeast (that ferments well up to 62°F).
I added the starter to 3/4 gallon of Apple Cider, affixed an airlock, and it's now fermenting in my basement (at 60°F).

QUESTIONS:

- 1) How long should I expect the fermentation process to last?
- 2) What would an ideal fermenting temp. be for such a concoction?
- 3) Is my result going to be a Hard Cider, or a (strange) Lager Beer?
- 4) I plan on conditioning the fermented result with either 1/6 cup of Corn Sugar, or 1 to 2 cups of Apple Cider - and then bottle it. First of all, is it necessary to do this conditioning? If it is, what ingredient is best, and how much should I use (for a 1 gallon batch)?
- 5) How long will such a (lager) cider last in bottled form?
- 6) Should I have submitted this query to rec.crafts.pyrotechnics?

Date: Tue, 13 Apr 93 10:02:39 -0400
From: Philip J Difalco <sxupjd@anubis.fnma.COM>
Subject: is it beer?

Now what did I do now?

I decided to stray from dry (Ale) yeasts, and start using liquid yeasts. My first endeavor is with the California Steam Beer Lager Yeast - Wyeast #2112, which is to ferment well up to 62°F.

I also decided to stretch out this supply. I made a 1/2 gallon starter, and then bottled it (making 6 samples).

Before making a foray into a 5 gallon batch of Steam Beer, I thought I'd make a 1 gallon test-batch of something - to test out my yeast-stretching attempt, and to guard against potentially wasting a 5 gallon investment of beer ingredients.

First, I made a 1 quart starter from one of the bottled yeast samples. After the starter was ready, I made a test wort.

My test batch consisted of about 1.5 lbs of light DME, 3/8 oz. of Northern Brewer Hops, 4 oz. Clover Honey and 2 oz. peach marmalade - all boiled for about 45 mins. This yielded about 1 1/4 gallons of wort (I never took an SG reading). After the wort cooled, I added the starter and wort to a gallon jug, affixed an air-lock, and placed it in the basement (at 60°F). I got good blow-off the first day and a half. It's been almost 6 days now and the beer is still actively fermenting (bubble approx. every 15s).

QUESTIONS:

- 1) This is my first attempt at a lager. I've never seen fermentation this active after 6 days. Is this because it's only a 1 gallon batch, or is this because of the qualities of a lager yeast?
- 2) Wyeast #2112 is supposed to ferment well to 62°F, but would it hurt to put this in a colder environment (my fridge)?
- 3) I'm not planning on bottling until the apparent fermentation ceases, or 3 weeks have elapsed, whichever is soonest - is this wise?
- 4) What should I call the resulting beer?

From: Ted Manahan <tedm@hpcvcbp.cv.hp.com>
Subject: Honey Wheat recipe
Full-Name: Ted Manahan

Don Leonard is looking for a honey wheat beer recipe. I have one that I have been quite happy with. This recipe originated as an attempt to take advantage of a sale on Brewmaker beer kits at our local homebrew supply store. Here it is:

Soak:

6 oz 20L crystal malt
2 oz chocolate malt
in water while heating. Remove malt when water reaches 170F. After the water boils, remove from heat and add
3.2 lb can Brewmaker Export Beer kit
3.3 lb can Munton & Fison Wheat malt extract
1 lb honey
1 t brewing salts (optional - my water is quite soft)

Bring to a boil. Hop schedule is as follows:

45 minutes: 0.5 oz 5.7 alpha Northern Brewer
20 minutes: 0.5 oz 5.5 alpha Cascade
5 minutes: 1.0 oz 5.5 alpha Cascade

Force cool with immersion chiller, pitch Steinbarts ale yeast in a 1 quart starter. After one week, rack to secondary. After one more week, rack to a keg and dry hop (in a bag) with 0.5 oz Cascade.

OG=1.050 FG=1.020

A few notes:

- 0) This produces a complex, brown beer with a lot of flavor. Dry hopping in the keg really makes a lot of difference in the hop aroma!
- 1) The OG reading seems a bit low, but I have gotten it twice. I also got 1.064 once using John Bull hopped extract instead of the Brewmaker kit. I suspect the Brewmaker kits of contributing less fermentable material than the "name brand" extracts. Another factor is that I am probably not consistent in the amount of honey I use.
- 2) I don't remember if I crushed the crystal and chocolate or not.
- 3) Steinbarts ale yeast is a mutant form of Wyeast Chico ale yeast.

Subject: Canned Guinness

We've got it here (Washington, DC). I picked some up because there was an article in Advanced Imaging last year about the can construction (the imaging tie-in was that a vision system was used to inspect the construction of the cans). The cans have a plastic button in the bottom that releases gas into the can after it is open (to simulate how it would be if it just came from a tap). It's a cute gimmick. I don't know, I don't care for the stuff myself.

Subject: Chimay: types and clones...

Greetings all,

I just had a friend bring me a bottle of Chimay (it's difficult to find in Utah) and was wondering which type it was. Miller mentions Chimay having three different colored caps (red, white, and blue) for different styles and Papazian mentions Belgian ales typically being done in three styles (House brew, double, and triple). I was wondering which was which. The bottle I have has a red cap.

Also, now that I've finally gotten a bottle of Chimay I couldn't resist the temptation to try and brew with the yeast from the bottle. I popped open the bottle last night, put the yeast into a starter and then thoroughly enjoyed the Chimay (good stuff!). I was planning on using Miller's all grain recipe for brewing Chimay. Has anyone used this and care to offer advice/modifications?

Thanks in advance,

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Filtering beer

John Isenhour spoke about his efforts at filtering beer in the last digest.
John the reason your beer didn't filter well is probably due to colloidal haze particals. These haze particals and proteins must connect together to form a large enough partical to filter out. The best way to do this is to chill the beer to 32 deg f for at least a week. If you can't get to 32 deg f then as cold as you can get it. I have filered beer with a .5 um filter and not improved the clarity! The quantity of these colloidal hazes is very dependent on the malt quality. After I switched to GW malt (from Breiss) my beers are much clearer before filtering. I also think I have noticed some head problems with the .5um filtration. I am planning a split batch filtration vs no filtration to prove this to myself. I'll post the results.

Subject: Mashing temps

I was amused by Carl J. Appellof's comments about what Michael Lewis at UC Davis said about mashing American grain. I have heard him say just the opposite! I sometimes think that Lewis loves to "tweak" people about the opposite of what they think is the only way to do something. He IS a teacher and this challenge to his students is a good idea. However, he seems to take it to the extreme. Cases in point. I have personally heard him say all of the following. "We here at Davis have never noticed anything (flavor or aromatic) from dry hopping", "decoction mashing is silly, our modern day malts only need a single mash temperature for complete conversion", and on and on. I would love to hear comments from students at Davis on Mr. Lewis's teaching techniques. From what I've heard and seen I'm not too impressed. He however does have an excellent staff! Mary Maranda is one of those that is overshadowed by Lewis and under recognized, IMHO.

Subject: Malted Rocks

All this frivolity about malted rocks has me worried. My father-in-law and I have put many hours into building a nice motor driven mill and I really don't want to crush any rocks, or have any rocks crush my mill. Any great suggestions for a sieve to filter out large rocks? With 10+ pounds of grain it is impractical to find them by hand. I haven't, BTW, found any rocks in the American or British malt I've used so far, but I've only done about 5 all-grain batches. The Zymurgy grain mill avoids major damage by rocks by holding the rollers with engine valve springs. I, on the other hand, skipped this option and am now wondering if I should regret that decision...

Cheers,
Norm

Subject: 3 micron filters; New Orleans

John Isenhour asked in HBD#1120 about the availability of filter cartridges.

I got my 3 micron filter several years ago from Zahm+Nagel in Buffalo. Their phone number is 716-833-1532. Ask for Al Lap. Their products are designed for commercial operations, and are priced accordingly.

Discussions with Jim Busch and others have convinced me that the 5 micron filters available to homebrewers can do just as good a job as the more expensive versions. Perhaps Jim can give us a review at the appropriate point of his own experiences.

George Fix

P.S. I hope those attending the IOB conference in New Orleans will look me up. Conrad Keys has informed me that he will be there with the first production version of his RIMS system.

From: Eric Wade <ericwade@CLASS.ORG>
Subject: Yeast Culturing Equipment

Thanks to those who replied to my request for sources (mail-order and otherwise) of lab glassware, etc. for yeast culturing. I've contacted the following four companies and requested their catalogs. I haven't received them yet so I can't determine if they have what I want nor how good their prices are.

Cole Parmer (708) 647-7600.
Friedrich & Dimmock (800) 628-2629
Chiron (800) 776-9154
Sigma (800) 325-3010

Notes: I believe I've seen Cole Parmer mentioned on the HBD before. Dean Lee, who sent me info on Sigma, says they are good about dealing with individuals, will take credit card orders, etc. Chiron sells products from more than one manufacturer and they want to know which manufacturer's catalog you want. Their catalogs list case prices but you can call them for prices on lesser quantities.

In all cases I identified myself as an individual who does yeast culturing at home; none of them had any problem with the fact that I wasn't a large corporate or university client.

For local sources: See if your local library (or employer, check with the procurement department) has a copy of the Thomas Register. It is an enormous catalog of industrial services and supplies. See volume 7, pp. 12,781+ "Glassware:Laboratory". Entries are listed geographically.

Finally, I know that yeast culturing can be done in beer bottles, milk bottles, wine jugs, etc. (I've got two 1/2 pt. milk bottles myself), I just like the toys and catalogs, you never know what you'll come across!

Repeat request: Any good sources of Belgian beers in the SF bay area, esp. east bay?

From: Mark Taratoot <SLNDW@CC.USU.EDU>
Subject: Beer Bread method (pretzels too!)

Greetings.

There was some talk a while back about making beer bread and several recipies and ideas were exchanged. Since then I have been doing a bit of experimenting on my own and have come up with a pretty good method.

Beer has been called liquid bread. I feel bread could also be called solid beer :) Indeed they are similar in their ingredients. There is nothing like enjoying a "slice" of liquid bread with a "hunk" of solid ale! Below are methods for making pretzels and bread from beer dregs. They are quite tasty!

I used to dump out the yeast cake from my fermenters onto my compost pile. My philosophy was that if more of the yeasts I like live in my environment, then if I get an infection in my beer, it is more likely to be a "beer friendly" yeast. I thought it would be a good idea to let the yeast live again and so I modified the L.A. Times pretzel article that was posted previously. The method is:

1. After siphoning off beer (to bottle/keg) swirl carboy around really hard to get as much of the yeast cake into suspension as possible. Pour it into a jar (to save the yeast to use within the next few days) or a bowl (to use immediately).
2. Add a bit more beer or other liquid to the carboy (dregs from bottles work fine). Swish this around and get the last of the yeast.
3. Add more liquid as needed (the more liquid you add, the larger the batch)
4. Add just a bit of sugar or honey.
5. Add flour to get the propper consistency (for pretzels, I have found that 2 cups liquid to 4 cups flour works. I use half whole wheat and half unbleached white flour.)
 - 5b. If you add an egg, it will rise more.
6. Knead. Allow to rise until doubled in volume. Knead again.
7. Roll into "snakes" and form pretzels. Put on greased tray.
8. Brush with one of the following, then sprinkle with salt if desired:
 - Egg (shiny rich crust)
 - Milk (crispy)
 - Butter (soft)
 - Nothing (easy)
9. Bake at 400 degrees for 10 minutes (approx) until just golden.

Pretzels are yummy and are a great idea for a homebrew club meeting. However, they are best eaten right away and they don't save well.

Making bread from beer dregs is also very simple:

Follow steps 1-4 above. I like to make large batches of bread so I can get 3-4 loaves from one breadmaking endeavour.

5. Add 2 cups flour (I use whole wheat) and let sit for half hour.

6. Add "stuff" (1-2 tsp salt, 1/3 cup melted butter or oil, 1/3 cup sugar or honey, and up to a couple of cups of the following: nuts, seeds, spent grains, etc.) and mix well.

7. Add more flour a little at a time (again, I use mostly whole wheat, but if you like white bread, use unbleached white flour) until the dough is firm.

8. Turn out onto a floured board and knead for 15 minutes adding flour until the dough is not sticky.

9. Put in oiled bowl and allow to rise, then knead again for another 15 minutes.

10. Form loaves. I like round loaves, so that's what I make. For loaf pans, grease them, for round loaves, sprinkle a tray with corn meal and put loaves on trays. Allow to rise again.

11. When doubled in volume, brush with melted butter (or other items listed above for different crusts) and bake at about 375 for 30-40 minutes.

12. Allow to cool 10-30 minutes, then enjoy.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)
Subject: The State of Beer in New Mexico

Strangely enough, there have been several requests of late about what there is to do in New Mexico with regards to beer. Even more peculiar is that I had gotten all of my info together before these requests came out :-)

Anyway, I have taken it upon myself to be the keeper (at least for now) of the "New Mexico Brewing FAQ". In it I catalog anything that has to do with both New Mexico and brewing/beer. I will send it out to anyone who requests it by email (my address is <hall@lanl.gov>). Here is the table of contents:

Contents:

1. Commercial Beer Establishments

- Albuquerque
- Santa Fe
- Los Alamos
- Taos
- Elsewhere

2. Homebrew Clubs

- Albuquerque
- Los Alamos
- Close to NM

3. Judges in NM

4. Competitions

5. Homebrew Supplies

6. Publications

7. Other

I think that this would be a good idea in other states too (or smaller areas, e.g. "The San Francisco Bay Area FAQ"). Maybe someone in each state would volunteer to keep track of all the info in his/her state.

Subject: cold break and blowoff questions

Seems like the more I brew, the more questions I have.

I'll still be an extract brewer for a little while. When I pour my gallon and a half of boiling wort onto three and a half of cold water, is that the dreaded Hot Side Aeration, or is that just a pretty good way of getting a cold break? Does the answer depend on whether or not I use a strainer to catch the hop gunk while pouring? (following Charlie)

So now I got my cold break. Do I have to rack the wort off this stuff before pitching yeast? or can it wait a few days until I rack to secondary?

There's a lot of talk about blow-off tubes lately. I assume you folks all use a carboy for primary AND secondary, since I don't see how a tube on my plastic primary would ever spit anything. (I may skim the next one, as js recommends.) I suppose too that you always brew exactly the same quantity, since blowoff volume would vary with the level of the wort in the vessel?

Well I just did my first Wyeast. And I had even made a starter. That baby was chugging 14 hours after pitching. By the way, how much extract syrup (not DME) does it take in a pint of water to make 1.020?

Thanks everybody. 'On a toujours besoin d'un plus petit que soi' (La Fontaine)

If only 1 in 3 gush, then I'd say either you did not mix the priming solution well with the green beer or you have inconsistent sanitation of your bottles.

Agreed that undermodified malt needs either a step-infusion or decoction mash for best results (protein splitting into amino acids, etc.), but the proper mash temp is dependent on what kind of dextrin profile you want in your wort, not on the grain type. I'm pretty sure that the DeWolf-Cosyns Pale and Pils malts are both fully modified (I'll check tonight and post a followup tomorrow) and can be used without a protein rest.

If you want a dextrinous wort, high in unfermentables, then do the sacchification rest (regardless of the mashing method) at the higher end of the saccharification temperatures (i.e. in the vicinity of 158F). If you want a highly fermentable wort, then do the saccharification rest at the lower end of the range (i.e. in the vicinity of 104F). Temperatures in between (e.g. 153F) will give you wort that is neither very high nor very low in dextrins.

Indeed it is easier, but just as you suspected, I've found that the hop bouquet is much, *much* more intense from dryhopping than from using finishing hops (last 5 minutes). Not only is contact time an issue, but the wonderful aromatics in hops are very volatile and therefore it takes very little boiling to drive them off completely. I'm afraid I don't have the answer to your question on water volume and extraction.

>1901 Guinness Extra Stout (In Ireland)
> 1075 6.3/7.91014 90

Note the year: 1901. A lot has changed since then. The Guinness on tap in Ireland is actually *lower* in gravity than the Guinness we get in bottles. Judging from my tastings of the Guinness in the special cans, I'd say that it's OG is also lower than the bottled variety, but it's been quite a few years since my last pint of Guinness in the Isles, so I could not say if in fact it was the same OG as the on-tap version there.

See Jackson's Pocket Guide for the exact gravities on modern Guinness.

>add some bitterness? How many i.b.u. worth? Does anyone think that
>lactic acid should be added?

I don't think you need to re-pitch champagne yeast -- I think the
#1084 will handle the OG you propose. The heavy stouts can handle a
great deal of IBUs, upwards of 100 to 200 -- my last Imperial Stout had
(I believe) 180IBU, but that was with an OG of 1120. I don't think
that lactic acid is needed -- the dark grains will provide plenty
of acidity -- in fact you may want to add a couple of teaspoons of
Calcium Carbonate to mellow the acidity unless your water is already
high in Carbonates.

Subject: sparge water acidification

Does anybody know of a cheap source of food-grade lactic or phosphoric acid? This would be used for acidification of sparge water. I'd like to not use more commonly available organic acids like wine acids or ascorbic acid. I can get lactic and phosphoric acids from the usual scientific supply houses (Carolina, for one) but the prices too high for "consumer" use. Has anybody heard of any homebrew supply shops selling this stuff via mail order for a reasonable price?

Here's a crazy idea for your collective speculation on its potential: Since colas are fairly loaded with phosphoric acid, and the pH of a cola is in the range of 2-3, I'm guessing that it would not take much cola to reduce the pH of my tap water to the desired range of 5.3 to 5.7. If the volume of cola required to bring the pH down is indeed quite small, I would guess that it's flavor contribution could also be quite small - if not totally unnoticeable in even the lightest beers. So, whaddya think? Is this plausible?

In response to: Subject: Reuse of Bottles in the USA, 11:27AM, 4/13/
93,
Russ Wigglesworth, et al.

The PETE bottles that soda comes in make excellent beer containers. Just make sure that they are the type with the plastic, versus the metal, top. They are available in one, two & three liter sizes, as well as the smaller sizes. The sanitization procedures are identical to those associated with sanitizing glass. In response to your suggestion re: standardization of containers, Switzerland, I have read, has a law that all beverage and food containers MUST be manufactured of PETE. Each container bears a \$0.10 (equiv. in SWFR) tax, which is used to finance the recycling of these containers. So, although the containers are not, per se, reused they are recycled on-mass with no separating, etc. I also consider myself an environmentally concious person and am delighted to be a recycling non-consumer by homebrewing. No taxes either (yet!).

Subject: Hops Primer

A Hops Growing Primer (ca. 1990 w/ additions)

- -- Acknowledgements to Peter Soper for writing the majority of this primer. --
- -- Thanks Pete! --

Hops for beer making grow from the rhizomes of female hop plants. Rhizomes look like root cuttings but have buds growing from them that will become new vines. Rhizomes also contain stored nutrients to support initial growth.

Hops grow vertically as one or more vines that spiral up a twine or anything else convenient. Depending on latitude, location, and variety, they sprout from about mid-March or April and grow through the summer and early fall. A single plant can easily grow 40 feet tall when it is mature but growth in the first year is usually much less. In most instances by the second or third year the plants will exhibit full growth. Height is very closely linked to the amount of sunshine the plant gets.

Hops grow best in full sun and you should pick a spot with the best possible southern exposure. Hops grow best in loose, well drained soil. Blended peat moss and sand make a good hops growing environment. In cases of poor soil drainage, it can be helpful to create a mound of soil a foot or so tall which will aid drainage.

Hops need lots of water. As they grow be sure to give them a very good soaking at least once a week. Mulch in the summer helps with weed control and also holds additional water. Also, hops have big appetites. Composted cow manure has been reported to be an excellent well balanced fertilizer.

Once a bed has been prepared the rhizomes are planted about four inches below the soil surface with any obvious buds coming from the rhizome oriented to point upward toward the soil surface.

After several inches or so the new vines should be thinned such that just the most healthy and vigorous three vines are left to continue growing. This will be an ongoing process as new shoots may show up later but the initial thinning

is an important one. It's been reported that the young shoots that are culled may be steamed and eaten like asparagus. On the other hand, some growers espouse cutting the new shoots at all, allowing all vines to grow to full height.

As the vines grow over a foot tall they should be trained to grow up a twine. This can be done by twisting the vine around the line. You may have to repeat this for a few days before the vine gets the idea. Remember, like most plants, hops will "follow" the sun, and so have a natural tendency to wrap from east to west, or counter-clockwise looking up for a south facing plant.

The most common hops trellis consists of strings running from the roof of a building down to stakes driven into the soil near the plants. Another option, often used by commercial growers, consists of a large central pole, with strings running from the top of the pole down to the foot of each plant, similar to the spokes on a wheel. Expect the string or twine to hold a lot of weight as the vines grow tall. A 25+ foot plant may weigh 20+ pounds.

Hop blossoms start out looking like large sand burrs and then take on a characteristic cone shape and grow in size. The size of a fully developed cone depends on the variety, varying from one to two inches long by one half to one inch in diameter.

The hops are fully mature and ready for picking when two changes take place. First, immature hops have a damp, soft feel and when squeezed slightly tend to stay compressed. Mature hops feel more like paper, spring back when squeezed and feel noticeably lighter. The second key test is to pick an average hop and cut it lengthwise down the center with a knife. When ready to pick the yellow powder (the lupulin sacs containing the essential oils and bitter substances that are "where it's at") will be a dark shade of yellow, like the stripes on a highway, and it will be pungent. If a light shade of yellow then chances are the hops are immature.

When ready to pick it is best to snip the stems of the cones with scissors or a knife to avoid jarring the hops and knocking lupulin powder out or worse, pulling the center of the cone out with the stem, causing a great loss of lupulin. Touching hops plants can cause skin irritation in some people; gloves and long sleeves can help in this matter.

Just picked hops are roughly 80 percent water; if left alone they spoil rapidly. For proper storage most of the water is removed by drying. A good

drying method it to lie the hops on a card or screen in an attic. Just a few hours during the heat of summer or a few hours more in cooler weather is enough to dry the hops. Use a before and after weighing and trial and error to try to achieve about 7-10 percent residual moisture after drying.

After drying, hops keep best at low temperatures and away from oxygen. A kitchen freezer easily takes care of temperature but to get the hops away from oxygen is difficult. Tightly packing hops in canning jars will minimize the trapped air but be careful not to use too much force and break the all important lupulin sacs since this accelerates oxidation. Purging the canning jar of oxygen by blowing in carbon dioxide from a kegging system will also help prolong freshness.

It's common to get 4 or 5 harvests per year by picking the biggest, most mature hops every two weeks or so as the flowers ripen. Patience and judgement are important since cones left on the vine too long turn brown and are obviously oxidized and spoiled, while immature hops have little lupulin in them.

At the end of the growing season when the leaves have fallen or turned brown, cut the vines at the surface of the soil and if possible remove the twine. After cutting back the vines a layer of three or four inches of mulch and composted manure can be put over the exposed vines for insulation and nutrition during the winter.

Japanese beetles are the number one nuisance in many areas. A common remedy is to position a "Bag a Bug" type beetle trap about 30 feet directly up wind from the hop vines. There is some concern that the "Bag a Bug" traps may actually attract more beetles than they catch, but that probably depends on the situation. Certain plants such as rose bushes may also attract the beetles, so it's best to keep those plants away from your hops. Also, the beetles' larvae live in the ground, and in cases of extreme Japanese Beetle infestation the surrounding lawn may need to be treated accordingly. A number of other pests, such as aphids, can harm hops, and can be treated with any number of pesticides. Remember, though, that you will be consuming these hops, and should use low toxicity natural pesticides, such as 1% Rotenone dust, for direct pest control on the plants. As with any consumable, you should ensure that any pesticide is well washed off before using the hops.

One other hazard is animals. A short fence of rabbit wire will keep cats, dogs, rabbits, etc. at bay. Deer have also been reported to be fond of hops.

Rhizomes are available from an increasing number of sources. American Brewmaster in Raleigh, NC and Freshops in Philomath, OR are two well-known suppliers. Cost is usually a few dollars each. They should be kept in plastic bags, moist and cold in your refrigerator until they are planted.

Additional information about hop growing can be found in "Homegrown Hops" by David R. Beach. Also, the 1990 special issue of "Zymurgy" is devoted to hops and contains an article about growing hops by Pierre Rajotte. The AHA also has additional hops-oriented publications.

> $(\Delta q) = m \cdot C_p \cdot (\Delta T)$
>where m =mass flow rate of water
> C_p =heat capacity
> (ΔT) =temperature difference= $T_{out} - T_{in}$
>So, if the flow rate increases, the heat removed increases, and if the
>temperature difference increases, the heat removed increases.

You're OK until you define ΔT , the ΔT that is important here is $T_{wort} - T_{water}$ at each point along the chiller.

To keep this ΔT high you need to keep T_{water} as low as possible, if T_{out} is high then the ΔT through the wall of the copper tubing is low for the last part of the chiller, wasting cooling potential.

If you want to cool the wort as quickly as possible, you want the chiller to be as cold as possible for as much of its length as possible, the way to do that is to run as much water through it as possible, starting as cold as possible.

Stirring helps. On both sides of the copper. It might help to install a wiggly wire through the length of the chiller to cut down on laminar flow through the tubing.

I believe the whole problem is really quite simple, it's alot like putting ice into a glass of soda, more ice cools it faster.

Carl

When I stop learning, bury me.

>
>
>

I think you misunderstood what I meant. I was showing the equation for the amount of heat removed from the wort by the chiller. This equation should be correct for this. If water at 40F goes in and comes out at 150F at a flow rate of 1 gal/min there will be a certain amount of heat removed from the wort(I didn't bother to calculate it). I was just showing that you can pretty much get the amount of cooling you want with a given chilling coil. If you increase the flowrate you are not going to get as much of a temperature drop. I do agree with you in that the amount of heat transfer depends on the temperature gradient from the wort to the water.

If someone could figure out the heat capacity of wort, you could figure out how much heat you needed to remove to get it to a certain

temperature. You could then calculate how long your wort chiller would take to cool the wort. (You could calibrate your wort chiller by cooling a volume of water and measuring the flowrate and the in and out temperatures)

Now, if I could only build a shell and tube heat exchanger for a wort chiller I'd be happy!!

Subject: Rollers

>From: pyle@intellistor.com (Norm Pyle)

>My father-in-law and I have put many hours into building a nice motor driven mill and I really don't want to crush any rocks, or have any rocks crush my mill. Any great suggestions for a sieve to filter out large rocks? With 10+ pounds of grain it is impractical to find them by hand. I haven't, BTW, found any rocks in the American or British malt I've used so far, but I've only done about 5 all-grain batches. The Zymurgy grain mill avoids major damage by rocks by holding the rollers with engine valve springs. I, on the other hand, skipped this option and am now wondering if I should regret that decision...

Perhaps, now that there are about 700 MALTMILLS (tm) out there, we have enough statistical evidence to suggest one of two things:

1. Relax, don't worry.....
2. Relax, don't worry if you have a MM

On the assumption that no news is good news, and I have only shipped one set of replacement rollers to date, we can assume that:

- a. rocks are few and far between
- b. customers are silently suffering
- c. the design of the MM makes it relatively immune to stones.

Commercial mills and the one in Zymurgy and Norm's have one thing in common, they use large diameter rollers. Generally speaking, these are preferable because they do not require knurling or texturing of the surface to get the grain to feed properly. They also have a higher throughput at a given speed. They also happen to be far too expensive for a mill designed to retail at under \$100.

The MM uses 1.5" diameter rollers with linear grooving to ensure proper feeding of the grain. The smaller diameter rollers just MAY make it very difficult for a stone to feed into the gap and just go round and round. It does not appear that any special safety arrangement is necessary.

The one set of rollers that a customer did destroy was done in by a wood

screw which probably was not in the malt. It was also running unattended with an electric drill doing the work. Not a good idea in the first place. To damage the steel rollers, a significant amount of noise and vibration would clue one in to turn it off. This also is another reason why a belt and pulleys are preferred to a direct drive. The belt will slip when the rollers jam.

I doubt that rocks would be a problem at all with hand cranked mills.

As far as a sieve to remove rocks, I would suggest that the most dangerous rocks are the ones about the same size as the malt and a sieve would be useless.

The .5" mesh screen that is on the MM is intended to keep fingers out. Anything smaller than this severely restricts grain flow.

Eric Wade <ericwade@CLASS.ORG> writes:
>Repeat request: Any good sources of Belgian beers in the SF bay area,
>esp. east bay?

Well, a couple. But they don't have what I'm *really* looking for:
Liefmann's Goundenband and Frambozen (available from the Admiralty
Beverage
distributor in Portland), and Rodenbach Gran Cru (probably not
available anywhere in the States).

o The Cannery Wine Cellar in SF had Timmerman's, Chimay, Orval,
Grimbergen, and I think St. Sixtus and more last time I was there.

o Cost Plus wine store in SF had Grimbergen, St. Sixtus, Chimay,
Orval, and some French Biere de Garde's and more last time I was there.

o Whole Foods in Palo Alto carries Chimay (including the small
bottles of Red!), Orval, Duvel, Hoegaarden, Steendonk, Grimbergen
Triple, Lindeman's, and the Celis brews.

o Safeway (!) in Mountain View carries Chimay Red, Orval,
Lindeman's.

o Liquor Barn Mtn View carries Chimay White and Red, Orval,
Duvel, Lindeman's, Satan, and I think a couple more.

Any more sources are Very Welcome.

Subject: Hard Cider

I'll address some of Phil's questions on hard cider, having dabbled with it myself and throw in my own two cents here and there...

As long as you start with sweet cider, the fermented result is hard cider. Add malt and you get a strange beer.

WRT yeast, I find there are three paths to take:

- * Control the ferment
- * Influence the ferment
- * Stand back and let it ferment

I prefer to influence the ferment. All I do is dump the cider on the yeast cake of my previous brew and let 'er rip. The yeast outnumbers the bacteria in this scenario and I've had good results thus far.

You can sanitize the cider with campden tablets, pasteurization or other means and introduce the yeast of your choice. I like ale strains for the ease of maintenance and the esters add complexity to the cider.

The opaque cider you get from a farm stand is already teeming with yeast. If you're a gambling type, just let it warm up and go it's merry way.

Conditioning: I like sparkling cider. The rate of 1/6 cup corn sugar to a gallon of cider sounds good to me. (3/4 cup to 5 gal, 3/20 cup to 1 gal is about 1/6 cup)

The cider should be ready for priming when it starts to clear, could be a few weeks. It should last indefinitely in the bottle, assuming you keep it cool.

P.S. This is the right place for this question, unless you over prime!

Regards,
John Calen -- Calen@vnet.IBM.COM

>I got good blow-off the first day and a half. It's been almost 6
>days now and the beer is still actively fermenting (bubble approx.
>every 15s).

First of all, if you wanted to test the yeast, you probably should have avoided bizzare ingredients such as the marmalade, I feel. Secondly, the marmalade has had pectin added and intentionally set, therefore your beer will have clods of pectin floating around in it.

Onward...

>QUESTIONS:

>1) This is my first attempt at a lager. I've never seen fermentation
> this active after 6 days. Is this because it's only a 1 gallon
> batch, or is this because of the qualities of a lager yeast?

Lager yeasts in general tend to be slower fermenters. Just because you used lager yeast doesn't mean you're making a lager -- it's the temperature that decides this. At 60F, you indeed, are making a steam beer, a sort of lager/ale hybrid halfway between a lager and an ale on the fruitiness scale.

>2) Wyeast #2112 is supposed to ferment well to 62°F, but would it
> hurt to put this in a colder environment (my firdge)?

It would slow the ferment down even more and make the beer more lager-like in the end.

>3) I'm not planning on bottling until the apparent fermentation ceases,
> or 3 weeks have elapsed, which ever is soonest - is this wise?

Wait till fermentation ceases -- if you bottle based upon time and not activity, you're asking for glass grenades.

>4) What should I call the resulting beer?

Call it Apricot Marmalade Steam.

>for the stuff myself.

The plastic bubble in the bottom of the cans is full of beer, not gas.

This

plastic bubble actually separates the can into two sections, a small one and a large one. When you open the can, the pressure drops in the big section. Now there's a pressure differential between the big section and the small one. This forces a stream of beer from the high-pressure small section into the beer in the low-pressure large section, through a small hole, causing the beer in the large section to foam. Gosh, the stories people come up with -- when these cans were just introduced, some people dreamed up all kinds of stories about nitrogen being in the bubble and dry ice being in the bubble!

Personally, I like the bottled version better.

Corby writes:

>in three styles (House brew, double, and triple). I was wondering which
>was which. The bottle I have has a red cap.

There are actually, four varieties of Chimay available in the US. I feel that the 750ml, corked bottles are different enough from the 330ml, crown-capped versions, to be considered a different type. I would not have investigated this difference if it had not been pointed out by Jackson in his Pocket Guide to beer. I agree with him that the corked versions tend to age slightly differently, due to the porosity of the cork -- I feel they tend to be more oxidized, but it adds an additional complexity to the beer.

There's a problem with the AHA's definitions in the Trappiste Beers area. Indeed, there are several beers that are loosely in the Dubbel style and several in the Tripel style, but a great many that don't fit into these categories. For example, Orval is a House brew, and Westvletteren's Abt (available here as St. Sixtus, albeit brewed by a secular brewery) is not a House, Dubbel or Tripel. It would be better if the AHA created a subcategory called "Trappiste, Other" and specified that further clarification must be listed (as they do with Fruit or Herb beers). I'll make this suggestion if I'm asked again to be a member of the National Homebrew Competition Committee.

Luckily, Chimay's red fits the Dubbel category quite closely, so that's what you tasted. The Blue-capped 330ml bottles are similarly a Dubbel, except brewed from a higher gravity. The White-capped 330ml bottles are much paler -- too pale for a Dubbel and quite highly hopped. Although it's new name escapes me, the Burgundy-labeled 750ml bottles are the

jumbo-version of the red, the 750ml Cinq Cents are the jumbo-versions of the white and the 750ml Grand Reserve are the jumbo-versions of the blue. The blue-capped 330ml bottles are vintage dated.

Bob writes:

>John Isenhour spoke about his efforts at filtering beer in the last digest.

I'd like to add that there's a good article in the 1992 Beer and Brewing (AHA Conference Proceedings) on filtering by Steve Daniels. He advocates only the polypropylene pleated filters and warns of all the problems he encountered before he switched to this style of filter.

I wrote:

>Agreed that undermodified malt needs either a step-infusion or decoction
>mash for best results (protein splitting into amino acids, etc.), but
>the proper mash temp is dependent on what kind of dextrin profile you

>tonight and post a followup tomorrow) and can be used without a protein
>rest.

I've checked (according to Noonan's descriptions) and indeed the DeWolf-Cosyns Belgian Pilsner malt is fully modified -- the acrospire (sp?) is consistently the entire length of the kernel.

Subject: filters/Dr. Lewis/biscuit malt

In the last digests:

<Went to a presentation by Dr. Michael Lewis from U.C. Davis a few
<weeks ago where he said that a temp. step mash was absolutely
<essential to give best extract yeilds and fermentability when using
<American lager malt (aka "klages" in this neck of the woods). He
<also said that with British Pale Ale malt, a single temp infusion mash
<was best. I get the idea that the mash temp profile really depends on
<what your malt was designed for.

Ahhh, from the guru that claims that domestic 2 row converts in 5
minutes!

I have to agree with Bob Jones on the statements made by Dr. Lewis, take
them

with a grain of undermodified 6 row. The bottom line in my opinion is
that

all malts have thier attributes and many a fine beer can be made using
one of the three common techniques, step mashing, single infusion, and
decoction. Most malts to be found in the US (domestic or imported) can
produce a well made beer using any of the three techniques. In the past
I always used a step mash with 2 row domestic. Recently I do a infusion,
rest at 154, then mash out at 170. Works real good. The fun part of
brewing is to mix ingrediants with techniques and still create wonderful
beers. For a supper malty bock/speciality beer a decoction is almost a
must (even when using domestic 2 row). For a wheat beer with more than
40% wheat malt, again a decoction is a must. For many pale ales, and
porters/stouts one can use a infusion or a step. An issue to be aware of
when doing a step with domestic 2 row is that the time it takes to rise
the temp from 122 to the 150s will have several minutes in the 140s and
lots of conversion is taking place at these temps, resulting in a higher
fermentability, regardless of the sacchrafication rest temp. Note that
Dr. Lewis was pointing out how to maximize extract and fermentability,
and a step mash will indeed do this. When using the "Worlds Greatest
Yeast,tm" fermentability is the last of my problems, I do everything
I can to maximize my dextrin pool.

Re:filters, I believe submicron filtration is the wrong way for
homebrewers

to go. Cold conditioning, followed by filtration down to 3-7 microns
works

for my primary goal, yeast removal. If the still beer is not
rediculously

high in yeast cells, 5 microns works for me. I had a keg that was primed
with sugar, already had way too much yeast, and after filtration at 5
microns,

still was way cloudy. But, the beer went from undrinkable (looked like
Widmers "hefeweizen" :-)) to cloudy but delicious. BTW, I used a store
bought

spun filter to "coarse" filter my Barleywine and it worked. Disposable,
though is not too efficient.

RE:Biscuit malt. I used about one pound of this in a pale ale that had
50 lbs 2 row domestic, 5.5lbs caravienna and 2.4 lbs caramel 40, 3 lbs
Belgium Munich. I made this same recipe with aromatic instead of
Biscuit,

and was I suprised to see how much darker the biscuit made the wort. Some
pretty powerful stuff. Too early for taste results as it is currently
fermenting away.

Good brewing,
Jim Busch

>with malt extract
>(1 1/4 cup to 5 gal) and now about 1 in 3 bottles gush. Is it possible
>fermentation was stalled that long and picked up in the bottle? This is
>not a big problem, since we can easily open bottles over a sink, but I'd
>like to be sure when fermentation is complete.

I have been kegging this year, but I eliminated my bottle carbonation problems in the past by using a sugar analysis test kit. These kits, which are basically just diabetic urine kits, allow you to measure the amount of residual sugar in your beer and then prime accordingly. If you let your beer ferment out, then this is unnecessary. But if you have a long slow fermenting batch or just don't want to wait, determining the residual sugar is a big help.

On batches that I have bottled, I have found that I usually didn't need the full dose of priming sugar and scaled back accordingly. On one batch, the test revealed that I didn't need to prime at all! My carbonation levels have been very consistant using this technique.

The kit I bought from a homebrew store cost about \$20 and included a bottle of tablets, a test tube, a small pipet and some instructions. You could probably get away cheaper if you bought a kit directly from a pharmacy and worked out the conversion (from urine test to beer test) yourself. But the kit comes with 100 tablets, so the cost is only about \$0.20 per test.

As to why your beer did what it did, I can only speculate, particularly without additional information. That sounds like a little too much priming extract to me, but that may not be a problem.

Beer is mysterious.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>
Subject: cold break, stout

Kirk Anderson's questions about cold break were discussed at some length back in the fall. However, in the interest of reviving old topics (there may always be some new information), here's what I have been doing.

(1) I boil about 4 gallons, which shrinks to three after a one-hour boil.
(2) I don't have a wort chiller, so I put my brewpot in a sink full of ice & cold water, and I dump in two gallons of pre-boiled and chilled to almost-frozen water on top. This produces a good cold break and gets the temp down to the high eighties or so in a half hour or less.
(3) I DO rack off the cold break into a bucket, where I then add yeast starter solution and stir vigorously to aerate.

Then I rack into 5-gal. glass primary and use a 1-inch bolwoff tube (Diameter of course, not length!:-))

It seems to me that racking off the cold break and blowing off have produced better beer, but I can't prove it. I've only made about twenty batches (last half dozen or so this way) and I find these procedures relatively easy to handle for a not-very-experienced brewer.

Regarding stouts, here is a recipe which I made recently and liked quite a lot.

6 lbs. William's English Dark

1/4 lb each dark crystal, black patent, & roasted barley

hop schedule went something like:

1/2 oz. Chinook, 60 min.
1/2 oz. Chinook, 30 min.
1/2 oz. Fuggles, 15 min.
1/2 oz. Kent Goldings, 5 min.

Wyeast Irish

3/4 c. corn sugar to prime

I steep the grains for a good long while (at least an hour) in a separate pot and then sparge through a strainer into the brewpot. I don't have a thermometer to control the temp., but I guess this is sort of a "partial mash," or at any rate I think I get better results than when adding the grains to the pot in a bag and then taking them out before boil is reached.

This is a delightful stout, if on the light side (like I hear bottled Guinness is these days anyway) and even came out with a little bit of a

Guinness-y "tang." I wasn't using a sour mash or anything - maybe it's the recipe, or maybe just a lucky infection :)

Regarding the "Irish" Wyeast: I love it! And I made an Imperial Stout with it too, and the Irish yeast chomped through it just fine, so I would say it handles high-gravity brews pretty well.

"Date: Wed, 14 Apr 93 11:01:10 -0400
From: Philip J Difalco <sxupjd@anubis.fnma.COM>
Subject: Hard (Lager) Cider?"

"QUESTIONS:

1) How long should I expect the fermentation process to last?"

A couple of months. Lots of complex sugars in cider.

"2) What would an ideal fermenting temp. be for such a concoction?"

Depends on the yeast. You're using lager ? 55 F.

"3) Is my result going to be a Hard Cider, or a (strange) Lager Beer?"

Cider. (Shades of Lysenkoism !!)

"4) I plan on conditioning the fermented result with either 1/6 cup of
Corn

Sugar, or 1 to 2 cups of Apple Cider - and then bottle it. First of
all,
is it necessary to do this conditioning?"

No.

"If it is, what ingredient is best,"

I think cider is a good choice.

"and how much should I use (for a 1 gallon batch)?"

Wing it. Try 1/4 cup to start.

"5) How long will such a (lager) cider last in bottled form?"

Dunno. Depends on local conditions and taste. You are on the frontier of
brewing, there are no precedents, you are making them as you do this.

End of HOMEBREW Digest #1122, 04/19/93

Date: Sat, 17 Apr 93 10:09:52 -0700
From: pascal@netcom.com (Richard Childers)
Subject: Immersion chiller architecture

"Date: Wed, 14 Apr 93 11:47:29 EDT
From: eisen@kopf.HQ.Ileaf.COM (Carl West)
Subject: Re: Immersion chiller

"Stirring helps. On both sides of the copper."

Agreed, I don't think this is being addressed at all.

Despite the desire not to aerate the wort, if the wort is not moved around, somehow, it will develop relatively weak convection currents that will act to move the wort around very little. As a consequence, an insulating wall of wort of intermediate temperature will build up around the coil, much as an intermediate layer of water, in a foam-layered SCUBA suit, warms up to body temperature and then acts as an insulating layer between one's body and the colder outer ocean.

This can be corrected by building a immersion chiller strong enough to be used as a slow stirring mechanism, also. Unfortunately, this leads to thicker walls on the copper tubing ... which translates into less efficient transfer of heat from hot wort to cold water. Perhaps a 'skeleton' of a stronger wire could be wrapped, helix-style, around the softer and thinner copper tubing, to hold it and protect it from being bent by impact against the sides of the container.

"I believe the whole problem is really quite simple, it's alot like putting ice into a glass of soda, more ice cools it faster."

On that thread, has anyone considered a parallel chiller architecture ?

It would increase the available surface area available to the coldest water, as it enters the chiller and contacts the hottest wort (which would, I'm speculating, be at the top, assuming no heat is entering the system), and, all other things being equal, I speculate that there would be a fairly straightforward linear relationship between the speed wort chilled at and the number of fixed-length, unstricted-surface-area chiller segments in operation ... just as there is between the number of ice cubes one drops in a glass of water, and the speed at which it cools (again, assuming that the actual surfaces through which the heat is transferred remain free of obstructions).

I must say, this is a fascinating little thread and I'm waiting for someone to integrate it all and generate a matrix of optimal architectures out of the cross-indexing of length, diameter, wall thickness, architecture, and flow rate. (For purposes of simplification it seems best to assume that the wort will start out at just below boiling, worst case, and the water at just above freezing, say, 35-40 F, worst case.) While there may be no absolutely 'best' solution or architecture, there absolutely is a set of, shall we say, optimal solution to this particular problem in physics, just as there is a fairly finite set of possible container geometries within which the chiller is immersed ...

Date: Mon, 19 Apr 93 07:55 CDT
From: arf@genesis.mcs.com (Jack Schmidling)
Subject: BREAD YEAST

One of the first "Momilies" I addressed shortly after starting to read the Digest was the seemingly hidebound belief that bread yeast makes lousy beer.

This was shortly before I became a born-again yeast culturer.

I decided to check out the bread yeast momily but knowing what I had learned about culturing, it seemed only reasonable that the test should be done on a pure cultured bread yeast. I suspected the real problem with bread yeast was the same as in all dry yeast, i.e. contaminants other than the culture yeast.

I pure cultured some Fleishman's bread yeast on petri dishes and then to slants. The real problem became one of committing a batch of beer, with all the expense and time that entails to the experiment. So the slants sat in the fridge for months.

Well, I finally got around to doing it. On March 12, I brewed up a 7 gal batch, using "only the finest ingredients". I even got a yield of 33 on this one and I pitched the bread yeast.

The primary at 55F was nominal and I pumped it to secondary a week later and noted a decided clove taste. As of Apr 16, it was still fermenting moderately with not a sign of clearing.

I decided I had tied up the equipment long enough to learn what I wanted to learn and kegged 5 gallons of it. I force carbated this and took it to a CBS meeting to share this great science with the rest of humanity.

With the notable exception of one nameless individual who thought it was "kinda nice", there will not likely be a sudden conversion to bread yeast at CBS. When I later made the rounds with a rather good lager, people sort of turned around and made like they didn't see me. I had to do a real sell job to get them to try this one.

The clove taste was, in my opinion, overpowering and rendered the beer more or less undrinkable. What is interesting is that I have made this very same beer before using Red Star beer yeast, even to the never-ending fermentation.

My suspicion is that Red Star beer yeast is either severely contaminated with

their bread yeast or IS their bread yeast.

.....

I also finally got around to trying a Wyeast primarily because Tim Norris practically forced it on me. It was the 2206 Bavarian and I pure cultured before using it. I brewed a batch of Munich style lager and it made a decent beer but can really say not much else about it. It was pretty nominal as far as my taster is concerned.

However, it is worth nothing that the two petri dishes have been sitting on my lab table for 6 weeks now and there still is not the slightest sign of contamination. I innoculated two plates directly from the package just by dipping the innoculating needle into the liquid. I dipped twice, once for each plate, to increase the possiblity of picking up a contaminant. One was opened once to innoculate slants and the other has never been opened. This speaks well both for the yeast and my procedure.

Subject: Pet peeve--Belgian beer "styles"

Al Korzonas recently took a jab at the AHA's beer style classification system, with particular reference to their Belgian beer categories. Way to go, Al! Usually I preface this sort of thing by saying "Don't get me started", but since it's too late already...

Where does the AHA get off classifying these beers as doubles and triples?

It seems to me that this classification is based on the beers of Westmalle, but there are lots of examples that don't conform. Orval is obvious. Rochfort offers its beers in 6, 8, and 10 degrees, as to many "abbey" brewers. If the 6 is a double and the 10 is a triple, what's the 8--2.5? Where does Chimay's Cinq Cents (a partial-wheat beer if I'm not mistaken) fall into this? Frankly I think it's ridiculous to have style parameters when the entire population of breweries in this style only equals five.

Sad to say, I think that Michael Jackson is responsible for much of the incongruity we see in the style listings, as these closely mirror his own scheme in the World Guide to Beer. Personally I've never heard a Belgian refer to Liefman's as a Flanders Brown, for example. I think Pierre Rajotte was a lot closer to the mark when he stuck to commonly accepted terminology and the Belgian classification system based on O.G.

Sorry, I'll get off the soapbox. However, I must say it irritates me to submit beers to contests where judges who may have only had a few beers of any given type in their lives will be ranking my beer based on these misconceived numbers.

Subject: a few observations

First, thanks to whoever started this conversation about rocks in malt. Never heard of such a thing, until this Sat. when the Corona went "crunch" on one. Nothing broke, just don't start talking about severe infection problems, ok?

Anyway, the grain (minus the rock) seemed quite soft when I was grinding it, which I attribute to it being stored in a not-exactly-dry garage for the last few months. But it crushed beautifully, in fact I had to admire how perfect the crushed grains looked. It mashed/converted just fine, and, it sparged sparkling clear immediately. I mean the first few *drops* were clear and it stayed that way, with an unrestricted flow. This is with the Gott cooler type of lauter tun. My guess is that the moisture in the grains allowed the Corona to sort of squeeze the shells open rather than grind them to dust; there was much less flour than usual.

Unfortunately, damp grains are not usually a good idea (they tend to spoil), so don't go soaking your grains to get a great sparge. I just happened to be lucky.

Again I chopped the whole hops in a coffee blender, and I'm getting convinced this is a very good idea. Besides the probable better utilization, they helped form a solid trub bed in the brewpot, and filtered so well I was able to rack almost all of the liquid from the pot. There may be a connection with the World's Greatest Sparge (tm) here also.

I plan to dryhop one of the batches with ground whole hops in a mesh bag; I'll report back anything interesting.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Immersion chillers

I finally got around to making my immersion chiller over the weekend. I used 25' of 1/4" tubing in a plani-spiral (like an electric stove burner). The input and outputs hook over the side of the pot, and the final (outer) coil cuts straight across the bottom of the coil (perpendicular to the input), and down to the bottom of the pot, across and back up to the coil before joining the input end over the edge of the pot.

Thus it supports itself about 2" or so below the surface of the wort.

From

test runs (I haven't tried on an actual beer yet) I can recommend that anyone wishing to use 1/4" tubing to save money (like I did) either go for

the 3/8", or make sure your connections are really secure. 1/4" tubing has

a very high resistance to flow. Remember, resistance to flow is the 4th power of the diameter of the tubing (ie reduce diameter to half, resistance goes up 16 fold).

In my case I (perhaps stupidly) bought 1/4" tubing because it was \$7 cheaper than the 3/8", and I already had most of the connectors, whereas

I would have had to dish out an additional \$7-8 on connectors for 3/8" tubing. I first connected it with rubber lab hose to the sink, and the hose swelled up like a ballon.

Anyway, any suggestions on whether to cool from outside in or inside out?

From: "UARS::COOK"@CDHF1.GSFC.NASA.GOV (Chris Cook)
Subject: Rocks in Belgian Malts

On the subject of rocks in the malt, I've had small rocks jam my MaltMill in two out of the last 8 or so batches. In both cases I had to stop, take the grains out of the hopper and actually unscrew the hopper to get the rock out of the mill. Worse, the rocks left scars on the rollers in both cases, smearing an arc of those careful grooves flat. Jack was right, though, when he said that, with the o-ring, the second roller would just slip, saving the mill from any serious damage.

I've been using the Belgian malts almost exclusively, so I don't have any idea whether this problem is widespread or just with these malts.

Mind you, one thing that aggravates my problem is my ongoing affair with high-gravity beers. It's been a problem ever since I started all-grain brewing: if it's less than 10 pounds of grain, I don't make it.

It's all Jack's fault: his mill made things too easy.

Chris Cook

From: "UARS::COOK"@CDHF1.GSFC.NASA.GOV (Chris Cook)
Subject: First and Second Runnings

Speaking of high-gravity beers, he said, I've been going to really big beers recently, with a grain bill from 25 to 30 or more pounds of grain for 5 gallon batches. The first runnings are the barley wine, double bock, Russian Imperial stout or whatever, and the second runnings are enough (with a pound of DME) to easily make an ordinary beer.

Easy was the surprising keyword, too. I'm all set up for the first beer anyway: I've got the pots dirty, the starter's foaming away, the sterilizer stuff mixed up, the hoses soaking and small parts waiting, the immersion wort-chiller all hooked up, everything. It becomes kind of an assembly line affair.

You can figure the procedure. After getting enough wort for the first beer, continue the sparge for the second. Chill the first batch while finishing up the boil on second. When the first batch is cool, pitch using 2/3 of the starter (I use more starter for this batch because of its gravity). Finish any last-minute hopping on the second wort, take it off the stove and move the wort-chiller (immersion) from the first pot into the second. After a little sloshing and swirling (if you like that kind of thing) start the first beer syphoning. The syphon usually finishes before the second batch is cool; I just leave the hoses in place until I'm ready. When the second wort's cool, I pitch the last of the starter in that wort, swirl again and move the syphon hose to the second wort.

I'm using the same equipment, I'm just using it twice instead of once. I plan the batches using the same yeast, so there's only on starter. I've noticed that the second beer is quite a bit lighter than the first, and you can always make more changes by adding more malts to the lauter-tun. The hopping is completely up to you, of course.

One thing that helps a lot is using a second cooler to hold the sparge water. That frees up the stove, calms my mind and generally organizes my frenetic procedures. The poor thing's a swelling 44 quart Coleman cooler I wouldn't choose on purpose, but it's what I had for free in the basement and it works. I fill it with the sparge water at 185 to 190, and I'm good to go for both batches. I know that that's too hot, but the water has to stay hot after heating the cooler, waiting for up to two hours and running slowly through the plastic hose into the lauter-tun. My sparge pH is naturally low, and I figure that, if it's not perfect, I'm only making beer.

I remember an article in Zymurgy where someone recommended brewing two batches staggered together, but I thought it would be way too much work. I think I was wrong. It took me a little longer, but only an hour or so, and

that's completely without prior planning. The cleanup was the same. If you're interested in high-gravity beers, I recommend going for two.

Subject: 1993 Mazer Cup Mead Competi

Subject: Time:11:13 AM
OFFICE MEMO1993 Mazer Cup Mead Competition Date:4/19/93

We wish to announce the 2nd annual Mazer Cup Mead competition. Full information and entry forms have been published on the mead lovers digest. They may be obtained from me via e-mail either electronically (preferred) or via snail mail upon request. An edited version follows.

1993 MAZER CUP MEAD COMPETITION

ELIGIBILITY:

This is an AHA sanctioned event. All Makers of Mead are eligible. You may enter as many categories as you like, but are limited to one entry per category.

ENTRY REQUIREMENTS:

- (1) Each entry will consist of TWO (2) BOTTLES of at least 177 mL (6 oz) but not more than 750 mL (25 oz) preferably, 12 oz. Both corked and capped entries are acceptable. Black out identifying marks on bottles or caps.

[snip]

WHEN, WHERE, HOW:

- (1) Entry fee is \$5.00 per entry. All North American entries will be accepted between Monday June 7 and Friday June 18, 1993. International entries will be received anytime before June 18.
- (2) First round judging will be held on Friday, June 25.
- (3) Best of Show judging will be held on Sunday, June 27.
- (4) Make checks Payable to: Dan McConnell, Mazer Cup Mead Competition.
- (5) Entries can be dropped off or shipped to the following location:

MAZER CUP MEAD COMPETITION
c/o Dan McConnell
1308 West Madison
Ann Arbor, MI 48103

AWARDS AND PRIZES:

The beautiful mazers are hand-thrown at the prestigious Pewabic Pottery.

- (1) The AHA/HWBTA 50-point rating scale will be used, with 25 points required for award eligibility.
- (2) The brewer of the 1st place in each category will be receive a ribbon and a mazer.
- (3) The brewer of the 2nd place in each category will be receive a ribbon and a mazer.
- (4) The brewer of the 3rd place in each category will be receive a ribbon and a mazer.
- (5) The BEST OF SHOW will receive the Best of Show ribbon and the coveted hand-crafted communal mazer.

FOR MORE INFORMATION, CALL:

Ken Schramm, Competition Director 313.291.6694
Dan McConnell, Competition Registrar 313.663.4845
Hal Buttermore, Judge Director 313.665.1236
Mike O'Brien FAX 313.485.BREW

MISC INFORMATION:

- (1) e-mail to Dan McConnell will get you a snail-mail copy of this flyer (in color!) and entry forms. Last year entries-check your mailbox.
- (2) User printed forms are acceptable and encouraged.
- (3) Qualified Mead Judges are invited to judge this event. Contact Dan McConnell via e-mail or Hal Buttermore by telephone.

MEAD CATEGORIES:

1. SHOW: Mead consisting of honey, water and yeast ONLY. No spices, fruit or other flavoring additives permitted. Addition of water treatments and acidification is permitted.
2. TRADITIONAL: Mead consisting of honey water and yeast. Other flavoring additives are permitted in small amounts, but the primary flavor must be of honey.
3. MELOMEL: Fruit, other than Grapes or Apples.
4. CYSER: Apples.
5. PYMENT: Grapes.
6. HIPPOCRAS: Spiced Pymment.
7. METHEGLIN: Herbs and/or Spices.
8. BRAGGOT (BRACKET): Malted barley (must be at least 50% honey).

SUBCATEGORIES:

- a) Sparkling.
 - b) Still.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: getting rid of DMS

Having narrowed down the causes of my lager off-flavours to (way-)too much DMS either from bad yeast or slow cooling, I was wondering if there is any way to flush out the excess DMS? Is there any way to encourage the yeast to consume it, or will renewing fermentation at a higher temp scrub out some of it? It's pretty undrinkable now, is there anything I can do apart from bottle it in 2L bottles and hand it out to my friends who don't know any better? Is there anything (non-toxic) that will remove or neutralize DMS (like maybe fruit acids or hot peppers)? I really hate throwing away a brew.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: dry hopping - HELP!

I tasted my first batch of dry hopped beer yesterday. The effect was great, but I was disturbed to see all this "stuff" in the beer. It was sticking to the sides of the bottles, which had to be rotated to loosen it so it would sink. It only "sort of" sank and they all have this fairly thick, loosely packed layer on the bottom - not at all pleasant.

Undoubtably the problem is that I dry hopped with pellets and just threw them in the secondary (allowing extra space for the frothing which occurred). I assumed they'd all sink to the bottom but apparently there was enough in suspension to give my sediment problem. I left them for a total time of one week. I can think of two ways to get around it and would like comments from those with experience.

(a) Use a fine-mesh hop bag for the hops. Would this reduce the extraction?

(b) Use the same hop bag tied around the end of the racking cane when siphoning out. Would this become clogged?

Any comments are most welcome.

Peter

P.S. In my darkest nightmares I have the picture that the sediment is not hops at all but due to some horrible infection. Is any infection likely to produce stuff like this?

From: jay marshall <marshall@sweetpea.jsc.nasa.gov>
Subject: clarity (Breiss vs GW)

in #1121 Bob Jones says:

> After I switched to GW malt (from Breiss) my beers are much clearer
> before filtering.

Does anyone else care to comment on the clarity of beers brewed with malts from different suppliers? I had not noticed any differences, but then I've not been looking for it either. I usually attribute variations in clarity and other qualities to my tendency to continually try new methods.

I have not looked specifically for those kinds of differences between the various suppliers. The reason I ask this is because I believe I remember a thread a while back about Breiss-based beer having higher levels

of DMS (due to their direct-kilning methods and the need to reduce nitrosamine levels using some kind of sulphur-based stuff??). If there is

a clarity difference as well, would it also be a by-product of their kilning methods, i.e. direct vs indirect?

BTW, I have two local suppliers of malt. The closest one has Breiss, the other (25 miles further away) carries GW where there is an option. If there is a consensus on this clarity issue, I might try and get the closer one to carry some GW.

I have been using 5 gallon carboys with a blowoff hose. It's a rare yeast that does not blow off enough room for an ounce of whole or plug hops. I tried dryhopping with pellets, but was disappointed with the results -- it appeared to me that the pellets sank to the bottom and were covered with dying yeast, thereby negating their contribution. The whole hops and plugs that I use now float for at least 10 days (although I've found that much more or less than 7 days provides less bouquet than 7 days exactly). Also, since the whole petals are much bigger than the small particles of pelletized hops, they are less likely to get sucked-up by the siphon hose. Last night, I bottled a batch of American Pale ale. The 1 ounce of whole Cascades had been in the carboy (the primary) for 10 days (a bit longer than I wanted, but unavoidable due to scheduling problems) and 95% of the petals were floating on top, 5% were just sort of suspended. I siphoned all but about 12 ounces out of the primary into the priming carboy and only one petal made it into the priming carboy. There was no clogging of the siphon. Even if that one petal had been sucked up during bottling -- I'm certain it would not have made it past the bottling valve.

Few bars still use "bar bottles" but you only need to find one. If you can't, you can try finding a liquor store that sells Huber or Rheinlander or even Budweiser in bar bottles (I know that Mainstreet Deli and Liquors

in Countryside does). If they sell the beer in bar bottles, they accept the empties. Mainstreet will sell you a case of empty Rheinlander bottles for \$1.20 and you get a nice, strong, waxed-cardboard box too.

> or 3 weeks have elapsed, which ever is soonest - is this wise?

I've used the 2112 for a half-dozen 5 gallon batches of steam beer,
I think what you're seeing is pretty typical of this yeast.

The yeast seems to be a fairly slow worker. I've fermented my batches
at 50F-58F, ambient basement temperatures at my place during the winter.
In each case, it took 9-14 days for the krausen to fall, and a good three
weeks for the beer to completely ferment out. My first batch, kegged
after
two weeks, had a fair amount of residual sweetness. An additional week
at 55F cleared that up, but I'm not surprised you still had significant
activity on day 6.

I believe 2112 is actually a lager yeast, one that doesn't produce
harsh
flavors at warm fermentation temperatures, hence it's use for steam beer.
It wouldn't hurt to put it in the fridge, but I don't think that you
would
get the muddy, rounded phenolic character of steam beer if you do. The
batches I made that were fermented at 58F had noticeably more of this
phenolic
character than the batches fermented at 50F.

It's always advisable to hold off on bottling until fermentation
ceases,
unless you're into glass grenades :-). Based on my experience with this
yeast, I'd advise you to wait at least three weeks.

Cheers,
Jim

FROM: Dennis B. Lewis <InterNet:dblewis@jscprofs.nasa.gov>
SUBJECT: Bulk malt

I have a question for the net regarding storage of bulk malt grain. I've started moving toward all-grains and I'd like to start buying the grains in the 55-lb sacks from a mail-order place to save some cash. One problem I can see right now is storage of the grains. I live in Houston and it gets pretty humid here in the summer. While the house is air conditioned, I'm not sure that the humidity is low enough to protect the grains. Anybody have any ideas? Is it worth my time and money? I suppose that I could do it seasonally and buy grains from the store for summer brews. I would probably go through a 55 lb bag in 2 maybe 3 months at my current brewing rate.

Thanks in advance for all the expert advice.

Subject: Re: Hops Primer

Russ Gelinias writes:

> Hops grow vertically as one or more vines that spiral up a twine or anything

...

> single plant can easily grow 40 feet tall when it is mature but growth

So we are talking a plant which after a year or two could reach 40 vertical feet. Maybe I am missing some obvious trick (can you train or force the hops to grow horizontally), but how do people handle such growth? Do you have weather balloons with twine attached to give the plants full growing room or just use telephone poles as the "plant stakes"?

And in either case, do you harvest using a crane or can you just scale the critter? Perhaps getting people to skydive in and grab a couple of cones on their way down would work, but I would probably have to cough up a homebrew for each in repayment and that would make for a tough trade.

Not that I am worried, mind you. I expect my brown thumb alone will confirm that none of my hop plants grow more than a manageable 4-5 feet. But in case my best efforts are unable to control their growth, what should I (have you) done?

Thanks.

From: l200-cu@garnet.berkeley.edu (mARK WITTEMAN)
Subject: "objective" beer tasting

I write this note as a humble submission for help from a group of people who obviously know their beer a whole lot better than I. I have been subscribing to HOMEBREW for about three weeks now, initially for the novelty of it, but now for the fun facts and information it gives me.

Besides being a beer enthusiast, I am also a masters student at UC Berkeley's School of Library and Information Studies. I am looking to wed an academic term project with my pension for good beers. More specifically, an instructor in the School has asked that we create a mock cataloging system for a collection of things (real or imagined -- and not necessarily bibliographic in nature) for a hypothetical library or other collection. My bright idea is to create a catalog for the bottled beers of California Micro-breweries! The catalog would allow for a detailed description of the beer including such things as:

- * Name of beer
- * Brewer and bottler
- * Ingredients (right down to the region or variety of hops and other stuff)
- * Color, nose, and flavor
- * Seasonality (Winter Ale? Spring Bock?)
- * Stylistic family (Porter, dry stout, IPA, etc.)

What I need help with is defining the proper terms and definitions needed to describe the type of beer (stylistic family, above) and the essential qualities of beer (color, nose, and flavor, above). Is there a handy book that lays out the rules of "objective" beer tastin and judging? Where am I likely to find it? For that matter, is there a source that will list all the brews of California?

Obviously, I am an amateur at the beer and ale game. I don't need mountains of information, just a detailed outline.

Perhaps you're thinking,

"Hey! This guy is a grad student, and a future librarian besides! Why can't he find this for himself?" Well, I've tried. If such a tome exists, it has eluded my best formulated search strategies. Take pity on me and send whatever information you think might help.

Thanks in advance.

Subject: Hops Primer: a historic addendum

Thanks to Russ Gelinias for sharing his primer. After reading it, I wondered if some of the books in my dusty library contained any relevant information. I was surprised to find a short essay on growing & harvesting hops in an old Family Encyclopedia. I have typed the material as best I can, any mistakes are probably mine and not in the original text. I wonder if anyone has a copyright on something this old?

A New Family Encyclopedia; or Compendum of Universal Knowledge: Comprehending a Plain and Practical View of Those Subjects, Most Interesting to Persons, In the Ordinary Profession of Life\_. Edited by Charles A. Gooch, New York, 1831. Section II, Art of Gardening, or Horticulture, p459.

" HOP. Any bit of a root will grow and become a plant. The young plants should be planted in the fall, three or four together in a clump, or hill, and the hills should be seven to ten feet apart. The first year of planting, put four rods, or little poles, to each hill, and let two vines up each pole, treading the rest of the vines down to creep about the ground. In a month after the vines begin to mount the poles, cut off all the creeping vines, and draw up a hill of earth around the poles a foot high, covering all the crowns of the plant. At the end of another month, draw some more earth up, making the hill higher and higher. When the fall comes, cut off all the vines, that have gone up the poles, a foot from the ground; take down the poles; dig down the hills, and open the ground all round the crowns of the plants; and before winter sets in, cut all down to the very crowns, and then cover the crowns with earth three or four inches thick. Through this earth, the hop-shoots will start in spring. You will want but eight of them to go up your four poles; and the rest, when three inches long, you may cut, and eat as asparagus. This year you put poles 20 feet long to your hops. Proceed the same as before, only make your hills larger; and this year you will have plenty of hops to gather for use. Be sure to open the ground every fall; and cut all off close down to the crown of the plants. They are fit to gather when you see, upon opening the leaves of the hop, a great deal of yellow dust, and when the seeds which you will find at the sockets of the leaves of the hop, begin to be plump. Gather them nicely, and let no leaves or stalks be among them, and lay them out on a cloth to dry in the sun, taking care that no rain or dew fall on them. When perfectly dry, put them, very hardly and closely pressed into a new bag, made of thick Russia linen; and in this state they will keep good, and fit to use, for twenty, or perhaps, three times twenty years."

The Complete Book of Edible Landscaping\_ from Sierra Club Books, 1982, includes the following information:

The vine can attain 25 feet in a season. A hop vine can be trained on a trellis or with support posts to become a small weeping tree, and therefore can be grown in a container or planter box. The vines require rich soil, good drainage, plenty of water after growth starts, and full sunlight. The book also recommends thinning the shoots early in the spring, and eating what you harvest. Mildew, aphids, and mites can be a problem.

An organic gardening encyclopedia I have contained information about what to do with the spent hops, including amounts of nitrogen and phosphorus, if anyone is interested. I was going to send it as well, but this has gotten pretty lengthy and my fingers are worn out.

Subject: Whitbread warning

In HBD #1122 George Fix suggests calling Seth Schneider at Crosby and Baker for first hand information regarding the Whitbread and Mauri yeasts. Curiously, my posts on this subject were in part based on first hand information contained in recent conversations with Seth. These chats were in fact prompted by George's earlier posts. It was Seth's opinion, in view of all the data including George's plate counts, that the new Whitbread should be regarded as neither inferior nor superior to the old Whitbread. As of two weeks ago, Crosby and Baker had not decided whether or not to distribute the Mauri yeast.

Subject: damp barley grind, bread yeast, historical

hell all,  
Russ Gelinas (hbd1123) mentioned getting good results by chance, when he used a corona to crush "damp" malt. Well, this is sort of similar to the wet grinding that is often used in mainland europe to crush grains. The theory is if you could wet the outside of the grains without doing the same to the inside, then the husk would just split (being more elastic in a moist state) and the goodies inside would still be crushed finely. In practice, it works. However, usually there are two alternatives to wetting:

1. using steam treatment;
2. Contact with the strike water (which for these mashes is at ca. 30 deg. C, decoction) for a certain amount of time ---- down to 7 seconds!!.

I've been experimenting with lager grains from Hurlimann (which just crumble to dust in a Marcato Mulino mill) by spraying them with a plant sprayer just before the crush. This makes a great improvement, although I imagine nothing like a MaltMill(TM). Once I have my method down

I'll post full "instructions".

\*\*\*\*\*

Jack in the same hbd mentioned his experiment with fleishmann's (sp) bread yeast. I have also tried a couple of brews, with the locally available "bread" yeast. In all honesty one batch was highly clovy, but the other (albeit a heavy dark beer) was not overwhelmingly so. I suspect that my yeast was not actually bred for bread use, but was actually produced by a brewery. I must say, given another source of proper yeast, I'd never use bread yeast again.

\*\*\*\*\*

Finally, I'm still getting inquiries about the historical recipes from the 1820's book I've got a copy of. I have posted all but the table beer, but these may have been missed.

Could you mail me with a subject line: history yes if you think I should post again.

If I get sufficient responses I'll post, otherwise I'll send direct (if you already asked me directly, could you remail me, we have a serious disk space shortage on this machine, which means I get scrubbed very often.)

Rob Thomas.

P.S. how does everyone do those trailing remarks/quotes.... I presume they are automatic.?

>I was at my neighborhood hardware store recently looking for ss screen for an easymash (home made) when I spotted some springs, some of which were loosely coiled (i.e. had about 1/8 to 1/2 inch spaces between coils. If I bought one that would snugly fit over copper tubing, and pinched off the other end, this might work great (especially if I waited until alter the mash and placed the copper tube siphon-like into the mash kettle. Anything wrong with this idea?

Nothing other than the range of "1/8 to 1/2 in spaces". That goes from almost adequate to just about useless. The mesh size I use on the EM strainer is 32, i.e 32 holes to the inch. That makes the opening considerably less than 1/32" when the wire size is taken into consideration.

Furthermore, the spring is likely to bend and change the spacing during use.

You can buy the screen you need for about 10 cents and I don't see any advantage in the spring.

Subject: Chimay Yeast Problem

I recently cultured yeast from a bottle of Chimay and used it in an ale recipe. The fermentation went fine but the yeast are extremely reluctant to settle out. It's been in the secondary for 10 days and only the top inch has clarified! Two questions:

- 1) Has anyone had problems w/chimay taking a long time to settle out?
- 2) Any suggestions for helping out the process? I could add some clarifying agents but at this stage I'm concerned about infection sense fermentation is complete and no CO2 is being produced.

From: "Robert C. Santore" <rsantore@mailbox.syr.edu>  
Subject: RE: dry hopping - HELP!

In HBD 1123 Peter Maxwell notes:

> I tasted my first batch of dry hopped beer yesterday. The effect was great,  
> but I was disturbed to see all this "stuff" in the beer. It was sticking to  
> the sides of the bottles, which had to be rotated to loosen it so it would  
> sink. It only "sort of" sank and they all have this fairly thick, loosely  
> packed layer on the bottom - not at all pleasant.

Ah, Peter. Let me relate a similar dry-hopping experience. It involves a pale ale I brewed that I wanted to try dry hopping . . . like your batch, this was the first time I ever dry hopped. I used Cascade pellets in the secondary, about 5 days before bottling. When I bottled the beer tasted fantastic, and with a beautiful hop aroma. I put the batch down for the requisite conditioning, and after ten days wanted to have my first carbonated taste. To my horror, there was this almost feathery white growth throughout all of the bottles. I chilled one and tasted it - YUCK! It was undrinkable. I was devastated. I imagine some beastly got in with the hops. I know the batch was not otherwise contaminated, because I used a cup of the yeast from this batch's primary to start another batch that came out wonderfully well. Anyway, I left the beer in the cellar thinking that some day I'd have to open all those bottles and dump it down the drain. I had never had a throwaway and was not looking forward to it. Well, I'm good at not getting around to do unpleasant tasks, so I waited about three months before I dragged the cases upstairs to do the dirty deed. At the last minute I decided to put one in the fridge and wait 'till the next day. Incredibly, this batch turned out great! It is unlike anything I've ever had before. Whatever awful flavor developed early on is completely gone. I have no doubt that there was an infection. Even now there is this very fluffy sediment that stirs up easily, and the beer is over-carbonated. That is an unfortunate combination, because as soon as you pop the top, the bubbles rising up through the sediment cause it to mix all throughout the bottle. What I do now is get the bottles real cold, then take an opener and crack the top just enough to let out the gas, then recap (with the same cap) and stick it back in the fridge. That solves the overcarbonation problem. When pouring I leave an inch in the bottle to pour a clear glass, or if it's just for me I don't even worry about it. So the moral is, even if you do have an infection and some nasty tasting beer, don't be too hasty to dump it. I am not sure I'd want to repeat this brew (it really is wonderful, but man is it hard to wait four months before you find out if you have beer or sewer water). I've been reluctant to dry hop ever since, but the hop-tea alternative just does not give the same result.

Anyone out there have a way of sanitizing hops without destroying the aroma?

From: coronell@cadesm24.eng.utah.edu (Charles Coronella)  
Subject: Metallic Cherry Beer, or the cheapskate always loses

I recently made my third annual cherry beer. I was excited to use my new 4-gallon (aluminum) pot for the boil. I got this pot real cheap(\$12), and it would allow me to do nearly full boils. When I transferred the beer to secondary, the taste was pretty good, but had a slight metallic flavoring. Unusual, but I'm used to strange flavors in my beers. Hell, that's one of the reasons I brew. I thought nothing of it. But apparently, the taste got stronger with time. It was prominent at bottling, and the metallic taste has become overwhelming in the bottled beers. For the first time, I find myself pouring my own brews down the drain!! :-(

My previous pot was aluminum, but gave no perceptable metal flavors. I've been looking for a low cost, full sized kettle, and thought that I'd found an inexpensive alternative. Guess I was wrong. Let this be a warning for all the cheapskates out there. Any suggestions on where to find 28-quart stainless kettles for less than \$150?

Wonder if all this aluminum has anything to do with my recent memory loss problems...

-----  
On another note, I'd like to congratulate all the recent contributors to the HBD for being so well behaved. And especially, I'd like to thank Rob for maintaining the HBD. Also, I note that there's been a small backlog of submissions, so that a note might not appear for a day or two. I think it would help if everyone tried their best to keep posts short (including .sig files and quoted text from previous posts.)

From: atzeiner@iastate.edu  
Subject: lauter tun and fridge questions

I am going to start partial grain and then all grain brewing soon and I have started to make a Zapap lauter tun. I drilled all the holes in the bottom of a 4 gal. pail and the bottom of it is around 3 inches from the bottom of the other 4 gal. pail. I think I remember reading that it's better to have only about 1 1/2 inches from the strainer part to the bottom of the outer pail. Is that right?? Also, how far from the bottom of the outer pail do you want to make the draining hole??( I think I read 1/2 inch) Another question I have is, what is the best way to disperse the sparging water into this kind of lauter tun? I know it should be sorta sprinkled rather than just poured into the tun. Is there a specific HBD digest that has good info on sparging technique? I would like to know a little more than the basics that are in TNCJOHB...

Also, I just bought an old fridge so I can brew in the summer and it's the old kind with just a single door. The freezer part is just a little metal thing at the top with a small plastic door. I figure that I would remove the door from the freezer so that when the thermostat turns the fridge on, the freezer section will cool the rest of the fridge. Is there any reason to not do this?

I am also wondering what kind of external temperature controllers are the best and where they can be gotten the cheapest... I saw a couple of ads in Zymurgy for these for \$30 and \$32, but I don't know what kind they are.

Thanks...Andy

feet.  
> But in case my best efforts are unable to control their growth, what  
> should I (have you) done?

My plants went about 20' the first year. I simply tied strong brown twine (the really coarse kind) to the exposed beams at the second floor roofline. They climb like mad. This year, I am adding more lengths of twine. I have two hop plants in planters, one on each side of my porch. They each grow up a 6'x 1' vertical trellis rooted in the soil in the large pot, onto a 2'x 8' horizontal trellis mounted to the fence on each side, and from there to four strings reaching from each side up to a central point on the roofline. This should create a really nice shady hop canopy for those hot summer months. Harvesting is as simple as reaching out my second floor bedroom window and snipping the twine.

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Oregon hops and storing grain

Recently Joel Birkeland asked about hops in Oregon and whether there are any U-Pick hop fields. First of all, the Mt. Angel area is a big hop growing center, at least a thousand acres of hop fields of every imaginable variety. Unfortunately for the homebrewer, U-Pick hops doesn't happen as far as I know. The hops are machine harvested and immediately kilned and baled, and then sold either directly to the big brewers under contract or to any of a number of brokers.

Yakima, WA is definitely the US hop center with Oregon and Idaho in 2nd and 3rd positions. California and New York were both historically hop producers but are not commercial today. Hops will grow just about anywhere but to be commercially competitive requires just the right conditions (Yakima being as close to perfect as the US has to offer).

Hopefully those of you coming to our fair state in July for the conference will have an opportunity to tour a hop yard or two. Let me know via email if there is much interest and I may be able to set up something (no promises) since several of the big Oregon hop farms are just up the road from my farm.

Cheers,

Glenn Tinseth

From: eisen@kopf.HQ.Ileaf.COM (Carl West)  
Subject: Immersion Chiller <swan song>

One last try, after this, I give up.

Given any particular wort chiller, the object of the game is to remove heat from the wort as quickly as possible until it reaches the target temp. The way to do this is to keep the chiller as cold as possible for as much of its length as possible. If the output water is hot, the last portion of your chiller is warmer than it should be. The way to keep the chiller cold is to run as much cold water through the chiller as possible, the limiting factor here is mechanical, not thermodynamic; how much pressure can you put on your chiller before you blow a fitting? :) IF you are putting maximum available flow through your chiller, you're getting the fastest cooling your system will give you.

Yes, this uses a lot of water.  
Do you want to save water or get a good cold break?  
That's the question you have to answer.

Keep in mind when you think about this that heat and temperature are different concepts and that raising the temperature of the cooling water is not the object of the game, the object of the game is to pump as much heat as possible out of the wort as quickly as possible.

- -- Carl

Keep the chiller as cold as possible.

There, I'm done.  
Was it good for you?

From: frank@Solbourne.COM (Frank Jones)  
Subject: Re: Immersion chiller architecture

In #1123 richard childers asks

->On that thread, has anyone considered a parallel chiller architecture ?

Well, yes I have. . . more than considered it, I built and use one.

I've been following this thread with some interest myself. When first presented with the problem of a wort chiller, my thoughts were that the surface area of most commercial chillers is insufficient. My thought process was that the majority of the heat exchange would take place in the first few feet, and as the temperature of the water inside the tube approached the temperature of the wort the heat exchange rate would flatten off, so that the rest of the tubing would be mostly exhaust with little heat exchange properties. This is more intuitive than proven fact, not wanting to go to that much effort to build bunches of test chillers. I have some experience with auto air conditioning design and construction in a previous lifetime (BC :=: Before Computers :) ). It was the normal practice of condenser and evaporator design to split the flow of coolant into multiple paths, and to obtain maximum tube surface area by finning the coils. With that preamble. . .

My chiller: I dismissed the concept of finning the tubing because of cleaning issues (but that would undoubtedly make it most efficient). The design I ended up with needs one modification (e.g., I need to build another one to fix it, and haven't yet) which I'll cover after the description. The chiller uses four circuits of 1/4 inch soft copper tubing, each coil is about 9' to 10' in length and is coiled like an electric stove burner element, with the exit tube running under the coil (from the inside) to return to the outside of the coil (and support the coil as well) approximately 2" from the inlet tube. I attached these coils to an inlet and exit manifold that was made from a 1" rigid tube, elbowed vertically, with an elbow on top for the hose attachment. This allows several things to work together, in that the manifolds are close together (convenient hand hold), the coils are made to be about 4" smaller in diameter than my brew pot and vertically only take up about 5" of space, so the coils are below the surface of the wort. This allows me to use a gentle side to side motion while the chiller is running, but keep the coils below the surface, and with the manifolds together I can keep the lid mostly on the pot, to keep airborne stuff out. I used 1/4" tubing because the volume to surface area is greater than on 3/8", and it is easier to bend by hand without kinking. The 4-to-1 manifold was made by flattening a short section of 1" rigid tubing so that 4-1/4" tubes would slip fit into the flattened tube, then it was staked with a small chisel between the 1/4 tubes to minimize the gap area needed to be filled with solder.

I had wanted to run some "scientific" type tests against a friend's commercially built chiller to see how fast it is under the same conditions, e.g., start with boiling water, same cold water source, and measure times to drop to certain temperatures, but haven't had much time for that kind of thing lately. (I intend to do so in the near future.) My chiller will take boiling wort down to 60 deg F in less than 10 mins, which if memory serves me is faster than my

The return from the coils drains into another 'T' setup and out a drain hose. I assembled it using a wire tube bender, 1/2" rigid pipe and fittings, lead-free solder and a propane torch. I had to resolder some joints after I pressure tested it. I cleaned it, cleaned it, cleaned it, and boiled it. It seemed to work pretty good. :-) I sorta goofed, I wound the 1st coil one way and the remain three another. It still works. I would suggest using 1/4" tube for tighter coils and less wort displacement. Also, wind all the coils the same way, starting from the outside winding inwards and coming out from the center. I separated the coils with books while I soldered them into the 'T's. Kinda tricky :)

From: Ulick Stafford <ulick@bizet.helios.nd.edu>  
Subject: Fleishman's yeast, wetting malt

In 1123 js spoke of a beer he made with plated out Fleischman's. A pale bock I made by adding adding a number of cakes to the wort won a ribbon in a competition. In another competition the worst comment was some ale character, high temp fermentation? or dried yeast? Hardly a total disaster. The other judge thought it might be oxidized but he was listed as a novice and the first of 5 judges or so to so judge the beer. Last competition I am entering. It is disgraceful to enter a contest paying someone money to drink your beer and not even getting a qualified judgement. It is about time I wrote AHA a snotty letter. Oops a bit of a sidetrack. Anyway, I suggest that Jack's plated out yeast was one of the contaminent yeasts rather than the predominant one. Fleischmans is not pure culture, but it is probably no worse than good dried yeasts.

Russ Gelinas spoke of a good grind he achieved in a Corona with damp yeast. I read somewhere (a German source, I think) that better grinds can be achieved by soaking the grains for 40 seconds prior to grinding. I guess the reason for this may be that the outside of the husks is lubricated slightly reducing shredding. Wet milling is another commercial technique. I think i'll try misting the grains slightly next time I brew to see if it helps.

Subject: Bring the king's taster!

Yesterday I carved a hole in my old fermentation bucket (I now use glass carboys for both stages) in order to fashion a bottling bucket with spigot. I got carried away and ended up with a hole too big to fit the spigot gaskets well enough to keep water from trickling out. Out of desperation and in fear of having to buy a new bucket if I felt like continuing, I closed part of the hole up with a silicon sealant. Does anyone else think this was a bad idea? The sealant does not say that it's food grade, nor does it say anything about the health risks of the cured silicon (only the ropy stuff that stinks of molten horse bones). Will this affect my beer if it's only in contact for 10-20 min as I run it through whilst bottling? Should I peel the silicon off and try larger gaskets?

Date: Wed, 21 Apr 93 07:41:04 EDT  
From: fingerle@NADC.NAVY.MIL (J. Fingerle)  
Subject: golden ale, dry hopping, fusels

Anthony Johnston writes:

I just wanted to write in after seeing the messages on skimming out of a plastic fermenter. My last batch that I brewed (a "Golden" ale that I placed in a plastic fermenter for the primary fermentation.

Strangely enough, me too.

Anyway after 4 or 5 days I racked to my glass secondary and after a few days I noticed what looked like large spots on the surface of the brew but closer inspection showed them to be composed of tiny bubbles.

Again, strangely enough, me too. Actually a friend pointed out the spots which, as I suspected, were actually clusters of very small bubbles. To me, this is nothing more than the evidence of continued fermentation. I have had them before with no problems.

I popped the airlock off and smelled the brew, but couldn't detect any off odor. I swirled the contents around and the bubbles dissipated, but within a day they were back. It just doesn't look like anything I've ever seen before, and I thought that once the beer was fermenting and alcoholic that it wouldn't support an infection. Has anyone had such a problem before?

Yeah, me, but I'm not so sure its a problem. While the alcohol in the beer will aid in preventing an infection, it is my understanding that it is not an absolute guarantee. As for what you are describing, I'd suggest that your batch is ok.

Other topics:

There's been a lot of talk lately about dry-hopping, hop tea, etc. Are there any guidelines on what quantity of hops to use? A half ounce, an ounce, what?

Regarding the subject of blowoff and/or skimming the krausen foam-I generally rack to the secondary after the vigorous fermentation has slowed, but before the krausen head "de-bubbles" and settles into the beer. What ends up happening is that the siphon removes the beer from the middle of the primary, leaving the sediment (bottom) and krausen (top) behind. Is this sufficient to keep the fusel oils and off flavors of the krausen out of my beer?

And, finally, a personal thanks to Joe Mulligan for the recent recipe. Sorry to waste BW, but mail to him keeps bouncing!

re: Chuck coronellrjds@che.utah.edu

I purchased a stainless steel 20 qt (5 gal) pot at Lechmere's (discount department store chain in New England) for \$25.00. SO far, it has worked very good. I tend not to boil much more then 3gal worth in there. This is not one of those heavy-duty resturant types - it is pretty flimsy (read: thin).

Again, it works well, and for \$25.00 for stainless steel, I ain't complainin'!

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Celis beer gossip

Last night (Tuesday) was the first of three nights of Belgian beer tastings at the Brickskeller; the same program will be offered each night. The program included the Celis line (with Pierre in attendance), the return of Rodenbach Grand Cru, and Timmerman's Framboise, Scaldis, and Saison Dupont. The F. Boon beers were originally scheduled in place of these last three, but they mysteriously disappeared somewhere en route between Belgium and Washington. (Anybody seen Mike Sharp lately?) Anyway, here's some information gleaned from the Celis portion of the program.

General:

- 1) Hops: all the beers use Willamette and Cascade (!) except for the Golden, which uses Saaz.
- 2) Yeast: Pierre uses his own for all but the Golden, which uses a Czech yeast. Yeast is used once and discarded. (This was touted as a purity thing, but I suspect the stuff is hard to work with; I'd heard from a Belgian brewer that the Hoegaarden strain had become infected about two years ago and had been replaced. Also Pierre Celis is obviously a knowledgeable businessman, and undoubtedly realizes the economies that can come from reuse.)
- 3) Packaging: all the beers except the white are filtered.

The beers:

- 1) Golden: a lager. Well, I'll believe it if they say so, but...you sure could have fooled me! This is a very soft beer with a wild-honey character. Don't get me wrong--I like the stuff, but Pierre admitted it was the first lager he'd ever made, and I suspect he doesn't have a German-style lager bone in his body.
- 2) Pale bock. Much to my own discredit, this one had always had me puzzled, as it sure doesn't taste Belgian, or like a bock beer either. It turns out to be a....pale ale. Actually, once this was mentioned it made immediate sense--has British-style hopping, good crystal malt color, and caramel flavor. Let it go flat and it could pass for a glass of Evrard's. The story (subject to reality checks as mentioned below) is that a beer can't be called an ale in Texas unless it is a minimum of 5% ABV. This one is just below that, so they called it something else.
- 3) The white: Before the tasting I had a bottle of Dentergems white, and was patting my back for doing so well with my own white clone. Then we had the fresh, kegged Celis white, and it was like when they go from black and white to color in the Wizard of Oz. Back to the drawing board. Yet more proof, if any is needed, that fresh kegs from a good brewery are unbeatable, while old bottles from a good brewery most certainly are. The first thing I'll do, too, is to triple the coriander. They use a blend of various orange peels--brewable details were not forthcoming.
- 4) Grand Cru: No special information was offered.

Pierre is quite talkative, although his English is more

functional than fluent, and very friendly. He does speak French as well as Flemish, so anybody out there who wants to practice can get a workout. We conjugated verbs together during the break.

All said, I'm pretty sure that some of the information we received had been tailored, embroidered, omitted, or spin doctored for public distribution. Nothing malicious, but perhaps devious in a sporting way. For instance, they went into great detail about the dangers of autolysis, which seems to me to be an excuse for filtering beers that were never filtered back in Belgium. There was the bit about the yeast, and they also went on and on about "Why Austin"? Explanations included the sunshine, the water, central location, location of his previous importer (who is now director of marketing at Celis). Well, all this is probably true, but Pierre's also pretty conservative, real entrepreneurial with a strong work ethic, and would probably fit into Texas without too much trouble. He thinks Europe doesn't have much of a future (he may be right), and prefers a place where people get rewarded for hard work. At any rate, he seems to be settling into the U.S. quite comfortably.

Those familiar with Celis' partnership problems and the Interbrew buyout will be pleased to hear that the new brewery was financed with the buyout proceeds and that there appear to be no pesky partners on the horizon.

Subject: Re: Immersion Chillers

I made my chiller out of 1/8" id copper tubing (it was the right price - \$4.00 for ~ 20'). I made a couple of connectors to attach it to a garden hose.

It works great, ~30 minutes to take boiling wort to pitching: could have used a few more feet of tubing... cold water in at the top of the helix to aid in convection...but I still stir it around a fair bit...

Subject: anodizing my cheap aluminum pot?

I gotta question for all you metallurgy type folks out there. Can I get my cheap aluminum pot anodized? A friend of mine, a metallurgist, says probably, (what a help). She says that many aluminum pots sold in the US are already anodized, and that local shops can do it for a price, but at what price, she didn't know. Also, there are apparently different types of anodizing, and I'm guessing that some would be less toxic than others. Bob Konigsberg, bobk@NSD.3Com.COM, called a local anodizing shop that told him no way, too dangerous, FDA won't permit it. So my specific questions are these:

- 1) Is there a nontoxic (and legal) method of anodizing my cheap Al pot?
- 2) Can I get it done cheaply, and at what kind of shop?
- 3) Can I expect that an anodized pot to keep its durability for a long while?

BTW, thanks to everyone who suggested places that sell cheap SS pots. Looks like I could get a 32 qt SS pot for ~ \$100.

Subject: SS Pot and Propane Cooker

Hi everyone,

Here's something I thought I'd pass along.

I was at Pace Warehouse this past saturday. They had an outdoor cooker for sale which looked perfect for brewing. It is in the same line as a Cajun Cooker except the stand is about 3 feet high. Also, it comes with a 6 gallon Stainless Steel pot with strainer basket. Price was \$85. All you need supply is the propane tank. The stand looked strong enough to hold the weight of 6 gallons. Hopefully it is since a 6 gallon pot comes with it. Is anyone else using one of these?

Subject: Stinky yeast

Hello hb-ers...

Last weekend, my brew partner and I mixed up an extract recipe as follows..

500g crystal(crushed), 250g choc-malt(crushed), 1kg clover honey, 2kg light-dry-malt, 1kg dark-dry malt, 100 g halertau hops, 2 pkgs edme dry ale-yeast (rehydrated in water 30 min before pitch). We use full boil, and cool in the bathtub with ice-water in a ss 10 gal pot. The resulting wort had an og of 1.078 !! (yikes). Anyhow here's the thing the yeast in the warm water REALLY smelled, BIG TIME! Being our first experience with Edme... in it went. The Brew took off like crazy about 4 hours later, and just slowed down this am. Still has that smell though... Should I worry???

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: Honey Beer Recipe

A while ago someone asked about recipes for honey beers. This is a bit tardy, but perhaps people will find this of interest.

"La Souriciere" Belgian-style Wheat and Honey Ale

2.5 kg hard red wheat (husked) crushed and put into 12 L of water with 1.5 tsp of gypsum. Heated to boil over 1 hour with stirring.

1 kg malted wheat (British)  
4 kg 6-row pale malted barley (N. American)  
0.5 kg Munich malt  
0.335 kg Ireks crystal malt

All ground together, put in mash tun. The hot wheat/water was added along with 5 L warm tapwater, mash stabilized at 65C. Mash continued for 3.25 hours until iodine test showed starch conversion complete. Decoctions removed periodically to maintain mash temperature. Mashout by decoction to 83C for 30 min.

Sparged with water at 78-82C to a effluent gravity of 1.010.

Added 500 g buckwheat honey to the boiling pot.

1 oz Saaz plugs (90 min)  
1 oz Saaz plugs (60 min)  
.5 oz Hallertau flowers (30 min)  
2 g coriander seed (15 min)  
Irish moss (15 min)

Pitched Wyeast 1214 Belgian Ale starter. OG 1.077 in 21 L of wort. Fermented at 23C 4 days, racked to secondary. Continued fermentation at 23C. It was necessary to re-pitch active Wyeast 1214 after 1.5 months and again after 2.5 months to obtain complete fermentation. FG 1.021. Primed with 2/3 cup glucose.

COMMENTS: The hopping schedule doesn't really make much sense, and in retrospect, I would not add the hops so soon. The brew is perhaps a bit too bitter for the style, and not aromatic enough. I would have preferred to use Styrian Goldings rather than Hallertau. The honey character required the long fermentation and aging to smooth out, but the buckwheat gives a rich smooth taste to the brew. This stuff is potent, and seems to have an effect beyond what one would expect from the alcohol content. The re-pitching is probably due to inadequate aeration in the primary, but active fermentation was obtained after each addition.

Anyhow, hope this is of interest to the honey/wheat beer fans out there. P.

There are plenty of strains of bacteria, mold, and yeast that can and will live in fully-fermented beer. This is a prime cause of the infamous "bottle gushers" since bacteria or wild yeast keep eating (so-called) unfermentable sugars after the lager or ale yeast has given out, producing more CO<sub>2</sub>, resulting in pfft when you open the bottle.

HOWEVER,

this does not necessarily mean your beer is infected. You've sniffed it: that's a good first test. Now sterilize a glass turkey baster and draw off a couple ounces of beer, and taste it. Does it taste OK? Then at this point it *is* OK.

Keep an eye on it, especially after you bottle. Prime it lightly, and sample it after a week and every few days thereafter. If it shows signs of gushing then you have to decide what to do. If at any point it starts tasting bad, then you've definitely got a bad batch.

Until then, relax.

From: garetz@brahms.amd.com (Mark Garetz)  
Subject: Dry Hop Sterilization, SS Pots, Temp. Controllers

Bob Santore asks:

>Anyone out there have a way of sanitizing hops without destroying the  
>aroma?

Firstly, I doubt that the hops were the source of the contamination, assuming they were handled correctly. There has been some published research done at UC Davis that showed there was no contamination risk from dry hopping, and beers such as Liberty Ale and Sam Adams Lager (both dry hopped) would have infection problems.

Anyway, if you are really concerned and want to "sterilize" the hops first without destroying the aroma and/or putting something nasty in your beer, I would suggest soaking them for a few minutes in some Everclear or 100 proof vodka. Strain the alcohol, or add it, your choice. If you strain, don't throw it away. It makes a tasty drink on ice, cut with some water.

Chuck Coronella asks about a source for cheap SS pots. High grade Vollrath SS pots (with aluminum clad bottoms) are available from Superior Products, a restaurant supply, for \$90 plus \$24.50 for the lid for the 38 qt model. 24 qt is \$69 plus \$18.50. Superior is nation-wide. 800-328-9800 for a catalog and the location near you. They also have the best prices on CO2 regulators (\$37 for twin gauge, \$30.50 for single) and other beer stuff like thick wall beer line, taps, etc.

Andy asks about a source for temperature controllers. I am using the Hunter Air-Stat that homebrew suppliers sell from \$30 up. I got mine at the local hardware super store (Home Base, but Home Depot also has 'em) for \$19.50.

Subject: Stirring and Cakes

>From: "Bob Jones" <bjones@novax.llnl.gov>

>In the last digest Richard Childers suggested an immersion chiller that might be stirred and parallel cooling chillers....

One of the most significant advantages of the immersion chiller is that by the time the wort is chilled, the trub has settled out and is left behind when the wort is run off.

Why on earth would you want to keep it all stirred up? You will either have to wait the additional time to settle after chilling or run the trub out into the fermenter. It will take some heavy science to convince me that chilling in 10 minutes vs 20 minutes will have a detectable effect on the end product.

>From: Ulick Stafford <ulick@bizet.helios.nd.edu>  
>Subject: Fleishman's yeast

>In 1123 js spoke of a beer he made with plated out Fleischman's. A pale bock I made by adding adding a number of cakes to the wort won a ribbon in a competition.

Two comments here. First of all, putting cakes in beer seems a bit of a reach and if the judge happend to be a chocolate freak... but then, you didn't really tell us what kind of cakes they were.

> Last competition I am entering. It is disgraceful to enter a contest paying someone money to drink your beer and not even getting a qualified judgement.

You should stick to cake beer. Everybody knows what good cake tastes like.

>Anyway, I suggest that Jack's plated out yeast was one of the contaminant yeasts rather than the predominant one.

The procedure I use makes that very unlikely but I will not deny the possibility. However, it seems far more likely that your success with cakes was based on such a fluke.

>Fleischmans is not pure culture, but it is probably no worse than good dried yeasts.

I am not sure how you can know that with such certainty. I would concede that it is probably no worse than dried Red Star but I already stated that.

The preponderance of evidence is that good dry yeast makes good beer far more often than not and possibly always for many. The small sample of inputs from those intrepid experimenters who have tried bread yeast, is exactly the opposite.

Finally, I make no claims for all bread yeast nor for "cakes". The yeast I used was from a small packet of Fleischman's dried baker's yeast. It was pure cultured to assure that the dominant yeast was cultured and bacteria left behind.

Those who have been around here for awhile, no doubt note that even old cranks can learn new tricks. I have always been a firm believer in the notion that when lightning strikes 3 or 4 times, it's time to rethink my position.

Subject: Wyeast 1214

Just a Wyeast data point: I cracked a packet of Belgian (1214) last week that was dated September 30, 1992. That means 6.5 months old. Within 48 hours, it was fully puffed and I made a happy, healthy starter which I pitched about 40 hours later. The beer is bubbling merrily as I write.

Admittedly, I bought the yeast 4 days old, brought it straight home and kept it in the fridge throughout the whole period. Nevertheless, I'm pretty impressed at the keeping properties of this stuff.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: End of the season looming

It's a typical spring day on Long Island (mild and rainy) and I'm already contemplating the end of the brewing season :-( :-( :-(

A Belgian dubbel will occupy the secondary for a few weeks and a late-May trip out of town makes it hard to schedule another batch before the hot days of June-July-August. With neither a basement nor AC, it's hard to brew anything except possibly high-temperature Belgian-style stuff. Has anybody had any REAL success brewing quality ale using the "wet t-shirt" method when the ambient is above 80F? (Disclaimer: this is not a sexist joke. The idea is to place a carboy in a shallow pan of water and drape a t-shirt on it. The shirt acts as a wick, drawing up water. The water evaporates, alledgedly cooling the carboy to ale temperatures.)

Looking back over a successful season (11 5-gallon batches plus a 2-gallon barley wine and various apple and honey potions) my major regret is that so many good bottles of beer aged past their prime. I don't drink fast enough!!! I don't want to increase my alcohol consumption. Brewing a 3-gallon batch is just as much work as a 5-gallon batch. If I brewed less frequently, I would suffer from decreased variety. Perhaps the answer is to get find a brewing partner, so that I get only a case or so from each brew and cut the work down accordingly.

Any other recommendations? Any thoughts as to whether the HBD is a suitable forum to post a "personal ad" sseeking a brewing partner?

Date: Thu, 22 Apr 93 08:15:02 PDT  
From: tima@wv.MENTORG.COM (Tim Anderson)  
Subject: Beer with body

Last night, as I was drinking one of the last few bottles of my "Mincemeat" Christmas beer, I was thinking how it really belonged in a crust with a scoop of vanilla ice cream. This got me to thinking about various ways this could be accomplished. One idea was to make beer jello. Another is to use a bunch of apples in the brew, go ahead and boil 'em and let the pectin set.

In the particular beer I was drinking, the recipe was based on a mincemeat recipe in The Joy of Cooking, but I left the apples out because of the pectin. Perhaps I should have left them in.

Anyway, I had a packet of Knox unflavored gelatin, so I made a cup of beer jello. I didn't want to waste a cup of precious homebrew, so I opened a bottle of Rogue Ale I had in the fridge. I just followed the microwave directions on the packet, substituting beer for fruit juice. (The microwave method has you warm a quarter of the "juice" and use the rest cold. I don't think I lost any alcohol at all). The result was less disgusting than I expected. In fact, I'm convinced that in the hands of a trained professional, good things could be done with this. I was thinking of adding, in place of the traditional sliced bananas and fruit cocktail, maybe sliced polish sausage, pretzels and pickled eggs?

Back to the pectin, would gelatinized wort ferment ok? Would the consistency prevent fermentation? Would fermentation prevent gelling? I can picture a magma-like glob working its way up the blowoff tube. I suppose bottling would be out of the question. Maybe wide-mouth canning jars. Then you could serve it with an ice cream scoop.

On a related note: Since apple cider is just apple juice allowed to ferment, and apple jelly is just (sweetened) boiled apple juice allowed to set, why not hard cider jelly? Boil, chill, pitch yeast, spread on toast.

Subject: Yeast and Tin

Like others, I have some equipment with (lead-free) soldered joints. A comment made by Randy Mosher in the recent Zymurgy gadget special indicated that there is a potential problem with tin and yeast. Being new to this forum, I don't know if this issue has been resolved or not, but a quick calculation tells me that it takes 2.6 cubic millimeters (mm<sup>3</sup>) of tin to give 1 ppm in 5 gallons. My trusty counterflow wort chiller has two joints (3/8" copper tube) in the wort flow path, each of which I estimate used 16 mm<sup>3</sup> of solder. It seems that if even 1 ppm of tin were being dissolved into the wort, the device would soon fall apart. It hasn't. I am interested in finding out just how toxic tin is to yeast. Does anybody have any documented info on the concentration level which would adversely affect yeast performance?

From: sslovac@atss.calstatela.edu  
Subject: Carbonation w/ Dry Ice (February 24, 1993)

#### Carbonation with Dry Ice

Carbonation with dry ice can be done - we did it for years when I lived in Ithaca and had a ready supply. However, we used CO\*2 tank, removed the valve, broke the ice into smaller pieces, filled the tank about 1/4 full, recapped and connected tubes to the regulator. It worked fine and never imparted an off taste. Of course, we were carbonating kegs of beer, not bottles, but if you have a keggng system then you can buy (or make) a counter pressure bottle filler for \$15 - \$20 to bottle carbonated beer from the keg.

Concerning the proposal to use pieces of dry ice in each bottle, I would worry about the potential for explosion and wildly fluctuating pressure in the bottles owing to the expansion ratio of CO\*2 ice to gas: I seem to remember that water is roughly 1:17,000 so CO\*2 can't be too far away. So I don't recommend trying individual bottling with dry ice, unless you can safely and precisely experiment with measured amounts of (probably tiny) chips. Also, individual bottle carbonation is highly labor intensive - much like priming each bottle with a 1/2 tsp of sugar.

From: Stephen Brent Peters <sp2q+@andrew.cmu.edu>  
Subject: 5 litre kegs and N2O

I recently purchased a tap for 5 litre cans operated by those little N2O cannisters you can use to make whipped cream (among other uses). This little device is mighty keen, but I have already run out of N2O. Does anybody know where I could purchase these little things at a decent price? I currently live in Pittsburgh, but I'd be willing to mail-order.

I love the 5 litre keg thing, it is great! A very convenient size, and easy to use. If anyone else is interested in trying this, Randy at Brew Ha-Ha will sell you everything you need to keg and tap 5 gal batches for 40\$, or just the tap for \$20. Email me for his address (I don't have it with me)

Also, here's a question: I noticed in the instructions he gave me that the kegs are lined with plastic and they explicitly state that chlorine should not come in contact with it. I have been brewing for over a year and have never used anything other than chlorine and use it to sanitize my plastic bottling bucket. Is this just a cheap pitch to sell more b-brite, or is there a good reason behind this?

From: rush@xanadu.11nl.gov (Alan Edwards)  
Subject: Growing Hops Horizontally

#### GROWING HOPS

Last year, when I started growing hops, I mentioned my setup and that I would give a report on how it worked.

I grow the hops up 8 feet, then horizontally about 16 feet. My setup works really well. I run the vines up some nylon twine to a galvanized steel wire, that is stretched across two posts, and then across to the eaves of my house.

The first year, only two varieties made it most of the way across to my house, for a total of about 20 feet--Chinook and Nugget. This year, I expect more growth, and may even find some of the vines wanting more line. As I write, three of the varieties have already reached 8 feet.

You only need to twist the new growth around the horizontal part of the twine about every couple of days. It's not that big of a deal to get them to grow horizontally. And it makes picking MUCH easier. I don't need to take the vine down OR use a ladder; I usually stand on a chair-- a step-ladder will do nicely.

#### DETAILS

- I have seven hop plants of different varieties about 3.5 feet apart. The whole garden is about 24 feet by three feet.
- The garden is along my North fence, for maximum sun.
- Two 8 foot 2x4's are nailed to the wooden fence (at the corner and at a 4x4 post, for support), with a galvanized steel wire stretched across the tops (with a turnbuckle for tightening).
- Nylon twine is hung from the steel wire and staked into the ground near the hops. I would advise against using jute (natural fiber) twine. I used jute twine last year and after weathering, some of them snapped. Also, they stretch out over time, requiring retightening every so often (plan for this).
- The horizontal twines are tied to the steel wire and fastened to the eaves of the roof with screw-eyes.
- Some vines are not aligned with the house. And in those cases, the twine goes to a second steel wire stretched between the North-East corner of the house and an 8 foot 2x4 attached to the East fence. That wire forms an extension to the North side of the roof, where the other twines are attached.
- The garden is fenced in with a simple 2x4 frame and some chicken wire. If you have pets, you must fence it off. Don't trust your dog. I did two years ago, and he wrecked the garden. I had to start all over again.

#### CHANGES

This year, instead of training three vines from each plant up one twine, I am training four vines from each plant up TWO twines. All twines are equally spaced. This gives the appearance of having twice as many vines and should make harvesting much easier. Last year's crop got pretty bushy and hard to pick on the more prolific varieties. I also hope that the horizontal part will create some nice shade on my back yard, since

the vines will be 1.75 feet apart. I seriously doubt that they will grow together and cause me to misidentify the varieties. I also expect a bigger harvest from this configuration, since I can let more vines grow without worrying about clutter.

#### GROWING TIPS

Keep new shoots pruned until you see hop cones, then let a couple of vines emerge and wind around the existing vines. You'll have another harvest a few weeks after the first. Keep doing this and you can have several harvests in one season.

If you have some varieties that aren't doing too well (less than 6 vines emerge), go ahead and train them all--it may be your only chance. I had a pretty poor first harvest from my Willamette and Mount Hood last year. Tettnanger didn't do too well either. Some varieties just don't do as well as others. If you are growing Nugget, Cascades or Chinook, expect to trim them regularly. They grow very well. If you don't keep cutting shoots, things can get hairy quickly. The same goes for the long runners that you get coming out of the sides of the vine. Also, if you have the choice, put the least prolific varieties in the part of the garden that gets the most sun--they need all the help they can get.

If at all possible, water the hops with some kind of automatic system. They need much water, and often. I've got mine on a timer that waters them twice a day.

Good luck, and most of all HAVE FUN!

-Alan

Subject: New version of THREAD program for searching HBD

-----  
---  
Announcing Version 2.1 of THREAD for MS-DOS computers, by Tom Kaltenbach  
-----  
---

I've just completed a new version of my THREAD program, which is designed to search the back issues of the Homebrew Digest and extract those messages that follow a certain "thread" of conversation. The new version is a much-enhanced program, now faster (w/multitasking!), neater, and easier to use. This program, like earlier versions, is released to the public domain: no licensing fees or donations are required. The only restriction is that the program may not be sold or otherwise used for commercial purposes.

THREAD searches for conversation threads by extracting all messages that contain specified key words; as a consequence, the program also functions as a general subject-searching program. For example, if you wanted to search for all messages related to kegging, you might use "kegging" as a key word. Logical combinations are also possible; for example, if you wanted all of the references to Jack Schmidling's MALT MILL, you could search for "malt" AND "mill" NOT "miller" (the NOT "miller" excludes the many references to Dave Miller's books). The key words are not limited to a single word, for example, you can search for messages mentioning "dave miller" OR "dave line". Up to 10 key word specifiers are allowed. Each matching message is displayed, with all key words highlighted, for the user to view, save, skip, etc. An automatic mode allows non-interactive searches to be performed.

THREAD operates on IBM PC or compatible 8088/80286/80386/80486 microcomputers running MS-DOS, so it does require that the digests are stored as ASCII text files in a directory on the PC hard disk. The program has been uploaded to the archives at sierra.stanford.edu, where it can be found in the /pub/homebrew directory. The files are as follows:

|              |                                                          |
|--------------|----------------------------------------------------------|
| thread21.exe | ver 2.1 binary file, MS-DOS program executable           |
| thread21.pas | ver 2.1 source code, written in Turbo Pascal 5.5/6.0     |
| thread21.uue | uencoded version of thread21.exe, for those without ftp  |
| thread21.xxe | xxencoded version of thread21.exe, for those without ftp |
| thread21.doc | documentation and program description                    |
| thread21.new | list of new features and enhancements in version 2.1     |

NOTE: the "thread21.exe" file is a binary file and cannot be requested using the listserver. The uencoded and xxencoded versions are included for use with the listserv archive server, which sends files via mail. The uencoding format is more popular, but fails with some IBM mainframe mail nodes. Xxencoding is required in these cases. An xxencode/decode program for MS-DOS computers is available from the Sintel-20 archives.

A note to those not using MS-DOS: version 2.1 of THREAD is highly customized for MS-DOS computers. Consequently, version 2.1 probably will

not be translated to "C" for porting to other platforms. I recommend that any non-DOS users of THREAD version 1.2 continue to use that version, which, for the most part, is functionally equivalent to the new version.

Any comments, questions, or suggestions can be sent to me at the email address below.

From: raudins@galt.b17d.ingr.com (Glenn Raudins)  
Subject: Bully Porter

I recently had the opportunity to have some Boulevard Brewing (Kansas City) Bully Porter delivered to me (thanks Ken.) In response to a recent review, I decided to see if the metallic taste John Fitzgerald found was evident in this six pack. The review follows but to sum it up. I tasted no metallic taste. Very Clean. Anyone know what yeast they use?

Bully Porter from Boulevard Brewing  
-----

Aroma: Roasted Barley or Black Patent  
Hints of Chocolate Malt  
No hop aroma

Flavor: Hops not identifiable  
Dry Finish

Color: A bit dark but would fit the Robust  
Porter style (AHA).

Carbonation: Appropriate

Body: A little thin for the style. (American or English)

Overall: AHA "Robust Porter" w/o the body.  
It is a bit too dry to be a porter, it resembles a dry stout with some of the roasted barley removed and the body taken away.  
Not an English Porter, it lacks the complexity and "fruitiness."  
An American Porter (though not smooth like Anchor.)  
A nice drinkable beer overall. (I like dry stouts.)

Notes: Expiration Notch on the Label (May)  
There was no metallic taste as John Fitzgerald reported.  
Many thanks to Ken Schmidt for delivering from Kansas City to the Alabama beer wasteland.

From: mdcsc!gdh@uunet.UU.NET (Garrett Hildebrand)  
Subject: direction of hop vine climb

I am growing three kinds of hops in my Southern California backyard, and they are all doing the same thing: climbing the stake \*clockwise\*.

I have planted my hops, initially, in planters, and this is their first year. The pots are dead center in my yard. I put a stake by each plant, and let the plant figure out which way it wanted to climb, rather than trying to train it. They all found the stake, and they all climbed it the same way.

So, I'd have to say that training them to go up a stake counterclockwise might be a challenge. Two points of reference: These are Cascade, Willamette and Nugget, with the Nugget being the real eager beavers; and the viewpoint for observing the direction of wrap on the stake is looking down from the top of it.

From: Paul Andrews <PANDREWS@hpb.hwc.ca>  
Subject: Foam and kegging problem

hi,  
I finally got a good price on a 50L keg equipped with gauges and tubing and a 16 Lb CO2 tank...Ok.great I thought. but being a bit naive about this I just forged ahead. I brewed up 23 L of my favourite pilsner to try it out.  
I racked it over to a secondary , clarified and siphoned into the keg after about 18 days. I pressurized to 50psi (at room temp).. let sit overnight.. (it went down to about 30 psi) after 16-18hours. I decided to see what it tasted/looked like the next day. Ugh.. most foam and very little carbonation.  
Ok.. I dropped the pressure to about 10 psi.. and kept this head pressure with the CO2.. same thing.. hmm.. maybe chill it.. Dropped the tank in my laundry tub and filled it with ice.:result not much better.. ALthough drinkable, There was a GREAT deal of foam.. and little carbonation. (very small bubble). Well I persevered and just filled pitchers with it.. drank it that way.  
Ok. I'm checking with some friends who have more experience to see what I did wrong. but I appreciate any comments from experienced keggers. The keg is 50L stainless with 1/4" copper tubing dip tube and 1/4" "tapping tube, both silver soldered into a stainless steel plug in the top of the keg.  
Any help.. or tell me what I did wrong?. I'm dying to have my first keg party.

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
**Subject: Fascination with Stainless**

Either stainless steel or enameled steel can be used satisfactorily for brewing. Aluminum is the big no-no.

The reason for preferring stainless is simple durability. If you ding an enameled pot, the enamel chips off, and if that happens on the inside, the required thorough cleaning becomes impossible. Enameled steel also weighs quite a bit more than stainless, adding to the already considerable weight of five gallons of (hot) wort.

> Has anybody had any REAL success brewing quality ale using the "wet  
t-shirt" method when the ambient is above 80F?

My guess is that this would work about as well as an evaporation type  
air conditioner on Long Island. Seen any lately?

For this to work at all, requires very low humidity ala Arizona.

BTW, nice to see you survived your experience with the World's Greatest  
Beer.

Make that second greatest... a red ribbon sure is humbling.

>Any other recommendations? Any thoughts as to whether the HBD is  
a suitable forum to post a "personal ad" seeking a brewing partner?

Sounds more like you need a drinking partner.

Date: Fri, 23 Apr 93 10:47:30 PDT  
From: troy@scubed.scubed.com (Troy Howard)  
Subject: Easy Yeast Culturing 2

I wanted to follow up the compilation of responses to Easy Yeast Culturing with my own experience.

I followed Rick's method with my latest batch, a dopplebock. I made the 1/2 gallon "mother" starter, and bottled 5 12 oz bottles. Stored them in the fridge for three days. Next, I took one out, let it warm to room temp, then pitched it into about a pint of 1.020-1.030 wort. This I used as starter for my brew. I let this starter ferment for a couple of days. On brewing day I poured off some of the "beer" sitting atop the yeast cake in the starter (tasted ok, seemed to have high levels of diacytl), swirled the remaining beer to stir up the yeast, and pitched into the wort.

12 hours later I had a FABULOUS krausen going. One of the fastest starts I have ever seen. Fermentation looked like it was almost done in about 36 hours.

I have not tasted it yet, but so far I am quite impressed. I am bottling this weekend, so I'll taste it then.

Just wanted to post a data point that this method does indeed result in viable yeast (one of my fears as I started). I will post more data as I collect it. So far, though, so good.

Greetings all,

I have recently been inundated with email requests to forward summaries of the responses I received from my questions on Easy Yeast Management.

Since there has been so much interest, I thought I would post a compilation of responses.

Enjoy,

Troy

-----  
First, thanks to Rick (R.) Cavasin who posted the article which started the discussion. Here is (briefly) his idea:

>Step 1:

>Prepare some starter wort (S.G. = 1.020), see Miller's book for  
>recipe. Basically, you need about 1/2 gallon, but if you make  
>more and can it in mason jars (using standard canning procedures),  
>you will not have to prepare more at a later date.

>

>Step 2:

>Place 1/2 gallon or so of starter wort in a suitable container  
>(1 gallon glass jug), pitch (inflated) Wyeast package at correct temp.  
>and fit air lock. This is the 'master' starter.

>

>Step 3:

>Allow to ferment to completion. When fermentation has ceased,  
>agitate the 'beer' to suspend all sediment, and very carefully  
>bottle it.

>

>You will now have about 6 bottles of very thin beer with a good  
>deal of viable yeast sediment in each bottle. Use each bottle  
>as you would use a package of Wyeast - ie. prepare a starter  
>culture a couple days before brewing. This is facilitated by  
>canning wort when you prepare the master starter. All you need to  
>in that case is pop open a mason jar of wort, dump it into a  
>sanitized bottle/jug of appropriate size, pop open one of your  
>bottle cultures, add it, agitate vigorously, and fit an air lock.

>

-----  
Next, Daniel F McConnell <Daniel.F.McConnell@med.umich.edu> writes:

>I used to use a similar method-I would simply bottle 4 -6 bottles from a  
>batch  
>and keg the rest. Your method would yield even greater yeast cell  
>counts and  
>better, faster starts. I would purchase 2-3 Wyeast packages per year,  
>usually  
>an ale, a lager plus one that I had not yet tried, thus would have  
>sufficient

>cultures for more than 15 batches. I'm the kind of person that is rather  
>faithful to my yeast-I would stick to one ale (1098) and one lager (2206), get  
>to know them and understand when the fermentatuion has run into trouble.  
I  
>have carried some strains through a second generation with this method and had  
>no problems.  
>  
>I have since gone to other methods (top cropping, slants etc.-no longer with  
>Wyeast BTW), this method was not abandoned due to problems.  
>  
>Potential problems: 1) You must be extremely careful about sanitation. That is  
>why I would bottle beer, not starter wort-you can taste any off flavors.  
2)  
>keep the starter gravity low (<1.050) to prevent mutation. 3) keep them cold  
>once they have carbonated. 4) hop your starter but not so much to mask any off  
>flavors. 5) did I mention sanitation?  
>

Are there draw backs (like problems with autolysis, or the yeast just dying)?

>In the cold autolysis will be present but is not a problem. Your Wyeast is  
>autolysing too in the cold!!

Rick mentions he has had bottled yeast last 6 months. Will they last longer?

>I always purchased new cultures each season so I dont know about lifespan. This  
>insures success.

Are those 6 mo. old yeast just as good as those from a new Wyeast packet?

>Probably better. Good luck

- - - - -

Then, Dennis B. Lewis <InterNet:dblewis@jscprofs.nasa.gov> adds:

> About yeast stretching: Sure, you can do that and it makes perfect sense. Make  
> damn sure the stuff is completely fermented out or you'll get glass grenades.  
> About four days before brewing, take out your starter, pour off the beer on  
> top, pour in about 6 oz. of fresh, heavily-hopped wort (1.040 check Papazian  
> on this. He gives good directions on how to bottle wort for later use in  
> culturing.) Make sure you flame the mouths of the bottles before transferring.  
>  
> Attach an airlock to the bottle and let the yeast reactivate. After about 2.5

> days, pour off the top liquid (if it has started to clear again) and  
pour in  
> some more wort. Then about 6 hours prior to pitching, do the same  
thing. If  
> you care to do this much screwing around with your yeast, you will get  
> tremendous starts and almost no lag time. I just did this with some  
Whitbread  
> (Wyeast 1098) that I cultured from a bottle of ale that I had. It was  
glubbing  
> like crazy 7 hours later.

-----  
And finally, "William A Kitch" <kitchwa@bongo.cc.utexas.edu> suggests:

> I've recently moved away from dried yeast and like you didn't want to  
pay  
>\$3.50 a shot for liquid yeast cultures. For what it's worth here's my  
>experience.  
>  
> I didn't know a yeast from a slug before I started and have been  
brewing  
>great beer from my own cultures for six months. So my rule #1) anybody  
>can keep good yeast cultures if their careful and can think. I highly  
>recommend getting the "Beers & Yeast" special issue of Zymurgy. It has  
>a bunch of good and easily understood articles on everything from how  
>to get a culture from bottle conditioned beer to how to maintain culture  
>stocks.  
> Having read the Zymurgy yeast issue, some HBD threads on the subject,  
and  
>talked to other homebrewers this is what I have found to work for me.  
>

From: William Shirley <william@chemres.tn.cornell.edu>  
Subject: Wort Cooling

Why wouldn't it be possible to boil the wort down to a smaller quantity and then add a gallon of ice? The ice can be made a day in advance by putting boiled water in a sterilized refillable gallon container from a super market.

As for the optimum design for an immersion cooler: usually good ideas can be obtained by looking at designs which have withstood the test of time. In this case the car radiator seems go be a good model. If it were possible to obtain one without lead sodder then it might work well...

Subject: hops direction

Just so it's clear that we agree, yes, hops will climb "clockwise \*looking down\*". The Hops Primer states it as "counter-clockwise \*looking up\*". The reason for that orientation is that "up" is the direction of growth, ie. imagine that you're a hops plant....

Subject: Westchester, NY homebrew club meeting

To all Homebrewers in Westchester, NY:

There will be a meeting of the Wort Ever Ales You homebrew club at my house, 219 Central Ave, Rye NY, on Tuesday April 27, at 7:30 pm. All those who wish to attend can contact me for directions at (914) 337-5897 at my office, and at (914) 921-4081 at my home in the evenings.

If you can not attend, but would be interested in joining the club, please contact Andrew Schmidt at (914) 238-4549 for more information. We are a fairly new club that has been started in the last year. We have about 20 members from all over Westchester Co. The membership includes some very experienced brewers, a certified beer judge, as well as quite a few beginners. All are welcome to join.

Also, Saturday, May 1, is National Homebrew Day, and our club will be participating in a homebrew demonstration, as well as other brew activities, at Mannion's Tavern, 640 Mc Lean Ave in Yonkers at about 1:30 pm until about 6:00. This event is open to the general public in order to promote homebrew awareness. Mannion's phone # is (914) 476-2786.

Mannion's has a large selection of bottled beer from around the world, as well as a tasty menu. Come one, come all, admission is free. Bring the kids. I hope to see you there.

Thanks,  
Erik Zenhausern

From: sims@pdesds1.atg.trc.scra.org (Jim Sims)  
Subject: coupla questions

Being new to homebrewing (since January, ~ 7 batches), I have a coupla questions:

(1) I've noticed that several of the batches dont have much head. I've seen the comments about spotlessly clean glassware, etc. I seem to notice a trend I'd like comments on: The batches i've done that had brewers sugar (or honey) seem to have a good head, the no-sugar batches seem to lack a good head. Anyone else observed this? Ideas why?

(2) Where can I get some hop plants?

(3) Can someone email me (or send me the ftp location for) the yeast culturing notes that were (apparently) posted here not too long back?

Please email me directly, I'll summarize to the list in a few days to conserve bandwidth.

THANKS!

From: gjfix@utam.uta.edu (George J Fix)  
Subject: Competitions and Dry Yeast

I have been entering a lot of competitions primarily with high gravity amber and dark lagers. The objective has been to get a measure of the new Belgian malts. A summary of our findings plus a general analysis of these malts can be found in an article I wrote for the first issue of Brewing Techniques. This issue should appear at the beginning of May. Our own cultured lager yeast was used for all these brews.

I have also made full scale brews with the dry yeast that was sent to us from Crosby and Baker, and these were also entered in sanctioned competitions.

In each case, the following "German Wheat Ale" was used:

Vol. = 50 liters  
Grain Bill - 7.5 kg. D-C pale ale malt, 2.5 kg. D-C wheat malt  
(SG = 1.048)  
60 grams Hallentau leaf hops, 60 grams Tettnang leaf hops  
(IBU = 26 mg/l)

This is a mild flavored beer, and was chosen for that reason. Any defects in the yeast used would stick out like a sore thumb in this one. The Belgian grains were used to remove malt quality as a issue.

Beer using the Mauri yeast from Australia that was sent to me by C+B was entered in the 3rd Annual March Mashfest in Ft. Collins, Co. The judges were

Skip Madsen and John Landreman. Both are in the "recognized judge" category.

One gave a score of 41 and the other 39. The beer took first place in the its category. I would be willing to bet that this beer was eliminated early

on in the BOS judging. This strain IMHO is not capable of producing beers that can compete at that level. Our analysis and the Ft. Collins results show that this yeast can nevertheless make creditable beer.

Beer made from the new Whitbread strain was entered in the March Pittsburgh

competition, the Bluebonnet, and the recent competition in Chicago. The judges

in the Pittsburgh competition were Cliff Beringer (certified) and Jim Desmond

(apprentice). They gave the Wheat Ale scores of 36 and 37, respectively. It won

a second in this event. The same was true for the Bluebonnet, except the score

sheets have not as yet been sent out. Jim Busch and a few others on this network also won ribbons. Presumably these and the score sheets will be sent

out soon. I also entered a Brown Ale which took 1st place. This one was fermented with a cultured yeast (BRY-204, a Belgian ale yeast from Siebel).

I have not seen the official results from Chicago. Al, when will we get this?

I personally prefer the Mauri strain to the new Whitbread, and indeed the old Whitbread to the new version. The latter can, however, make creditable

beer. Copies of all the relevant score sheets will be sent to C+B where

they will be kept on file with our analytical results.

None of this refutes Mr. O'Connor's assertion that my yeast evaluation procedures are invalid. They are rather simple, but then I am a simple homebrewer and never claimed to be anything else. Given Mr. O'Conner's depth of understanding of yeast and related matters I would love to taste some beer he has brewed. For reasons I do not understand, he has chosen not to participate in Texas events like the Bluebonnet and Dixie Cup. I have been told that he has sent samples of his beer to Chicago. They apparently called it "O'Conner's O-Ring Beer". Does anyone know anything about this?

Subject: RE: Wyeast 1214, Parallel immersion chillers

Hi All,

In HBD#1126, Rob Bradley writes:

>Has anybody had any REAL success brewing  
>quality ale using the "wet t-shirt" method when the ambient is above  
>80F?

I've used this technique several times, it does work well. I do have a basement, but it still gets to 75F-78F during the dog days of July and August. In addition to putting the carboy in a basin of water and covering it with a wet towel, I use a small computer fan to circulate the air around the carboys. This keeps the evaporation rate high enough to cool the carboys the 6-8 degrees or so necessary for ale fermentation. The fan itself draws very little current, so it doesn't cost much to run it 24 hours a day, even at the larcenous rates that Public Screwing, er, I mean, Service of New Hampshire charges.

I've also been successful brewing dunkelweizens in warm weather using Wyeast 3506 Bavarian wheat yeast. The warmer fermentation temperatures seem to help this yeast produce more of the clove phenolic that's desirable in a weizen.

>my  
>major regret is that so many good bottles of beer aged past their

>Any other recommendations?

Sure, throw a party! I have the same problem, as much as I enjoy drinking homebrew, I enjoy brewing it even more. On those occasions when I've developed a backlog of several cases, my friends have been more than happy to relieve me of the excess :-).

\*\*\*\*\*

Also in HBD# 1126, Al Korz writes:

>But seriously, I've got a 50-foot, 1/4" OD immersion chiller (about  
>1/4 of which is not even in the wort on a 5 gallon batch) and it  
>cools my boiling wort to 70F in about 15 minutes. All this math  
>and physics may indeed give me a chiller that is 20% more efficient,  
>but all that means is that it will cut my 15 minutes down to 12 minutes.  
>Is it really worth it? Let's not lose touch with reality, eh?

I built my immersion chiller from 50' of 3/8" OD copper, and like Al's, about 1/3 of it is not even submerged in a 5 gallon batch. It too will cool my wort from boiling to under 70F in 15 minutes. While this has been a fascinating thread, with all of the discussion of heat transfer

and convection currents, I confess to being totally unscientific in the construction of my chiller.

The copper came in a 50 foot coil, I was too lazy to cut it. I just sat down with a pin lock keg, and started wrapping coils. I left a few feet on either end for the inlet/outlet, and wrapped some bare 14 gauge copper wire vertically between the coils to give it some structural strength. I did the whole thing in about 30 minutes, it works great, and never once solved a heat transfer equation.

Cheers,  
Jim

Subject: Re: Hops

Bravo! Nice info on the Hops report, Alan. I'm more of a gardener than a private brew master, so this was of great interest to me.

I would like to make a small clarification.

- The garden is along my North fence, for maximum sun.

Alan doesn't state which side of the North fence. This information of course, is dependant on what part of the world you live on. For most, if not all of the US, the "Southern Exposure" is what you are striving for. The side of a fence or house is nice because it stores and reflects heat/light for sun loving plants.

From: roberts735@aol.com

**Subject: Carboy Drain/Fill**

Not only will the carboy drain faster with the Rack hose venting air, it will also fill faster if you are dunking it in a large container, as I do. I use a very large cooler to hold by sterilizing water/chlorine mix, and put the entire carboy in there, with a hose in it. It fills very quickly, without the bubbles and splashes too.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Steel Kettles

>From: Keith A. MacNeal<macneal@pate.enet.dec.com>  
>Subject: Wort Pots

>What is this fascination for using stainless steel pots to boil wort  
in?  
It seems obvious to me that the way to save about \$100 on a boiling pot  
is  
to pick up a brand new enameled steel canning pot. I've seen them for  
around  
\$30.

Let me take a guess. Your responses will run ten to one about the evils  
of  
chipping and how rust and iron will permeate your beer and make it  
undrinkable.

You will also get a few remarks about how the handles break off at the  
most  
inconvenient times.

I used one for years for everything from fish boils and maple syrup to  
beer  
making and although it was chipped in a number of places including a  
hole in  
the lid that actually rusted through, it worked just fine. Scrubbing  
off any  
rust before use seems to be all that is necessary and if you take care  
of it,  
there is no reason it should chip. I was very rough on the pot and  
deserved  
every chip it got.

I have never had a problem with the handles on my fossilized kettle but  
the  
new ones do creak and crackle when flexed. I would, under no  
circumstance,  
trust them with a full kettle of boiling liquid but they can easily be  
lifted  
by the outside lip with potholders or gloves.

My first easymasher was installed in such a pot along with a false  
bottom.  
The false bottom has been abandoned as a dinosaur and the easymasher is  
now a  
commercial product.

There are several issues that seem to be limiting the universal  
acceptance of  
the em and the most significant seems to be the cost of a large pot and  
the  
fact that most people are unaware of the existence of the 33 qt  
enamel-on-steel canning kettle.

There also seems to be a very powerful reluctance to drill a hole in a  
nice

new kettle. I am not sure what drives this paranoia but to buy a kettle for the sole purpose of brewing beer and not go the additional step for the ultimate in convenience seems a bit strange.

Finally, a product does not seem to exist until Zymurgy does a review of it.

Well, one thing led to another and I am now offering the EASYMASHER kit installed in the 33 qt canning kettle, ready to mash, sparge and ferment.

Yes, in spite of all the momilies, they make great primary fermenters IF kept in good condition.

email for details.

If you have received the Kettleashing article, just ask for POT info.

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Whitbread History

Apparently-To: homebrew@hpfcmi.fc.hp.com

Here is the recent Whitbread history as I understand it. The original 3 strain culture was produced at an old yeast plant, operated under license by Whitbread. It was distributed in the US to HB shops and micros by Siebel. This plant was shut down ~2 years ago as a part of Whitbread's company wide modernization program. Siebel then had the yeast sent to another plant in Canada to temporarily produce it there until Whitbread's new yeast plant went into production. This is where wild yeast infection occurred. It caused quite a scandal in California and Canada, the regions that apparently got the bulk of the bad yeast. Siebel promptly dropped distribution of this yeast. A short time later Crosby+Baker contracted with Whitbread to have some more production runs done at the old plant, and started distributing it.

Both versions of Whitbread can be found in homebrew shops, at least this is the case in the Southwest. The C+B version comes in a 14 gram packet, while the other version comes in a 12 gram packet. I have tested both, and the samples were quite acceptable as far as lactics and super-attenuators are concerned. The yeast in the 12 gram packets are now very old, and its viability was unacceptable in 2 of the 3 samples tested.

In general, the detection of wild yeast is extremely subtle, however the detection of super-attenuators is a piece of cake. One need only inoculate a sample of the yeast in a sterile dextrin extract and measure metabolic activity. As I mentioned in a previous post, the yeast was also checked with Rodney Morris' incremental actidione test. I have found this procedure to be very useful in my own personal brewing. If there is anyone out there who actually brews beer and who has evidence to the contrary, then I would be glad to exchange both beer and data.

The situation may become more complicated in the next few months. The Whitbread yeast that was sent to me from a test batch at their new plant appears to be quite different from the old mixed culture. First, I believe it is a pure single strain yeast. Secondly, it tends to give a soft, slightly woody flavor not unlike Wyeast's London Ale strain. It is a far cry from the crisp and snappy tartness produced by the old mixed culture. It, like Wyeast's London Ale yeast, is exceptionally clean and has >90% viability. Feedback on the new strain would be welcome by me when it becomes available. The hope is that it can serve as a beginner's version of the London Ale strain.

George Fix

Take care.

George Fix

From: u4imdmre@cpc41.cpc.usace.army.mil (Markham R. Elliott)  
Subject: Best British Beers

Fellow Brewers,

Thought I would share with you the contents of an article from the May issue of Bon Appetit. The article is the "Tasting Panel Report", and for May, they pick ..."the 10 best British brews available stateside."...

Listed in alphabetical order, with *their* comments:

Bass Pale Ale, England (\$1.50/12 Oz). This world-renowned brew is clean and bright, with a light color and lively, malty, well-balanced flavors.

MacAndrew's Scotch Ale, Caledonian Brewery, Scotland (\$3.00/17 Oz). A smoky, spicy ale that is marketed with a lovable Airedale on the label, and the slogan "Man's Best Friend." We can't decide whether this refers to the dog of the ale.

McEwan's Scotch Ale, Scotland (\$1.50/12 Oz). Anthony Dias Blue describes this dark ale as "dense, sweet and rich, with hints of molasses and fruit."

Newcastle Brown Ale, England (\$1.30/12 Oz). It isn't really so brown, but this ale does have nice flavors of spice and malt, with a crisp, fresh finish.

Samuel Smith Nut Brown Ale, England (\$2.50/Pint). A fine Yorkshire product that's smokey, toasty, lively and loaded with flavor.

Theakston Old Peculier Yorkshire Ale, England (\$1.50/12 Oz). This brew with the peculiar spelling of peculiar is lush and toasty, with a great finish.

Thomas Hardy's Ale, Eldridge, Pope & Co., Dorset, England (\$3.00/6.33 Oz).  
Named for Dorset's most famous writer, this ale, bottled with its natural yeast, will improve with age. Dark and complex, with Porter-like qualities.

Traquair House Ale, Scotland (\$5.00/12 Oz). Yes, it's expensive, but Traquair was tops with us. It's made on the estate of a historic Scottish manor house that was once occupied by Bonnie Prince Charlie. Angela Freire of Wine and Spirits magazine finds Traquair "earthy and hoppy".

Welsh Ale, Felinfoel Brewery, Wales (\$2.50/Pint). This brew was a favorite of the poet Dylan Thomas. It is loaded with attractive spice and is "full and

thick with a nice bitter finish," according to one panelist.

Whitbred Traditional Pale Ale, England (\$1.00/12 Oz). Bright, with fresh, snappy flavors. "Fine balance and structure," says panel member. Cirilo Octaviano.

\*Listed prices are approximate and may vary from one state to another.\*

Gosh, not too descriptive. By no means am I a qualified judge, but it sounds to me like the panel doesn't get around to judging beer too often, or at least they don't use the same language in describing things like you certified folks out there in HBD land do.

Wish they would have ranked them.  
Noch einmal, bitte!! Mark

Assuming you live in the northern hemisphere, the sun also travels around the stake clockwise (clockwisdom being a holdover from sundials). Could there be a connection? Are the plants following the sunlight?

Or maybe it's the Coriolus effect. :-)

Subject: Wooden trellis for hops?

Greetings--

I have persuaded a friend to let me grow some hops in his yard. To be specific, it is on the side of his house. I planned to use twine to make a trellis, but my friend's wife decided a wooden lattice-type trellis would look better. It seems to me that a wooden trellis, while more aesthetically pleasing, would get in the way during the harvest.

I'd like to know if a wooden trellis would be worthwhile. Anyone out there have one in use?

Thanks!

Subject: old style beer (not the bra

Subject: Time:4:48 PM  
OFFICE MEMOold style beer (not the brand) Date:4/26/93

Hi All:

Last year some of our club members and members of another club got together for several weekends and brewed beer (imagine that) at an outdoor Renaissance Fair.

These beers were brewed with a three tier gravity/stainless steel keg/propane burner system. There were many interested potential homebrewers and the events were a great success. The beer was good as well. This year there are plans to repeat the performance. All this got me thinking....why not take a giant leap backwards in technology?

Stainless is great at home, but primitive might be fun as well. I envision not a ss mash tun, but one made from half of an oak barrel, a large pot (cauldron) boiled over an open fire. A single infusion mash using a procedure in which the grain is doughed in at ambient water temperatures and boiling (or hot) water added to reach mash strike. Draining to the boiler the first runnings and a second mash possibly with no sparge.

Well, I am in the process of building such a beast out of a 55 gal used whiskey barrel, at least as a proof of concept. Noonan's Scotch ale gives guidelines for old style brewing ie. second mashing so I have something to start with. I suppose decoctions are not out of the question either.

Has anyone tried something similar to this that can offer some guidelines? Can you think of a better mash tun or boiler? I'm not sure how to cool this stuff without entering the 20th century.

DanMcC  
.....oh no, think'in again

SUBJECT: Culturing Chimay

BILL SOLVIBILE writes:

>THERE IS ACTIVE YEAST IN THE CHIMAY BOTTLES. WE FILTERED IT OUT AND  
>ATTEMPTED TO CULTURE IT. WE THOUGHT WE WERE SUCESSFUL, BUT OUR BEER  
>WAS NO CHIMAY.

I have had several discussions with people on the net about Chimay yeast. I believe I read (in HBD probably) that Chimay yeast is a combination of 5 different strains plus some other microflora. One person said that his plate of Chimay yeast had several "different" colonies of yeast on it, while another said that his plate looked all the same. I think they got their yeast from bottle dregs, not from Wyeast 1214.

I'm starting to culture my own yeast and am curious about Chimay and other Belgian strains. Is it worth plating out the yeast or do you lose other important side strains? I would think that culturing the bottle dreg in wort and keep repitching until you get enough yeast slurry to pitch would be the way to go. Then keep repitching the slurry until there is a noticeable difference like one of the side strains taking over. I'm not worrying about it, because I don't have a batch in the fermenter, etc. etc., but I am curious. Thanks in advance for all the expert advice.

FROM: Dennis B. Lewis <dblewis@jscprofs.nasa.gov>  
SUBJECT: Soda adjuncts

In a recent HBD, someone asked about using cola to acidify the sparge water. This idea rekindled the one I had about using Coca-Cola as an adjunct in making a porter. So I gave it a sample try. While the labelling didn't indicate that there were any preservatives in the mix, there are "natural flavors" which, of course, can be preservative in their own right.

My test went like this: measure OG and pH; buffer with calcium carbonate to 5.4 or so, pitch yeast and yeast nutrient. The OG was a whopping 1.042! That's a pound of sugar (high fructose corn syrup) per gallon. Or a teaspoon per ounce. (Next time you have a can of Coke, think about eating 4 tablespoons of sugar. :-b) The pH was below 4.5, probably more like 3 something. Turned my pH paper bright yellow. I didn't bother to boil the Coke, but I did decarbonate it. I put 8 oz in a bottle with 1/2 tsp of dried ale yeast (rehyd) and a little yeast nutrient.

The resulting cloudy mixture gave 2 glubs total and then the yeast started dropping out of suspension. The SG didn't change much and the taste was terrible and not the least bit alcoholic. Moral: Don't bother with colas or other sodapops. They have stuff that will knock out your yeast and don't really taste that good. Blech.

From: gxd@po.CWRU.Edu (Guy DeRose)  
Subject: Chimay culturing question

After 6 batches of extract/specialty grain/dry yeast beer, I'm about to make my first attempt at culturing yeast. I would like to make a Trappiste style ale using the yeast from a bottle of Chimay. I have read and enjoyed the recent thread on HBD about yeast culturing and Papazian's and Miller's book descriptions of culturing. My question is: Is there a difference between the yeast in a big (750 ml) bottle and in a small (~11-12 oz.) bottle of Chimay red? Thanks for any feedback.

Subject: SUMMER MUST BE COMMING, QUESTION ON O2

Summer must be comming not much traffic on the Homebrew digest and we had a day without Jack!

Question? Have any of you out there used direct O2 before you pitched your yeast? I have read tails of some using direct injection of O2 instead of AIR and some problems with too much and getting way too much yeast growth. How much is right? What range of volumes do you use? Since I'm a welder and have the equipment to inject O2 it would seem a better way to go than with AIR.

**Subject: Premier Malt Extract**

Yesterday while grazing at the grocery store, I noticed a can of "Premier Malt Extract" next to the cereal section on the bottom (dusty) shelf.

It said it was malt extract used for brewing and baking. Has instructions under the lid along with unmarket packet of dried yeast. Bright yellow label.

Interestingly enough it was 2.3 pounds or so... at about \$4.50. Detailed label gazing revealed ingredients of malted barley, corn, and hops. Also sid it was made in United Kingdom for a U.S. company.

Any ideas what this stuff is?

Thanks

Bob

From: David McDow <dmc dow@emx.cc.utexas.edu>  
Subject: Decoction mashing...

My first post to this here forum (gulp)

I am an all grain brewer, (7 batches) and have been doing the one step infusion method of mashing grains. The last 2 batches have been somewhat of a disappointment. They have been wheat beers, and my extraction has been poor. Previous to these 2 attempts, all have been barley batches and extraction has been acceptable. Someone (sorry forgot) mentioned that wheat beers should be decocted.

I would like to learn more about decoction mashing. If anyone would care to share their method I'd be appreciative.

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: old style brewing

hello all,

Daniel mentioned that he was thinking of brewing in an old/ancient way. I thought I'd send this extract in, for it's general interest:

Extracted without permission from Corran's History of Brewing:

.....The mash-tun, according to Nordland, who calls it the filter vat, was the only specialised piece of brewing equipment; it was generally reserved for brewing, whereas other vessels might be used for different purposes.

Filter vats were of coopered wooden construction, and some had individual staves lengthened to make legs. Others sat on tripods or T-shaped supports. Nordland's investigation extended to philological aspects of brewing, and he shows that one of the names for the filter vat is related to stampf or stumpf, the stub of a tree, and hence to wooden vessels or containers made by hollowing out logs.

Such vessels predated coopered vessels, but in more recent times were used only for crushing grain or bark into flour or for storing dry goods such as flour. Reference is also made to a trough-like filter vat made from a hollowed-out trunk and kept together by strong wooden half hoops and cross pieces at the ends. Taps were made of wood, generally beech, until well into the nineteenth century, when brass taps were introduced. Strainers for the mash were a source of much variation. Straw was used from Egyptian times for this purpose. The old Norwegian practice was to put down a grating of sticks, usually of juniper or alder, which supported the straw that did the straining. Notched sticks were also used to support the grating; later on came the wooden perforated bottom, which has almost certainly been used since medieval times by brewers in England. Juniper was widely used in Norwegian brewing, both for flavouring the malt and the beer. It was also included in the hot water used for cleaning brewing vessels. The importance of cleanliness was well understood. Before brewing, the wooden coopered vessels were made watertight by being put in running water. They might be kept filled with clean water, but a juniper extract was more efficacious, a decoction of the plant being boiled and poured into the vessel. But in order to make quite certain the vessels were not sour, the Norwegian brewers used 'stone boiling'. The practice of using hot stones for boiling liquids is known in many parts of the world, and is particularly associated with the processes of brewing and cooking. Although the use of stones for boiling has long vanished from Sweden and Denmark, Nordland states there were stone breweries in Finland and the Baltic countries within the twentieth century. The last known survival, as far as is known, was at Newmannsdorf, near Klagenfurt in Austria, where beer was still brewed by this method up till 1917, with the consumers' strong approval. This brewery is now installed in the Technical Museum in Vienna and comprises

(a) A fireplace for heating the stones. This was usually a hole dug in the brewery yard, 2m x 1m, bricked on three sides with a sloping fourth side. Long logs and stones the size of a child's head were piled in layers.

(b) A wooden mash-tun on wooden supports, with a low plat form surrounding it; its outlet hole, which can be closed by

a bung on the end of a pole, gives on to a wooden trough made from a hollow tree trunk.

- (c) A primitive wooden pump, also made from a hollow log, which pumps water into a trough that conveys the water to the top of the mash-tun.
- (d) Two other wooden vessels, one evidently for heating water and the other for fermenting.

The brewing procedure was as follows:

- 1 The malt was ground and the mash-tun outlet prepared by covering it with juniper twigs.
- 2 The stones were heated and dropped into the mash-tun, which had been filled with water and with the prescribed quantity of hops.
- 3 The liquor was boiled. (BY THE HOT STONES)
- 4 Cold water was added, followed by ground malt, and mashing took place.
- 5 The mash was heated again, by means of larger hot stones this time, and the mash worked with a mashing oar. (An oaken cradle was used for carrying hot stones from the fire place.)
- 6 When mashing was finished, more juniper branches were put vertically into the mash to facilitate filtration, which began after 1hr.

Meanwhile 'sparging' liquor was heated in the second vessel with the help of stones. Wort was ladled back into the mash-tun if it did not come through clear. When it was clear, it was run into the fermenting tun, which was placed in the cellar. It was easy to cool in the winter, but during the hot season it might be chilled by means of cold water and ice in some sort of floating vessel.

The similarities of a good deal of this procedure to the findings of

Nordland in Norway make it probable that here we have a picture of early ale and beer brewing in all the countries of Northern Europe.

#### Hops and Flavouring

The mixture of herbs known as gruit was extensively used in Scandinavia, just as it was further south. The most important ingredient, certainly in Norway, was the bog myrtle. Evidently the ale was potent when bog myrtle was added, and it was often used in addition to hops. *Hypericum perforatum*, St John's wort, was also used, as was yarrow (*Achillea millefolium*). Tansy and wormwood are also mentioned. Pine roots and spruce chippings might sometimes be added to prevent the ale from turning sour. There are further references to caraway, pepper and even potato leaves and tobacco ('but that kind of ale was no good - it made them sick'). Nordland considers that bog myrtle may still be used in western Norway. Hops might be put in a bag and boiled in the wort, which saved subsequent straining, or they might be strained off after boiling, for which purpose there were hop strainers of basket work, vegetable fibres or hair, or even perforated wooden boxes. Some indeed were small coopered vessels.

#### Yeast

Old Norwegian ale was top-fermented and the yeast was removed from the fermenter with a special skimming spoon, though the brewer's right hand might also be employed. The ale was generally drawn off before fermentation was finished,

and it fermented further in the cask. The brewing yeast was used also for baking.

SORRY ABOUT THE VARYING LINE LENGTHS.

ROB. THOMAS

Subject: Nottingham yeast problem ?

This is my second batch with nottingham ale yeast. After 48 hrs, still no activity. With my first batch after 48 hrs I gave up and pitched a different yeast which promptly got the bubbles going. Is Nottingham a particularly slow starting yeast ? For info, the OG was 1.052 and I rehydrated the yeast "by the book". I'm getting real nervous about letting it sit with no activity (68 deg F) although I use an airlock.

Subject: thanks to hbd

I didn't want to take up too much bandwidth but since the HBD has been sparse lately, I wanted to thank the HBD and the people I met in Finland. Because of contacts through the HBD I was able to meet 2 very nice homebrewers in Helsinki, Finland this past week. I wanted to thank Kari Nikkanen and Hanna for showing us some of the best in Finnish beers. For those who get a chance Koff porter and lager are quite good, but the standard Lapin Kulta, while better than most American lagers, was nondiscript and "watery." I also wanted to thank Ilkka Sysil and Anita Mikkonen for inviting us to their home and sharing their excellent beer. They make a truly fine lager--better than many I tried that won contests in the States. They also have a very interesting engineered system that he might be encouraged to share over the HBD.

In HBD 1128, Kari Nikkanen raises the question of using N2O:  
"... since Guinness uses N2O, why shouldn't I."

A properly poured Guinness only uses 20% Nitrogen. The remaining 80% is CO2. The Nitrogen definitely helps in the smooth head, but most important is the baffle plate and atomizer within the tap which "aerates" the stout.

From: rjsmith@iron.afsac.wpafb.af.mil (Randy Smith)  
Subject: Typical Lager Fermentation Time?

Started my first genuine lager yesterday that will go into my Hunter Air Stat controlled fridge for fermenting. Most of what I've done in the past is ales. Usually we wait 2-3 weeks and then bottle. I do have a hydrometer, but never really use it. Just too lazy to track the readings, etc. Everything has come out good for the past few years, so we've been doing ok so far. I'm concerned with the lagering and how long it will take to be ready to bottle. How long is probably long enough? I used 6.6# of liquid malt extract, Y-yeast Bavarian yeast (forget the number), and will ferment at 48 degrees. Used Tetnang and Saaz hops, but that shouldn't affect the ferment time, right? Didn't take a hydro reading (the lazy part), but am making a typical 5 gal batch. My big fear is making two cases of beer grenades. What do you think?

Subject: Addr: Premier Malt

In response to the question about Premier Malt: I occasionally use this because it sells at our local grocery for \$3.99 for a 2.2 lb (?) can. It USED to be \$2.99 until about last year. I have always found it to be a good product, and will use three cans for a 4 1/2 to 5 gallon batch of "kitchen sink brew," where I just throw in all the left over ingredients I have. I have used the packet of dry yeast, at times, when I don't have any liquid, and have had surprisingly good results. I have no brewing store nearby, and the price is right. I'd like to hear comments from other brewers about this Premier.

>lagering at 40 and a week at 32 to settle out yeast and proteins. I  
would  
>have to say that the description is different from the result. It did  
not  
>produce a strong malty flavor. I have heard other brewers have the same  
result.

I tasted this brew recently, I'd have to agree with Lee's assessment.  
While the beer was quite good, it did not have the pronounced maltiness  
and  
slightly sulfury notes of a Bohemian pilsner. Instead, the malt  
character  
was "softer" and much more subtle.

I find this of interest because I provided both the undermodified  
pilsner  
malt and the decoction mashing procedure Lee used for this brew. We both  
brewed pilsners about one week apart, we both used Saaz exclusively.  
Using  
this same malt and style of mashing, I've produced Bohemian-style  
pilsners  
with the maltiness and sulfury notes I've come to know and love. The  
only  
difference in ingredients and procedures was that I used the Wyeast 2206  
Bavarian, one of the strains recommended by Miller in his "Continental  
Pilsner" book. For anyone planning to brew a Bohemian pilsner, the 2206  
produces a beer much closer to style than the 2124, IMHO.

I have seen this type of thing before, where beers were brewed with the  
same malt, hops, and procedures, but pitched with different yeasts to  
produce  
distinctly different beers. Never ceases to amaze me, though.

Cheers,  
Jim

It is my understanding that the sugar/soda extract combination does not have enough nutrients (other than sugar, of course ) to support a fermentation. Folks that make their own sodas rely on this fact since most recipies I've seen suggest mixing up your extract/sugar, pitching yeast, and bottling immediately. The yeast can maintain just enough activity to carbonate the mixture before dying of some horrible yeast malnutrition. This may explain why your test 'brew' didn't do much. Of course, it does not rule out the possibility that preservatives are at fault as well. A test with a soda/malt combo should be decisive.

**Subject: Alcohol and other drugs**  
Full-Name: Ted Manahan

I wrote this article for our local club's newsletter. In the interest of generating controversy, I will post it here.

Ted Manahan

-----  
At the recent Home Brew U, [In Seattle, WA] I heard Gene Ford speak. He publishes the Moderate Drinking Journal, which is devoted to reporting on the positive medical and therapeutic aspects of drinking. He is on a quest to counter the attempts of neo prohibitionists to limit access to beer, wine, and spirits.

One of Mr. Ford's basic philosophies is that our culture has a long history of using these drinks in moderation. They are social lubricators, and promote relaxation and well being. With this I agree. He also objects to the use of the term "alcoholic drinks" to describe beer, wine, and spirits. He feels this term is used to create a link between these legal drinks and illegal drugs. He claims there is a fundamental difference between alcohol and illegal drugs.

At the AHA conference last year, the keynote speaker presented this same point of view. Charlie Papazian put forth this same claim in a Zymurgy editorial. I have heard other homebrewers with similar opinions. I don't agree that there is any fundamental difference between these different types of drugs.

Homebrewing was legalized only in the last couple decades. At various times in history, alcohol has been out of favor, and even illegal. Alcohol is a very potent drug, with the possibility of death resulting from abuse. We homebrewers, as producers and consumers, need to be aware of this.

We also need to be vigilant against someone deciding they know what is best for us. The potential for abuse does not justify taking away the liberty to use. This certainly holds true for other substances. The current "war on drugs" is a prime example of creating criminals out of honest citizens, just as prohibition created criminals out of honest drinkers.

The main effect of the "war on drugs" is to guarantee a monopoly on drug profits to those willing to break the law. What newspapers call "drug related violence" is really money related violence - the most common drug related violence is bar fights between drunk people.

It is foolish to self righteously decry the attacks neo prohibitionists are making, while failing to see the connection with our own intolerance of, for instance, marijuana use. Homebrewers need to be aware that intolerance is contagious. People with "Zero Tolerance" will quickly see that alcohol is more dangerous than most illegal drugs. The urge to control people's behavior soon extends to everything we personally don't do.

So don't fool yourself. The next time your friends complain about the effort to lower the DUI limit to one beer, point out that they may be

contributing to the political climate that views government control of our lives as acceptable. Take note of your own attitude next time you hear of a drug bust. Would you have felt the same way about the BATF busting a homebrewer twenty years ago? Next time, it could be you!

Subject: Clockwise Hops

Just joined this list and am mighty impressed by the brewing knowldege of you all. I can't contribute much there, but I do know a thing or two about botany. Twining of vines appears to be unrelated to either sunshine

(they do the same under artificial light) or coreolis effect (I believe they may have even tested it in the space shuttle). It is controlled by internal factors related to planes of cell division and distribution of plant hormones. Some species are innately counterclockwise twiners, and others, like hops, go clockwise. Yes, it is conventionally viewed from the plant's point of "view", looking up. An unsupported hop shoot, viewed

with time-lapse photography, makes clockwise spirals (a type of movement called "nutation") in mid-air, until it touches something; then it twines around that support. So unlike the whirlpool in your toilet, it will also

go clockwise in the southern hemisphere.

By the way, re. British beer reviews, I agree they aren't very discriminating. Anybody who can use the same adjectives to describe Bass and Old Peculier must have no taste buds, and then to make no mention of original gravity??? Is it any coincidence that these "10 best" happen to correspond to the 10 brews most commonly found in a fairly good (but not spectacular) liquor store? Not much research done, I suspect.  
Cheers.

Subject: Carbonation, Nitrogen, Yeast

>From: Paul Andrews <PANDREWS@hpb.hwc.ca>  
>Subject: Foam and keggng problem

> I pressurized to 50psi (at room temp).. let sit overnight..  
(it went down to about 30 psi) after 16-18hours. I decided to see what  
it  
tasted/looked like the next day. Ugh.. most foam and very little  
carbonation.

Shake the blazes out of it and it will be carbonated in a few minutes at  
50  
psi. I would suggest that you reduce the pressure to about 20 lbs when  
the  
big rush is over or you run the risk of over carbonating it although at  
room  
temperature, that is not very likely.

The problem you will have carbonating it at room temp is dispensing it.  
I  
use a cold plate to chill it as it is dispensed but without that, all  
bets  
are off.

>From: NIKKANEN@ntcclu.ntc.nokia.com (Kari Nikkanen, design engineer)

> So you are using N2O instead of CO2? Do you get  
better (smoother) head in your beers than with  
CO2? I think I'll start keggng my beer too, and  
I just thought some time ago, that if Guinness  
uses N2O, why shouldn't I. Does anyone else  
have any opinions?

After reading George Fix's article on nitrogen, I had to give it a try.  
I  
have been experimenting with a product called Aligal. This is 20% CO2  
and  
80% nitrogen and is sold in a cylinder with CO2 fittings, making it  
convenient to try. Unfortunately, it is only available as a rental and  
costs  
\$4.50 per month plus \$18 for the gas.

The first problem I encountered was when I attempted to carbonate a  
batch of  
with it. After pressuring up the tank to 50 psi, there was not the  
slightest  
absorption, no matter how much I shook it. I had to bleed of the gas  
and  
switch to the straight CO2 in order to carbonate it. When it was just  
about  
fully carbonated, I bled of the CO2 and switched back to the mix and let  
it  
sit at 50 psi overnight.

The results are very interesting but I am not sure it is worth the  
trouble or

expense. I have done 3 batches with this set up and although each one acts a little different, the common ground is a head that builds from the bottom up in a very peculiar manner. The beer can come out of the tap without a bubble and fill the glass with foam but it disipates in seconds, leaving about an inch that will stay for hours if you don't drink it.

What is interesting is that typical foam leaves a mostly empty glass when it dissipates but this foam just turns to beer. I c-p bottled some and took it to a CBS meeting and it acts the same way when poured from the bottle. It is really fun to watch.

I put it in the catagory of cute but not sure what value it has for homebrewers.

>From: sims@pdesdsl.atg.trc.scra.org (Jim Sims)

> (1) I've noticed that several of the bartches dont have much head. I've seen the comments about spotlessly clean glassware, etc.

My experience has been that head retention is a problem primarily associated with extract beer. "spotlessly clean glassware, etc." may be important with a marginal beer but since I started making all grain beer, it has become totally irrelevant how, if or with what, I clean the glass.

> (3) Can someone email me (or send me the ftp location for) the yeast culturing notes that were (apparently) posted here not too long back?

If you are referring to mine, it is on the way. Actually, it is on the way regardless.

>From: woessner@psych.purdue.edu (Leo Woessner)

> I am also interested in locating possible sources of yeast slants which contain yeast which is hard to find. Is there a mail order place(s) which specialize in yeast culturing??

This is a small scale operation run by Paul Farnsworth. He has lots of yeast and everything you need to deal with it. I have used 4 of his yeasts including Pilsner Urquel with good results.

>From: SMUCKER@UTKVX.UTCC.UTK.EDU

>Summer must be comming not much traffic on the Homebrew digest and we had a day without Jack!

Sorry to let you all down but if you note the dates on the two articles  
in  
the most recent Digest, you will see that it was not my fault.

>Question? Have any of you out there used direct O2 before you pitched  
your yeast?

Not personally but I just got a call from a customer who claims near  
Kreusen  
within 20 minutes of pitching with O2. Not sure if that's good or bad,  
just  
another data point.

Subject: Brewing partners?

I'm not sure about brewing partners. But would others be interested in trading one or two six packs of your better brews for those of other brewers. It seems that this way many of us could enjoy a wide variety of brew. Perhaps a means of placing ads of which styles one had available and was willing to trade would be helpfull. Any interest or alternative ideas?

From: korz@iepubj.att.com  
Subject: Guinness

I just thought some time ago, that if Guinness uses N<sub>2</sub>O, why shouldn't I. Does anyone else have any opinions?

Actually, Guinness uses a nitrogen/CO<sub>2</sub> mix. I believe it's about 65% N<sub>2</sub> and 35% CO<sub>2</sub>. The reason for this is so they can dispense at high pressure without dissolving too much CO<sub>2</sub> into the beer. Pure CO<sub>2</sub> at their dispensing pressures would make for uncontrollably foamy beer.

This weekend, I had my first opportunity to drink ale drawn by hand pump in the US. After the judging at the Bidal Socielty of Kenosha homebrew competition judging, one of the brewers from Brewmaster brought over his \*portable\* beer engine! A Black&Decker workmate was set up with an open stainless keg underneath and the 3-by-3-by-3-foot wooden box in which the beer engine was mounted. At first, the beer was still a bit fizzy from the being originally, naturally carbonated, but eventually it became appropriately "flat" and the beer was more authentic. It was actually more of a novelty, but was nonetheless cool!

From: rush@xanadu.11nl.gov (Alan Edwards)  
Subject: Re: Growing Hops Horizontally

In HBD #1128, davidr@ursula.ee.pdx.edu,  
David Robinson writes:

Bravo! Nice info on the Hops report, Alan. I'm more of a gardener than a private brew master, so this was of great interest to me.

Thanks David.

I would like to make a small clarification.  
- The garden is along my North fence, for maximum sun.  
Alan doesn't state which side of the North fence.

On MY side, silly. (Sorry, couldn't resist!)

This information of course, is dependent on what part of the world you live on. For most, if not all of the US, the "Southern Exposure" is what you are striving for. The side of a fence or house is nice because it stores and reflects heat/light for sun loving plants.

Seriously though, I live in California, so the plants are on the South side of the North fence, to get maximum Southern exposure from the sun. Clear as mud? Well, I drew a little picture to help clarify my setup. (I guess I should've done this in the first place.)

ARIEL VIEW

In HBD #1126, I wrote:

- I have seven hop plants of different varieties about 3.5 feet apart.  
The whole garden is about 24 feet by three feet.

| - The garden is along my North fence, for maximum sun.  
| - Two 8 foot 2x4's are nailed to the wooden fence (at the corner and  
| at a 4x4 post, for support), with a galvanized steel wire stretched  
| across the tops (with a turnbuckle for tightening).  
| - Nylon twine is hung from the steel wire and staked into the ground  
near  
| the hops. I would advise against using jute (natural fiber) twine.  
| I used jute twine last year and after weathering, some of them  
snapped.  
| Also, they stretch out over time, requiring retightening every so  
often  
| (plan for this).  
| - The horizontal twines are tied to the steel wire and fastened to the  
| eaves of the roof with screw-eyes.  
| - Some vines are not aligned with the house. And in those cases, the  
| twine goes to a second steel wire stretched between the North-East  
| corner of the house and an 8 foot 2x4 attached to the East fence.  
| That wire forms an extension to the North side of the roof, where  
| the other twines are attached.  
| - The garden is fenced in with a simple 2x4 frame and some chicken  
wire.  
| If you have pets, you must fence it off. Don't trust your dog. I  
did  
| two years ago, and he wrecked the garden. I had to start all over  
again.

A clarification:

| This year, instead of training three vines from each plant up one  
twine,  
| I am training four vines from each plant up TWO twines.

That's two vines per twine, four from each plant. You might want to try  
three per twine (six per plant), but I'm not sure that it would increase  
your harvest or not--it might. It would certainly increase the  
harvesting  
difficulty if the plants get too bushy, but it's not that big of a deal.  
According to the book I have, there IS a point of diminishing returns,  
and I think that six vines per plant is probably pushing it.

If you are only using one twine per plant, then the book I have says to  
train three or four vines.

| If you don't keep cutting shoots, things can get hairy quickly. The  
| same goes for the long runners that you get coming out of the sides of  
| the vine.

I'm not sure about the runners that come out of the sides of the plant.  
The book I have doesn't mention them. I think it's probably better to  
wind them up with the main vine. That's what I'm doing currently, and  
that's what I think I did last year.

What book am I referencing? Good question. I don't have it with me,  
but you've all probably seen it, at least in Zymurgy. I think it's  
titled  
"Growing Hops". Its the small paperback with hops all over the cover.

Good luck, and have fun,  
-Alan

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Priming Scotch Ale

Part 1: I've been told the scotch ale (heavy OG 1.040) I've currently got in my secondary should be bottle to produce "low carbonation". I normally bottle ale with 3/4 cup of corn sugar for a 5 gal batch. This generally produces what I'd call a normal carbonation level. (Except when I'm hasty to bottle the I get high carbonation and wish I'd been more patient.)

Question 1: What amount of priming sugar would one use to get the 'low carbonation' appropriate for Scotch ale? (5 gal batch).

Part 2: I sometimes get varying levels of cabonation within a given batch. That is some bottles are more carbonated than others. I usually prime in the following way: 1) boil sugar w/a few cups of water & let cool. 2) Start syphoning beer from secondary to bottling bucket. 3) When about 4" of beer are in bottom of bucket add sugar solution. 4) Keep syphon near bottom of bucket hoping to provide enought mixing to uniformly disperse bottling sugar.

Since I still get different carbonation levels methinks I'm not properly mixing the bottling sugar with the beer. I'm reluctant to stir the beer for fear of oxidation and/or infection. Suggestions? Comments?

Subject: Re: British Brews/Chimay yeast/O2/Hop growth

Mark writes:

>Thought I would share with you the contents of an article from the May issue  
>of Bon Appetit. The article is the "Tasting Panel Report", and for May,  
>they pick ..."the 10 best British brews available stateside."...

then later goes on to say:

>Gosh, not too descriptive. By no means am I a qualified judge, but it sounds  
>to me like the panel doesn't get around to judging beer too often, or at least  
>they don't use the same language in describing things like you certified folks  
>out there in HBD land do.

Yes, indeed, it's too bad that they did not enlist the talents of anyone who had experience in judging or writing about beer. Also too bad that they missed Young's Special London Ale, Samuel Smith's Tadcaster Porter, Oatmeal Stout and Imperial Stout and Mackeson's XXX Stout. Kudos are due for drawing attention to Traquair House Ale and Caledonian Ale (marketed here as and misnamed MacAndrew's \*Scotch\* Ale (a Scotch Ale it's not)) two of my favorites.

\*\*\*\*\*

Dennis writes:

I have had several discussions with people on the net about Chimay yeast. I believe I read (in HBD probably) that Chimay yeast is a combination of 5 different strains plus some other microflora. One person said that his plate of Chimay yeast had several "different" colonies of yeast on it, while another said that his plate looked all the same. I think they got their yeast from bottle dregs, not from Wyeast 1214.

Periodically, people write in the HBD that Chimay yeast is a mixture of 5 yeasts, so you may have read it here, however, it is NOT TRUE. Chimay \*used\* to be brewed with a yeast that contained several strains, but Father Theodore (I believe with the help of DeKlerck) isolated a strain out of many in their yeast which they have been using as their single strain yeast for (I believe) at least two decades. The label says that they bottle with an addition of yeast, but people who have brewed with Chimay bottle-cultured yeast that I've talked to have reported very Chimay-like beers, so I suspect that the bottling yeast is the same as the fermentation yeast. To answer Guy's question, the yeast in all the Chimay bottles, red, white, blue, 33ml and 750ml is all the same strain.

Orval, another Trappiste Ale, is a completely different story. They too ferment with a single strain yeast, but bottle with a mixture of 5 yeasts. I've successfully cultured what I believe is the Orval fermentation yeast just by trial and error. Orval also has a bit of lactic sourness, which means that there's some kind of bacteria involved which may be mixed-in with the fermentation yeast or just part of the

bottling menagerie.

\*\*\*\*\*

Dave writes:

>your yeast? I have read tails of some using direct injection of O2  
>instead of AIR and some problems with too much and getting way too much  
>yeast growth. How much is right?

I don't know how much O2 is right, but too much O2 can be toxic to the yeast, so be careful how much pure O2 you add to your wort.

\*\*\*\*\*

There were several posters speculating about the climbing of hops, suggesting that perhaps they are simply following the sun, which causes clockwise (as viewed from the top) growth in the northern hemisphere. Yes, it's the plant following the sun.

From: jkirsch@dolphin.uri.EDU (Jay Kirschenbaum)  
Subject: Help! Overbubbling!

Hi,  
A friend and I are making our first batch of Irish Stout. He has brewed a lager before, but this is my first batch of beer. We followed the directions that came with the beer kit (Irish Stout from Eastern Brewers Supply) but used a liquid yeast instead of the dry yeast supplied (on the suggestion of EBS).

We are fermenting in a ~6.5 Gal plastic primary fermenter, but now, two days after we pitched the yeast the wort is bubbling VERY vigorously. It is bubbling so much that it is getting in to the fermentation lock, which was 3-4 inches above the level of the brew when we began.

Did we do something wrong, or is a stout supposed to ferment that violently?

The ambient temperature is about 70-65 F as suggested in the recipe.

Thanks in advance,  
Jay Kirschenbaum (and Dave)

Subject: organizing a BREW-OFF!!

Hi.

i just wanted to share a few notes on an 'annual' brew-off that we have going here at UTSouthwestern Medical Centre. The school is essentially composed of graduate students (almost all Ph.D. students), post-docs and fellows, and faculty and of course staff. There are millions of labs here, all doing some form of biomedical research.

There are a few of us who also brew in the little free time we have. We have a GSO party (paid for [artly from the student fees) held every month where we (GSO = Grad Student Organisation) serve beer and titbits...

The GSO council decided, on a wee little brewing voice's suggestions, to have an annual brew-off where the students, faculty etc would brew a batch for the school and bring it in at one of the monthly parties that would then be designated a Brew-Off!! It truns out that we have quite a few brewers in the university and the event was very well received, with brewers of all levels bringing forth their products. Lots of fun !! The brewers also get reimbursed for the supplies (inggredients)for the one batch they bring in, but so far very few people have brought receipts in.

So, we have a greast time. The brewers get a chance to spread the good beer (cheer :- ) ) and get some general ffeed-back on their styles...

i thought that some other univ people might be interested in hearing about this fun event.

Ciao

And happy brewing.. Here's to tiny bubbles..

>activity (68 deg F) although I use an airlock.

I've used both Nottingham and Windsor. As a side note I  
preferred the Windsor. However, the packages are rather small  
... I believe containing approximately only 5 grams. Since the  
pitching rate is important in terms of the lag time, I have been  
adding two packages of Nottingham for a single batch. This is still  
less yeast than a single package of Whitbread. The lag time  
I've experienced, when pitching at 60F is approximately 1 day.  
On lag times like this I occassionly shake the primary until  
notable fermentation kicks in. IMHO I think this helps reduce  
the lag time.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Belgium Wheat Malt & Biscuit

Hi all,

I like to brew german HefeWeizens using 70% wheat malt, and following a decoction procedure as described by Eric Warner in his excellent book on weizens. The last two batches I made used DeWolf Cosyns Wheat malt. In both cases, my extract efficiency was way off. I used to use Bavarian wheat malt and always had great results. This is a bothersome result, but it could be due to other factors, notably both of these batches were produced in my newer brewery and it is possible that my decoctions are not as before. I am looking for feedback from the digest with respect to yields when using this wheat malt. Email me at busch@daacdev1.stx.com

The results are in from my latest celebration clone. I used a small percent of Biscuit in addition to large amounts of caramel malts. The biscuit resulted in an extremely pleasing light "roasted" character. It is subtle but evident. The ale is on the dark side of a pale ale, but the complexity and maltiness/roasted character is blending well with the spiceyness of Cascade and Centennial hops. The biscuit malt would seem ideal for use in Scotch Ales and other darker ales and even in small quantities in amber ales.

Good brewing,  
jim Busch

Some of the batches of beer that I've made with Nottingham took some time  
to start, but eventually everything worked out alright. You said that  
you followed rehydration methods "by the book." Well, there has been  
some contradictory information on rehydration in the past. Some  
descriptions

fail to mention a temperature differential between the "starter" and the  
wort.

I contend that this is still very important. You rehydrate the yeast in  
plain water between 104F and (I believe) 115F and then let it sit between  
15 and 30 minutes, right? Then you dump this 8 ounce "starter" into 5  
gallons

of 65F wort. This will definately shock the yeast. What I do with dry  
yeasts, is rehydrate them in 104F boiled water and then let them sit for  
30 minutes in a covered (with plastic wrap) pyrex measuring cup. In  
those

30 minutes, the "starter" has cooled to about 85F. I then pitch this  
into

my wort which I have intentionally only cooled to 80F (instead of the  
usual

70F) and aerated well. Even with this procedure, one batch took 48 hours  
to  
start.

For Wyeast batches, I warm the package to 70F and then pop the nutrient  
pack. This gets incubated at 70F and then pitched into a 70F starter.  
That gets subsequently gets pitched into a 70F wort. Positive pressure  
is obvious in the airlock/blowoff hose after 12 hours and kraeusen is  
formed in 24.

Ted writes about alcohol and the "war on drugs."

Theoretically, I feel that it is not the government's job to protect  
us from ourselves. Let's face it... many things that are good in  
moderation are bad in excess. Then there are the things that are  
legal although there has been no evidence of any positive effects from  
these substances -- case in point: tobacco. Alcohol can be abused,  
but so can model airplane glue and aspirin and caffeine and automobiles  
and Whipped-cream propellants and... Education on the dangers and  
\*reasonable\* warning labels, and then "buyer beware." That's my  
position.

\*\*\*\*\*

Chris writes:

>yeast). How is this new product packaged? Any information on how  
>to identify this particular Whitbread from the other two would be  
>appreciated.

I thought it was the 14 gm packages that were the "old variety" and  
the 12 gm packages that are the "new variety," but I could have it  
backwards. I didn't particularly like the "black-bread-crust" flavor  
of Whitbread Ale and thus chose to use other yeasts instead of Whitbread,  
so I don't have any personal experience with it.

>the plant's point of "view", looking up. An unsupported hop shoot,  
viewed

I guess I should have left it to the botanists to give the final word.  
Everything that I had read had said that the plants were "following the  
sun," but then again, mine were all homebrewing-related sources and not  
botany texts/journals/etc.

>In Ashburg, Virginia.

>How are their beers, in general?

>Do they have any particularly good ones? Are they a Micro or a brewpub?

Dominion Brewing (Ashburn, VA) is a microbrewery located in the flight path of Dulles Airport, outside Washington, DC

They brew several year-round beers, Dominion Ale, Dominion Lager, Dominion Stout and perhaps others I've forgotten. They also produce seasonal brews, the Christmas Ale was excellent, the current a Spring Bock I've yet to taste.

They also produce "house recipe" beers for a growing number of metro-DC area bars.

They conduct tours on Saturday afternoons, call 703-860-BEER for details. Last time I went, the president, Jerry Bailey, gave an excellent tour.

Subject: Decocting and Concocting

David McDow asks about decoction mashing:

>I would like to learn more about decoction mashing. If anyone would  
>care to share their method I'd be appreciative.

Particularly if you're interested in real wheat beers, you should pick up a copy of Eric Warner's book on German Wheat Beers, published by the AHA. Eric's decoction procede is straight-forward and easy enough to accomplish (particularly on the stove), plus it makes a killer beer. Greg Noonan's book on Lager Beer contains a much more complicated and much longer decoction mash. Judging from my reading in other sources, Noonan's procedure is unnecessarily complicated given the malts we have to work with these days and you should be able to use Eric's method for other beers as well.

>Chris

There was a time a few years ago when it seemed every brewpub in California was using Whitbread yeast, either their ale yeast or their "lager" (which made remarkably ale-like lagers!). This was apparently due to the influence of UC Davis' Michael Lewis, who was busy convincing potential brewpub owners/brewers that anything else was too complicated and not worth the effort. The results were pretty spotty, and convenient or not, the yeast apparently did not respond well to re-pitching, which meant the brewer had to keep buying more. I wrote a report about a trip through the brewpubs back in 1988 or so and singled out one horrible example in Santa Rosa. Byron Burch wrote to say that, ordinarily, the pub turned out very good beer but that they'd had some real problems with their dry yeast (Whitbread -- and by-now familiar problems). The local homebrewers stayed away until the beer was cleaned up (although why the brewery was serving such awful stuff, I don't know).

I don't know for sure, but I suspect brewers down there have become a little more sophisticated in the last few years, and learned that "easy" is not always the best choice.

Subject: Update to Pub list

The latest additions to my Publist have been made available on the Homebrew archive at sierra.stanford.edu in the pub/homebrew/docs directory, thanks to Stephen Hansen. The file is publist.Z (compressed with UNIX compress I believe). Listserver users just need to say "get homebrew publist".

This list includes brewpubs, pubs, restaurants, and beer (liquor) stores which have good beer. There are also some microbreweries, home-brew shops and the like, but these are not as complete.

The goal of this is to give travelers a reference on where to find good beers including sources to buy bottles to bring home.

My database which parses and searches this list currently says:  
#Done reading in the pub db, Pubdb Version 1.2 July 1, 1991  
#Recognized a total of 1417 pubs from 18 countries and 582 cities.  
---- (and the like)

I am trying to port the search program over from Sun to a PC, but don't hold your breath until the C++ class I'm teaching is over.

If you have any information especially about new brewpubs or beer pubs, brewpub closings, or useful notes/corrections please send me a message

Subject: Re: CO2 cartridges

Steve,

You can also get the CO2 cartridges used for Seltzer bottles, the kind that let you make and dispense your own.. I've never actually tried the sporting goods store route. I've always used the small CO2 carts used for Seltzer. Should still cost a lot less than Nitrous. They come in a package quite similar to the Nitrous carts.

The ultimate would be to rig an adapter that goes from the 5L taper gas thing to a real CO2 tank with a good regulator. In my experience, those ggas cartridges leak a lot. I seem to lose 1/2 my gas before I dispense any beer.

If I find an adapter, I'll let you know.

Subject: Re: Mashing on an Electric Coil Stove

In HBD1130 David Ferguson asks about mashing on an uncontrollable stove:

I would suggest using decoction mashing when suitable for the beer you're making. You'll only need the hottest and nothing settings. An other method (which also buffers temperature drop) is placing the mash-tun in a larger kettle with water. (if you have a number of cheap enamel on steel pots ranging from 5 to 40L(1.5-10Gal))

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: historical recipes,part 1

Historical Recipes by F Accum 1821  
translated by Rob Thomas.  
All recipes are adjusted to give 4 UK gallons  
of beer at fermentation (i.e. 5 US gallons).  
All measurements are UK units (same as US, except  
gallon US = 0.8 gallon UK)

PART 1

Brown Stout Porter.  
- -----

Ingredients.  
13.99 lb malt, 1/5 pale, 1/5 amber, 3/5 brown  
5.3 oz. hops.

Mashing.  
Mash 1: 2.375 gall of water at 165 F, 1.5 hours.  
Mash 2: 1.875 gall of water at 160 F, 1.5 hours.  
Mash 3: 1.938 gall of water at 186 F, 3/4 hours.

Boiling.  
mash 1 boiled with the hops for 1.5 hours.  
mash 2 boiled with the used hops for 1.75 hours.  
mash 3 boiled with the used hops for 2.5 hours.

Produces 4 gall at 1071.  
fg. 1024.  
- -----

London Ale.  
- -----

Ingredients.  
25.45 lb pale malt  
9.29 oz. hops.

Mashing.  
Mash 1: 1.820 gall of water at 175 F, 0.5 hours,  
then add a further 0.91 gall at 175 F, 2 hours.  
Mash 2: 2.180 gall of water at 180 F, 1.75 hours.  
Mash 3: 1.270 gall of water at 150 F, 1.25 hours.  
Mash 4: 1.270 gall of water at 150 F, 1.25 hours.

Boiling.  
mash 1 boiled with the hops for 1.5 hours.  
mash 2+3+4 boiled with the used hops for 3 hours.

Produces 4 gall at 1068.  
fg. 1026.  
- -----

Table Beer.  
- -----

Ingredients.

10.1 lb pale malt

1.92 oz. hops.

Mashing.

Mash 1: 2.880 gall of water at 160 F, 0.75 hours,  
then add a further 1.71 gall at 160 F, 1.5 hours.

Mash 2: 2.700 gall of water at 180 F, 1.25 hours.

Mash 3: 1.980 gall of water at 185 F, 1.25 hours.

Boiling.

mash 1 + 1/2 mash 2 boiled with the hops for 1 hour.

rest of mash 2 + mash 3 boiled with the used hops for 2 hours.

Produces 4 gall at 1035.

fg. 1012.5.

Subject: BEER WITH THE BENDS

In HOMEBREW Digest #1130 of Thu 29 April 1993, Ed Hitchcock writes:

:> Although perhaps impractical as Jack mentions, it does provide  
:> aesthetics. To some, good head is part of a fine beer, but heavy  
:> carbonation may add an acidic tang, and deffinitely makes for a \*  
fizzy\*  
:> product. By nitrogenating the beer, you get good head without the  
soda pop  
:> fizz. The reason for this is, as Jack discovered, N2 is virtually  
:> insoluble in water at low pressures, which is why the pressure didn't  
drop  
:> in the keg. Ideally the beer in the keg should be naturally carbonated  
:> (primed like a Real Ale) before being dispensed this way, not force  
:> carbonated. Force carbonating defeats the purpose. The insolubility  
of  
:> nitrogen is the reason for the small bubbles, the beer gets "the  
bends"  
:> when it comes out of the tap.

As a SCUBA diver, I would like to clarify the term "the bends" or as it  
is also know as "decompression sickness" (DCS). DCS is caused by  
dissolved  
N2 coming out of solution from the blood, muscle and other fluids and  
body  
tissues when a diver ascends too rapidly. This forms tiny bubbles that  
cause neurological and physiological damage to the body.

Although diatomic nitrogen (N2) is a very stable element and is  
relatively  
inert at low temperature and pressure, it is easily dissolved in fluids  
such as blood, water or beer. I can't say if or why it causes a good  
head  
on beer, but I can say that it will dissolve in it.

Subject: Scotch Ale/Caramel Flavor

I tried to make a Scotch Ale six weeks ago or so, and I've just opened the first couple of bottles. I used about 1/4 pound of "Mexican" brown sugar in the five gallon batch. Mexican brown sugar seems to be highly unrefined, and has an absolutely delightful molasses taste to it.

Now that the yeast is firmly on the bottom of the bottles, I can tell that there is very little molasses on the nose, and just a faint aftertaste. Just for fun the other day, I went out and bought some MacAndrews and McEwain's Scotch ale to compare. Since I like the MacAndrews better, I'll talk about IT. The first thing I noticed was a strong malt/caramel nose and flavor. We're talking strength like drugstore candy. More caramel than malt, I think. Tasty. My attempt doesn't come close. MacAndrews has more hop bitterness than mine does, but with all that caramel it probably needs it. The color, body, gravity, head, and the rest are fine in the beer I made -- what's missing is the caramel flavor.

It was an all-grain recipe:

5# 2-row  
4# Cara-Vienne  
1# Cara-Munich  
1/4# Mexican Brown Sugar  
Wyeast 1098  
7 HBU Kent Goldings bitter

Mashed at 155 F to get unfermentables up

The question I have is "How do I get the stronger caramel flavor?" The only thing I can think of to try is to get a few quarts of the strong first runnings from the lauter tun, and boil the h\*ll out of it while sparging the rest to caramelize the sugars. Or maybe melt the brown sugar in a saucepan, and caramelize it before adding it to the boil pot. Or maybe buy some Brach's (tm) caramel cubes and dissolve `em in the wort instead of the brown sugar?

Got any ideas for me??

From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>  
Subject: Single Malt Scotch Whiskey

Re: Bottling.

Single Malt Scotch Whiskey refers to the Whiskey coming from a single barrel. A whiskey like Chivas Regal is a blended whiskey. In a blended whiskey the intent is to produce a product with identical taste from year to year. With a Single Malt whiskey each barrel will have different taste, however subtle that provides a tasting adventure to the drinker.

If what you have is indeed barrels of single malt whiskey. I would bottle the contents of each barrel separately and label accordingly and enjoy the nectar of the heather.

Regarding bottling and flame point, If flammability is an issue do it in a well ventilated place like outside. Reusing glass liquor bottles with screw caps should be acceptable or wine bottles with corks. The liquor bottle and screw cap seems more practical with regards to re capping.

On principle I would not use plastic liquor bottles.

>bed from the copper pipe manifold on the bottom of the mash/lauter  
>tun. I think the use of a vent pipe would go a long way toward  
>reducing the compaction problem. Bob, did you try a vent pipe?

I have not tried a vent pipe, but I would guess that due to grain  
compaction  
you will get a very large flow through the vent pipe and this would make  
for  
alot of HSA and poor heat transfer in the heater due to all the foam. ie  
I  
don't like it. Still an anti-RIMS zealot!

There are still alot of micros using dry yeast. The dry yeast used to  
come  
from Siebels and was of a pretty high quality. I understand from Micah  
that  
they are now being sold by Crosby and Baker (I think). He is planning on  
using them at Murphy's Creek. The use of dry yeast in brewing at micros,  
when you pitch a brick of yeast in a batch provides a large population of  
good guys to bad guys and I haven't seen much problem around here that I  
would contribute to dry yeast use. Now bottling (which Murphy's Creek  
plans  
to do) is another story. Those small counts of critters can cause  
problems  
when the beer is not stored and handled properly (which IS always the  
case).

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Re: RIMS, vent pipe, and channeling

In HBD 1130, Michael.Burgeson@Eng.Sun.COM (J. Michael Burgeson) writes about a proposed RIMS system, and says:

> With a RIMS system, channeling during the mash would not be a problem.

I am not sure this is the case. The purpose of the recirculation is to evenly distribute both the heat and the enzymes/starches/etc. If significant channeling is occurring, this distribution will not be as efficient, thus reducing the potential gains from the recirculation.

> What I would like to propose is using a vent pipe, but running it > outside the mash/lauter tun.

While putting the tube outside will certainly eliminate this as a source of channelling, I am skeptical as to whether this vent tube is worth having. My understanding of the compaction problem is that it is due to the suction from the recirc pump. If this is so, then a vent tube will not help (regardless of whether it is inside or outside the vessel). The tube will merely act as a manometer, displaying the suction inside the vessel as a drop in liquid height in the tube. The exception to this is if the suction is great enough to drop the fluid level in the tube below the level of where it enters the vessel, in which case air will be sucked into the vessel from the tube. This will "clamp" the suction in the vessel at its present value, not allowing it to increase any further. However, (1) you may already have significant compaction at this level of suction, and (2) air will be entrained into your recirc stream, possibly causing loss of pump prime, and hot-side aeration.

My suggestion is to use the vent tube, installed outside the vessel, but use a clear tube so that you can observe the fluid (suction) level. Find a level (by trial and error) where compaction does not occur, and set your pump flow rate to maintain approximately that level. (This would probably require constant monitoring, or better yet, a closed loop feedback system.)

Another suggestion, which I throw out for discussion, is this: why not recirculate upward through the grain bed? It seems as though this would reduce the compaction problem, as you are no longer creating suction within the bed...

Disclaimer: My degree is in Chemical Engineering, so I am very familiar with the physics involved here; however, I speak from in experience, as I have not built nor used a RIMS system. I am planning one, but will have to wait to get sufficient \$\$\$ before I can build one. Anyone from the Salt Lake area want to pool resources???

Good Luck,  
Kelly <k-jones@ee.utah.edu>

Subject: Mash Temp

>From: David Ferguson <davidfer@microsoft.com>

>I am a semi-experienced homebrewer contemplating my first all grain batch. I'm wondering though if I will be able to use an electric stove to maintain the precise temperatures needed for a successful mash.

I think it is worth stating an opinion which other may choose to disagree with.

Contrary to popular opinion and probably one of the many momilies that keep extract brewers from taking the plunge into all grain is the perceived need for precise temperature control for a "successful mash". If by a successful mash we mean producing a good beer at a nominal extract yield, I suggest that you can achieve that even if your mash temp wanders randomly between 150F and 160F for 30 minutes or more.

With the right equipment and attitude, the "plunge" into all grain really becomes more like falling off a log.

The notion about precise temperatures is based on the theoretical action of enzymes on starches which produce slightly different amounts of different sugars at various point in the temp range.

If that is important to a first time all grainer, I would be very surprised. These details are important for acheiving nominially different character for different styles of beer but I seriously doubt that very many home brewers are capable of maintaining the kind of temperature control required to prove the point.

From: David Ferguson <davidfer@microsoft.com>  
Subject: Mashing on an Electric Coil Stove

Thanks to all who replied to my question regarding mashing on an electric stove with limited heat settings. Sounds like it's not that big a problem. The following is a short collection of replies:

>From Tim Fairclough

I mash in my oven and boil on the electric coil stove all the time. By mashing in the oven I mean: setting my oven as low as it will go which will hold a mash at 150 degrees perfectly. I stir occasionally during the mash period and heat the sparge water during the last half hour or so of the mash period. I have done three partial mashes and one full mash this way with great success (IMHO). I should mention I have only done infusion mashes. Good luck.

>From Karl Sweitzer

I use a .25 inch thick plate of brass over my coil stove to more equally distribute the heat. I found that I got coil burn marks in the bottom of my thin boiling pot (even with extracts!).

>From Jason Goldman

I mash on an electric stove and I've been very successful. The trick is not to be in too much of a hurry. In other words, if you are 10 deg shy of your target temperature, don't turn the stove on red\_hot to get it up quicker. When I do ales, I heat my mash water to around 180 def F. Then when I add the grain, it settles out to about 158 deg F. After stirring in the grain so I achieve a good mash in, I take it off the stove and put the lid on. If the temperature was too low (or if the mash temp drops), then I put it back on the stove on hot/less hot for a while to raise the temp. Grain is a very good temp buffer on its own.

> From Ed Hitchcock

If you're making a lager, you can do a decoction mash. Heat the mash water to about 135-140F and add grist. Let rest 1/2 hr. Remove a portion of the mash (grain and liquid) and bring that to a boil on the stove and add back to the mash to raise the temp. You may want to do rests at 149-145F and 159-155F, so you'll want to remove maybe 3 quarts or so (I've never actually done a thick decoction, so I can't give you the exact numbers) to boil. You can take small amounts and repeat a few times which takes a little longer, but you won't cook too much of the mash, nor overshoot your target temperature.

\*\*\*\*\*

I couldn't resist throwing in my \$.02 on the Alcohol and other drugs thread too. The only reason I see to outlaw the use of drugs is to protect the public against people who use them. IMHO the government should have no right to tell me what I can and can't do to myself, but if I start affecting those around me I am beyond my rights. With that in mind, I would say someone high on a stimulant would be more likely to affect those around them and hence would be more dangerous. Alcohol, being a depressant, slows people down. Although they can

still be violent and troublesome, I think the general opinion is that they would not be such a threat to the public as someone on a stimulant, hence less regulation.

I am opposed to regulation of \*most\* drugs (although I use no illegal drugs by my own choice) and will never understand the arguments for legalizing alcohol, but not marijuana (sp?).

From: lconrad@poincare.Prime.COM (Laura Conrad)  
Subject: oatmeal

How do other people incorporate the oatmeal into an oatmeal stout (or other beer)?

I've made 3 or 4 batches, and previous to last weekend I had used Quaker oats from the supermarket, and added them to the mash.

Last weekend it was easier to go to the natural food store and buy rolled oats from the bulk bins.

I frequently taste the grain when the sparge is through, to verify that it is tasteless. This is usually the case. This is confirmed by the fact that animals (including birds when there are other food sources) don't seem to be very interested.

However, last weekend, there was still definitely oatmeal flavor in the "spent" grains.

I don't remember whether I've tasted the Quaker oats batches. However, I donate my spent grains to a friend who uses them for landfill/compost. He reported that there was definitely some animal who had been eating around that batch.

Would I get better extraction if I cooked the oats before adding them to the mash? Or is the flavor of the oats not really the point anyway?

Thanks,

Laura

Date: Thu, 29 Apr 93 13:06:28 -0700  
From: Drew Lynch <drew@chronologic.com>  
Subject: A few questions about mashing...

I am planning to brew the following two batches this weekend.

- 1) Imperial Stout  
Desired Yield: 5.5gallons@.1075  
Estimated Extract Efficiency: 27 (pts\*gal/lb)  
Total Malt: 15.5  
  
.5 lb Chocolate  
.5 lb roasted Barley  
.5 lb flaked (barley or red wheat)  
14 lbs Klages  
Method: Overnight single step infusion mash starting at ~155F (should end at ~145F)  
Sparge with ~5 gallons 180F water (No Mashout)  
Boil 30 minutes  
Hops:  
Boil: 60 IBU Chinook (1 hour)  
Flavor: 10 IBU Cascade (15 minutes)  
Aroma: 1.5 oz Cascade (15 minute steep)  
Immersion Chilled to 80F  
Yeast: Wyeast Irish Ale (.5l starter from slant)
  
- 2) American Brown Ale  
Desired Yield: 5.5 Gallons@1.045  
Estimated extract efficiency: 27 (pts\*gal/lb)  
Total Malt: 9.25lbs  
  
.5 lb 40L Crystal  
.25 lb black Patent  
.25 lb Chocolate Malt  
.25 lb Flaked (barley or Red Wheat)  
8 lbs Klages  
Method: 2 hour single step infusion mash at 156F (should end at ~154F)  
Sparge with ~5 gallons 180F water (No Mashout)  
Boil 30 minutes  
Hops:  
Boil: 25 IBU Cascade (1 hour)  
Flavor: 5 IBU Cascade + 5 IBU Willamette (15 minutes)  
Aroma: .5 oz Cascade + .5 oz Willamette (15 minute steep)  
Immersion Chilled to 80F  
Yeast: Steinbart's Brown Ale (.5l starter from slant)

And, I have a few questions (imagine that!):

- 1) In the past, I have made my own roasted barley by toasting milled 2 row klages at 350F for 15 minutes. The beer came out *very* cloudy. Any ideas how to avoid this?
- 2) When a yeast's attenuation percentage is listed, is that %(fermentable sugar) or %(total sugar)
- 3) How can one determine the fermentable/unfermentable ratio *prior* to mashing? What percentage fermentables can I expect at 158F mash? At 148F mash?

4) I have never gotten the iodine test to go negative in less than 2 hours in the 153F-156F range. The top of the mash may test negative for starch, but upon stirring, the test will go positive. I always wait until the stirred mash tests negative. I also tend to get very alcoholic, thinner bodied ales. I would prefer a fuller bodied lower alcohol (4.5% desirable) brew. Should I be stopping the mash before the test goes negative?

5) I prime with 1.5qts 1.040 sweet wort for bottling. This is roughly equivalent to 3/4cup corn sugar. Should I increase this for the stout due to the high gravity?

Phew...

Thanks in advance,  
Drew

From: djt2@po.CWRU.Edu (Dennis J. Templeton)  
Subject: Long distance dispensing

I haven't yet resolved with my spouse the issue of space in the kitchen fridge for a beer keg, but I thought up this compromise the other day:

How about putting the keg and CO2 tank in the basement and running a 1/4 inch line up through the kitchen floor into the fridge, then through a steel cooling plate and a tap? This way, a single glass of beer would be cooled enough, and for a group, you could put the cooling plate into a tub of ice.

My major concern is that I'd have to crank up the pressure to get a good flow through about 12 feet of tubing, then the brew might be too gassy when it's finally dispensed.

I'd appreciate hearing from folks who have used a long line between the tank and the tap, and just what kind of problems you encountered.

From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)  
Subject: RIMS

In HBD1130 Michael Burgeson mentioned possible differences in efficiency between a "conventional" sparge and a recirculating sparge ala RIMS.

I have used both methods, and both worked OK with virtually no difference in efficiency. So use whichever method you're comfortable with.

about channeling:

I also have never observed any channeling in my mashes, but to be honest, I've never really been looking specifically for that. I'll look a little closer next time.

about vent tubes:

The vent tubes I have used in the past worked very well for minimizing mash compaction due to suction from the pump. The tubes become less effective as the quantity of grain increases. I'm not sure, but there probably is a point where sheer weight of the grain is a factor. When the vent tubes do suck air, there is foam generated, and HSE could be a factor. HSE never seemed to be a problem for me, but it could be a concern in a RIMS setup. So far, I like my current method ( described later ), but being an obsessive tinkerer, wait till next week. :)

On my last two batches, I have used the vertical screen tube in the middle of the mash until sparge time, when I removed it and recirculated the wort at a slow rate ( no heat ), and then performed a "conventional" sparge. On the first batch with the tube, I simply had the copper return tube with a few holes drilled in it submerged below the surface of the wort. On the last batch I had a 3/8" copper tube ( again with holes drilled in it ) coiled in a spiral around the screen tube and spaced approximately halfway between the screen tube and the side of the mash tun. This setup gave a very consistent temperature in all parts of the mash, with no compaction at all.

As Bob Jones correctly pointed out, the ultimate test of a RIMS setup is a large batch using predominately wheat malt. I plan to try that sometime this summer.

Cheers,  
Alan

From: agerhardt@ttsi.lonestar.org (Alan Gerhardt)  
Subject: Refrigerator Idea

A few months ago, I successfully staged a coup de etat and gained possession of the family freezer, hooked it up to my airstat, and brewed happily it it while using my other beer fridge for serving temperatures. Unfortunately, after a spousal counter revolution combined with decreased availbility of food, the freezer is now a freezer again .. with food in it instead of beer.  
Oh well.

Now I have a dilemma with Texas summer coming. I need a 48-50F fermenting environment, and a little lower temperature for serving.

I have an idea I have been considering:

With the airstat set at 49F, and the plastic freezer baffles set for minimum freezer temp, I placed a container of water with a thermometer in the freezer compartment. The water temperature stays at about 34F, and has not frozen after about 3 days inside. The temperature inside the rest of the fridge is 49+-2F

Since the fridge holds 4 5gal soda kegs, I want to have two fermenting, one aging, and one serving. My idea is to construct the equivalent of a jockeybox inside the freezer compartment. ( A cold plate would be nice, but they are kind of pricey ) The beer from the serving keg would pass through the coil and be chilled some, depending on how long the tube was, flow rate, etc.

Has anyone tried anything like this?

Is this a crazy idea?

Any comments are welcome.

Cheers,  
Alan

Dan Philbrick  
DANP@URSUS1.URSUS.MAINE.EDU

Well he name is MUD for some of us because he has LOTUS syndrome, i.e. he wants to sue people.

He has tried to sue the Boston Beer Works a new brewpub in Boston who used the name boston in their name. He says people will try their beer not like it and it will hurt his sales. Well, ask people on the street who makes Samual Adams Boston Lager, and i will be it ask 10 people maybe one will say The Boston Beer Co.

Being unsuccessful at sueing the Boston Beer Works he then proceeded to bring suit against Commonwealth Brewery for having the name Boston on their neck label, well Commonwealth was the first brewer/pub in Boston so why not use the name.

Since this did not work he brought another suit against Boston beer works. This time it seems to have ended. BTW he lost again.

If you support small startup breweries and don't like the way big business tries to squeeze the small guy. Don't BUY Samual Adams, it seems like a good reason to boycott a product.

This is written up in the Yankee Brew News, last issue of 1992 i think, titled: The Boston Beer Wars..

From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>  
Subject: Scotch Ale Caramel/Defense of Koch

In defense of Jim Koch, he has done something that no one else except maybe Fritz Maytag has done, and that is to produce some interesting and characterful beers which have displaced some of the imports in pubs, restaurants, and even grocery stores nation-wide. His marketing tactics are rather aggressive, but maybe that's what it takes to be heard among the large domestic and imported beer marketeers (Anchor has succeeded in a much quieter, more dignified manner, though). If Koch has told a few white lies, or miss-represented himself, he is not the first to do so in the promotion of beer sales, nor will he be the last. The point is that he is helping significantly to awaken the public to the diversity in the world of beer which has been all but lost in the American market. I don't think anyone can argue that Koch's products are not of the highest quality, and generally representative of the style which they purport to be. The glaring exception to this, of course, is the ridiculous Cranberry "Lambic".

\*\*\*\*\*

In response to the inquiry by Tom Leith about caramel flavor in scotch ales, I suggest that the addition of some of the Belgian (DeWulf-Coysens) "Special B" caramel malt is what is wanted. This is a very dark caramel malt which, as mentioned in Pierre Rajotte's Belgian Ales book, is produced specifically for brewing (Belgian) Scotch Ales. It is available from several homebrew shops at outrageous prices, about \$1.30 per lb, usually. Bulk-buyers can get it for much much less.

From: Steve Dempsey <steved@longs.lance.colostate.edu>  
Subject: AHA National Homebrew Competition, Western Region Round 1

AHA National Homebrew Competition  
Western Region 1st Round

[ The length of this posting is intended to inform folks in the region of significant changes for our site over past years. I know a number of people who have refused to participate when a number of problems started to appear over the last couple of years. We have tried to address these by changing the way the competition is organized and run.]

The first round of the AHA NHC for the western region will be held Saturday, June 5 and Sunday, June 6 at the Wynkoop Pub and Brewery in downtown Denver, Colorado. Judging sessions will run approximately 9:30am-12:00pm and 1:30pm-4:30pm each day. We will also have space available at the pub Saturday evening for socializing and potential extracurricular activities still in the planning stages.

We expect some 800 entries to arrive and will need many judges and stewards to complete the judging on schedule. Participation of every available judge is essential to the continuing success of this competition.

Some significant changes will be implemented this year over previous first round sessions held in Boulder. Organizers from each of the four major regional sites have been working together to ensure uniform procedures are used everywhere.

The first major change for us is registration for judges. We plan to schedule sessions in advance so judges will know their responsibilities for attending a specific session to judge a specific style. In the past, one could simply show up at any session, gather in groups of two to four judges, pick out a flight of beers, and have at it. While this offered great flexibility, it also presented the organizers with great anxiety in guessing how many sessions would be required and how many judges would show up -- and if the judging would actually be completed in time.

Large competitions such as the Blue Bonnet, the GABF Professional Panel Blind Tasting, and several prior NHC 1st and 2nd rounds at other sites have all used this format successfully. In order for it to work, judges will need to contact the organizers with their availability and preference for judging specific styles (see below). BJCP judges and registered clubs and retail suppliers will receive detailed information mailed on April 30.

All experienced judges including BJCP registered judges, professional brewers, industry consultants, and any

other individual with experience at large regional or national competitions is encouraged to judge. Beginning judges who have experience at one or two local competitions are also encouraged to participate as apprentice judges, and will be placed on a panel with more experienced judges. Anyone else wishing to participate is welcome to help with stewarding duties. A steward is responsible for maintaining order at the table by assisting judges with supplies, etc. and has the opportunity to observe the judging process and even sample some of the beers, but leaves the evaluation of the entries to the judges. One of the best ways to start learning about judging is to work as a steward and watch what goes on without having the responsibility of evaluating the entries.

The second major change this year will be the method for selecting entries qualifying for the final round. In the past, we have tried to go by numeric scores alone. The first round held in Chicago in 1992 used a two-tier approach: all flights of a particular style are judged simultaneously and a few of the best entries are collected by a leading judge. These contenders are gathered quickly and passed to a second panel of judges including one judge from each of the first groups. These judges decide which entries will advance to round 2. This two-tier system overcomes problems with skewed or inaccurate scoring by any panel of judges, and comes much closer to accurately determining the best beers from categories with large numbers of entries.

Judges and stewards may register by e-mail to:

<steved@lance.colostate.edu>

Please use a subject of "NHC". Include your name and phone number(s), a postal address if you are NOT on the BJCP or club mailing list, and indicate at least three or four beer styles you feel best qualified to judge. Once we know the judging schedule, you will be contacted by phone and/or e-mail to confirm the styles and sessions you will work. If e-mail does not go through, call me at (303) 491-0630 [day] or 482-1403 [evening]; you can leave a message with the above information at either number if I'm not in.

From: shaver@zeppelin.convex.com (Dave Shaver)  
Subject: New brewsheet now available in the HBD archive

Over the last year I've been working on a new brewsheet for keeping track of my batches. Stephen Hansen was kind enough to add it to the archives. My sheet is very similar to the existing brewsheet in the archives created by Chris Shenton, but it has a few more bells and whistles.

I used FrameMaker to create the sheet, so both MIF (Maker Interchange Format) and PostScript versions are available. FTP users can get them from the archive on sierra.stanford.edu as:

```
/pub/homebrew/docs/brewsheet2.mif.Z
/pub/homebrew/docs/brewsheet2.ps.Z
```

Listserver users should request them with:

```
get homebrew brewsheet2.mif
get homebrew brewsheet2.ps
```

Happy brewing,

```

From: l200-cu@garnet.berkeley.edu (mARK WITTEMAN)  
Subject: A little more help

To all HOMEBREW Readers:

About three weeks back, I posted a request for help on my homework -- more specifically, I was looking for lists of California Microbreweries, info on the families or styles of beers, and info on the "objective" description of beer.

The response I've gotten has been stupendous. In all, about 30 people responded and everybody was wildly helpful even though they were obviously dealing with an ammateur. (Meaning me.) I wasn't able to respond to everybody individually, so I hope this will suffice as a thank you.

But aside from expressing my gratitude, I must make one more request. About two weeks back, a fella from AHA offered to e-mail me some info on beer judging and how to become a licensed beer judge. I meant to save his message and respond with my own message asking that he please send it my way -- it's just the sort of thing I need. But, as you can probably guess from the tone of this request, I lost the message.

If the author of that message, or anyone else for that matter, could e-mail me the aforementioned information, I'd be, once again, ever so grateful.

Sorry to fill the HOMEBREW screens with my personal projects. I'm not a HOMEBREWER, but subscribing to this newsletter has convinced me that some day, when I'm no longer a starving student, I will give it a shot.

Thanks for entertaining my request.

Subject: beer bends/mashing questions/long draft runs/Koch animosity

Tom writes:

>Although diatomic nitrogen (N2) is a very stable element and is relatively inert at low temperature and pressure, it is easily dissolved in fluids such as blood, water or beer. I can't say if or why it causes a good head on beer, but I can say that it will dissolve in it.

It is my understanding that although N2 may be soluble in beer, it is \*MUCH\* less soluble than CO2, which is why it is used by Guinness to dispense at high pressure without uncontrollable foaming.

\*\*\*\*\*

Drew writes:

> I am planning to brew the following two batches this weekend.  
>  
>1) Imperial Stout  
> Desired Yield: 5.5gallons@.1075

Note that this is at the low-gravity end of the Imperial Stout range. My last one had an OG of 1120.

> Hops:  
> Boil: 60 IBU Chinook (1 hour)

60 IBU of Chinook may be a bit abrasive. Many HBDigesters have reported harsh bitterness from excessive use of Chinook hops. As high alpha hops go, I use Nugget, which I find much more pleasant even at high hop rates.

Make sure you aerate well. High gravity ferments mean that the yeast are going to need a lot of oxygen.

>1) In the past, I have made my own roasted barley by toasting milled 2 row klages at 350F for 15 minutes. The beer came out \*very\* cloudy. >Any ideas how to avoid this?

You were making roasted malt (Brown, probably) not Roasted Barley. Roasted

Barley is made from \*unmalted\* barley. I don't know why the beer was so cloudy unless you roasted \*all\* the grain in the batch and denatured all the enzymes -- but then the starch test would have been positive forever.

>2) When a yeast's attenuation percentage is listed, is that % (fermentable sugar) or % (total sugar)

It's apparent attenuation (actual attenuation is much less, but alcohol is thinner than water, so it gets thrown off). Say for a 75% apparent attenuation, if the OG is 1.050, the FG you can expect would be about 1.0125

$((1.050 - 1) * (1 - 0.75) + 1) = 1.0125.$

^^^^^^^^^ ^

| | | This is because you're putting the water back

This is because you want to know what gravity  
is left, not what was taken away.

This is because the water won't be attenuated.

>

>3) How can one determine the fermentable/unfermentable ratio \*prior\*  
>to mashing? What percentage fermentables can I expect at 158F mash?  
>At 148F mash?

I'm sure you know the answer to this question, but all this talk of fermentables and unfermentables tends to make things seem complicated. Prior to mashing the malt is virtually all starch, so it's 0% fermentable and 100% unfermentable. I don't know about the exact numbers, but last night, I was re-reading George's article on Evaluating Yeast in the 1992 AHA Conference Proceedings and he mentions 65% fermentable wort if mashed at (I believe) 154F. Is that right George? Did your source for those numbers perhaps have other temps and percentages too? Of course these would all be thoretical ideals because of variations in grains from year to year and maltster to maltster, no?

>

>4) I have never gotten the iodine test to go negative in less than 2  
>hours in the 153F-156F range. The top of the mash may test negative  
>for starch, but upon stirring, the test will go positive. I always  
>wait untils the stirred mash tests negative. I also tend to get very  
>alcoholic, thinner bodied ales. I would prefer a fuller bodied lower  
>alcohol (4.5% desireable) brew. Should I be stopping the mash before  
>the test goes negative?

No, no, no. If you want a fuller beer, you want a more dextrinous wort. Mash at a higher temperature, approaching 158F. Don't linger at the low-temp end of the saccharification temperature range (148F) or you will convert too many dextrans into fermentables. 2 hours seems quite long. I suspect either that your pH is off, your water chemistry is impeding the enzymes or your thermometer is off and you're actually mashing at 145F.

>

>5) I prime with 1.5qts 1.040 sweet wort for bottling. This is roughly  
>equivalent to 3/4cup corn sugar. Should I increase this for the stout  
>due to the high gravity?

1075 is not really that high, but I used 1/2 cup corn sugar for priming my 1120 Imperial stout and it carbonated quite well.

\*\*\*\*\*

Dennis writes:

4

>inch line up through the kitchen floor into the fridge, then through a  
>steel cooling plate and a tap? This way, a single glass of beer would  
be

>cooled enough, and for a group, you could put the cooling plate into a  
tub  
>of ice.

>

>My major concern is that I'd have to crank up the pressure to get a good  
>flow through about 12 feet of tubing, then the brew might be two gassy  
when  
>it's finally dispensed.

You're right, it would be quite gassy. You're right about needing a lot of pressure to push the beer that distance, but the \*real\* culprit for needing high pressure is head (the change in height that you will have to push the beer up). It's all quite involved, but not too complicated to figure out. I suggest you pick up the 1992 AHA Conference Proceedings.

In there, you will find an article by Dave Miller which will give you all the formulas and step-by-step instructions for figuring out what you need to do to make your system work. HINT: the key will be using a bigger diameter hose.

\*\*\*\*\*

Dan writes:

>Can someone tell me why Jim Koch's name and products seem to be MUD on  
>this network. I just read a real caustic message about him and I  
>remember several about six months ago along the same lines. What did he  
>do?

Koch's entrance onto the HBD doo-doo list was thanks to his suing the Boston Beer Works brewpub for trademark infringement. This apparently was done for no other reason than to get some publicity since beer drinkers with enough taste to tell the difference between Bud and Sam Adams certainly have enough intelligence to tell the difference between Boston Beer Works and Boston Brewing Company. Not only did Koch sue in a lower court (which ruled in favor of BBW), but took the case to a higher court (which rules again in favor of the BBW). Hence the "starve a lawyer... boycott Sam Adams" motto was born.

A second reason for our hatred of Koch is due to his misuse of the appellation "Lambic" which he used on a weak Cranberry Beer, that I guarantee was not made by spontaneous fermentation as a true Lambic must be (in the vicinity of Brussels, no less).

Koch's recent ads in the Chicago area (the ones where Koch says he started the microbrewing revolution) would have probably been ignored by us HBD'ers if not for his "beating up" on a upstart brewpub which has far better things to worry about than court appearances.

All of this is too bad. Frankly, I think that Sam Adams makes some of the best beer that is available nationwide and at a reasonable price. His ads (incorrect as they may be) have, indeed, made inroads into changing the average American beer-drinker's taste. I would much rather see every second customer at a liquor store carrying a case of Sam Adams than Budweiser or Miller or Coors (as I see today), if only Koch would stop this litigative nonsense and stop with the false advertising. A public apology would be nice too...

Has anyone mentioned that Koch should have called his Doppelbock "Litigator?"

Al.

Date: 30 Apr 1993 13:53:39 -0600 (CST)  
From: SWEENERB@msuvx2.memst.edu  
Subject: Compressed files/Extraction rates

Pardon my ignorance, but...

What program do I need to decompress the files with the '.Z' extension in the Sierra.Stanford archive? Is this some type of Unix program? Our system

here at Memphis State is a DEC VAX to which I can download to either a PC or a

Macintosh. Are there programs available on these platforms to decompress these archives? Please email soon as my account here may be taken away next

week when our semester ends. N\_ts!

Also, I brewed my first all-grain batch last week and some questions about

extraction rates have been bugging me ever since. I used 9 lbs of grain total

(7.5 lb klages, .5 lb cara-pils, .5 lb dark crystal malt, and .5 lb wheat malt)

and got an OG of 1036, which computes out to about 20 pts/lb/gal. This seems

low compared to some of the extraction rates I see bandied about on the HBD.

However, when I went examined some of the receipes in the Winners Circle section of Zymurgy I computed rates between 19 and 28 pts/lb/gal, with an average of about 24. Even these supposedly very good beers--I mean they placed

in a national contest so they must be good, right?--were lower than the 30-35

pts/lb/gal rates I often see quoted on the HBD. So what gives? Rates, I assume are related to the grain crush, the type of grain, pH, and the mashing

and sparging methods and temps. (My grains were Corona crushed, with a single

infusion mash in a picnic cooler with 3 gals h20 at 154 degrees for 90 minutes

- --with the first runoff at an OG of 1070, then sparged with 3.5 gals of 170

degree h20 @ 5.4 pH.)

I guess my question is, are higher rates necessarily better, since these winning

beers had lower extraction rates. Or are these lower extraction rates just

more common in the homebrewing community and therefore more likely to win at

contests? What are the disadvantages to having too high extraction rates, if

any? Are there other factors affecting the extraction rate than those listed?

Are there any glaring errors in my mash/sparging procedures? How do you know

when your grain crush is adequate? What is the air speed velocity of a fully

laden African sparrow?

There, I feel much better now. Thanks for letting me unload.

Date: Fri, 30 Apr 1993 13:37:02 -0800 (PDT)  
From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: help with 1st time partial mash

I'd like to augment my to-date extract-only brews with a partial mash. My plan is to use the oven, set at 150, and heat the mash on the stove top prior to putting it in the oven. My question relates to the initial heating. Everything I can remember reading about mashing talks about heating water to a higher temperature so that it comes down to the correct temp when the grain is added.

Why can't I put the grain in cold water and heat it all up together? This seems obvious, but what am I missing?

A second question relates to use of a manifold for sparging. When is the manifold put in? After mash-out (where I presume I'd have to stir everything up to get it on the bottom of the pot) or is it in the pot the whole time?

Thanks in advance for any help.

Peter

Date: Sat, 1 May 93 22:04:31 MDT  
From: Herb Peyerl <Herb.Peyerl@novatel.cuc.ab.ca>  
Subject: Tour of Canada Malting.

Today; our brew club (Marquis de Suds) had a tour of the Canada Malting facility and I thought it would be of interest to people on hbd.

I don't remember a lot of details since there was a certain amount of imbibing going on...

It started with us meeting the Head Maltster who took us into one of the malting "houses". He explained that they currently have 4 houses with a total output capacity of ~500 tonnes/day (I'm presuming metric tonnes). They're currently building a new house which will allow them to shutdown 3 of the current ones and it is of a european design which is apparently more efficient. It will allow them to layoff half of their staff (they gave the staff a 1 year notice of this and have allocated \$3000CDN to assist the staff in training for new careers. (\$3000/person)).

We looked at the steeping silos where the barley is brought in; steeped with water to facilitate washing of the grains. This is done in several cycles which are determined by the production manager. The current batch was a 6-6-10-8-6-7 steep/aeration cycle. This works like so:

- 6 hours of wash
- 6 hours of aeration
- 10 hours of wash
- 8 hours of aeration
- 6 hours of wash
- 7 hours of aeration

A wash consists of pumping water into the bottom of the silo until it overflows into an overflow reservoir and then letting it sit.

Aeration consists of draining the water and pumping air through the silo from the bottom.

The cycle is determined by several factors:

- a) customer spec (protein solubility; color; etc)
- b) The characteristics of the grain shipped.
  - i) They use a strain called "Henning" (sp?)
  - ii) Each batch of grain is different due to the farm season.

>From there; the grain is drained into what they call a "piece" which is basically a large (200yds long) concrete fenced off area where it sits to germinate at a depth of about 3 feet. It sits there with air flowing over it and through it (from the bottom) until the germination is at the level they expect (I believe this is about 15 hours)..

The grain is then dropped into a spray room which was a very damp loud place and I was unable to hear exactly what the purpose of this was...

>From there the green-malt is transferred to the kilning piece where it sits for another period of time to kiln according to colour again. The temperature varies also according to the level of diastatic potential that is required by the customer...

That's basically where the tour stopped. My main interest aside from the general process was in the machinery used. There is a large concern for excessive handling of the grain so as to minimize crushing of the husks. However; if during the aeration and germination stage; the grain isn't mixed then aerobic heat gets too high and this affects germination. So the trade-offs are there and are treated seriously.

Points of interest:

A) there were bags of sulphur outside the grain house and it was explained to us that grain tends to have "DNMA" (sorry) which apparently is carcinogenic so the sulfur is introduced into the flame of the kiln-burners and burnt. Apparently the sulfur binds to the DNMA and reduces the levels substantially. The sulfur is used at a rate of .2 to .6 Kg / tonne depending on the grain and even the amount of air-pollution in the area at the time (I guess smog contributes to the DNMA levels). Maybe one of our resident chemists can explain this further.

B) They use a naturally occurring growth hormone to encourage germination. Again; depending on the batch of grain; some are more sluggish than others. Specifically the 6 row tends to be more sluggish than the 2 row. (Labatts uses a 50/50 mix of 2/6 row whereas Molsons is 100% 2 row.). Apparently the customers know that a growth hormone is used but they don't want to "hear" about it... ie "I don't wanna know". It occurs naturally in the grains anyway apparently; they're just increasing the amount.

C) Due to the high humidity (upto 100% relative); approximately every three weeks they spray the humid areas with a bleach solution to keep the mold and fungii at bay.

D) They use approximately 800,000 gallons of water a day which they treat according to spec. Our fine city isn't normally a water-sensitive area (ie: We have plenty and it's very GOOD!).

E) They use the heat generated by germination and steeping to pre-heat the water in order to conserve energy and control the temperature of the grains.

F) They don't have "extra" bags of malt hanging around. :-)

G) 20% of their grain comes from the Huddersites in our area.

After the tour; we went to the coffee room and all partook of homebrew. Someone (A German member of our club) brought a keg of Wheat beer which the Maltster and his asst thought was just fantastic until someone used the "W" word. :-)  
Apparently they've tried to malt wheat and rye but they just soak up water and turn into a mush really easily with the husks falling right off. So; they just stick to barley. They don't do any specialty grains since that's too small a market for their operation. (Each piece holds approximately 10 tons of barley). They are apparently capable of producing color up to 3.0 but most of their orders are in the 1.6-1.9 lovibond range.

Well; sorry for the lack of detail. I hope some of you found this of interest. If you ever get a chance; I'd suggest you try to take a tour of a malting facility. It's eye-opening.

From: drose@husc.harvard.edu  
Subject: Cornelius Kegs

Hello:

After 6+ years of homebrewing, I am getting ready to move away from bottles and into draft. It looks like the cornelius system is the way to go.

I have a source for the equipment, but kegs are \$40 a piece, and this sounds

steep to me. I would welcome any information anyone can offer on where you

got your kegs, how much you paid, the pros and cons of reconditioned kegs verses as-is used ones, and the exact type of keg which is preferable (I have some vague notion that their are "ball-type" and "pin-type" setups, or something of this ilk), I would appreciate this. As these probably qualify as FAQs, the answers may not be particularly edifying to the HBD readership as a whole, it might be best to email me directly (drose@husc.harvard.edu). Thanks.

Date: Mon, 3 May 93 12:44:51 MET DST  
From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: dmna, sulfur etc

hello all,

Herb wrote about the Maltery trip in hbd 1132.

> on the question of DMNA, it's dimethylnitrosamine, the major (in terms of amounts and toxicity) nitrosamine found in beer. It gets there all the way from the malt. More often than not malts are treated with burning sulfur during kilning. The effect of this is to decompose the nasties into nontoxic dimethylamine. A side effect, appart from filling the atmosphere with sulfur dioxide, is that the malts contain more sulfur (in the form of sulphates etc) and often the acidity of the malt is increased.

> as to the hormone used in germination, it's gibberellic (sp) acid. This is indeed found in nature, in very many seeds and seedlings. It is what is found in "rooting powder" used by gardeners to make plant cuttings take root. It isn't in any way related to mammalian (human) hormones, and has no effect on the body. (A related hormone is acetylene, this stimulates the ripening of fruit... try putting a young tomato (green) in a bag with a little. It'll ripen alot quicker.. but watch out for flames otherwise it'll be fried tomato.)

Returning to malting, I tried making caramel malt this weekend. It turned out quite good, though the real test will be a full batch of ale brewed with it.

My process was as follows:

steep 1 kg whole lager malt in water for 12 hours (over night) then drain and put the grains in a covered pyrex dish in the oven at 65-72 degC for 2 hours. This mashes the insides of the fully moistened grains. The temperature is the theoretical optimum under these (abnormal) conditions.

After this time, the grains could be squeezed between my fingers releasing the hot(!!!) sweet contents. I didn't do this to all of them ofcourse, otherwise I'd get no malt.

I then warmed the oven to 120 degC and dried/baked the grains, being careful to stir regularly, otherwise toffee quickly formed on the bottom of the dish.

The length of time you leave the grains influences the final colour, I left mine for 2 hours to give a medium (sorry not very scientific description) roast.

The insides of these grains is like toffee, though possibly still a bit wet (sticky).

Any way, that's all I wanted to say,  
Rob Thomas.

From: Ed Hitchcock <ECH@ac.dal.ca>  
Subject: manifold use

Peter Maxwell asks:

>A second question relates to use of a manifold for sparging. When is  
the  
>manifold put in? After mash-out (where I presume I'd have to stir  
>everything up to get it on the bottom of the pot) or is it in the pot  
the  
>whole time?

My manifold is in a bucket, not the pot. I do one of three things.  
I can mash in the pot and dump it into the bucket on top of the manifold  
for sparging. I can put hot water and grain in the bucket on top of the  
manifold and do a single stage infusion mash (ie just let it sit there  
for  
a while), then sparge. I can put warm water and grain in the bucket on  
top  
of the manifold and do a decoction mash. Some people have the manifold  
in  
the pot, but mine is made of PVC, so I don't like the idea of placing it  
on  
a burner.  
Have fun!

From: pascal@netcom.com (Richard Childers)  
Subject: drinking, diving, momilies, etc

Ed Hitchcock says :

"Don't drink and dive."

In passing, I wanted to add that alcohol's influence increases as you go deeper ( IE, as pressure builds up ). I forget the formula but it's a fierce increase in influence. Really, don't drink and dive.

The Schmidmeister says :

"ANNOUNCING THE EASYS-PARGER"

Cool !!

Tom Romalewski says, regarding "momiles" :

"I haven't been able to find this word in any dictionary. I have seen this word used before. Could it be that the author really wanted to say "anomaly"? Or is this a slang term used in homebrewing lingo?"

I think it's slang. Dunno the etymology or derivation but it translates, roughly, into "wives' tale", if context is a correct guide. IMHO, this does not mean it is untrue, rather, unverified grapevine gossip that may be true but needs further examination.

And Carl notes :

"Unlike the usual sort of channeling, I would expect channeling in a mash to put you in contact with future spirits."

< groan > (-:

Subject: FTP ing

Could someone please enlighten me on FTPing to sierra? More specifically, I want to ftp a digest, are they available in a DOS format? zipped somewhere?  
I am under the impression that the ftp-able files under /pub/homebrew/digest are unix based zipped files. Is there a way to convert them? Help please.

I thank you ahead of time. Please e-mail directly unless you feel others may benefit.

I have never posted before (never needed to, it seems like every time I am about to my question is answered that morning!). I cannot tell you all how much I enjoy this listserv.

(I swear one of my hop shoots grew an inch on Saturday afternoon!)

From: Robert Schultz <Robert.Schultz@usask.ca>  
Subject: Cooker/boil post combo

Has anyone tried the 10-15 gallon electric water heaters for mashing/  
boiling?

I saw one on sale:

12 gallon (UK), 115 volt (220 would be better) for \$115 CND  
(that should translate to about \$90 US).

These are glass lined, so one would have to be careful cutting (grinding)  
the  
lid off, but otherwise the unit is insulated and temperature controlled,  
with  
the added feature of a 'bottom tap'.

I would put money on the fact that they would be great for mashing, but  
I wonder how they would work for boiling???

The Costco 120,000 BTU sounds like the right size to boil 10 gallons of  
wort. Coleman also sells a camp cooker - but only 45,000 BTU.

I am in the throws of ripping apart an old natural gas water heater and  
converting the burner to propane for cooking my wort, but it too was only  
rated

at about 40,000 BTU. Gas water tanks have the flame tube running up the  
centre  
which doesn't do much for a 'pot'

Robert.

From: richer@desi.HQ.Ileaf.COM (Al Richer)  
Subject: Guinness on the high seas...

This is from the "Irish Emigrant", an email newspaper featuring items of interest to Irish expatriates and those working abroad.

- The two ships which carried bulk Guinness from Dublin to Liverpool have made their last voyage. The crews of the two vessels staged a protest against their redundancy terms for the last few weeks but this was eventually resolved. About 40 seamen have lost their jobs. Guinness will in future be taken from the brewery in special tanks and loaded on board other ships.

If they used this same technique to ship elsewhere, could this perhaps explain the distinctive "tang" in guinness here in the States?

"The bilges are flooding, Captain!"

"Pump it into the container tanks. No one will notice..."

Tongue firmly in cheek,

Alan J. Richer

Date: Mon, 3 May 93 11:09:20 CDT  
From: hinz@memphis.med.ge.com (David Hinz)  
Subject: Am I ready to go all-grain?

Greetings.

I've got half a dozen extract batches under my belt (some were with specialty grains), and I really enjoy the brewing process. I \*THINK\* I'd like to try an all-grain batch, and I'd like to make sure that I understand the basic principles involved. So, here's what I understand the process to be:

- 1> select a recipe & get the ingredients
- 2> crush the malt (or buy it crushed)
- 3> start the WYeast pack, then make a starter (I'm already using this method)
- 4> malt the barley

OK, this is where it gets complicated, right? I want to basically make a barley soup type of concoction, and keep the mixture at 150-160 degrees, temperature decided by how much fermentables vs. body I want. Right?

OK, now I've let it sit at, say, 155 degrees. What's a protein rest? What's this about heating it up to two different temperature levels so the different enzymes can do their stuff? Am I worrying?

OK, so I have my 'soup'. Now, I need to sparge. So, I take my soup, pour it into my lauter tun (which I haven't made/bought yet). Which design is best? (uh oh, I'd better not start that one. How about 'which design is fairly easy to build and will last, cost isn't all THAT important')

So, I sparge, limiting the flow so that I get good extraction from the grain bed. I go through my sparge water, and recirculate it until clear? Is that the case? I'm not too clear on that bit.

Anyway, I finish my sparging, and I have somewhere around 5-6 gallons of wort at this point, right? From here, it's familiar.

So, have I missed anything, or misunderstood anything (probably)? Is that all there is ??????!?! It really doesn't seem like a lot more than just using specialty grains, with the exception that the specialty grains aren't sparged as completely, it seems.

Thanks for any info you can provide. The differences between my all-extract and my "some specialty grains" (is this partial mash?) batches have convinced me that it's worth the extra effort!

Thanks!

>Subject: On-line brewing resources

> I just looked at the on-line brewing resources from the listserv. As an avid user of the GENie system I'd like to put a plug in for it. I've been on it for over a year and enjoy it quite a bit. For users with local nodes there is no charge other than the \$4.95 monthly fee (most people have local nodes),....

Let me add my two cents here also. On the downside is that it can get pretty slow during the busy periods but considering that it is free compared to Compuserves oppressive fees, it is a great trade off. The only other problem is that it is not as active as CIS or HBD but that seems easy to rectify.

To re-iterate, GENIE beer forum participation is included in the \$4.95 monthly fee. Compuserve charges \$6 per hour for participation in their beer forum. That may not sound like much but for any kind of interactive participation, keeping it under \$100 per month is not easy.

I suppose the AHA got in bed with CIS before there was a Genie but at this point in time, I think it is time to reconsider the association. It is really a dis-service to promote a service that is so expensive when other alternatives are available.

If anyone wants sign up info on Genie, just call... 800 638 9636

Subject: Cosmic Brew

Hello Fellow Brewers,

I'm back to share a newsworthy item I found in the Saturday, 1 May edition of my local daily newspaper, the Jackson, MS Clarion Ledger. The article is one of about 8 that appears each day "highlighting" little snippets of info about world events (with arrows to a country on a world map, as to enhance our geographical education).

Dateline OBERPFAFFENHOFEN, Germany

Beck hopes yeast in space brews cosmic beer

- ---Don't look now, but the German beer of your future may be orbiting overhead on the shuttle Columbia. A tube of Beck and Co.'s ingredients is fermenting aboard the shuttle to determine whether weightlessness and cosmic rays can genetically alter yeast to produce tastier beer. Experts at the University of Munich will make sample batches after the yeast is returned, said company spokesman Hans-Joachim Allgaier. Beck may know by the end of the year whether it has a commercially viable mutant. "We wouldn't sell it as space beer," Allgaier said. "We're too conservative to market beer like that. Besides, it wouldn't taste like space."  
===== END OF ARTICLE =====  
====

?Beck and Co.? Is this the same Beck as in Beck's beer from Bremen? I hope something works for them, 'cause even though I like a dark beer, their stuff don't do it for me, especially after having had a sampling of some dark home-brewed.

Noch einmal, bitte!! Mark

Subject: Coming Soon: Beer That's Out of This World ?

\*\*\*\*\*

The following article was drawn from the Associated Press and appeared in the May 2 Seattle Times:

"OBERPFAFFENHOFEN, Germany - Don't look now, but the German beer of your future may be orbiting overhead on the space shuttle Columbia. A spiral tube of Beck and Co.'s finest ingredients is fermenting aboard the shuttle, to determine whether the weightlessness and intense cosmic rays of space can genetically alter yeast to produce tastier beer. Germans may be tittering that their national passion for beer has been taken to the limits, literally. Beck's lovers hope the already prized brew will taste even better. The yeast is among the less weighty of the 88 experiments in Columbia's payload, which is being monitored at a space center outside Munich. The \$570 million program includes research into everything from energy-conserving turbine blades to semiconductors to robotics. The yeast experiment is one of several aboard the shuttle enabling scientists to observe changes in living cells in a weightless environment."

OK - let the beer naming begin!!  
"Weightless Beer" (it's less filling)  
"Intergallactic Ale"  
"Star Wars Stout"

Date: Mon, 3 May 93 14:57:35 EST  
From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: mash efficiency

Bob Sweeney writes in hbd1132

>section of Zymurgy I computed rates between 19 and 28 pts/lb/gal, with  
an  
>average of about 24. Even these supposedly very good beers--I mean they  
placed  
>in a national contest so they must be good, right?--were lower than the  
30-35  
>pts/lb/gal rates I often see quoted on the HBD. So what gives? Rates,  
I

2 points. I brew 5 gallon batches or so, but always want 6+ gallons of  
wort.  
Up to 1 gallon will be the hop trub, I will collect wort for priming, and  
will lose some volume to yeast trub in racking, and even through  
evaporation  
and loss of volume. Therefore the actual wort efficiencies of those  
batches  
may well have been higher.

The second point is that lesser extraction can result in less astringency  
and  
hence smoother - better beers. However, many consider this to be  
wasteful.

Yesterday I brewed and extracted about 8.4B per lb per US gallon -  
highish  
but I am usually over 7.5 (30 sg points approx) for the 6 gallons I  
collect,  
but for the 5 gallons of beer I produce, the efficacy drops to 28 for my  
batch yesterday, or better  
than 25 for the average.

From: gummitch@techbook.com (Jeff Frane)  
Subject: I don't "hate" Jim Koch

In the most recent Digest, Al Korzonas explains why "we hate Jim Koch." I don't hate anyone (except, perhaps, my ex-wife and Eliot Abrams); certainly I don't hate Jim Koch, and I'd rather Al Korzonas didn't speak for me.

In reality, Koch's bad odor goes back a lot farther and includes a lot more than his overly-litigious behavior or his ridiculous "lambic" beer. He's a wheeler-dealer, and is guilty of most or all the excesses associated with wheeler-dealers. But the microbrewery business has its share of wheeler-dealers, too; not necessarily as successful(!) as Koch, but they are out there. And, as others have pointed out, Koch -- for all his deceptions -- has succeeded in awakening a mass audience for flavorful, all-malt beers that is much larger than anything the micros could have done alone.

Personally, I'll reserve my hatred and outrage for people who commit far greater crimes than Jim Koch's marketing ploys.

From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>  
Subject: Extraction Rates

Whenever I read the tremendous extraction rates people get it reminds me of the comment one of my golf partners said: " I Always do worse when someone else keeps score"

That aside. Mashing and sparging technique will impact extraction.

A poor crush and poor mash , ie incomplete conversion, will reduce the potential extraction. A poor sparge will leave converted sugars in the grain further reducing extraction.

I get between 28 and 30.

Equipment can also be a factor. I noticed when I reduced the height of the false bottom in my Zappap lauter tun I improved extraction. Over sparging for the sake of better extraction can lead to astringent flavors 'from the extraction of husk tannins.

A usual cause for poor extraction in the beginning phase of all grain brewing. Is sparging. What was the grain bed temp? The PH of the sparge water? Temp of sparge water? Did you stir the contents of the brew pot before taking a sample? Did you temp adjust the samples sg before doing your calculations?

What method was used to calculate the extraction: I use  
(temp adjusted sg of pre boil wort \* vol of preboil wort) / total grain bill

From: dra@jsc-ws.sharpwa.com (Darren Aaberge)  
Subject: liberty ale

To my knowledge I have never tasted a beer that has been dry hopped. I have always been happy with the results of steeping the hops at the end of the boil. But this last weekend I was able to taste Anchor's Liberty Ale. Wow! If I closed my eyes I could believe I was drinking a glass of hops. Being from the Pacific Northwest, this is a good thing.

So now I have to try dry hopping. Does anybody know what kind of hops Anchor uses for dry hopping? Does anybody know what kind of yeast they use for their liberty ale? I am assuming that since they call it an ale they do not use the same yeast as they use for their steam beer. Is the yeast in the bottle the yeast that is used for fermentation or do they add a different yeast for conditioning?

Darren

From: Sandy Cockerham <COCKERHAM\_SANDRA\_L@Lilly.com>  
Subject: 3 gal kegs revisited

I posted several months ago asking for info on 3 gal. kegs. Slowly, I got replies. In the middle of all that I took a vacation to the Bay Area (where I visited Anchor and some other great places). Needless to say, I have been procrastinating on the keg thing... BUT, in the meanwhile I had a birthday and was given a \*complete\* system including a 3 gal. keg. Of course, we all know that one keg isn't enough. So, here is the information I was given.

1. Brewhaus in Knoxville, TN 1-800-638-2437 3 gal(??fitting) 39.95
2. St.Pat's of Texas Brewer's Supply 1-512-832-9045 3 gal pin 38.00  
3 gal ball 47.00
3. BCI in Brighton, TN 1-800-284-9410 3 gal(pin or ball) 34.50  
they also have 10 gal.kegs.
4. Brewmaster in San Leandro, CA 1-510-351-8920 no longer carry the  
3 gal for 25.00 (BUT, the 5 gal are currently 20.00!)
5. Brewmeister(not sure of location) 1-916-356-5602 3 gal kegs 45.00  
(all new rubber and stainless plugs).

These are posted in the order I received the information. I have since ordered from BCI, but have not yet received my order. Hope this helps someone find a source!

Here are the results of the Evanston First,  
Third Homebrew Challenge.

BEST OF SHOW

First Place: Bill Seliger, Classic Dry Stout  
Runner up: Gary Kramer, American Pale Ale  
2nd Runner up: Daniel Mossell, German Wheat

CATAGORIES

LIGHT LAGER

First Place: Jack Schmidling, Bohemian Pilsener  
2nd Place: Bill Seliger, German Pilsener  
3rd Place: Carle Rollins, American Standard Lager

DARK LAGER

First Dan Kasen, Traditional Bock  
2nd Ray Daniels, Traditional Bock  
3rd Walter Gude, Dopplebock

LIGHT ALE

First Gary Kramer, American Pale Ale  
2nd Scott Brandt, American Wheat  
3rd Jon Fischer, Belgian Strong Ale

DARK ALE

First Bill Seliger, Classic Dry Stout  
2nd Bill Seliger, Robust Porter  
3rd Al Korzonas, Sweet Stout

MIXED

First Andy Badeker, German Kolsch  
2nd Daniel Mossell, German Wheat  
3rd Ray Daniels, German Dunkelweizen

MIXED-SPECIALTY

First Ray Daniels, Sparkling Mead  
2nd Bill Seliger, Herb Beer  
3rd Glen McDavid, Specialty

.....

For the easymasher skeptics, at least two of the winners that I know of  
were made with the system that can't work.

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: Whitebread Yeast and Brewpubs

Another datapoint in the saga of the "old" Whitbread yeast.

The local brewpub, a fine outfit worthy of many more tourist dollars BTW, has always used a Whitbread yeast. At about the same time that George Fix tells us the production of this yeast was switched to a Canadian plant and the problems began, I and several other fans noticed serious consistency problems in the lovely hand-pumped real ale served at this pub. One week, yummy, the next, yucky. Too much of odd fruit flavours and way overattenuated. Tasted like cheap homebrew, you know the sort of stuff I mean.

Anyhow, of late these problems have tapered off, and recent pints are back to being pretty yummy again. So, I for one think the data fits the proposed history.

BTW, I also would like to get a Maltmill but nobody in this neck of Canada has ever heard of the \*&#\$%\$% thing. Also, the cost of importing just one would bankrupt me. Jack, do you have any suggestions for us? As a political aside, perhaps this is a good example of why IMHO the so-called free trade deal sucks big rocks.

Cheers, P.

> in small quantities in amber ales.

Yes, I tried some in a batch for a basic ale and found that the biscuit malt adds a distinct taste from the usual crystal malt. For the next batch in this style I will probably increase the amount used. Since a common name for Scotch beer is "Wee Heavy" maybe I could call this ale a "Wee Light".

Subject: re:brewpubs in Columbus OH

Greetin's

I can supply some info regarding Alan Christopher Braddock's request for brewpubs in Columbus OH. The newest (and I think best place in town) is called Barley's Ale House. It's located on High street just north of downtown across from the convention center in an area called the Short North. They have a nice pale ale, an irish red ale and an excellent porter all of which can be bought in pint or 1/2 yard glasses. The food is quite good too.

Alternatively, check out Hoster's in the Old Brewery district (just south of downtown also on High street). They have a varying array of light and dark lagers and also a very nice menu for dinner.

Enjoy!!

Date: Tue, 4 May 93 07:42 CDT  
From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Correction, PU on Draft

For the record, I referred to an article on nitrogen use in brewing by George Fix and he has been inundated with questions on it.

Unfortunately, the article was not written by Fix. It was sent to me by George and I got so engrossed in the information that I never bothered reeding the authors names.

It is from the MBAA Technical Quarterly, Vol 29 and the authors are David Taylor, Bamber, Brown and Murray, all in the UK.

Sorry George.

.....

My wife and I had dinner at the Edelweiss Inn, 7650 Irving Park in Norridge, IL and stared at a point of sale ad for PU through most of the dinner. We presumed it was the usual skunky, sedimented six pack stuff so we just sampled the Germans wines. When the wine was gone, I started drooling over the PU again and much to our delight, the waitress told us it was on draft. At this point, in the meal, I couldn't really appreciate it but for those in the area, it's there and \$2.50 will get you ten ounces in a genuine PU glass.

Sure be fun to bring the C-P filler and send a few plain brown bottles off to the National. Who me?

Actually, I wouldn't take the chance because real people probably don't like it anyway untill someone tells them it's the world's greatest beer and they must like it.

From: dspalme@mke.ab.com (Diane Palme x2617)  
Subject: Where's the hops?

Hello all!

I just have a quick question which would serve to dispell any worries I might be having about my newly planted hops. About 2 weeks ago I planted 3 hop roots in the back garden and I have yet to see any progress. Now, the weather up here in Wisconsin has been far from perfect (lots of rain, pretty chilly, temps in the mid-30's to low 60's, usually around 45). I am starting to wonder whether or not my little ones will ever poke their pretty little hoppy heads out above the ground or if they are just shy. Any input from some other hop growers in the upper-midwest would be greatly appreciated.

By the way, should I be fertilizing these guys? If so, what do all of you recommend? I have some ordinary vegetable fertilizer but is there a particular brand which works the best. Ohmigosh(!), they might grow even faster if I start to fertilize them. Hmmm. Maybe I had better bolt the door after I do that (assuming they cooperate and start growing) :-).

Much appreciated in advance...

Diane

Date: Tue, 4 May 93 9:55:03 EDT  
From: Jim Busch <busch@daacdev1.stx.com>  
Subject: extraction & Zapap

About this thread on extract efficiency and in particular the use of a Zapap lauter tun:

<Equipment can also be a factor. I noticed when I reduced the height of  
<the false bottom in my Zappap lauter tun I improved extraction. Over  
<sparging for the sake of better extraction can lead to astringent flavors  
<'from the extraction of husk tannins.

Two comments here: 1) When approaching the end of the lauter, tip the buckets so that they lean forward at an angle. Put something under the back of the buckets to support them. Watch for grain matter coming out & terminate runoff at this time. What this does is clear out the higher SG "trapped" runoff in the false bottom below the outflow.

2) Build the sucker with a BOTTOM outlet. Design it so the spigot is as flush as possible to the inside bottom of the lauter tun. In this arrangement, the amount of false bottom "dead space" is irrelevant. The grain particulate matter will be flushed out early in the recirc process and will run clean until the final runoff carries grain matter to the spigot. Your extraction will improve. This is my current lauter tun design and it works great. you just need to suspend the buckets/pot so that the spigot will clear the support structure.

Good brewing,  
Jim Busch

Subject: More on Cosmic Beer

Another note on beer in space, as a follow-up to my posting on Cosmic Beer on 3 May.

Anyone catch The Tonight Show with Jay Leno the night of 3 May? Apparantly he too heard about the Beck beer experiment, and had a comment or two about the shuttle Columbia's problems and cargo. Went \*something\* like this..

You guys hear about the trouble the space shuttle has been having lately? First the toilet breaks, to conserve energy they have had to shut off most all of their lights, and have got no hot water. Oh yea, they are having a good time on the shuttle. And .... they are making beer up there!

Really, no kidding. Some German company has sent up some stuff to see how it does. Can you imagine, a bunch of guys, weightless, no lights, with free beer and a broken toilet ...

Well, he told it funnier.  
Noch einmal, bitte!! Mark

Subject: liberty ale notes

Liberty Ale is fairly high in gravity, at 1.060 - 1.062 in starting gravity. Malts are all U.S. pale malt, though I would be inclined to throw in a bit of light crystal. Color is on the light side. Hops are all Cascades. Liberty Ale is fairly bitter, and I think has something like 45 IBUs of bitterness. As a homebrewer, add Cascades several times during the boil, and dryhop with some Cascades. Try 1/2 ounce to 1 ounce of Cascades hops for at least a week in the secondary. Pellets are more convenient. Regarding yeast, I don't know what Anchor uses, but the homebrewer can use Wyeast "American" Ale or culture some Sierra Nevada yeast from a bottle of Sierra Nevada Pale Ale. In the bottle, Liberty Ale sometimes tastes a bit one-dimensional. I had some fresh on draft recently and it was deliciously balanced and perilously drinkable.

Subject: Fear of Clear Beer

I was sitting down with the Boston Globe this morning, when I happened upon a article that caught me totally off guard: "It's Clear, All Right, But Is It Beer?" Featured in the article is a picture and a review, of sorts, of Miller's latest creation, "Miller's Clear."

This may not be news to many of you, but here are some of the things written about this "beer" in the article. 122 calories per bottle, with a "full-flavor" [according to Miller, that is.

The author took this complimentary six pack and wandered around Boston, getting bartenders to try the beer and give their opinion. All but one said basically that they think that "most beer drinkers will try Clear once before quickly returning to their regular brands."

Some of the more colorful quotes were these:

"It tastes like sparkling water with a hint of beer."  
"If you keep filtering and filtering beer, you eventually get back to water."  
"It tastes like Alka Seltzer that's gone flat. It has no grit. I couldn't give it away."

The one bartender who did like the stuff is apparently a bartender in a rather upscale hotel, whose work uniform consists in a black wasitcoat and tie, with a Hawaiian orchid in his lapel...and worked for Miller for 14 years.

Finally, here's the end of the article:

"But I think you should put the color back. I think you should put the flavor back. And especially I think you should do what most of these Boston bar-tenders suggest: Put the beer back.

-Nathan Cobb"

Subject: Priming with Honey?

This past weekend I was at a homebrew exposition and one of the guys there was hawking honey for mead and beer. We got to talking (and drinking his fine mead) and I asked about using honey to prime beer with. He told me that in order to prime with honey you need about a pound (standard small jar available in supermarkets) and that it takes about a month to carbonate. Is this information accurate? Has anyone ever done this before?

Any and all responses are appreciated.

Subject: dmna, sulfur etc

Disclaimer: This is not a flame, I just couldn't pass up the opportunity to get some use from the plant physiology courses I have taken (programming usually doesn't require you to know about plant hormones :) )

>In HBD #1133 Rob Thomas says:  
> .....as to the hormone used in germination, it's gibberellic acid. This  
>is indeed found in nature.....It is what is found in "rooting powder" Actually GA is used to force blooming. The class of compounds that I think you're thinking of is auxins. Auxins stimulate rooting and cause elongation of stems (etiolation). Many commercially used auxins and GAs are in fact completely synthetic. (I vaguely remember that Agent Orange is auxin-like)(Maybe someone with better information can correct me)  
> (A related hormone is acetylene, this stimulates the ripening of fruit. ..)  
I think you're thinking of ethylene. Ethylene does in fact accelerate ripening.

Brewing Question:

I have just dissolved a small business that sold homebrewing kits, so I have ~110 #s of pale Laaglander malt extract to use up. I also have 50 #s of 40L crystal, 50 #s of roasted barley, and a lot of cascade(alpha 5.4%) and galena(alpha 14%). I have found that the malt extract recipes that I have made just aren't as good as the all grain brews I've made. I do a full volume boil, use a wort chiller and Wyeast, but it's still not as good, and its nearly as much trouble as a full mash. Does anyone have any suggestions for improving my extract brews so that I can use up this DME and grain? Also if anyone has any good recipes using just the ingredients I have I would really appreciate it if you could post them or mail them to me.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Re: Sammy Adams & Belgian Malts

Sam Adams is not and never has been a microbrewed beer. From its inception it was contract-brewed, originally in Pennsylvania and for the last couple of years here in Portland at the Blitz-Weinhard Brewery. I think they also did some pilot brews in Germany, although this might just be Kochype.

People interested in purchasing Belgian malts ought to contact Tim Norris, who runs a small business out of his home in Chicago. I don't have his address handy, but he can be contacted by e-mail at his CompuServe account: 71650.1020@CompuServe.COM

Tim offers an excellent selection of the malts, excellent prices and his service is impeccable. I recommend him highly. I just received, as a matter of fact, my second order of Belgian malts. Even with shipping costs from Chicago to Portland, the malts cost about 2/3 what they would have cost from my local retailer -- if he carried them.

From: Ed Hitchcock <ECH@ac.dal.ca>  
Subject: sparge water volume

I seem to recall that in Fix's article on HSA (at least I believe that is the source) it was mentioned that the volume of sparge water should not exceed 1.5 times the mash volume. I don't quite see how this works if you want to make beers of different gravity. One uses different volumes of mash water with different quantities of grain to make a 1034 bitter or a 1060 bock. For the 1060 beer you may get away with using 1.5 times mash water for sparging, but for the bitter it'll be more like 2.5 times, otherwise you just won't make up the volume of wort to 5 gallons. Did I misremember? Does this make sense?

From: Daniel Butler-Ehle <DWBUTLER@MTUS5.cts.mtu.edu>  
Subject: momilies

In Homebrew Digest #something-or-other, Tom Romalewski says the following:  
>In the Homebrew Digest #1131, Jack Schmidling uses the term "momilies" in  
>the following message on mash temperatures:

.....  
>  
>I haven't been able to find this word in any dictionary. I have seen this  
>word used before. Could it be that the author really wanted to say  
>"anomaly"? Or is this a slang term used in homebrewing lingo?

Neither is really true. "Momily(tm)" comes from a series of books by someone whose name I can't remember. The books are about things your mother always told you that weren't quite true. The term "momily" is trademarked by the author.

About a year(?) ago, someone on this list started applying the term to all those millions of things that some people think are LAW but really aren't. (Oh my gods! If don't siphon the cooled wort off the trub, your descendants will MUTATE! You're entire batch will be DESTROYED if you don't have your pH adjusted to exactly what Miller recommends!)

I guess that identifying momilies(tm) helps us keep in mind that for every "law" in homebrewing, there is a beer that won awards by breaking it.

Cheers!

Subject: Special B Mail Order Source, Anchor Liberty Info

> Andy A asks if there are any mail order suppliers for Special B and other Belgian Malts

St. Pat's of Austin (512) 832-9045 carries Special B and other Belgian malts. Great stuff.

> Darren Aaberge asks about Anchor Liberty Ale:

The hops used are Cascade. In homebrew terms the dry hopping rate is about 2 ozs per 5 gallons for about two weeks at reduced temperature (around 50-55F). At Anchor they are added to the conditioning tank. Also be aware that Liberty also receives a healthy dose of finishing hops. For more information on \*how\* to dry hop, my article on this topic will be out in a few weeks in the next Zymurgy.

As to their yeast, the only thing I know for sure is that it is a different strain from the Steam yeast. Liberty is fermented in deep tanks (as opposed to the shallow tanks for their Steam and Porter) and at a slightly higher temperature (but not much). There is a good chance that Sierra's yeast is related to the Anchor, but this is pure speculation on my part. Anchor did help the SN boys get started. Anyway, you won't go wrong with SN yeast when trying to clone Liberty. Culture from a bottle or use Wyeast "Chico".

Subject: The effect of Light on Beer

Message Creation Date was at 5-MAY-1993 09:18:00

Greetings,  
I'm curious about the effect of light on beer. I've always been told that light can cause a "skunky" off-taste, so I've always covered my carboys, bottled at night, bottled in brown bottles, and stored the bottles under cover. Evidently this has worked since I have not been getting any "Skunk" flavors. After considering my brewing/bottling process I've started to wonder if this is over-kill. Am I going to extreme lengths for minimal gain?

Does anyone know the wave-length of the "harmful" light? I mean are we talking UV, visible, IR, or some other wave-length? If visible light is a culprit, are the lights in my house enough to cause problems? How much light, in terms of strength and duration, is required to cause problems? I'd hate to find out that visible light from light-bulbs could potentially cause problems - On a stressful day there's nothing better than sitting on the floor, sipping a home-brew, and staring at all the bubbles of an active fermentation. Ahhh!!

> accurate? Has anyone ever done this before?

I have primed several batches with honey. In some of these batches, honey also made up a significant portion of the fermentables, in others, the only honey used was for priming. I don't know about the weight, but I found that 1/3 Cup will give a pleasant light carbonation, and anything more than 1/2 Cup will produce soda-pop fizziness. Boil it in water as you would corn sugar, but also skim the scum off as it boils. It will probably contain a bit of wax and pieces of bee armpits.

A month is excessive, but it does take a little longer than, say, corn sugar. At the tiny quantities used for priming, you won't be able to tell the difference between clover, blackberry, or anything else, so use what's available, it's all just bee barf. Some will disagree with that. Those who do are wrong. :-|

Mark Garetz asked:

I think you're worrying a little too much and too early, give them some  
time. Here in NJ the Cascade have just broke the surface and the  
Willamette are 3 feet long (with other varieties somewhere inbetween).  
These are established plants. You've got quite a bit cooler weather up  
there and you're starting with new plants, give 'em time.

Did the cuttings already have some shoots and were they "crisp" and  
seemingly alive (as opposed to dried out)?

>By the way, should I be fertilizing these guys? If so, what do all of  
you  
>recommend? I have some ordinary vegetable fertilizer but is there a  
particular  
>brand which works the best.

A slow, continuous release fertilizer seems to work best, I use bone  
meal with good results with an occasional overspray (the hops are  
adjaicent to my veggie garden) of Miracle Grow.

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Sparge Water

Ed Hitchcock asks in HBD#1134 how a bitter with SG = 1.034 can be brewed with the ratio of sparge water to mash water being no more than 1.5. I personally let the mash thickness float, and indeed have found this to be a relatively unimportant variable within a reasonable range. In particular, plots of yield vs. mash thickness tend to be quite flat in the range 25-40 liters/kg.

To cite some examples, suppose we want to brew 50 liters. In my system this would require

$$50 * (4/3) = 66.67 \text{ liters water}$$

(due to 12.5 % of the water used being left in the grains, and a 10% evaporation in the boil). Suppose 33.3 liters of water is used in the mash, and the same amount is used for sparging. If 10 kg. of base malt is used (adjustments are needed if adjunct malts are used), then typically 56 liters of wort would be collected in the brew kettle at a gravity of 1.045. This would boil down to 50 liters at SG = 1.050. A grain bill consisting of say 7 kg. of base malt typically yields 50 liters at 1.035.

In both of the above cases the yield is ~30 pts/lbs/gal. While this number is insensitive to mash thickness, it does depend strongly on the mash to sparge water ratio. In the above examples, about 2% of the extract is left behind in the grains. Had the ratio been increased to 1.5 (26 liters in the mash and 60 liters for sparging), the extract lost will typically drop to 1%. The most extreme case I have brewed had a ratio near 3.5 (20 liters mash to 46 liters sparge), and virtually no extract was left behind in the grains. The resulting beer was not to my taste, although clearly this is a subjective evaluation (as opposed to a scientific one). As I have noted before, I am not a yield aficionado. The major exception to this involves malt which has deteriorated due to excess moisture. I have alas had this happen, and the resulting yields were extremely low. In all other cases, I am indifferent to the yield a particular brewing configuration will give. The real issue is how the brewer feels about the finished beer.

George Fix

Subject: clear beer stuff

According to this week's Advertising Age, Miller Clear Beer is being test-marketed in Austin, Texas; Minneapolis; and Richmond, Va. Ad Age conducted a blind tasting in Chicago. Suitably chilled Clear Beer was poured into colored plastic cups along with Budweiser and Coors, and the lights were lowered. Some taster comments (tasters were Ad Age employees -- probably not a bad target group):

"It tastes just like a Bud."

"It seems a little more mellow, almost like flat beer."

"It tastes like watered-down beer."

"If you had a glass of beer and emptied it, then refilled it with water...that's what it tastes like."

One taster thought Clear Beer had more body than the other two brews.

Several tasters commented that Clear Beer had "a mineral water aftertaste."

Several male panelists said they judge a beer's quality and strength by the deepness of its color. "Don't people equate color with flavor? If so, that could be a problem."

Finally, one male panelist said color "makes a beer brand to me. It certainly would be weird to chase tequila with a clear beer."

SB> STEVE BOXER

First, I'd like to welcome you to the east coast--quite a change from  
SD, but we have our charms.

One of those charms is a relatively new brew shop and homebrew central  
(for things such as judging or tasting classes). It's called, get  
ready for the groans, "Little Shop of Hops." Its address is 15 W. 39th  
St., NY, NY 10018. They have a mailing list for their monthly (?)  
newsletter, and I'm sure they'd be happy to add you to it. I don't  
know a lot about them, since I've only been there once (I live on LI  
and have another supplier out here), but they looked like they were  
going to be pretty good (they had only been open for ~1 month at the  
time).

Subject: Free Belgian Beer Tasting

A Public Service Announcement:

On May 16th, from 1 to 5 pm, Mainstreet Deli and Liquors in Countryside, Illinois will be holding a FREE Belgian-style Beer Tasting. There will be over 25 Belgian-style Beers including:

Scaldis (in Belgium, Bush)

Saison Dupont (vielle Provision)

Rodenbach Gran Cru

Blanche De Bruges

Affligem Dubbel (and possibly the Trippel)

Grimbergen Dubbel & Trippel

Liefman's Brown, Kriek and Frambozen

Saison Dupont

Castelain Biere de Garde

Duvel

Orval

Westmalle Dubbel

St. Sixtus Abt

Chimay Red, Cinq Cents & Grande Reserve

Celis White and Grand Cru

Brigand

Corsendonk Monk's Brown and Monk's Pale

Lindeman's Kriek

Timmerman's Framboise

Maes Pils

There will be a limited supply of home-brewed pKriek, brewed by a regular contributor to the Homebrew Digest.

There is also a good chance that there will be a special guest beer (not available for sale) that is traditionally brewed by a non-profit brewery in Belgium but is available as yet only in one "state" in the U.S.

MAINSTREET DELI and LIQUORS  
5425 South LaGrange Road  
Countryside, Illinois

708-354-0355

Al.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: White beer recipe revisited

Some time ago I posted a recipe for a white beer I believe a fair number of people used as a starting point for brews of their own.

While I thought my own batch had turned out pretty well (still do), I also said that there was room for improvement and experimentation. Most of the people I know who are brewing white beer--myself included--are still figuring out how to deal with it, and the idea of the posting was to share my own experience in the hope that other people wouldn't have to start from zero.

In this same vein I'd like to ask those people who used this recipe--or have another one they like--to let us know how things worked out. You can send messages to me if you like, and I'll edit them into a single post. I'd be particularly interested in comments on grist ratios, spicing, and yeast.

If things didn't turn out well you're welcome to call me a scoundrel, too--I'll do my best to leave in any relevant feedback you have that might help someone make better beer, as well as any insults that seem especially witty.

Phil Seitz  
PSEITZ@MCIMAIL.COM

P.S. to Tony Babinec: so what DID the CBS say about this beer--from a brewing standpoint? I've got my bullet-proof vest on (borrowed from Jack), so for the good of the community let's have it.

Subject: Responses to Queries in HBD#1134

In HBD#1134,

Mark Garetz asks:

>Can anyone provide me with info and a contact number for the Oregon Brewer's

>Festival to be held after the AHA Conference? Thanks

Zymurgy tells us to call Widmer Brewing Company in Portland, Oregon, at (503)281-BIER (Note the GERMAN spelling of beer!). AHA Conference is July 26-30, and Oregon Brewers Festival is July 30-August 1. Both events are to be held in downtown Portland, OR, which is a beautiful city and a beer drinkers paradise!

And Steve Boxer asks:

>Does anybody know of brewpubs or more importantly home brew shops in

>[New York] city? Thanks in advance

Be sure to pick up a copy of The Barleycorn AS SOON AS YOU CAN. It is the

East Coast's equivalent to the Celebrator. I am looking at an old copy from

last December as I type this. There are LOTS of home brew shops listed in

New York state, but unfortunately my knowledge of New York geography is rather sketchy. There is one listed on Staten Island, though:

East Coast Brewing Supply

124 Jacques Ave.

P.O. Box 060904

Staten Island, NY 10306

(718)667-4459

You can subscribe to the Barleycorn by sending \$12.00 check or money order

along with your name and address to:

Barleycorn

P.O. Box 2328

Falls Church, VA 22042

(703)573-8970

Date: Thu, 6 May 93 09:45:10 EDT  
From: jimf@centerline.com  
Subject: Sam Adams being investigated

Today's Boston Globe reports that Sam Adams is being investigated by the New York City Department of Consumer Affairs for misrepresentation in advertising. The investigation was incited by the Brooklyn Brewery because of the advertisements stating that Sam Adams Lager has "won the Great American Beer Festival four years running."

It seems that they won in '85, '86, '87, '89, and '90 -- never more than three consecutive years. (The article also mentions that they won a gold and silver medal in '92 but they didn't mention that when talking about how many awards they'd won.) They didn't compete at all in '88.

Best quote, from Jim Koch, about why it's ok: "I used to say we won four years in a row. If you go to bat three times, get three hits and a walk, and then a fourth hit, didn't you get four hits in a row?"

Also disputed is the claim that Sam Adams is the only American beer imported into Germany. So are Brooklyn Lager and others.

Date: Thu, 6 May 93 09:51:44 -0400  
From: Timothy J. Dalton <dalton@mtl.mit.edu>  
Subject: Legal Problems for Sam(tm)Adams(tm)

Boston Globe, Thursday May 6, 1993. Pg. 77 (Business Sect.)  
Quoted without permission.

Barroom Brawl, by Frederic M. Biddle, Globe Staff.

" Beer isn't all that's brewing at Boston Beer Co.  
The Maker of Samuel Adams Boston Lager, described on bottlecaps and  
in  
company advertising as "The Best Beer in America," is barroom-brawling  
with a New York rival.

New York City's Department of Consumer Affairs is investigating  
Boston Beer  
for "possible violations" of the city's consumer protection law. "It's  
smarmy," Jim Koch, Boston Beer's president, said in an emotional  
interview  
yesterday. He said that the Brooklyn Brewery, which in New York  
distributes

Mass. Bay Brewing Co.'s rival Harpoon Ale, incited the investigation.

"That's ridiculous!" says The Brooklyn Brewery's president.

"That's irrelevant!" says a spokeswoman for the New York Department of  
Consumer Affairs.

What is relevant, all agree, is the New York agency's April 19 letter  
to

Koch. "Your current ads claim that Sam Adams Lager 'won the Great  
American

Beer festival four years running," the agency writes. "However, our  
preliminary investigation indicates that while you received awards in  
1985,  
1986, 1987, 1989 and 1990, awards were never received for more than three  
consecutive years."

Exactly what Sam Adams won is also in dispute. In the late 1980s  
Samuel

Adams Boston Lager actually won "consumer preference" polls of attendees  
of

the Association of Brewers' Great American Beer Festival in Denver.  
Plaques

accompanying those awards read: "Best Beer in America."

But in 1990 the poll was replaced by a Professional Panel Blind  
Tasting,  
following sore losers' objections. "It was becoming a popularity  
contest,  
and it didn't really reflect our mission," says association president  
Charles  
Papazian.

Now New York is telling Koch that "there is clear potential for  
consumers  
being misled when you refer in the aggregate to "winning" the Great  
American  
Beer Festival without being specific as to the nature of what you won."

[the articles continues on and on and on...  
highlights....

Meanwhile, Koch has fallen flat with competitors. For example: Brooklyn  
Brewery's president, Steve Hindy, disputes Boston Beer's claim that  
Samuel

Adams is the only American beer imported into Germany. Brooklyn Lager is, among others. "Many people are of the opinion that Jim's advertising is out of bounds," Hindy says.

[and it goes on...talking about the use of GABF awards in advertising and how the policy is changing, and how there are 32 gold medals there... SA got a gold and silver last year, but then again Pabst Brewing Co.'s Olde English 800 Malt Liquor got the gold in the Americal Malt Liquor category...]

From: Ed Hitchcock <ECH@ac.dal.ca>  
Subject: Re: Sparge water

Thank you George for responding to my question.  
I do, however, have a few questions and commentaries. Firstly, I recognize that the mash thickness can be varied to some extent with little change in the final beer. The question then is which has a greater effect on the quality of the final beer, brewing every batch with about the same mash to sparge volume ratios, or brewing beers with about the same mash thicknesses?

You wrote: "Had the ratio been increased to 1.5 (26 liters in the mash and 60 liters for sparging), the extract lost will typically drop to 1%. The most extreme case I have brewed had a ratio near 3.5 (20 liters mash to 46 liters sparge), and virtually no extract was left behind in the grains."

Perhaps I am missing something, but 26L mash and 60L sparge is a ratio of 2.3, and 10, 20L to 46L is also a ratio of 2.3. You lost me somewhere in there.

Lastly, was the 1.5 ratio solely for extraction rates? If so, I am less concerned than if this figure were for preventing tannin extraction or some other factor.

From: stevie@spss.com  
Subject: Miller Clear -- Less Yucky?

With Miller Clear Beer in test market in Richmond, it was no surprise that last Saturday's Washington Post had a feature on it. Customers at a local tavern were questioned. In general the comments were very much as in Ad Age (mentioned in Tony Babinec's post in the last HBD), with the most positive remarks coming from people who didn't really like beer. One couple, in particular, said that they had been drinking beer since college, but came to realize that they really didn't like it. Miller Clear was "less yucky" than regular beer.

The bar owner said Miller Clear was selling briskly, but it looked mostly like a fad. Most of the customers were trying it once, and then switching back to normal-looking stuff.

I didn't save the article, but I recall that Clear was only slightly lower in alcohol and calories than regular Miller products -- 122 calories per 12 oz. Tim Norris and I (we were in DC to judge at BURP's Spirit of Free Beer homebrew competition) thought briefly about a road trip to pick up a six to bring back to our pals in Chicago, but we opted for "yucky" Belgian stuff instead. We also only got as far south as Manassas, and lucky for us, Hero's didn't carry it.

Perhaps one of our DC colleagues can provide direct quotes from the Post?

From: Bob.Clark@Eng.Sun.COM (Bob Clark)  
Subject: Yeast trivia, Zima

I live in east San Jose, CA, just outside the area where there was a problem with the Mediterranean fruit fly (MedFly) last year. There's a fly trap in my front yard, and I talked with the guy who was checking it for fruit flies. It turns out that the bait they use is a mixture of borax and \*yeast\*. This struck a chord with others who have mentioned that their fermentation attracts fruit flies to their airlocks.

A friend brought a six-pack of Zima over last weekend. We split one bottle, and he refused to take the remaining five bottles home. It reminded me of the aftertaste you get with a really bad, cheap champagne. A bartender mentioned, too, that everyone who tried it in the bar had only bad things to say about it.

Richard Goldstein asks via private e-mail the following:

>Your mash ratio of 33 liters for 20kg of malt is roughly 1.5 qts/lb  
>(sorry, I'm not entirely comfortable leaving all this stuff in metric  
>units), and several of texts imply that this is at the high end of the  
>mash ratios, ie that this is a rather "thin" mash. I am assuming that  
>you are dispelling this notion by the statement:

>>plots of yield vs. mash thickness tend to be quite flat in  
>>the range 25-40 liters/kg.

>Do you really mean 25-40 liters/kg, or are you missing a decimal point?  
>Or am I missing the point? :)

Ops! What we have here is a tenured Full Professor of Mathematics with a Ph.D. from Harvard who can not do arithmetic! Doctor cure thyself! The correct range is 2.5 to 4.0 liters/kg. Thanks Rich!

The malt charge reported in my post was 10 kg., giving a concentration of 3.3 liters/kg. which is approximately 1.58 qrs/lb.

>I think that many homebrewers believe that a thicker mash is better, so  
>this is very interesting. Are yields vs mash thickness fairly  
>insensitive to mashing procedure? That is does your statement apply  
>equally as well to infusion/step/decoction mashing, or are there some  
>"better" thicknesses for each of these?

These results are for infusion mashing only. The situation for decoction is a good deal more complicated because of the volume reductions during boiling.

Theoretically a thick mash provides more thermal protection for enzymes, and this has been put forward as a point for a thick mash. On the other hand, enzyme activity is inhibited by the concentration of the products produced, and this tends to favor a thin mash.

There appears to be some disagreement about whether the effects cancel, or that they are simply weak effects. Our mathematical models (based on the nonlinear differential equations of enzyme kinetics) suggest it is a combination of both. In any case, it has been my personal experience with my own system that mash thickness is not a major issue.

The issue of over sparging and indeed hot sparging varies with beer style.

IMHO one can ruin many lager styles this way, however as Martin Lohahl correctly has pointed out a few months ago, some of these effects can and have been used to advantage in Belgian styles.

Thanks again Rich. I enjoy your e-mail!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Skunk beer?

I also have wondered about the incidence of mercaptan "skunkiness". So I propose:

Hey, Chuck! Could JudgeNet do an informal survey and report back on the incidence rate of skunky beer in contests? It seems to me that contest submissions would be the product of "reasonable" anti-skunk precautions.

I have read in literature from John I. Haas (a big hop supplier) that isomerized hop extracts are far more resistant to skunkiness. I've taken this to mean that most of the beer sold in clear bottles (Miller, Newcastle, Sam Smith, Corona, etc.) is hopped with the isomerized extract and doesn't use \*real\* hops. I'm only guessing.....

Paul.

Date: 06 May 1993 19:52:26 -0400 (EDT)  
From: WESTEMEIER@delphi.com  
Subject: Effect of light on beer

In response to yesterday's request for info on the effect of light on beer:

I've always found this fascinating, so I'll just outline what I understand to be the case, and let the experts fill in the gaps and correct the parts that are shaky.

What actually happens is pretty easy to understand (assuming you have a PhD in organic chemistry). The alpha acids in hops are changed chemically during the boil, becoming isomerized (which means the molecules are formed into long chains). These iso-alpha acids (as they are then called) are much more bitter than the naturally occurring alpha acids, and they are also much more unstable in light. When light hits them, they are changed chemically again, and they tend to react with some of the sulfur compounds present in all beers. That reaction produces a new chemical (to be precise, the loss of CO by the acyl radical forms the 3-methyl-2-butyl radical, which then combines with a thiol radical from sulphur-containing proteins to produce 3-methyl-2-butene-1-thiol, for those of you keeping score) which is familiarly known as a mercaptan. Mercaptans are also the active ingredient in a skunk's defense mechanism, and are easily recognized by the human nose at levels of a few parts per billion. OK, how much light does it take? If it's the right (actually, the wrong) kind of light, the answer is "not much." Any light with a wavelength shorter than 520 nanometers will do the job. Think about how sunlight is broken up by a rainbow or a prism. The longer wavelengths are at the red end of the spectrum and the shorter wavelengths are at the blue end. Red, orange, and yellow won't really cause you a problem. Green is getting dangerous (the yellow-greens are OK, the blue-greens are not). Blue, indigo, and violet are a definite no-no. Ultraviolet is right out. Since normal (white) light contains more or less the whole visible spectrum, you want to use a type of glass that filters out the harmful part. Anyone who has ever done serious photography knows that fluorescent lamps put out light that is more heavily skewed toward the blue end of the spectrum, and incandescent lamps toward the red end. Obviously, fluorescent lights are more harmful to beer than incandescent lights. What kind of lights are used in the beer display case at your favorite retailer? Uh-huh, that's right! Actually, it only takes about 24 hours of exposure to this kind of light to have an effect on beer in a clear bottle (have you had any Corona lately?). Green bottles help, but only a very little, since they just block a little of the red light and a little of the blue. Higher levels of sulfur compounds in some beer produced in green bottles can actually wipe out the advantage, so that

some beer shipped in green bottles is even more easily skunked than beer in clear bottles. Brown bottles help quite a bit, since they block almost all of the harmful wavelengths, but still let some of the harmful green light through. Some of the big guys actually apply a chemical treatment to their beer, so that light has little or no effect. Miller is the first one that comes to mind, and even though it's shipped in clear bottles, you're very unlikely to find a skunked Miller.

But who wants a Miller? We don't always get what we pay for, and it would really be worth your while to ask your retailer for beer that hasn't been exposed to the light. Get a six-pack from a freshly opened case in the back room, rather than a cold one that has been sitting in the display case under fluorescent lights for a week.

>  
> Did we do something wrong, or is a stout supposed to ferment that  
> violently?

I have had the same thing happen with my two previous batches. The first was the Sparrow Hawk Porter from TNCJOHB, which had an OG of 1.054. The second was the Dark Sleep Stout from TNCJOHB, which we perked up a bit by using 3 lbs of the dark DME rather than 1 lb. This had an OG of 1.067. The latter was so vigorous that it actually pushed up the lid on my fermenter (when the air lock became clogged) and spilled about a pint of foam on the floor. The stout is still aging in the bottles, but the porter turned out to be very smooth, so this was probably simply an inadvertent blowoff. By the way, both brews were fairly highly hopped. I didn't use a liquid yeast, but I do rehydrate religiously. That didn't change from previous batches, though, so I'm not sure that that can be the answer.

In any event, just clean up any mess, make sure your fermentation lock stays clear, and let it ferment to completion (which has probably already happened, considering the lateness of my posting wrt Jay's :~0).

Subject: Re: Methanol (aka wood alcohol)

In HOMEBREW Digest #1136 you write:

>Specifically, WHY isn't methanol produced during homebrewing  
>or I guess the question could be asked as how DO you produce  
>methanol? Thanks for the info in advance.

Methanol production requires:

- 1) the proper yeast (wild yeasts)
- 2) unique fermentables (cellulose == wood, grain husks)

As a homebrewer, you use a known yeast type that does not yield methyl alcohol as its primary waste product. The homebrewers of days gone by could not keep things clean; wild yeasts would get in and start eating the wooden vats used for fermenting, or in the case of moonshine production, the grain is left in the mash during fermentation and provides enough fiber for methanol production. After distilling the product, the methanol concentration is high enough to do serious damage. Nearly all methanol casualties are caused by consuming distilled spirits produced from an improperly controlled fermentation. Occasionally someone stupid mistakenly procures the cheapest alcohol he can find to spike his drink, not realizing that it's poisonous.

Traditional beer/ale homebrewing has never been a problem so long as the right yeast strains are employed. The wrong yeasts are hard enough to come by that it's not going to be a problem unless you ferment in wooden vats/barrels, or leave lots of grain in your wort during fermentation. Even so, the resulting beer would have lots of other off-flavor byproducts of the unusual yeast and you wouldn't want to drink it.

From: rxh6@po.CWRU.Edu (Randall Holt)  
Subject: Beer Machine Infomercial

I haven't seen the ad mentioned yesterday for a homebrew video, but I did catch the last few minutes of the Beer Machine (tm?) Infomercial. Since I haven't noticed any mention on this letter, I thought I'd bring it to attention.

The device they sell looks like a 2.5 gal. glass keg, laying on it's side, with a support stand, a tap and a screw-cap up on top. They demonstrate pouring in extract, adding water straight from the tap, add the yeast and screw on the cap ( I assume there's some kind of CO2 release). Wait for five days, then refrigerate (presumably after closing the release) and draw your own.

They only want \$34.95 for the kit (oh, times four easy payments, a typical infomercial small-print bullshit trick), so the real cost with shipping is about \$150. The extract they sell is Sun Country, which they will gladly supply for refills for about twice the cost at my local HB shop. But, hey, business is business.

Despite the excessive cost, this may introduce people into real homebrewing. The question I have, has anyone tried this system, or even tried brewing in this fashion, by fermenting and carbonating in the same container? I can imagine how tangy this beer would be, being poured right off the trub. Of course the happy smiling 'real people' are quaffing crystal clear, perfectly carbonated, 1 inch head, beer. I don't recall them ever mentioning the word yeast, which I would guess is a marketing strategy, but they do call their system "All natural". (So is the aboriginal practice of spitting in the mash pot to hasten the conversion of starch).

I also object to the trademarking of MY nickname.

From: Ming-chung Lin <MARS@suvvm.acs.syr.EDU>  
Subject: Sam Adams & other "microbrewers"

Last year I visited the F.X. Matt brewery in Utica, NY and was delighted to see a room full of GOOD BEER (not the usual Matt's fare). There were tanks full of Sam Adams, Harpoon Ale Brooklyn Lager, and others that I don't now remember. Matt's contract brews for many microbreweries, although I think the tour guide (whose knowledge I sincerely doubt since he claimed "beer is beer") said that they didn't brew Sam Adams, they just aged and bottled it. The others were brewed there.

For those of you in other parts of the country, Matt's is the nation's 11th largest brewer, far behind the likes of Miller and A.B. It's named after and owned by Frances Xavier Matt and also his brother. They produce a very low budget (and taste) line called Utica Club, a middle of the road line called Matt's (kind of like PBR), and also Saranac Lager which won some best beer of its kind award.

I find it curious that the brewers that are brawling in Boston all send their stuff to Utica.

Subject: RE: Effects of Light on Beer

Ed Westemeie writes:

"Get a six-pack from a freshly opened case in the back room, rather than a cold one that has been sitting in the display case under fluorescent lights for a week."

I'm curious if there is any relation between the protection from light and the better flavor of draft beer. I would imagine that there really are several reasons why draft beer tastes better including freshness and less temperature variance due to higher volume, but is light exposure a significant factor? Would any brewing gurus care to illuminate me (us) on the issue?

From: hinz@memphis.med.ge.com (David Hinz)  
Subject: All grain instructions - how's this look?

Greetings!

I've decided to jump in with both feet, and go for an all-grain batch. I've purchased a lauter tun, and will construct a cooking kettle out of a Stainless Steel 1/2 bbl and a water heater element tonight. I wrote up a checklist, and would like to run it past people here to see what comments you have. Obviously, it's a very basic checklist, but I want to make sure I have things in the right order, haven't missed anything, and so on.

I'm doing Papazian's "Silver Dollar Porter", with an extra pound of Munich malt per the suggestion of the local brewshop. My lauter tun is sort of a Zapap-type, but with a rotating sprinkler for the sparge water (probably fluff, but I'm lazy & impatient, so I didn't buy or build an easy-sparger..... yet)

So, here's my list:

- >Select recipe & obtain ingredients.
- >Start Yeast pack (2-3 days before brewing)
- >Add yeast to quart of starter wort (~12 hours before brewing)
- >Preboil 10 gallons of "brewing water", put in carboys when cool. (night before brewing)
- >Bring 1.33 qt H2O per pound of grist to 130 degrees (f) in mash kettle.
- >Add above water to grist, protein rest for (60?) minutes at 122 deg.
  - >Adjust pH to about 5.3 if needed
- >Start sparge water in cooker kettle, bring to 170(?) degrees. How much?
- >Raise mash temp to 155 deg, hold at this temp until conversion is done. (Can I do this with boiling water? How much do I use?)
  - >Adjust pH if needed
  - >Test for conversion with Tincture of Iodine
- >Raise temp of mash to 175 deg, for (20?) minutes, to mash-out.
- >Pour mash into lauter tun, let it compact, recirculate runoff until clear.
- >Put sparge water into sparging vessel, start the sprinkler. Keep the liquid level right around the top of the grain bed by regulating flow in and out of lauter tun. Collect this wort in the cooker.
- >Plug in cooker, bring to boil, add hops per schedule, boil per recipe.
- >Immersion chill, rack, pitch, shake, ferment, rack, settle, rack, prime,

bottle, keep in kitchen for a week, put it in the basement, wait, wait,  
wait, drink, MMMMMMMMMMMMMMMMMMM.

- - - -

Note that some of the times may be inaccurate, I'm doing this from  
memory,  
30 miles away from my books. Those, obviously, will be adjusted as  
needed.

Please e-mail or post if you can suggest improvements. I can't read R.  
C.B,  
so posts to the HBD would be better.

Thanks for any input,  
Dave Hinz

From: RBSWEENEY@memstvx1.memst.edu  
Subject: Oatmeal Stout

Does anyone on the HBD have a good all-grain recipe for an oatmeal stout.  
? Last month at the Bluff City Brewers and Connoisseurs awards banquet  
(Memphis, TN) Dave Miller was the guest speaker and brought along a keg of  
his delicious oatmeal stout--my kind of guest. Unfortunately, I was not  
able

to talk to him long enough to get the recipe, but the idea of oatmeal  
stout

will not go away. The hop bouquet on Dave's was heavenly, so I assume he  
must have dry hopped, and he did say the beer had been filtered using a  
DE?

filter. Emails would be appreciated.

As an aside, some of Miller's comments on making the transition from  
homebrewer

to microbrewer (his is in St. Louis) related to the brewers individual  
perspective on brewing. He basically divided the brewing community into  
'Germans' and 'Belgains'. The Germans being those who meticulously brew  
to

style, while the Belgains never want their brews to taste the same way  
twice.

His opinion was that as you make the transition to microbrewer you lose  
some

of your Belgain influence and become more German. He also strongly  
recommended

the filtering of beer, which he claimed brought out entirely new (and  
presumably better) flavor profiles. As I said, if his oatmeal stout is  
any

indication, he must be on to something.

Thanks in advance for the recipes.

Bob Sweeney

Subject: Cornelius repeat (oops)

Hello. I recently posted a question about sources for Cornelius kegs.

Thanks

to all who replied with some good input. One person in particular sent a lengthy piece on keg cleaning and reconditioning which was very useful. Unfortunately, I deleted it before I could get it on paper; could the person who sent it (whose name I also deleted) please send it again. I offer my sheepish thanks.

Also, regarding the use of yeast in medfly traps (HBD#1136): yes, fruitflies in fact do not eat fruit, they eat wild yeast that grows on fruit.

In the lab (*Drosophila melanogaster* is a favored organism for studying development) they are grown in little vials with yeast and some food for the yeast to eat. As a yeast geneticist working in a building populated by fly geneticists, this relationship is a particularly painful one. I will probably never recover from the repeated taunts of "my organism EATS your organism".

>I personally let the mash thickness float, and indeed have found this to be a relatively unimportant variable within a reasonable range. In particular, plots of yield vs. mash thickness tend to be quite flat in the range 25-40 liters/kg.

Not sure I can address what youse guys are talking about but I will use the discussion as a segue to what I want to talk about.

I have found that there are far more advantages to using a thin mash than a thick one. In fact, I don't know of any reasons for fighting a thick mash.

1. A thin mash has more mass and makes temp maintenance far easier.
2. A thin mash is far easier to stir and thereby assure thorough mashing and temperature homogeneity.
3. A thin mash requires less sparge water in direct proportion to the amount of mash water used.
4. A thin mash has less tendency to scorch or caramelize when kettlemashing.
5. It takes longer to bring a thin mash to temp but the time is well spent as the mash gets a sample of every recommended "rest" in the book and has the possibility of curing every il and adding a bit of every character possible.

For the record, I use 4 gals of water to mash 12 lbs of grain. I consider this on the thin side but have no qualms about using more water, just haven't tried it.

>From: WESTEMEIER@delphi.com  
>Subject: Effect of light on beer

>OK, how much light does it take? If it's the right (actually, the wrong) kind of light, the answer is "not much."....

I was waiting with baited breath to hear the answer but "not much" is not very satisfying.

All this science is real nice but when I see people putting bags over carboys of fermenting beer in the basement, I can't help but wonder if we haven't got another MOMILY out of control.

As a teenager, we joked about "Skunky Millers", so I am a believer in the principles involved but have serious reservations about the potential damage from occasional fluorescent lights over a period of a few weeks.

Seems easy enough to prove with a few simple experiments but I am so far from believing it, that I have better things to do.

So, I offer a challenge to some incipient MOMILY BUSTER. Split a batch in half and keep half in the dark and expose the other to 8 hrs of fluorescent light per day. Bottle some of both when ready, then do the same every 30 days till you smell a skunk and report back.

My bet is, you will run out of beer first.

.....

Does anyone know anything about the Bidal Society Competition? i.e., can someone post the results?

>enzyme activity is inhibited by the concentration of the products  
produced,  
>and this tends to favor a thin mash.  
>  
>There appears to be some disagreement about whether the effects cancel,  
>or that they are simply weak effects. Our mathematical models (based on  
the  
>nonlinear differential equations of enzyme kinetics) suggest it is a  
>combination of both. In any case, it has been my personal experience  
with my  
>own system that mash thickness is not a major issue.

It was Noonan that said: "...thick mash improves enzyme performance. In  
a thin mash, proteolytic and other heat-labile enzymes are destroyed in  
the course of the rest: in a thick mash, they may survive into the  
saccharification range."

Greg brews some great beers, on the other hand, he sometimes goes to  
extremes. Therefore, I'd just take this more as a data point than  
a definitive answer.

On the third hand (?), I've read, but cannot find it again (drat!), that  
a stiff mash favors one of the amylase enzymes and a thin one favors  
the other. Anyone have this data? Was that in Noonan also?

Al.

Date: Fri, 07 May 1993 10:49:58  
From: garetz@brahms.amd.com (Mark Garetz)  
Subject: Isomerized Hop Extracts vs. Skunkiness

>Paul dArmand asks about isomerized extracts and whether or not they are immune from ligh-struck or "skunky" effects.

Regular isomerized extracts are no more immune to skunkiness than hops. However, there *is* a treatment one can do to the extract (or presumably, the beer) that makes the beer more immune. Sam Smith's claims to use such a process, but IMHO it doesn't work very well. I have had many of their Nut Brown Ales that were severely light struck.

>Ed Westemeie states that isomerized alpha acids are much more bitter than their non-isomerized "natural" counterparts.

Nothing I have ever read on hops supports this statement. However, the non-isomerized alpha acids don't dissolve very well in water or beer, and so they have a minimal effect on the bitterness. The isomerized AAs are much more soluble. Maybe Ed was actually trying to state this, but simplified it.

Scott Stihler writes:

=>

I've got a question regarding filtering beer. I've been interested in filtering my homebrew for awhile but I'm somewhat confused as to what is the optimum filter size for beer. Does anybody out there happen to know? I'm afraid if I get too small a filter size I may lose body. Anyways, I'd appreciate here what  
=>

I was interested in this at one time also, due to some haziness I had with my brews. However, I figured out that instead of filtering out the haze along with body, I should fix the problems that caused the haze in the first place. I don't know what all was causing the haze, but I did a combination of things to fix it. These included: going all-grain, using a keg system, and changing how I did the mash.

The old timers on this digest will remember me and my mashing technique. Someday I will get out from under all the piled up duties at work and ship out a description of my mashing technique. Basically, I put all the sparge water in the mash at once, stir, and wait until the whole thing settles. Saves time and hassle, and I get nearly the same extraction as with the old textbook method. I'll detail it someday, I promise.

From: rdeaver@tecnet1.jcte.jcs.mil  
Subject: HBD submission

A while back, I recall somebody posting a comment about boiling wort. The post mentioned that if you brought the wort over a certain temperature (I believe it was 153 degrees F), you would convert some of the sugars to a non-fermentable form.

I only have a half-dozen batches under my belt, and most have seemed a bit sweet. The finishing gravities ave been around 1.002, but the brew had a heavy taste to it.

Planning to launch off on another brewing session of Heavy Scottish Ale, I dropped into the local brewshop for a strainer bag. The question raised was that if I did not boil the wort, would I have sterilization problems. I will be using Briess DME, and this time will be using some specialty grains. I always boil water ahead of time, to get rid of chlorine.

What is the general consensus? I have had this "sweet heaviness" with several batches; it is not recipe-specific. The last batch, I went as far as using yeast nutrient.

From: fiero@pnet51.orb.mn.org (Bill Fuhrmann)  
Subject: Miller CLEAR

Just realized that we are a test market, the rest of you haven't had the "honor" of tasting Miller Clear yet.

It looks and tastes like sparkling water. There is a very slight (very, very, very slight) bit of beer taste to it and a little bit more nose.

To a quick sniff, it smells like you didn't quite rinse out your glass completely. You have to swirl it around your mouth to notice any taste.

I expect that this will be popular with very under age drinkers since it does not require acquiring a taste for it, it won't be obvious what they are drinking (maybe also popular for drinking in cars for that reason), and won't be noticeable on their breath.

I bought it once to see what it was like and it appears to have lived down to even lower expectations than most of the people in the beer world expected.

The clerk in the store thought that I was buying an interesting combination of brews; Clear and Cerveza Caliente (cabos style chili beer). The Cerveza is brewed by the Minnesota Brewing Company in St. Paul (home of blonds and blond food).

If you want to brew a clone, just put water in the bottle, add yeast and the priming sugar. You'll probably come pretty close to the taste but not the 4.6 % (by volume according to the label) alcohol. Just think, you can mix this with a low alcohol beer and get a light beer.

Bill Fuhrmann, aka fiero@pnet51.orb.mn.org

SUBJECT: Collecting yeast abroad

I have the good fortune to be going to Germany (Cologne area) next month. I'd like to collect some yeast while I'm there. I have a few questions for the net:

1. How well does solid agar keep at approx room temp for maybe a week or so?

I'm pretty careful with sanitation.

2. What does the Customs Dept think when you come back with small vials of yeast on slants that are capped and all taped up? I know they get bent out of shape if you bring plants or animal products, so does yeast count?

3. Pierre Rajotte, in the Zymurgy special issue, sez to mail the vials back home, along with a business card from the brewery, mark it yeast sample, etc., and leave it to the postal inspectors to yea or nay it. Does this work?

4. Anybody know of any must see breweries/biergartens in Cologne?

Any responses would be greatly appreciated. If I get enough e-mail (as opposed to HBD posts) I'll collect the ideas and post them at once. Thanks in advance for all the expert advice.

From: KLIGERMAN@herlvx.rtpnc.epa.gov  
Subject: Belgian caramel pils

I hope someone can clarify for me the use of DeWolf-Cosyns Caramel Malt Caramel Pils. I was under the impression that these were crystal malts that did not need to be mashed; with cara-pils being the lightest and special B being the darkest. Today I was making a Pilzen style honey lager and wanted to use a pound a very light crystal (Caramel Malt Caramel Pils). As I usually do with an extract recipe, I crushed the grain, added it to about 3/4 gallon of cold water, and slowly brought the "mash" up to about 180 F. I then sparged with about a gallon of hot water (about 190 F). After this I looked at the grain and it looked like gelatinized starch. I did an iodine test and the result was jet blue-black. I decided to add more water and 1 pound of crushed Klages Pale malt and mashed at about 155 F. I then added this to my honey-malt extract wort. Question: The Belgian malt did not act like typical crystal malt--it gelatinized instead of dissolving. I thought this was supposed to be a crystal malt or if not at least self convert. It seemed to do neither--just form gelatinized soft grain. Can anyone please tell me where my assumptions or processes are wrong, else I will worry without having a homebrew. Will my Pilzen be cloudy from the first sparge of the apparently unconverted starch?  
Thanks,

From: Mark A Fryling <mfryling@magnus.acs.ohio-state.edu>  
Subject: Belgian souvenirs

Hi gang!

I've got a question for all of you worldly travelin' beer lovers out there. My girlfriend is going to be in Europe all of next month and will be spending the last week of her trip in Belgium. So naturally, I have asked her (and she has agreed) to bring me back some local Belgian beers. My questions to you are:

- 1) Whats the duty rate on alcohol over the duty-free limit (and for that matter whats the duty free limit)?
- 2) Is it best just to pack the beer carefully and carry it on the plane as extra luggage or to ship it?
- 3) Does anyone have any particular recomendations about Belgian beers not available here that she might easily find there? She will be spending most of her time in Antwerp.

Any and all assistance can be sent either directly to me at  
mfryling@magnus.acs.ohio-state.edu  
or posted if you think your comments are of general interest. Thanks in advance.

Mark

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Musings on Commercial Beer

My C-P bottler is down for re-design so I bought a bunch of commercial stuff to take to a party. Always wanting to turn a beer drink into a learning experience, I bought some things I have wanted to try/compare.

Draft Guinness in the can is not only lousy beer but the nitrogen gizmo is just plain silly. I thought the beer had a metallic taste and was lacking in anything worth mentioning.

Bass ale was about as bland as the Guinness but lacked the metallic taste and just about any other, for that matter.

Take the coloring out of Beck's Dark and you have Beck's regular. It seems a bit more beerish but hardly in line with the color.

The good news (strike me dead) was Miller Reserve Pale Ale. I tried the "all barley" larger a few months ago and it seemed a farce but this stuff is real ale. It's fruity and wonderful. It has a very marvey aroma and the taste that follows is exactly what you expect from the aroma. By far the best beer to come out of the biggies in decades. No doubt they found the right combination of chemicals to do the trick but at least it tastes like beer.

It does not taste like my ales but rather like most of the ales I taste at club meetings and the experts tell me that is what it is supposed to taste like.

Needless to say, I wait with baited breath to hear what others think of it.

Subject: re skunks

> So, I offer a challenge to some incipient MOMILY BUSTER. Split a batch  
in  
> half and keep half in the dark and expose the other to 8 hrs of  
fluorescent  
> light per day. Bottle some of both when ready, then do the same every  
30  
> days till you smell a skunk and report back.  
>  
> My bet is, you will run out of beer first.

I wouldn't suggest that anybody do this with a batch they value.  
Stiv Stroud runs periodic Dr. Beer sessions at which participants can  
sample beers with various off-flavors. At the session I was at a couple  
of  
years ago, the demonstration of light-struck beer involved some Molson's  
which he said had had a total of 6 hours of direct sunlight (well, as  
direct as you can get in February). The stuff was LETHAL; I could smell  
it  
a yard away almost the instant the bottle was opened and wouldn't even  
consider tasting it (I wanted to be able to taste something else that  
day).

I expect this will vary quite a bit according to factors like carboy  
geometry and how dark the beer is; my assessment in private email was  
that  
it wasn't likely to be a problem because most homebrewers don't have  
fluorescents where they ferment. I also don't have any data on typical  
spectra for fluorescent lights, only the datum that they're efficient  
lights only by comparison with incandescents---something like a mere 85%  
(vs ~93%) of energy used comes out as heat, which would suggest that  
fluorescents might have less energy in the high-visible and UV range  
than sunlight. However, there are probably enough carboy-sized places in  
the typical homebrewer's residence without sun or fluorescent lighting  
that  
it would be a silly risk to take.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Isomerized Hop Extracts vs. Skunkiness

May 1 (National Homebrew Day), the Kalamazoo Brewery had a free homebrew "conference". One of the speakers was a "hop chemist" from Kalsec (I think I got that right), a company in Kalamazoo that does "spice extraction". He talked about the chemistry of hops flavors & aromas. The best part was the box of vials of extracted flavor/aroma components that he passed around (ranging from "cheesy/funky" through "esters" to pure isomerized alpha&beta acids (he said it was 1,000,000 BUs)). Apparently, Kalsec makes the hops extract that "2 of the 3 largest brewers" in the US use (hint: AB is the one that doesn't). They do the light-stabilization thing that lets Miller get away with clear bottles (even though the hops are just about sub-threshold, I imagine the mercaptans wouldn't be).

(The rest of the day was fun, too.)

From: STROUD%GAIA@leia.polaroid.com  
Subject: Sam Adams..... a Microbrewery

Far be it from me to take the position of defending Sam Adams, but there appears to be some confusion in the HBD-world about where SA is and isn't brewed.

Jeff Frane sez:

> Sam Adams is not and never has been a microbrewed beer. From its  
> inception it was contract-brewed, originally in Pennsylvania and for  
the  
> last couple of years here in Portland at the Blitz-Weinhard Brewery.

Well, yes and no. Sam Adams LAGER was first brewed as a contract beer in the Pittsburgh Brewing Co. It still is, and in the last few years it has also been contract brewed at Blitz-Weinhard. The other seasonal bottled SA products are also contracted out of Pittsburgh. I don't know whether these are also brewed at B-W.

Sam Adams BOSTON ALE (bottled version and some of the draft) is brewed at Matt's in Utica, NY. Sorry, Lisa St. Hilaire, your tour guide was wrong. Utica does the brewing, not just the storage.

It gets more confusing, however, because Sam Adams (the Boston Beer Company) does indeed have a microbrewery here in Boston where they make numerous draft beers (including Boston Ale) that are available at local taps in the Boston area. Some of these beers are experimental (like the recent "triplebock" and last summer's "dunkelweizen"). The draft beers that SA's takes out to the GABF are also brewed here in Boston. I have been told by the head brewer that they also make occasional batches of Sam Adams Lager (draft) in the Boston brewery.

The heart of Sam Adam's microbrewery is a 10 bbl mashtun which was acquired from the now defunct Newman's Brewery in Albany.

So to say that Sam Adams is not and never has been a microbrewed beer is not true. While it is predominantly a contracted beer, at least here in Boston, some of the product is microbrewed.

Steve Stroud

Oh, BTW, the Sam Adams that is sold in Germany is supposed to be contract-brewed IN Germany. I don't know the name of the brewery.

Subject: Re: Beer Machine Infomercial

I did not see the commercial for this beer machine, but in the May 10 digest, Randall Holt (rxh6@po.CWRU.Edu) asks:

>The question I have, has anyone tried this system, or  
>even tried brewing in this fashion, by fermenting and carbonating  
>in the same container? I can imagine how tangy this beer would be,  
>being poured right off the trub. Of course the happy smiling 'real  
>people' are quaffing crystal clear, perfectly carbonated, 1 inch head,  
>beer.

I have done this with a "Brew Sack" (tm). Instead of using a glass or plastic keg, they use a woven plastic bag with a plastic liner.

The "Brew Sack" comes pre-loaded with hopped malt syrup in one of three varieties (Porter, Stout, Pilsner). Just add hot (~150 degree) water to dissolve the syrup, then add more water (20 pints total) to cool down to ~95 degrees and add the yeast. The bag is equipped with a pressure relief valve in the screw-on cap and with a tap near the bottom.

I kept mine for about 7-10 days at a reasonable room temperature, then moved it downstairs to a room at about ~55 degrees for 4 weeks.

It was pretty lively when I opened it, but the carbonation seemed external, somehow -- the beer never had much head by itself. I guess this is not surprising, since a plastic bag is not going to stand up to a lot of pressure.

The beer (a Porter) was very rich and quite tasty. It was \*not\* clear (even for a Porter), but I was not bothered by any sediments. I did choose to pass on the last 2 inches of brew left in the bottom, though I suppose it would be a good vitamin B-12 supplement?

This weekend I plan to start a Brown Ale that I will split between a standard single-stage fermentation technique and the "Brew Sack". Then in 6 weeks or so I will have an official comparison taste test --- provided that I can get the !@#%^&\* screw cap off of the Brew Sack....

From: u4imdmre@cpc41.cpc.usace.army.mil (Markham R. Elliott)  
Subject: Nepalese and Tibetan Chan(g)

I have a question for you beer scholars out there. This past weekend my father-in-law and I were quaffing a couple, and he asked me if anyone on the network had ever mentioned "Chang". He told me a story of when he went to Nepal and began a climb of Mt. Everest (real story, fully documented etc, etc. he never intended to go to the summit or anything, just wanted to 'climb' it, and he went and climbed to one of the traditional base camps).

At any rate, he said it is a brewed beverage, consumed during social and sometimes at ceremonial gatherings (sometimes spelled as "Chan" by those in Tibet). Said it was quite strong, and (given the altitude) would really 'do a number on you'. He wants to know if anyone out there in HBD Land knows a full history and recipe.

I've seen a couple of posts lately from some student(s) doing research on brewing, so come on guys and gals, here is your chance to show us what you've got.  
Noch einmal, bitte!! Mark

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Isomerization

Two issues ago my eye was struck by the statement regarding the processes involved in brewing and skunking "... isomerization is the process by which longer chain molecules are made." Well, I don't have a PhD in Organic chemistry, yet. Isomerization is simply a change in structure or connectivity in a molecule. I believe that in the alpha acids, the isomerization involves the shifting of double bonds to form a conjugated system (alternating double and single bonds in a chain) that would indeed be more photoreactive. I have been looking for a book that explains the chemistry of brewing in more detail from beginning (pH of Water, mineral effects) to end (the effects of light on beer, etc.) Does anyone know of any sources or titles that would have this sort of info?

Thanks

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Sugars

I decided the hot Texas summer months were a good time to brew stong Belgian ales. I figured I'd better read up on the subject first; I started with Pierre Rajotte's Belgian Ale (Classic Beer Style Series #6). A very interesting book w/a lot of info, but less than clear in a number of places. One of the unclear area is the subject of sugars. Rajotte devotes 6 pages to description of sugars used in brewing but left me confused. So I re-read Miller's (Complete Handbook of Home Brewing) section on sugars. Some of what Miller says seem to contradict Rajotte--more confusion.

Here's what I think I know about various sugars.

Corn sugar--aka glucose or dextrose. A single sugar 100% fermentable. Adds no flavor to beer.

Cane sugar--aka sucrose. A double sugar made up of glucose and fructose. Must first be broken into glucose and fructose before it can be fermented. Fructose is apparently responsible for the cidery flavor in beers using a large amount of sucrose.

Invert sugar--Sucrose that has already been split into glucose and fructose by acid reduction. Has pH of 4 to 6.

Brown sugar--Partially refined sucrose. Produces rum like flavor in beer.

Molasses-- I don't really know what the composition of molasses is.

Demerara-- ?

Treacle-- ?

Candi--Sucrose that has been refined by slow crystalization. May be light or dark or camelized?

Honey-- I don't know what sugars are in honey.

Malto-dextrin--Long sugars produced it mashing malt. Not fermentable and tasteless. Common homebrew lore it this adds body to beer but Miller (pg 61) says this is not so!

The questions are:

Can you fill the question marks above?

Any errors above?

If sucrose must be inverted before being fermented, how does this happen in the brewing process? Is there an advantage to using invert sugar?

Do you have sources for demerara, treacle, or candi?

What sugars have you used for strong ales and with what results?

Does malto-dextrin add body or not?

Any suggested reading?

Looking forward to your responses, WAK

From: gummitch@techbook.com (Jeff Frane)  
Subject: Re: thin mashes & not mashes

Into the discussion about thin vs thick mashes, I would interject another source. Unfortunately, I don't have my copies of the old Amateur Brewer (under Fred Eckhardt's editorship) in front of me to check numbers, but there was an issue focusing on the production of wheat beers. These were specifically Swiss weizens, which aren't necessarily remarkable (and in fact have an extremely complex mash cycle as I recall), but it was in that article that I first heard that thin mashes were proteolytic. I believe the article gave specifics on malt to water ratios.

I don't know the answer. My own experiences have been all over the map on thickness and I've yet to discover any real difference in the resulting beer.

Rdeaver is a bit confused:

>  
> A while back, I recall somebody posting a comment about boiling wort.

> far as using yeast nutrient.  
>  
Once the stuff is wort, all the conversions have taken place and no amount of tinkering with the DME itself will change the relative thickness of your beer. If you are really getting a finishing gravity of 1.002, it's pretty clear that the beer isn't finishing too high -- it's more likely that you are under-hopping (your bittering hops). Could it be that you're not adding hops at all but relying on a hopped extract?

Another possibility is that you're misreading the hydrometer. Could it possibly be 1.020? If so, then the problem is probably something involving your yeast: you're not using enough, or you're not aerating the wort at pitching time so that the yeast have insufficient oxygen and poop out without ever finishing their fermentation.

BOIL the wort! Make your best effort not to boil the grains you're adding, however, regardless of what certain books might advise. Better you should steep the cracked grains at about 150F for 1/2 - 1 hour, strain and rinse them with hot water and add your extract to the resulting liquid.

Keep plugging away.

- --Jeff

Subject: Mash Stiffness

In personal email, Rich Goldstein pointed me to the passage I was thinking of (in fact, he saved me the trouble of typing it in -- Thanks, Rich!):

Miller writes, in "The Complete Handbook of Homebrewing":

Another factor influencing enzyme activity is stiffness (thickness) of the mash. A thin mash -- say 2.5 quarts of water per pound of grain -- ultimately favors a more complete breakdown of carbohydrates in the kettle. However, because the enzymes are more diluted, breakdown takes longer to achieve. On the other hand, a stiff mash -- around 1.33 quarts per pound, as I recommend -- initially favors starch breakdown; however, as amylolysis proceeds, the increasing concentration of sugars in the mash inhibits further enzyme activity. A stiff mash favors breakdown of proteins in the mash kettle, and it provides one other benefit: it protects the enzymes better. At any temperature, the thinner the mash, the faster the enzymes will be deactivated [p. 128]

Also, Brian Smithey wrote to me mentioning that he begins his stovetop mashing with a stiff mash and then thins it out later, I assume when going from the protein rest up to the saccharification rest. In a insulated cooler step infusion mash, where the temperature is raised simply by adding boiling water, this is inevitable, but in a stovetop mash, this is optional.

This would be an interesting area for experimentation... no?

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: IBU's for Weissbierxxx zen

While reading the recipies in Warner's book on German Wheat Beer it seemed to me that the suggested amount of hops (2.6 HBU's for a 5 gallon batch) seemed too small to attain 15 IBU's of bitterness. Especially, since he recommends boiling 1/2 of the hops for 60 minutes, 1/4 for 30 minutes and the remaining 1/4 for the last 10 minutes. Using the formula from Rager's article in the Zymurgy Hops Special Issue

$$W(\text{oz}) \times \%A \times \%U \times 7462 \quad \text{HBU} \times \%U \times 74.62 \\ \text{IBU} = \frac{\quad}{V(\text{gal}) \quad 5} \quad = \text{HBU} \times \%U \times 14.9$$

we get

$$\begin{aligned} \text{IBU} &= 1.3 \times 0.30 \times 14.9 \quad (1.3 \text{ HBU's } 30\% \text{ utilization for } 60 \text{ min}) \\ &+ 0.65 \times 0.153 \times 14.9 \quad (0.65 \text{ HBU's } 15.3\% \text{ utilization for } 30 \text{ min}) \\ &+ 0.65 \times 0.06 \times 14.9 \quad (0.65 \text{ HBU's } 6\% \text{ utilization for } 10 \text{ min}) \\ &= 5.81 + 1.48 + 0.58 \\ &= 7.87 \quad (7.9 \text{ with rounding}) \end{aligned}$$

This seems significant since it is only a little more than half the target of 15 IBU's that Warner claims! Even if you assume the full 30% utilization figure for all the hops added the value is 11.6.

Checking the Glossary in Warner's book he uses the formula (bottom of p 139)  
for IBU as

$$\text{IBU} = H \times (a\% + b\%/9) / 0.3$$

(actually Warner has a typo and his formula for IBU reads HBU =...)

where

H is the weight of hops in grams per liter

a% is the alpha acid per cent

b% is the beta acid per cent

9 is a factor indicating that the flavoring power of alpha acids is about nine times greater than beta acids.

0.3 represents an approximate 30% efficiency rate in hop extraction caused by vaporization or precipitation.

It seems to me that since Warner is dividing by 0.3 he is in effect assuming a utilization rate of 33.3%. With this formula (I'll omit the details) you get 13 IBU's (neglecting the beta acid per cent).

Can anyone out there explain this discrepancy? I don't think that Eric Warner has a Ph.D in mathematics from Harvard so he shouldn't be making arithmetic errors (sorrly George).

The only other exlanation I could think of is that Warner is assuming a 33.3% utilization rate independent of the time of boil and that the beta acid content is always about 1.4 times the alpha acid content.

By the way, I think that Warner did a great job on his research for the book, and have found it otherwise well written and full of very useful information.

Bill Szymczak

Subject: Book recommendation

From: Matthew Mitchell

At the ASBMB last year, I picked up a copy of "The Biotechnology of Malting and Brewing" by J.S. Hough (Cambridge U. Press: 1985 :their address is 40 W 20th, NY NY 10011-4211!) which is now out in paperback.

I cannot recommend this book enough to those of you who have an interest in all-grain brewing, yeast culture, and any of the more technical aspects of brewing. It covers the entire process from barley to barrel, with descriptions of how commercial breweries produce their swill.

All aspects are clearly explained in terms understandable by someone who has taken freshman chem and bio in college. There are plenty of diagrams which serious homebrewers might try as a starting point for their experiments with equipment and technique. There's even some economic analysis and discussion of commercial aspects.

Howzat!?!

Subject: re ethylene and ripening

Did somebody call for a botanist?? Effects of ethylene on barley have been studied. It stimulates the release of gibberellin-induced alpha-amylase from the aleurone cells into the endosperm. In English, that means it triggers another hormone (gibberelin) to induce the formation of an enzyme that will convert starches into sugars. So I guess there's some potential here ... (?)

Subject: FX Matt Brewery

I was glad to see Lisa St Hilaire's posting in HBD #1137 regarding the FX Matt Brewery. There aren't a lot of things I miss about living in Utica, but that's one of them. I always bought Saranac when I was a local, but when I went back for a visit, even the draft Matt's tasted pretty decent.

I always sniggered during that part of the tour where you see the famous 'Brooklyn' beer, the 'Philadelphia' beer, the 'Boston' beer, and lord knows what others being created right there, two blocks from my house.

More important, my letter to the president, FX Matt III (I'd suggested he not charge for tours, and promote Saranac more vigorously), received a response that was warm, polite and personal. I was impressed.

In the same HBD, Randall Holt asks if any homebrewers have tried fermenting and carbonation in the same container. I was puzzled when I saw this is exactly what they do at Matt's (and the other big breweries, I assume). Is there a pressure control that guarantees the desired carbonation? Does their 'air lock' become a 'cork' at some point in the process? I don't think there was any mention of priming during the tour at all. How do dey do dat?

prosit! to all and to all a good night  
Kirk

Subject: FX Matts

The FX Matt Brewing Co is now supporting the homebrew community too. They have been the gracious sponsor of the Mohawk Valley Friends of Beer for about two years now. They converted a room in the back of their "Brewery Shop" into a test kitchen where we have taught homebrew classes and where we hold our meetings. They now also sell homebrew supplies.

Their Associate Brew Master, Jim Kuhr, is also a homebrewer. He has made 5 gal batches right in their lab! He and the Senior Brew Master Norm Grisewood are also studying for the BJCP exam. Pam Kuhr runs the homebrew shop. All of the people at the brewery have been very open about information and techniques, but don't try to ask about recipes.

Our homebrew club has had the luxury of going on private tours with the brew masters. Other homebrew clubs have also arranged tours with the brewery. Their address is 811 Edward St, Utica, NY 13502

To answer Kirk Anderson's questions, they do use high krausen wort to prime their lager beers. They also recycle the CO2 that is produced in fermentation for use later for purging empty storage vessels, etc..

Subject: Going Blind, Egg Drop Soup, Worms

>From: Steve Dempsey <steved@longs.lance.colostate.edu>  
>Subject: Re: Methanol (aka wood alcohol)

>Methanol production requires:

- 1) the proper yeast (wild yeasts)
- 2) unique fermentables (cellulose == wood, grain husks)

The "going blind" momily has nothing to do with making beer or even with distilling white lightn'n.

It has to do with the fact that, in the good old days, unscrupulous producers, middlemen and even a well meaning friend would add commercial alcohol to booz to stretch his fermented/distilled mash. If he used the wrong kind of alcohol, either methanol or denatured ethanol, the result was poison and one of the symptoms could be blindness. There is no way you can make anything that will cause blindness by mashing, fermenting and distilling the kind of stuff normally used in beer and whiskey.

.....

While on momilies, let's talk about the rolling boil and "great hot-break" momily.

I have always been a bit disappointed with the sleazy little bits of coagulated protein in my brew kettle. I boil on my aluminum melting furnace for at least 90 minutes in a 16 gal kettle. I can bring 10 gal to a furious boil in about 15 minutes.

Several weeks ago, I did a batch on my kitchen stove with an EASYMASHER installed in an 8 gal kettle just to prove that it can be done without any fancy burners.

The result was a "boil" that I would describe more as a circulation and I do not recall seeing a single bubble break the surface.

In spite of this, I evaporated the six gallons down to 5 and had coagulated protein floating around that I could have made lasagna with.

So it would seem that if one wants "great hot-break", ease up on the heat.

I also made believe I didn't own a wort chiller and let it cool naturally to pitching temp and, after cleaning and sterilizing the kettle, did the primary ferment in it.

It is now clearing nicely in a carboy and last night's sample would indicate that it is not significantly different from any other ale I have made with the same ingredients and far more bother.

I wait with BATED\* breath.

\* It has been pointed out to me that "baited breath" results from having a mouth full of worms.

From: "Marlene Spears" <hopfen!marlene@uunet.UU.NET>  
Subject: Koch, GABF, and Ancient History

Being a senior citizen of the Kochpeace foundation, I thought I'd recollect for the young whippersnappers on HBD and flame a little to warm the hearts of the gray haired set.

For you reference hounds, Summer 1987 issue of American Brewer magazine, page 15, Vince Cottone's article: "Beer & Loathing in Denver: The Great American Beer Festival 1986"; and Fall 1987 issue AB, page 26, Vince Cottone continues: "Movement in the Right Direction: The Great American Beer Festival".

Koch introduced the "sex even sells contract beers" slant at the 1985 GABF. Until he came along, the popularity contest actually had something to do with the taste of the beer. But he added freebies (baseball caps and tee shirts?) and had solicitous servers working the crowd. He won that year. The next year, he had some competition (Pennsylvania Pils had a nice Blonde urging you to try "the beer with body"), but his freebies turned the Trick again.

In 1987, however, Koch had some strong competition in the ballot stuffing category. He almost lost to Boulder Brewing, but he managed to pass out hundreds of free GABF tickets through his "assistants", with the only string being "vote for my beer". So he won again. BTW, it was Lightship that year, not the Boston Lager, which never won three years in a row. His advertising is kinda like saying George Bush won the Presidential election three times in a row (1980/1984/1988).

Get the picture? No? Well, in 1988 Koch wasn't ALLOWED to compete in the GABF "Best Beer in America" contest. So the GABF organizers belatedly got the picture. By then, though, they'd lost a lot of support from the sensible Northwest folk who had set up their own Oregon Brewers' Festival and didn't invite Smadams, even though it was indeed being produced under contract by H. Weinhard's.

But enough of history. Get back to your brew kettles!

From: hinz@memphis.med.ge.com (David Hinz)  
Subject: Fast fermentation - is this a problem?

<Insert standard greeting of your choice here>

I've done about a half-dozen batches, including my first all-grainer last weekend, and each of them have something in common - they all ferment out quicker than Papazian says they will. I don't know if this is a problem, a good sign, or what, so here's the details.....

For my last batch ("Silver Dollar Porter", all-grain) I used Wyeast "British Ale" (1098????), pitched into a quart of starter wort a day ahead of time. There was a bit of foam on the surface of the starter but no krausen to speak of. (foam was maybe 1/8" thick). I pitched it anyway because the wort was ready for it. I chilled the wort to 75(F).

The next morning, I got up, the wort was fermenting wildly, I needed to use a blow-off tube in a 6.5 gallon carboy. That's another thing Papazian says you'll never need to do, but I've done it on two batches. The strange thing is the temperature of the wort was up to 82(F), even though it was cool in the house that night.

I started the batch on Saturday, and this morning the bubble rate was down to once every 30 seconds or so, which to me means time for the secondary, and/or wait until saturday or sunday and bottle. It seems that that is the pattern, I brew one saturday and bottle the next. From what I've read, however, it's usually several to many weeks between cooking & bottling.

I can see a couple of possibilities here. 1> I'm just getting a good start with my yeast, and I'm worrying, 2> I'm not letting it finish (probably not the case, I bottle when the gravity stops moving for a couple of days and the bubbles are once/90 seconds), or 3> I should pitch at a lower temperature.

So, what's the deal? or is it 4> (insert reason here)?

Thanks for any info you can help with.

Dave Hinz

P.S. The many responses I got about going all-grain were fantastic, thanks to anyone who I might not have written to personally. The advice, hints, and "Don't forget"s were quite helpful!

Subject: Honey & Contests

Message Creation Date was at 11-MAY-1993 09:35:00

Greetings,  
I've a couple of questions I'd like to raise:

1. I just bottled a honey-beer. Honey contributed approximately 40% of the fermentable sugars. The OG was 1.060 and the FG was 1.007. I used Wyeast 1056, so I expected from 70 to 75% attenuation and an FG of around 1.016. I also had the beer spend 2 weeks in primary and 2 weeks in secondary.
  - a. Does honey ferment to a greater attenuation?
  - b. Did the long time in the fermenters combined with the use of honey cause it to ferment to so low an FG?
  - c. When I sampled a small portion during bottling the beer seemed to be full bodied. Am I worrying about nothing?
  
2. I just received the results from the two beers I entered in the "Nations Capital Spirit of Free Beer Competition". I'm not complaining about the results, but rather I'm not certain as to the purpose. I was told that I would be able to get helpful feed-back on my entries. In some cases I did, in other cases there would be no comments and just a number (lower than the maximum score). For feed-back purposes that sucks. However, if the purpose of the competition is simply to pick the best beer in each category, then I guess that is acceptable. Please inform me - just what is the purpose of these competitions?

Thanks  
Andy Anderson

Subject: Chang

In HBD #1138, Mark Elliott writes:

>I have a question for you beer scholars out there. This past weekend my father-in-law and I were quaffing a couple, and he asked me if anyone on the network had ever mentioned "Chang".

>At any rate, he said it is a brewed beverage, consumed during social and sometimes at ceremonial gatherings (sometimes spelled as "Chan" by those in Tibet). Said it was quite strong, and (given the altitude) would really 'do a number on you'. He wants to know if anyone out there in HBD Land knows a full history and recipe.

Well, since my colleague Wendy Aaronson and I will be giving a presentation on chang at this year's AHA Conference, I suppose this puts us in good position to help with your question.

Chang is one of many names given to the indigenous grain beers brewed throughout the Indian subcontinent and the Himalayas. The Indians call the beer pachwai and brew it mostly from rice. Nepali chang is brewed from rice, millet, barley, and occasionally corn. In Tibet, the beer (usually spelled "chung") is brewed almost exclusively from barley.

The key ingredient, however, is not the grain but the yeast cake known variously as bakhar (India), marcha (Nepal), or phap (Tibet). Preparation of yeast cake is a cottage industry throughout the region, and there is considerable pride taken in the quality of the various cakes produced regionally. Consensus among the Tibetans in our area is that yeast cakes from Darjeeling make the finest chang.

The yeast cakes contain a combination of *Saccharomyces* and other fungi, primarily *Aspergillus* and *Mucor*. The various microflora work in combination to convert the starch in the unmalted grains to sugars and then ferment them. The resulting beer is fairly low in alcohol initially but has potential to become quite strong if left to ferment for an extended period.

Preparation of chang is fairly simple. The grains (approximately 1/4 kilo per liter or roughly 2 lbs per gallon of finished chang) are washed, boiled until soft, then drained and spread out on a nampo or shallow basket. The yeast cake is crushed, mixed with a little flour or tsampa (Tibetan barley malt powder), then worked thoroughly into the cooled grain. The whole mass is then covered (traditionally with banana leaves) and left to ferment. After several days, much of the mass is liquified and converted to young chang. At this stage, it can be consumed as a thick gruel, or the remaining grain can be strained out, making a true beverage chang. As mentioned earlier, the beer can be left to ferment further and will become stronger over time.

Chang is consumed regularly in the home as well as at weddings, funerals, and other ceremonial occasions. A large body of tradition (and music) has been built over the centuries to accompany the ceremonial consumption of both young and old chang.

Anyone interested in these indigenous beers may want to attend our presentation at this year's conference. Wendy and I will be serving our own interpretations of chang as well as chicha (the ancient corn beer

of the Andes). It should be a lot of fun, and we look forward to meeting many of the regular HBD contributors.

Nemaste!

From: tony@spss.com (Tony Babinec 312 329-3570)  
Subject: sugars/belgian beer brewing

William Kitch had some comments on sugars in the last hbd. Here are some comments on his comments.

Brown sugar (in USA) is refined white sugar with added molasses.

Molasses is any of various thick syrups produced in refining sugars. There are two or three distillations, of which the thickest is blackstrap molasses. As blackstrap molasses is strongly flavored, look for mild molasses.

Treacle is found in England, and is similar to molasses.

Whether or not there are any differences in process or end result, what I can find as demerara or turbinado sugar appears to be the same thing. It is rocky and light amber in color, and is only partly refined. Various forms of this sugar are widely available. Turbinado sugar can be found in health food and natural food stores. I recently saw a 5 pound bag at GNC for about \$6. Raw Sugar and Sugar in the Raw are available at commercial grocery stores. Sucanat(tm) can be found in 1 pound cans.

Does anyone have any domestic sources for candi sugar? I recently got my hands on some from Belgium. The sugar is either light -- kind of frosty white, not glassy clear like rock candy -- or dark (brownish or dark amber). It also comes in two sizes -- small and large. I think Rajotte says somewhere that the simple sugar mix in candi sugar is desirable. Also, he says that sugars are used for coloring. A pound of the dark candi sugar added to a beer made with only pale malts would result in an amber-to-brown beer. The other reason to add sugar is to produce a high-gravity beer that is not all malt, because at high gravities an all-malt beer can be quite weighty and palate-satiating. In a similar vein, homemade brown malt (say oven-toast pale malt for 40 minutes at 400 degrees F) or Special-B (200 - 220L) malt used in small amounts will provide coloring without adding much of a flavor contribution. Note that Rajotte's recipes avoid highly-roasted grains (chocolate malt, black malt, roasted barley) and also avoid large additions of crystal malt.

Honeys should be experimented with in brewing. Light honeys, such as clover honey, alfalfa honey, thistle honey, or even orange blossom honey, could be used in light-colored beers, while darker honey, such as buckwheat or autumn wildflower honey, could be used in amber to dark beers. One of the Mad Brewer's beers -- is it Oerbier? -- uses some honey.

Finally, isn't invert sugar directly assimilable by the yeast? Other sugars must first be inverted or otherwise broken down by the yeast.

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: beer color in Fix&Fix VMO

All right, the semester's finally over, and I've got time to catch up on my digests. I've got quite a few questions and tidbits that have been accumulating, and now that activity on the digest has slowed somewhat, coupled with my new found time, it's time to post.

First, let's start with Vienna, Marzen, Oktoberfest by George and Laurie Fix. I just recently purchased this book and it's dynamite, although, as usual, Brewers Publications has done a sloppy job of printing. One of the first things I did was dig up the errata sheet posted by Laurie Fix way back in HBD 859. I seem to have the first printing, and I don't know if a second printing is yet out, but I did catch an error not listed on the correction sheet. In particular, on pg. 88 they are discussing the calculation of beer color. The example they are using has 7.5 lbs of 1.8L malt and 9/16 lbs of 20L malt, which gives a Lovibond rating of  $7.5(1.8) + (9/16)(20) = 13.5 + 11.25 = 24.75$ . But when they normalize to 5 gallons, they calculate  $25.75/5 = 5.15$ , which is a mathematically true statement, but has the wrong numerator (25.75, instead of 24.75). I believe the correct equation should be  $24.75/5 = 4.95$ .

Relatedly, concerning the nifty graph on p. 91 showing Lovibond as a function of dilution water added to a 20ml sample of 17L Michelob dark: I fit an exponential decay model to the data in the graph, and thought those of you who program or otherwise need the equation would be interested. The model is:

$$y = a + b \cdot \exp(-c \cdot x)$$

where y is the Lovibond to be calculated, x is the dilution in ml, and the constants are

a = 1.6545419  
b = 15.354601  
c = 1/65.709196.

The fit of the model is excellent ( $R^2 = .999996$ ), but only use it in the range 17L to 2L. The reason is because, as Darryl Richman points out in HBD 854, the curve flattens past 17L. The exponential decay, of course, does not, so extrapolating beyond 17L will give you major bad numbers.

-----

Date: 11 May 1993 11:44:53 -0400 (EDT)  
From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: review of THREAD v2.1

Those of you who search back digests with Tom Kaltenbach's THREAD program for the IBM PC will be happy to know that Tom has released a new version, THREAD 2.1, which introduces a few improvements over version 1.2. (See Tom's announcement in HBD 1127 and HBD 1131 for archive info, etc.) For those of you who have never used it, THREAD allows the user to input one or more search strings which the program then searches for in specified HomeBrew Digests. Because it is tailor made for the HBD, THREAD is much faster than generic text-search programs, and easily allows the user to follow a discussion thread, locate a specific article, or gather all articles on any subject of interest.

#### NEW FEATURES

The enhancements of version 2.1 that I particularly like are:

1. Overwrite protection. When the user specifies an existing file for output, THREAD 2.1 gives the user the choice of overwriting, appending, or aborting.
2. Numerical-order searches. Version 1.2 searched the digests in the order in which they appeared, whereas 2.1 searches them in numerical order. This is convenient if you want to interrupt the search midway through, so that when you return you can easily pick up the search where it left off.
3. Keyword highlighting. When an article is displayed on the screen, all occurrences of the keyword(s) are highlighted, making it easier to discern the context within which the keyword is used.
4. Improved cursor movement. The user can use the up and down arrow keys and PageUp and PageDown to move through the found article.
5. Naive multitasking. In version 1.2, THREAD would search for a message, display it, and then continue the search after the user had read the message and decided whether or not to keep it. In version 2.1, the program continues searching \*while\* the user is reading the previously found message, thus greatly decreasing the apparent search time.
6. Search statistics. When in automatic mode, THREAD displays a count of the number of files and messages searched, the number of matches found, and the number of matches written to the output file. The file count, in

particular, is useful inasmuch as it gives you an idea of how much progress has been made if you are searching a really huge number of digests.

#### PERFORMANCE

Being the geek that I am, I decided to do some comparative speed tests between the old and new versions. I happened to have 82 digests in a directory, so I used these to compare version 1.2 to 2.1. The machine I used is a very old 8086, so we're talking sloooow. I began by conducting a very broad search. I simply searched for "beer" in the 82 digests, and put the programs into automatic search mode (in the interactive mode, there really \*is\* no comparison--because of the naive multitasking, THREAD 2.1 wins hands down). THREAD 1.2 completed the search in 6 minutes and 20 seconds. THREAD 2.1 took 6 minutes and 58 seconds--slightly slower. I don't know why--maybe because of the search statistics. Next, I wanted to do a search that required a lot of gyrating because of a complicated boolean search, so I had the programs search for "malt and mill or maltmill but not miller". After I input this search criterion, I realized what a doofus I was since if the program found "malt" and "mill" it would also find "maltmill"--still, since the program evaluates the string anyway, the search criterion still meets my standard of being a (needlessly) complicated search. Anyway, THREAD 1.2 took 12 minutes and 17 seconds, whereas THREAD 2.1 finished in 12 minutes flat. Finally, I wanted to see how the programs would fare on a faster machine, so I copied the 82 digests to my 80486 (33 MHz) and reran the the above "malt ... not miller" search. THREAD 1.2 finished in 1 minute and 2 seconds, and THREAD 2.1 completed in a mere 43 seconds.

#### WHAT I WOULD LIKE TO SEE IN FUTURE VERSIONS

Only two things. The first is rather picky: When in automatic mode, while the program is updating the search statistics, the cursor jumps around the screen in an annoying fashion. This wasn't a problem in the previous version, because there weren't any search statistics. A list of files searched scrolled up the screen, so the cursor wasn't a problem. In the new version, although I \*like\* the search stats, I just wish the cursor didn't jump around. (I told you it was picky.)

The second enhancement I would like to see, though, is more substantive. Currently, when input strings are connected with logical operators, the program parses the input by simply resolving the operations left to right. I would like the ability to use parentheses to control the parsing. For

example, someone wanting to read articles about the beer color in Vienna, Marzen, Oktoberfest (sound familiar?) might reasonably want to conduct a search for (George or Laurie or Fix) and (SRM or Lovibond). Currently, the only way to do so would be to conduct \*two\* searches. One for "George or Laurie or Fix and SRM" and another for "George or Laurie or Fix and Lovibond". This works, but a single search would be nicer.

Unfortunately, my guess is that it would take quite a substantial revision of the logic of the program to allow parenthetical input. Even as it is, however, Tom's THREAD program is a gem. Before I got it, I would use Magellan or WordPerfect or something, and it took \*hours\* to search my HBD collection. Now I can finish it in minutes. Thanks, Tom!

- --frank

p.s. In addition to being a good programmer, Tom must be a pretty fair brewer, too. He took first place in the porter category at the recent Upstate NY Homebrewers Assoc. annual competition. Congratulations.

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: Anchor Steam practices: a compilation

Now that I mash, I thought I would try again to mimic Anchor Steam. My extract version was pretty decent, but it missed in a few key respects that I thought I might be able to rectify by mashing. In anticipation of brewing an Anchor Steam clone, I went through all my back digests as well as other materials I had lying around, and collected every scrap of information I could find. I have compiled it in a collection of notes, which I have printed below.

My purpose is two-fold. First, discussions of Anchor Steam come up every so often, but always in little bits and pieces. I thought it would be a good idea to have everything in one place. Second, of course, I want to \*brew\* this beer, so I thought by publishing this in the digest you could tell me what I've got right, what I've got wrong, and what I've got missing.

I cite my references by number in square brackets. A lot of the things I say below I say as though they are undisputed facts, when, in reality, they are opinions and guesses (we are back-engineering, after all). So, when I say something like "Anchor Steam is brewed with an upward infusion mash [1]" what I really mean is: "ACCORDING TO REFERENCE 1, Anchor Steam is brewed with an upward infusion mash." \*I\* don't have any first hand knowledge of the material below. Of all the references, number 1 is the most trustworthy (it's Fritz Maytag's article in the Beer Styles issue of Zymurgy).

Finally, I want to express my thanks to everyone on the digest who contributed the information I am summarizing, and also to Tom Kaltenbach for THREAD version 2.1, without which I would not have been able to compile these comments.

Ok, here we go:

#### GRAIN BILL

Anchor Steam is all-malt [1,5] made from 2-row pale malt [1,3,5,6,7] and crystal (caramel) malt [1,3,7]. No one has reported the proportion of pale to crystal, but this ratio will be in large part influenced (but not completely determined) by the gravity of the wort and color of the finished beer. See SPECS below.

#### MASH AND SPARGE

Anchor Steam is brewed with an upward infusion mash [1] that varies according to the particular malt varieties [1]. A typical (common?) mash schedule consists of 3 different temperatures [3], with a mash out of 160F [2] and, I believe, a protein rest of 125-126F. My evidence for the protein rest is an inference on my part from reference [6]. My copy of reference [6] is actually a reprint from BREWERS DIGEST, and on the cover of the reprint is a great big color photograph of Fritz Maytag standing next to what is very clearly the mash tun. An easy-to-read temperature dial on the tun reads 52C, which is 125.6F (unless I've miscalculated). I suppose it's possible that they were actually heating or cooling the tun at the time of the photograph, and the temperature was on the way up or down, with the photo being snapped at the moment that it was 52C. I find it easier to believe, however, that they were at a \*rest\* point, which says "protein rest" to me.

In any event, they conduct a 2-hour sparge [3] with 160F water [2].

#### BOILING AND HOPPING

Anchor boils for one and a half hours [3] with whole hops [5,6] added throughout the boil [3]. They use "a significant amount" of Northern Brewer hops [1], and bitter at a level of 33 IBUs [1], although others have claimed the rate is 40 IBUs [4]. I am inclined to believe the lower figure since it comes from Fritz himself. The quantity of hops used is approximately 1 pound per barrel [6], which (if I am correct that a barrel is about 31 US gallons), amounts to a shade over 2 and 1/2 ounces per 5-gallon batch.

Although most agree that Anchor uses only Northern Brewer hops in its steam beer [e.g., 7], one occasionally sees other hops mentioned, for example, Hersbrucker [4] or Galena [7].

With regard to dry hopping, the common wisdom is that Liberty Ale is the only regular Anchor product to be dry hopped, although there is indirect evidence to the contrary. In particular, reference [5] is promotional material that I received from the Anchor reps at the 1992 Buffalo Beer Fest. (Actually, they were probably representatives of the local distributor of Anchor Steam). Although the section on Anchor's steam beer does not \*explicitly\* state that it is dry hopped, the Liberty Ale entry says: "Hops are added [to Liberty Ale] during aging (a process called dry-hopping) [to] further heighten the aroma. This is one of the secrets behind the notable bouquets of \*all\* Anchor

Brewing's beers." Parentheses are theirs, brackets are mine, and the emphasis on \*all\* is mine. This sentence would seem to imply that Anchor Steam is dry-hopped. I asked one of the Anchor reps if my understanding of the sentence was correct. He was clue free, and I commented (jokingly and good-naturedly), "Gee they sent the wrong guy down here." A while later (when I went back for seconds), the rep had obviously checked it out, because he made a point of dragging me over to the side to tell me that, "Yes, they do double-hop it." Double-hop?!? Well, I figured he meant dry hop.

In any event, take this dry-hopping information with a grain of salt. It is based on inference and the remarks of a local distributor, rather than someone who actually worked in the brewery. Just from taste, I personally believe Anchor Steam is \*not\* dry-hopped.

#### FERMENTATION

A bottom-fermenting yeast is pitched at 60F [1]. Most everyone suggests using Wyeast California Lager, but I have also had good success with Wyeast American Lager. The fermentation is conducted at 60F [3], and the peak temperature is limited "very carefully" [1]. The fermenters are shallow copper pans. Anchor typically conducts a 3-day primary and a 3-week secondary [7]. The beer is lagered at 50F [3].

#### CONDITIONING

Anchor Steam is kraeusened [1,7] to give 2.8 volumes of CO2 [1]. It is conditioned in the low 50s (degrees F) [1], and the carbonation takes place in sealed stainless-steel containers over several weeks time [6]. It is flash-pasteurized at 170F and bottled so as to have extremely low levels of oxygen, with only CO2 in the headspace [7].

#### SPECS

O.G. = 1.049 - 1.050 [1]  
F.G. = approx. 1.013 [1]  
IBU= 33 [1]  
SRM= 11-13 [1]  
Alcohol = 3.9% (weight) [7]  
4.7% (volume) [1]

Subject: Sam Adams

As Steve Stroud says, some of Sam Adams is brewed in the Jamaica Plain section of Boston (which actually used to be the center of brewing in Boston because of its better than average water quality) but when I went on

a tour there, they said 5% of their beer is brewed there. The rest is contract brewed all over the country and at a place in Germany. The reason

they cited should sit well with all of you HBDers: freshness. Just as Anchor's beer is either unavailable or scarce on the east coast, because Sam Adams says it's concerned about its beer traveling over long distances and thus delivering a less fresh product to the consumer. I guess the way

they justify calling it a micro-brewer is that it brews in smaller batches

than AB or Miller and each brewery serves a specific area. Decide for yourself.

One other interesting note on SA is that even though they say they are so concerned with freshness, they pasteurize all their bottled beer because "we're worried a distributor will not take care of it properly and the consumer will blame us for a lousy product." So if you want to judge SA you should find it on tap.

From: richer@desi.HQ.Ileaf.COM (Al Richer)  
Subject: Possible problems with Wyeast 1028

I don't know if anybody else is going to be there, but I am going to be in Atlanta in early June for the DECUS Symposium. If anybody else is there, feel like getting together to talk a little homebrewing, and drink a little beer?

But now on to brewing stuff...

Recently I made a generic stout using Wyeast London Ale yeast, rather than my usual Irish Ale yeast. The recipe is (from memory) as follows:

9 pounds klages  
1/2 pound chocolate malt  
1/2 pound roast barley  
1 pound 80L crystal  
3/4 stick brewers licorice  
2 ozs. fuggles (hazy on this...)  
1 pound brown sugar

I used my standard infusion mash @ 152F, boiled for 90 min. with 3 hops additions, force-chilled and pitched. The yeast (a 1-qt starter) took 36 hours to take off, then pumped up to a nice krauesen. This is all well and good. Now comes the funny bit...

It fermented for 4 weeks...

I have never had a situation like this happen with any of my beers. It seemed like the yeast went super-attenuative, as the FG stopped at around 1.008. The stuff it produced is drinkable, but hellaciously alcoholic and with a pronounced particulate haze that seems to be yeast.

There are two possibilities here. The first is that I am just not used to using domestic malts (I've used British malts up till now). The second is that the 1028 did something wierd.

I consider the second a possibility, as I split the pack and made slants when I brewed this batch. The slants look really wierd in comparison to the slants of 1084 that I usually have. Anybody think it'd be worth the effort to send one of these to the Lodgsons at Wyeast?

\* When I say the cultures looked odd, I mean that, instead of forming a white layer on the surface of the agar, they formed a slimy white layer, replete with bubbles from the CO2 they were everting. It looked lie yeast, but really odd. I don't think it was a contamination problem, either, as all 12 of the slants came out exactly the same, with no other wilds or bacteria.

Yours,

Al Richer

From: Drew Lynch <drew@chronologic.com>  
Subject: Re: All grain instructions - how's this look?

- > >Select recipe & obtain ingredients.
- >
- > >Start Yeast pack (2-3 days before brewing)

In practice, the Wyeast package is usually swollen nearly to bursting in one day. Give it two or three only if it is several months old.

- > >Add yeast to quart of starter wort (~12 hours before brewing)

Good idea.

- > >Preboil 10 gallons of "brewing water", put in carboys when cool.  
(night  
> before brewing)

You only need to do this for extract brewing. All the water you use for all grain will end up being boiled in the brewkettle.

- > >Bring 1.33 qt H2O per pound of grist to 130 degrees (f) in mash kettle.
- >
- > >Add above water to grist, protein rest for (60?) minutes at 122 deg.
- >>Adjust pH to about 5.3 if needed

A protein rest is only necessary for undermodified malted barley. If you still wish to do a protein rest, about 20 minutes is sufficient.

- > >Start sparge water in cooker kettle, bring to 170(?) degrees. How  
> >much?
- I usually sparge with 5-7 gallons 170-180F water.

- > >Raise mash temp to 155 deg, hold at this temp until conversion is done.
- > (Can I do this with boiling water? How much do I use?)
- >>Adjust pH if needed
- >>Test for conversion with Tincture of Iodine

If you skip the protein rest, adding 171F water to room temperature grain will usually net you about 155F with about 1+ qt per lb of grain. The rule of thumb (for the temperature range desired) is that 1 lb of room temp grain will drop the temp of 1 qt of water 16-18 degrees. I heat some extra, as the mash tun will usually absorb some heat. For 1 10lb mash, I heat 12-14qts water to 173 for my desired 155 mash temp. When you are off a couple of degrees, add a \*LITTLE\* hot or cold water, stir, and check temp.

- > >Raise temp of mash to 175 deg, for (20?) minutes, to mash-out.

I don't think you need to hold the mash out temp at this stage, as it will be at this temp all during sparge.

- > >Pour mash into lauter tun, let it compact, recirculate runoff
- > >until clear.

Avoid compaction. It seriously slows sparge rate.

Subject: Re:canned Guinness & other beers

In the last digest Jack comments on several beers:

<Date: Mon, 10 May 93 08:00 CDT  
<From: arf@genesis.mcs.com (Jack Schmidling)  
<Subject: Musings on Commercial Beer

< My C-P bottler is down for re-design so I bought a bunch of commercial stuff  
< to take to a party. Always wanting to turn a beer drink into a learning  
< experience, I bought some things I have wanted to try/compare.

And I thought you could just pull the tap and decarbonate the beer into a bottle! Wait a minute, didnt you follow the "how to build a CP filler" that  
I sent you :-)

< Draft Guinness in the can is not only lousy beer but the nitrogen gizzmo is  
< just plain silly. I thought the beer had a metallic taste and was lacking in  
< anything worth mentioning.

Utter nonsense! I live in the Washington DC area where the canned Guinness was  
test marketed, and I can attest to absolutely GREAT canned Guinness. There  
is nothing silly about a device that works, and works well. The nitrogen has  
nowhere to go until the can is opened, then it gradually rises through the beer  
much the way a good draught version does. I have always enjoyed extra stout,  
even in my \*shudder\* Bud days. The differences in the draught vs extra are  
well documented. I have always loved draught stout and this device actually  
results in a very good version of canned draught beer. I do believe it is the  
best canned beer I have ever had.

< Bass ale was about as bland as the Guinness but lacked the metallic taste and  
< just about any other, for that matter.

No comment on Bass.

< Take the coloring out of Beck's Dark and you have Beck's regular. It seems a  
< bit more beerish but hardly in line with the color.

This is a bit harsh, no? There are dark malt notes in Becks, albeit not like a  
Munchner Dunkles. In defense of Becks, it is an all malt beer now, even if it

was not in the past. It often manifests the metallic flavor that can occur in many beers, especially some German beers made with Tettang hops.

< The good news (strike me dead) was Miller Reserve Pale Ale. I tried the "all  
< barley" larger a few months ago and it seemed a farce but this stuff is real  
< ale. It's fruity and wonderful. It has a very marvey aroma and the taste  
< that follows is exactly what you expect from the aroma. By far the best beer  
< to come out of the biggies in decades. No doubt they found the right  
< combination of chemicals to do the trick but at least it tastes like beer.  
< It does not taste like my ales but rather like most of the ales I taste at  
< club meetings and the experts tell me that is what it is supposed to taste  
< like.  
<  
Havnt had it. Good report from a quality local brewmaster, though. Still gotta wonder about "all barley". Sure doesnt sound like "all malt" to me.

< Needless to say, I wait with baited breath to hear what others think of it.

I bit. Probably lots of others too.

Good brewing,  
Jim Busch

Subject: Hefe Weissbier advice

I've been fortunate enough to experience a variety of true bavarian Weissbiers (mit Hefe) in Bavaria and now I want to make the real McCoy. I'm using the Papazian "lovebite weizenbier" recipe. I brewed on Sunday and the fermentation is going well. My question is that earlier in the book (pg 147) he described the general weizenbier method as "Traditionally, the special top-fermenting yeast is filtered out before bottling or kegging, at which time a more flocculant (better settling) lager yeast is added for natural bottle conditioning." The recipe doesn't call for this. This is my first attempt at Weissbier and would like to know if the addition of lager yeast is recommended. I don't do any filtering when racking the beer (other than leaving the sediment in the fermenting pail), so I believe some yeast would end up in the bottling pail. A response to HBD or email will be greatly appreciated. I'll summarize email if thats what I recieve.

By the way, southern Germany makes for a great vacation as well as beer tour. (I suspect you're not suprised by this. :-)) I say this since the major and minor tourist towns all had at least one local brewery which always had several great beers. (The only mediocre beer I had was an export beer I had at the airport on the way home.) Prague Czech. also falls into this category.

In response to:  
From: greenbay@vnet.IBM.COM  
Subject: Hops/2 Liter Bottles

- 2) I heard a customer at a homebrew store saying that homebrew could safely bottled in 2 liter bottles. Does anybody have any information on this?

Bob Crowley

While bottling my first batch I ran out of beer bottles. In desperation I began using anything vaguely resembling a beer bottle (various juice bottles and one 2 liter soda bottle). I was making a porter which prescribed 5 weeks aging in the bottle. In general I don't recommend these bottles since it didn't seem like I was getting a good seal. Thanks to tolerance from the beer gods all turned out pretty well. I did add plastic wrap between the bottle and cap to increase the seal. The juice bottled beer had limited carbonation/head. However the beer in the 2 liter soda bottle had almost the same amount of carbonation as true beer bottles. So if you're ever in a desperate situation, don't look a gift bottle in the mouth. :-)

Subject: chang

I spent last semester in Nepal, and for about a month I stayed monastery in Solu Khumbu, sort of on the way to Everest. The monks don't drink chang, but they don't mind if their guests do. The folks who live in that part of Nepal are Sherpas who are descendants of Tibetans, but I'm not sure what the exact history of chang is. It was made out of corn, rice, millet or wheat. I saw them make rice chang, and they did this by cooking up a big pot of rice, letting it cool, mixing in special chang yeast (marga) which was in powder form. They let it go there for about four days, then they transferred it to a big plastic jug for the secondary fermentation (I think I read somewhere that they used clay pots traditionally). From what folks told me, they didn't use sugar unless they wanted a particularly potent batch, and they didn't add much in the way of water. It was served warm, and was sometimes pretty chunky. I've tried to make it here, but the results haven't been so good. Maybe my standards have changed. The interesting drink to make would be thomba-- after millet is fermented it is put into a special thomba mug complete with filtering bamboo straw, and hot water is poured over it. It wasn't so alcoholic, but tasted great. The monk I live with also made a type of apple wine, in which he followed more or less the same process as with chang with dried apples. He didn't consider it alcohol as such, but it had a bit of a kick to it. In retrospect, the surprising thing to me was the utter lack of care about oxidation and also how the plastic jugs didn't blow up. I imagine they had slight leaks, maybe. I don't know if this helps. ps. about the recipe, I don't think they followed one, so if you want to recreate the effect start with rice & champ. yeast. see ya,  
A. Smith ps: i would be interested in any more technical information folks have about using starches in beer & wine making.

Subject: Campden Tablets

I had a reputable homebrewer once tell me that should I be interested in adding fruit to the secondary, I would be advised to ensure that I take sanitary precautions against bacteria and wild yeast. Agreeing I asked what might be a logical means of doing that. One of the answers I received was to use Campden tablets to treat the fruit before addition to the fermenting beer.

Questions are:

1. Is the above advisable?
2. If so, I have purchased Campden tablets from Crosby and Baker and would like to know how one might proceed. On the label it says "16 tablets per quart water = 1% solution."
3. Will there be any side affects (taste, aroma) that may result using the Campden tablets?

E-mail directly or general post (if of wide enough interest) would be greatly appreciated.

No the real reason: cheapness. For a beer that's got a expiration date  
post dated five months in advance, I doubt the week to truck the stuff  
around the country is going to make much difference.

A more correct reason is probably the same reason the Megabreweries as  
well as Coke has regional plants. They SAVE money by not trucking it.  
And frankly, most of it comes from Pittsburg which is no closer to  
Northern New Jersey than Boston is.

Does any of the 5% they brew go into bottles anyway?

From: Lee=A.=Menegoni@nectech.com  
Subject: Malt Aroma - Chilling - Boiling

The recent discussion of mash thickness, temp and sugars production leads me to the following question. What component of the mash produces the "malty aroma" and "malty flavor" found in German Octoberfests . Is this a function of the type of malt. Since decoction mashers claim these features are enhanced in that process. What happens in a decoction that doesn't happen in an infusion that produces these characteristics.

Chilling and Boiling: JS recently posted about a weak boil and no chiller brew with regards to hot and cold break. Isn't another reason for a strong rolling boil and a rapid chill the minimization of DimethylSulfide DMS production. The rolling boil drives off the DMS precursors and the rapid chill minimizes the time in the optimum production range? or is this another momily?

Subject: Beer Bread

Greetings.

A couple of weeks ago I posted a method of making bread and pretzels from the yeast cake at the bottom of secondary fermenters. Well, I have something to add.

Last week I made two beautiful loaves of bread from some dregs from a beer that I had dry-hopped. At first I was a bit apprehensive about doing this as I didn't know how the hop bits would affect the taste. I did it anyhow. The advice:

DO NOT DO THIS!!!

The resulting bread was too bitter to eat, even when smothered in honey. It may have made an ok garlic bread, but we were kind of put off.

One interesting note: We left the loaves sitting around until the weather got nice enough (and we had the time) to go "feed the ducks." Well, it was over a week before we finally got out. The thing that surprised me was that the bread had no mold on it. Then I realized that this was because of the hops!! Now if I could find some hops that I could add to the bread that would not make it so bitter I could increase the shelf life from several days to more than a week (but the bread usually does not stay around that long.)

Date: Wed, 12 May 93 11:40:13 -0500  
From: gjfix@utam.uta.edu (George J Fix)  
Subject: Yeast

Seth Schneider of Crosby and Baker has informed me that I might have in a recent HBD post reversed the package sizes of the Whitbread yeast available today. To make sure there is no confusion, note the following:

12 gram pck. = Whitbread from old plant that is distributed by C+B  
14 gram pck. = Whitbread that was produced at the Lallemand plant in Canada

The strain I tested for C+B came from the lab at Whitbread's new facility.

Tests on yeast from full production runs will be done in the near future. The tests on the Whitbread available today was not done as a part of my contract with C+B. I did these strictly for my own edification. The lactic

counts on both were acceptable as was the viability of the C+B version. The viability test (using Rhodamine B as a stain) showed % viable cells as low as 17% in the Lallemand version, which is completely unacceptable.

The recent work for C+B dealing with dry yeast has been quite an experience.

It been 15 years since I last used this type of yeast. Two practical points have come up using dry yeast that I have not seen in homebrewing books. They are the following:

1. It is useful to refrigerate dry yeast during storage. They will not lose viability as fast as liquid yeast at room temperatures, nevertheless they will lose viability with age and this process is accelerated at temperatures above 60F.

2. Very rigorous sterilization is needed for everything used in the hydration process. I now do this with a pressure cooker, using 10 mins. at 15 psi. I screwed up a perfectly good beer by being casual about this in one batch. The finished beer had a measured diacetyl level of .175 mg/l, which is above the threshold of .1 mg/l. Subsequent brews have indicated the error was mine and it occurred during hydration.

Al Richter in HBD#1139 asks about possible problems about Wyeast's London Ale strain (1028). Two micros in the Southwest had similar problems in the

past. This was the major reason I avoided talking about this yeast at the microbrewer's conference in New Orleans. However, the Great Lakes Brewing

Co. brought some of their Best Bitter to NO which was fermented with this yeast. It was IMHO one of the finest examples of this style I have ever tasted. The brewer kept apologizing that it was merely a "session beer", but what I was tasting was a very clean ale whose malt/hop balance was dead

on. The finish was soft, but marvelously complex. I have the feeling we are

going to be hearing a lot more from Cleveland (home of GLB Co.) in the future. I also tasted at the recent Beer Fest in Temecula, Calif. an outstanding Brown Ale brewed by Martin Lodahl using this yeast. Clearly the

time has come to do a few brews myself with this yeast to see what is

going on here.

Subject: Pre-boiling Water

Message Creation Date was at 12-MAY-1993 12:51:00

Greetings,

(I am writing this question on behalf of a friend whose address is too long to be accepted by the HBD computer.)

In yesterday's HBD, Drew Lynch, writing in response to a request for feed-back for a first all grain beer, wrote:

>> You only need to do this for extract brewing. All the  
>>water you use for all grain will end up being boiled in  
>>the brewkettle.

This was written in response to the statement:

>>> Preboil 10 gallons of "brewing water", put in carboys  
>>> when cool. (night before brewing)

My question:

I thought the reason for pre-boiling the water was so that the chlorine would be boiled away. The chlorine, being basic, could adversely affect the ph of the mash. Is this correct, or am I once again looped in the head?

2nd Item:

Yesterday I asked what was the purpose behind Home Brew competitions. Well, today I was informed. A friend who was taking a brewery tour while the judging was going on stated that based upon the number of times the judges staggered into the restrooms, the only real purpose of these contests is for the judges to get free beer.

(Oooh! I can already feel the flames!)

Cheers  
Andy Anderson

From: Hal Laurent <laurent@tamdno.UNET.dec.com>  
Subject: Step culturing of yeast

I see a lot of references to "step-culturing" yeast to increase the population of yeast cells. Why is it desirable or necessary to do this in steps? Is it bad to give the yeast too much food at one time? I've been pitching my yeast into one quart of sterile wort for a starter, but it still seems to have a 1 1/2 to 2 day lag time before the primary fermenter's airlock starts to bubble. I've been considering using two quarts of starter instead of one to get a larger population. Is it better for me to feed the yeast one quart first and then step up to two quarts? Can I just pitch the WYeast package into two quarts to begin with? Do I ask too many questions? :-)

From: garetz@brahms.amd.com (Mark Garetz)  
Subject: Anchor comments and clarifications

Frank Tutzauer writes about Anchor products:

>evidence for the protein rest...is a picture of the temperature dial...  
etc.

You are also making the assumption that they were making steam beer when the picture was taken. They could also have been making Liberty, Porter, Wheat, or any of their specialty ales. They all have different mash schedules and temperatures. Also, if it's the picture I'm thinking of and the temp dial is the one attached to the copper pipe where the water and grain are mixed as they flow into the tun, then this dial is measuring the temperature of the incoming water/grain mixture. The real "dial" (actually a digital readout) is on the programmed temperature controller, located in another room.

>mash out is at 160F

That's correct.

>Although most agree that Anchor uses only Northern Brewer hop in its steam beer, one occasionally sees other hops mentioned, for example, Hersbrucker or Galena

I was in Anchor's hop room. Only two varieties were there: Northern Brewer and Cascade. The NB is for the steam and Cascade is for Liberty. I don't know what they use for the Porter or others. Northern Brewer is added to the boil in three additions, and in about equal proportions. One at the beginning, one about half-way through and one near the end. I understand that Liberty is made with 100% Cascade (also in three boil additions plus dry hopping).

>General discussion about which Anchor products are dry hopped...

I was fortunate enough to interview Fritz for my article on Dry Hopping (due out shortly in the summer Zymurgy) so I think I can speak with some authority (is that a pun?) on the subject. Only three Anchor products are dry hopped: Liberty, Foghorn (barley wine) and the Christmas Ale. The rest are not. Anchor's dry hop rate for Liberty is "approximately" 2 ounces per five gallons and the hops are added in the conditioning tank and left for about two weeks.

>General discussion about fermentation...fermenters are shallow copper

pans..

The shallow fermenters are made of stainless steel. They are used for both the steam beer and the porter. I was told that fermentation temperature was 55F. The same yeast is used for the steam and porter. All other beers are fermented in deep, open top ale tanks with a "traditional" ale yeast, also at 55F.

One other important note: Just as we know to adjust bitter hop rates based on the alpha acid ratings, Anchor also adjusts the late and dry hop additions according to the oil content. I'm proud to announce that my company (HopTech) will be rating all its aroma hops with oil content in addition to alpha acid. Hops will be available in mid-June. If you want to get our catalog when printed (currently in process), then send a postcard to: HopTech, POB 2172, Danville, CA, 94526 or you can call 1-800-DRY-HOPS and leave a message. You could also fax to (510) 736-7950. Don't expect to get anything till the first week of June.

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Is this Stainless Steel any good?

I recently found an old industrial-size coffee brewer for sale for \$50. It has a 14 gallon stainless steel pot, with lid, enclosed in a SS case. It includes a bunch of auxilliary gear; such as heater, temp controller, timer, valving, thermometer, etc. which I figure might be useful in my brewing endeavours, especially if I decide to build a RIMS. (Note that all of these parts are of questionable operating condition.)

The problem is, this unit has been sitting outside in the rain for quite some time. The SS pot (the component I'm really after) has quite a few rust spots. This is not too surprising; I've seen other stainless items which rusted after exposure to severe conditions. The pot is a non-magnetic grade of stainless (and no, its not aluminum).

My question is, is this pot worth the money? I've no doubt that I could remove the spots with a steel wool pad and some elbow grease, however, does the fact that it is spotted indicate that the SS steel may be an inferior grade, unsuitable for wort boiling? Are there types of SS which one would not want to use for brewing?

What is the group wisdom on this? Any metallurgists out there who can comment on "rusted stainless"?

Thanks,

Kelly <k-jones@ee.utah.edu>

Subject: Removing labels?

Why would you want to remove the labels? I'm not sure. Most of my old stubbies still have the labels on them, although after 10 years, some are getting unreadable;-)

Just a hint on how to label homebrew so you know what is what. Condense name down to a TLA (two, or three letters) Write this on to of cap with indelible magic marker. This takes about 2 seconds per bottle. It requires caps with no cutesy logos or anything on them. Some letter combos are real fast like Mohawk Mild -> MM which is just four connected squiggles.

From: Martin Wilde <martin@gamma.intel.com>  
Subject: Usage of hops in Anchor Steam

In Digest #1139, Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu> writes:

>BOILING AND HOPPING

>Anchor boils for one and a half hours [3] with whole hops [5,6] added  
>throughout the boil [3]. They use "a significant amount" of Northern  
Brewer  
>hops [1], and bitter at a level of 33 IBUs [1], although others have  
claimed  
>the rate is 40 IBUs [4]. I am inclined to believe the lower figure  
since it  
>comes from Fritz himself. The quantity of hops used is approximately 1  
pound  
>per barrel [6], which (if I am correct that a barrel is about 31 US  
gallons),  
>amounts to a shade over 2 and 1/2 ounces per 5-gallon batch.

If you use this amount of hops, you will definitely get a hoppy beer. You  
have to remember hop utilization increases with batch size. Most brewers  
I  
have talked to when they brew a 15 gallon pilot batch and then scale up  
to  
20-60 barrels will cut back on the hops by 10% to allow for the increased  
utilization.

Subject: Hop Isomerization

In the May 7 HBD, Ed Westemeier wrote:  
" alpha acids in hops are... isomerized (which means the molecules are  
formed into long chains)."

This was a good expose on light-struck beer. Isomerization,  
however, is not the formation of long chains of molecules. That's  
polymerization. Isomerization is the rearrangement of the structural  
configuration of a molecule, without changing the general molecular  
formula. The simple sugars fructose and glucose are isomers, both having  
the formula C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>. The enzyme which interconverts these forms during  
cellular metabolism is called isomerase. I think hop alpha-acid  
isomerization refers to the conversion of the straight-chain form to the  
iso (branched) form. I think Miller's book has a good discussion of  
this.

Subject: recipes

Hi All

I am looking for recipes about a few styles of beer mentioned in a book first printed in 1932. The name of the book is The Homemade Beer Book. The four styles are as follows.

"Chica" A south american beer made fermented malt of indian corn.

"Purl" A verity of amber beer formerly in demand in London but now obsolete.

"Quarf" A Russin beer made from rye.

"Twopenny" An amber beer containing licorice and capsicum, used as a stimulant in cold weather.

Any help with these would be great!!!

Thanks Gary Cote

< My C-P bottler is down for re-design so I bought a bunch of commercial stuff to take to a party...

>And I thought you could just pull the tap and decarbonate the beer into a bottle!

I admit to being a slow learner (must be struck by lightning 3 times) but when I get it, I not only admit my errors but usually become a crusader.

> Wait a minute, didnt you follow the "how to build a CP filler" that I sent you :-)

Don't recall but I bumbled around and made (and re-made) one that works like a champ.

In all fairness, you can fill a bottle from a tap, if the beer is cold, the bottle is colder and retain good drinking carbonation but not enough to produce much of a head.

>Utter nonsense! I live in the Washington DC area where the canned Guinness was test marketed, and I can attest to absolutely GREAT canned Guinness. There is nothing silly about a device that works, and works well..... I do believe it is the best canned beer I have ever had.

We can simply agree to disagree on this one. I chose not to squander my daily beer ration by finishing the glass.

< Take the coloring out of Beck's Dark and you have Beck's regular. It seems a bit more beerish but hardly in line with the color.

>This is a bit harsh, no? There are dark malt notes in Becks, albeit not like a Munchner Dunkles.

Perhaps a bit harsh but I humbly propose that "a bit more beerish but hardly in line with the color" translates nicely into, "There are dark malt notes in Becks, albeit not like a Munchner Dunkles".

I think we said the same thing.

< The good news (strike me dead) was Miller Reserve Pale Ale....

>Still gotta wonder about "all barley". Sure doesnt sound like "all malt" to me.

I think one can make a case for the interpretation being NO RICE or  
CORN, i.e  
the only grain used being barley. One can claim to make an all barley/  
malt  
beer and still keep cost down by using sugar to get the gravity up  
enough to  
produce the proper amount of alcohol. The body and character of the all  
malt  
lager would suggest this approach.

>distilling the kind of stuff normally used in beer and whiskey.

Well, I doubt the well-meaning friend part because what's the point in stretching your inexpensive, home-made shine with expensive, whiskey -- no, I believe the unscrupulous producers adding cheap methanol, but it may also be from trying to ferment something other than mashed grain. I recently heard about many people in India going blind or dying from some cheap alcoholic beverage a \*commercial\* producer was making -- it appears that in the interest of increased profits, the manufacturer was fermenting garbage! Yes, that's right, city-dump-type garbage!

I agree that we're safe as long as we stick to sugars for fermentables.

>I have always been a bit disappointed with the sleazy little bits of

>So it would seem that if one wants "great hot-break", ease up on the  
heat.

I suggest that the quality of the break may not necessarily be measured by the size of the break particles. The amount of break is probably the same, but your vigorous boil causes the larger pieces to break up into smaller pieces of coagulated protein. Therefore, I feel that you probably get no worse a hot break from a rolling boil than from a simmer.

On the other hand, a rolling boil is important for two other reasons:

1. Better hop utilization -- I've noticed a much better hop utilization from my rolling boils on my new, 12,000 BTU gas cooktop than with my old, under-powered electric cooktop.

2. When your wort is above 140F, S-methyl-methionine (SMM) is being hydrolyzed to Dimethyl Sulfide (DMS). DMS smells like cooked corn -- if you can get a hold of G. Heileman's Old Style, you can smell DMS for yourself. You can also smell it by boiling a few tablespoons of malt extract in a cup of water and letting that cool overnight (I made this mistake when I recently switched-over to Erlenmyer flasks for my starters).

If you have a vigorous boil, you either boil-off or oxidize to Dimethyl Sulfoxide (DMSO) any DMS that gets produced. A weak boil or if you boil with the cover completely on the kettle will increase the amount of DMS that remains in your wort. Much of this will be scrubbed out of your beer

with a vigorous ferment, but if you create too much of it, enough will remain in your beer to be detectable.

>I also made believe I didn't own a wort chiller and let it cool naturally to  
>pitching temp and, after cleaning and sterilizing the kettle, did the primary  
>ferment in it.

I suspect this batch will have some serious DMS problems. As I said before, when the wort is above 140F, DMS is being created. This is true also as the wort cools from boiling down to below 140F. A chiller decreases this lag period and reduces the opportunity for wort-spoiling bacteria to give your beer vegetive aromas.

>

> There are two possibilities here. The first is that I am just not used to

>using domestic malts (I've used British malts up till now). The second is

>that the 1028 did something wierd.

Respectfully, I would like to suggest that perhaps you left out a possibility,

namely that a wild yeast or a bacteria from your brewery got into the batch.

You did not mention the temperatures of the starter and wort at pitching time -- I've found that lag times can be significantly increased when there

is a 10 or 15 degree difference between the starter and the wort. 36 hours

is not too bad, but I've had (and others have reported) lag times less than

12 hours using Wyeast with a starter.

Insufficient aeration and a temperature shock are possible culprits for the long ferment. I had a really long ferment once (Wyeast 1056) when I accidentally dropped the temperature quite suddenly down to around 60F from 72F. The brew took 5 weeks to ferment out and was not too high

an original gravity (1051).

I've brewed two batches recently with Wyeast 1028 and had no problems in either of them -- everything seemed normal and the resulting beer tasted as expected. One of them was a super-heavy Imperial Stout -- started at 1120 and finished at 1050. Granted, this is not what I had hoped for and in retrospect, I realize that I should have pitched some more-alcohol-tolerant yeast when the 1028 pooped-out from the alcohol, but my point for mentioning this is that it is just the opposite of Al Richer's super-attenuated, high-alcohol batch. The other batch was a more-conventional gravitied IPA, which came out as expected. Just two more data points.

Al.

Subject: Campden tablets and fruit

Frank asks about experience with Campden tablets...

I made a nice Raspberry ale last fall and for similar reasons used Campden tablets to disinfect the crushed berries. As I reported here then, I was aghast to watch the beautiful ruby color of the fruit fade to a piss yellow, which never really returned.

About side tastes, etc... there was a definite sulfur odor that came out of the airlock, and I let it sit in secondary for 2 months before bottling. The finished product has no discernable sulfur taste or smell, but it is a trace acid.

Others have suggested steeping the fruit in the hot wort, just as it begins to cool. Raspberries have so little pectin to begin with that extraction of pectin into the hot wort should be little problem. This is less true for many other fruits though.

good luck,

dennis

From: hinz@memphis.med.ge.com (David Hinz)  
Subject: Stainless Steel kettles & coffee pots & half-barrels

Kelly Jones asks:

- - - -  
My question is, is this <coffee> pot worth the money? I've no doubt that I could remove the spots with a steel wool pad and some elbow grease, however, does the fact that it is spotted indicate that the SS steel may be an inferior grade, unsuitable for wort boiling? Are there types of SS which one would not want to use for brewing?  
- - - -

I just made myself a 15 gallon, heated kettle, for about \$20.00. I found a half-barrel (grade 304 SS, I beleive) from the early 60's, with Miller Brewing stamped in the top. This is the keg-shaped type. It also has the nifty feature of the "Diamond" type tapping system, where you would put the CO2 in the top & draw the beer off the bottom. So, it has TWO valves, one on top, one on the side of the bottom. (would that be bottom of the side? Whatever....) Deposit on the 1/2bbl was \$10.00.

Anyway, I used a Sawzall and about 7 blades to cut the top off of the keg, but I'm going to use an abrasive saw blade next time in my circle saw. The valves are held in with a threaded ring, that comes out easily, and with a bit of lathe work I turned one of the valves into a couple of washers. I used a 2500 watt water heater element through the bottom hole in the half-barrel, used one of the washers to seal between that and the barrel's rubber seal, and clamped it in there with the threaded retaining ring.  
(Water heater element was about another \$10.00)

The whole thing cleaned up very nicely, inside and out, with Soft Scrub <TM> with bleach, and a washcloth. It will be pretty easy to add a spigot to the thing for my future (near future) tower system, and possibly a RIMS.

I guess my point here is that I would rather mess around for a few hours and cobble something useful together than to spend real money to buy something already made up. The fact that you're a homebrewer indicates you like the "do it yourself" type of stuff, and it's really not too much work.

Does anyone know if modern "keg" type 1/2bbls have the bottom hole in them, or did I find something unusual here?

From: cole%nevis.hepnet@Lbl.Gov  
Subject: Wyeast London Ale Yeast

Regarding Alan's experience with the Wyeast London Ale yeast:

>  
> Recently I made a generic stout using Wyeast London Ale yeast, rather  
> than my usual Irish Ale yeast. The recipe is (from memory) as follows:  
> [stuff deleted]  
> It fermented for 4 weeks...  
> I have never had a situation like this happen with any of my beers. It  
> seemed like the yeast went super-attenuative, as the FG stopped at  
> around  
> 1.008. The stuff it produced is drinkable, but hellaciously alcoholic  
> and  
> with a pronounced particulate haze that seems to be yeast.  
>

I have a Scottish Ale (OG 1.040) that I bottled 3 weeks ago that was made  
using the Wyeast London Ale Yeast. I don't have my notes handy but the  
grain  
bill was something like:

8# British Pale Malt  
1# British Crystal (~30 L)  
1/8# Chocolate Malt

I used a single-step infusion mash for everything except the chocolate  
malt which I added just before mash-out.

Hops: 12 IBU's (mostly fuggles) boil  
I also added 1/4# succanat during the boil.

I pitched at a temp of 68 degrees from a starter I had made the day  
before.  
The lag time was ~ 10-14 hours which is what I have come to expect using  
Wyeast ale yeasts with my starter preparation procedures. I would guess  
that over the whole fermentation period the average temperature was ~58  
degree.

This batch fermented the fastest of my last 5-10 batches finishing in 10  
days. It spent 1 week in the primary, 1 week in the secondary, but had  
completely cleared after 3 days in the secondary. The FG was 1.010. I am  
pretty happy with the result. This was my first attempt at a Scottish Ale  
and since I have little experience with the real thing, I'm not sure how  
true to style it is. In spite of the crystal and the succanat it is not  
especially sweet (as the FG would suggest). It has a rather complex  
flavor  
with the succanat providing a detectable but not overpowering molasses-  
type undertone. I was surprised that even with the low hopping rate, the  
hop bitterness really comes through. I don't know if this is a  
characteristic of the London Ale yeast or not.

I looked up the characteristics of this yeast in the Zymurgy yeast issue  
last night. The description was something like: produces a complex,  
woody,  
characteristic, medium attenuation and flocculation (from memory). I  
agree  
100% with the complex/woody description. I found the attenuation to be  
rather normal given the OG of 1.040. I disagree with the flocculation

description though. Having watched other batches clear very slowly (> 1 week) with several stages of yeast precipitation, I was surprised to see this beer clear in 2 days. When I bottled, I found that the yeast cake was basically glued to the bottom of the carboy, and when I had finished racking, I was able to pour out the last 1/2 cup of beer without disturbing the yeast at all. The last 1/2 cup was nearly as clear as the beer that had been racked. This behavior may be partially attributed to the cool fermentation temperatures and is reminiscent of the three lager batches that I have done.

In summary: I found the attenuation of the London ale yeast to be reasonable and the flocculation to be extremely good at the temperatures I used. I am pretty happy with the results I obtained using this yeast.

I know for a fact that Sam Adams is NOT the only American beer imported into the Bundesrepublik der Deutschland. While in Bonn last October, after visiting the Beethovenhaus in the old town, I noticed a restaurant across the street called (I kid you not) "The Chicago Pizza Pie Factory." On their menu, I was appalled to not only find that scourge of American zymurgy, Budweiser, but to also discover that it was more than TWICE the price of fine local brews like Bitburger (it was DM6.90 a glass, about \$4.00!) My friend Eberhard explained that the locals sometimes like to pretend they're Americans...

Subject: Adding fruit to the secondary

There has been some traffic regarding adding fruit to the secondary. Aside from concerns over bacteria and wild yeasts, I would caution against adding anything acidic (like the citrus fruits), because it will kill your yeast and give you a flat brew. In one of my earlier batches, I added a bit of orange peel to "liven up" the end product. Complete failure...

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Quasi-Turbinado

I just found some C & H "Washed Raw Sugar" at the grocery store. The package describes it as "turbinado-style". It is formed as very regular short cylinders (i.e. not crystalized). I brewed several batches of light and dark ales with 1/2 to 1# in the various batches. It adds to the alcohol level, doesn't give a cidery taste, and at the 1# level leaves a yummy sweet \*aftertaste\* if the hop level is not too high. This sugar seems very similar to the "Sugar in the Raw" that I sometimes find in restaurants.

I'm really tickled by the lingering sweetness. My guess is that there are significant amounts of unfermentable sugars that cause this. The batch with 1# in it had a OG of 1.072 and a FG of 1.034! Carbonation level is normal, no gushers, so I don't think the fermentation stuck, but haven't had a chance to try to reproduce it. This may be a good sugar for Belgian/Trappist makers.

Paul.

George,

How does one measure the level of Diacetyl? I have had undesirable levels (judging by taste alone) in several batches. I had always assumed that the diacetyl production was a product of fermenting the yeast outside of its preferred temperature zone. My brew closet stays around 65-72F this time of year. Is it possible that my methodology for using liquid yeast or yeast from slants is actually to blame for the level of diacetyl, or is your observation only pertinent to dried yeast users?

I use two sources of yeast:

1) Wyeast packages: Usually, I will pitch the contents of the swollen package into a 500ml starter of 1.040 bitter wort that I have canned.

2) Yeast stored on a slant: I use a flame sterilized nichrome wire loop to pick up a pinhead of yeast from the slant, and then wash this into ~50ml of 1.040 canned bitter wort. This is then stepped to 500ml just after high krausen.

Note: The slants I used are bitter wort/agar slants produced at home, and the yeast usually originates from a Wyeast package.

With either method, I pitch the 500ml starter into 5.5-6.0 gallons of 80F bitter wort. I usually see activity in 12-24 hours.

I use ehrlenmeyer flasks, plastic airlocks, and rubber stoppers for my starter vessels, and sanitize in ~1/8 cup household bleach in 2-3 gallons of water for 5-10 minutes.

Thanks very much for your time and postings to the digest.

Subject: step culturing

Hal writes:

>I see a lot of references to "step-culturing" yeast to increase the  
>population of yeast cells. Why is it desirable or necessary to do this  
>in steps?

>I've been pitching my yeast into one quart of sterile wort for a  
starter, but  
>it still seems to have a 1 1/2 to 2 day lag time before the primary  
>fermenter's airlock starts to bubble.

The lag time is the reason for step culturing. The longer it takes for  
the  
yeast to take over the better the chances of infection. If you \*really\*  
trust  
your technique, I wouldnt be too concerned about stretching the volumes.  
My  
big pressure cooker can hold one gallon glass jugs with a glass airlocks,  
and  
I've done wyeast packet to 2 quart starters in those with no problem. I  
do my  
transfers (via sterile syringe) in a hood, and I'm pretty sure theres  
nobody  
(bug wise) around to get into the wort.

From: davep@cirrus.com (David Pike)  
Subject: Put the label on the cap

Where it is easy to read while in a case or 6pack.

Try this: Being computer geeks, get access to a lase printer(not too hard).  
Then, go down to the local label or paper store, and get 3/4 inch stick on labels mounted on 8.5 x 11 inch paper. Then, get your favorite postscript, drawing, or text layout program and print onto these labels with the lase printer.

We print the batch #, the name(up to 3 lines, approx. 6 words) and the bottling date on each label. They are easy to stick on, and even easier to remove(they come off with the cap).

Get creaiive. Even though we havent done it yet, We've envisioned even printing the data in a spiral format to get more info on the label.

Cheers!

Dave

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Variuos

In the last diget, George Fix makes some comments about the Bitter from Great Lakes Brewing:

<However, the Great Lakes Brewing  
<Co. brought some of their Best Bitter to NO which was fermented with  
this  
<yeast. It was IMHO one of the finest examples of this style I have ever  
<tasted. The brewer kept apologizing that it was merely a "session beer",  
<but what I was tasting was a very clean ale whose malt/hop balance was  
dead  
<on. The finish was soft, but marvelously complex. I have the feeling we  
are  
<going to be hearing a lot more from Cleveland (home of GLB Co.) in the  
<future.

I cant agree more! Every time I get a chance to sample the beers from  
GLB,  
it is a worthwhile experience. I was at the brewery in March and I can  
imagine the brewer apologizing about a session beer. If this is the Moon  
Dog Bitter I had (won in the GABF) it is truely a fine example. This  
"session" beer is 12P (1.048) from a brewery that makes every other beer  
at least 14P! This is a brewery that likes a big beer. The Stout was  
19P! The Dort is also over 14P. They like hops and malt and it shows.

On another topic: Andy Anderson asks about removing Chlorine by boiling.  
I say take the simple an effective approach and use a carbon filter. The  
pH will be reduced by normal acidification of the mash which is helped by  
the presence of CA+ ions ( a bit of Gypsum will do).

Andy continues:

2nd Item:

Yesterday I asked what was the purpose behind Home Brew  
competitions. Well, today I was informed. A friend who was  
taking a brewery tour while the judging was going on stated  
that based upon the number of times the judges staggered  
into the restrooms, the only real purpose of these contests  
is for the judges to get free beer.  
(Oooh! I can already feel the flames!)

This is not a flame. I was a judge at this competition. I do not  
condone  
the concept of free beer. If a brewer chooses to reward one with beer it  
is the brewers choice, not responsibility. Those of us who think  
otherwise  
are not being serious about the buisness side of brewing. My friends at  
the  
Old Dominion Brewing Co did not provide free beer, our club bought a keg  
of  
Helles which was not even consumed completely. Judging beer is not a  
easy  
undertaking. I judged 18 "Belgium style" ales and I can tell you I did  
not  
do it for "free beer". In fact, there were many instances where the  
judge  
attempts to be constructive when it is far easier to point to poor  
brewers

technique. I am disappointed that the judge who sampled your beer was not more constructive with comments, but I can see it occurring.

One more thing: Mark Garetz writes about Anchor,

<all these beers are  
<fermented in deep, open top ale tanks with a "traditional" ale yeast, also  
<at 55F.

I believe these are "closed" Unitanks/Mueller Conditioning tanks. I do not remember any indication as to open fermentation when I was there.

Good brewing,  
Jim Busch

From: Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>  
Subject: that pesky Anchor temperature dial

Thanks to everyone for helping me get my facts straight about Anchor Steam. I will collect all the corrections and alter my previous post so that we have an updated version. After I revise, I'll post it so that all the information is in one place. It's kind of long, though, so I won't post it until the next slow period on the digest (Memorial Day, maybe?), although if anyone wants it sooner, let me know.

I particularly want to thank Mark Garetz for his very knowledgeable comments yesterday. My one question concerns the temperature dial on the mash tun. Mark writes:

>You are also making the assumption that they were making steam beer when the picture was taken. They could also have been making Liberty, Porter, Wheat, or any of their specialty ales. They all have different mash schedules and temperatures.

Duh... (hand slap to head as obvious fact finally makes its way into dense interior). I was so fixated on their steam beer that this very obvious possibility simply didn't occur to me. You are absolutely correct. Still, let us suppose that it is their steam beer they're making. Then:

>Also, if it's the picture I'm thinking of and the temp dial is the one attached to the copper pipe where the water and grain are mixed as they flow into the tun, then this dial is measuring the temperature of the incoming water/grain mixture. The real "dial" (actually a digital readout) is on the programmed temperature controller, located in another room.

You are correct about what dial I was reading: the one on the pipe where the water and grain are mixed. Is it therefore reasonable to assume that this puts a maximum on the actual rest temperature?

Thanks,  
- --frank

Subject: Invitation to Speak at 1993 Dixie Cup

You heard it here first!

This year's Dixie Cup (Houston Foam Rangers AHA/HWBTA/SPCA sanctioned competition and homebrew gathering of the tribes) will be October 15 and 16. We've got a new site (they figured us out at the last place), and we're actually working on the thing now.

To the point:

Anyone who is anticipating, planning to, or in general thinking about attending this year's only Galactic homebrew weekend, and who may have something to say on brewing-related topic(s) for about 45-50 minutes, and actually feels like getting up on Saturday morning (after the first round judging and Fredfest the night before) to relate this knowledge to a roomful of smelly (oh, sorry, that's just me!), groggy, and dazed people, is requested to contact me. Of course, an abstract of your presentation will be required, in triplicate, by next tuesday, with the full text, including color slides, graphs and photos two weeks hence.

Just in case I'm deluged by submissions, we've got 4 or 5 slots for speakers, and I'll be the judge of who is IMPORTANT enough (don't forget, it's not what you brew, it's who you know that brews) to speak.

Actually, in all seriousness, the conference is an enjoyable part of the whole Dixie Cup experience, and I would appreciate it if anyone who is coming and would like to share their knowledge would take the time to speak. Please extend this invitation to anyone you meet or know who is planning on coming.

Sean Lamb Dixie Cup 1993 Milli-conference Coordinator

Date: Fri, 14 May 93 08:02 CDT  
From: othon@ial7.jsc.nasa.gov (Bill Othon.LinCom)  
Subject: secondary/half-batch/Texas brewpubs

I have a couple of questions for the group:

1) How long is too long in the secondary fermenter? I have been reading that some people leave it for only a week, using SG as a guide apparently. Recently I dry-hopped in the primary (based on a Cat's Meow recipe) and after a week in the secondary, there was at least an inch of "mung" at the bottom of the carboy (I assume hops and yeastees). I decided to leave the beer in for the usual 3-4 weeks. Could this have been bad? I haven't tasted the final product yet to be sure, but i am pleased with the clarity of my beer to date.

2) Does anyone have a good half-batch all-grain recipe? I tried an all-grain last year with two brewkettles over a gas stove, and while it came out alright, it was a hassle. I'd like to get my feet wet with some small scale stuff (which also allows for easier experimentation if desired). For this type of batch, i guess i use half the dried yeast package, or half the wyeast starter.

On another note:

The battle for Texas rages on! After some strange schmanigans, the bill with the amendment to allow brewpubs in Texas has passed the house, and it's on to the senate. Someday an HBDer will have a business meeting in Houston and ask if there are brewpubs, and we'll be able to say "Hell, yes!".

Hoping for a Seattle-like beer culture in Houston  
-Bill

Subject: Darker with age...

Is discoloration (darkening) a typical result from "light exposure"??? I brewed a batch which when originally bottled was much lighter in color than it is now. The beer is in "Mason" jars, with double gaskets/liners to better the seal. (It worked). I had a problem with the initial conditioning of the beer, (very little carbonation), but when I removed the jars from the fridge for a couple of weeks and then re-refridgerated them, the bubbles were finally there (I'd brewed the batch 1.5 yrs ago, thought I was a victim of novice errors, hate to throw things out, and only recently read about re-conditioning carbonation-less beer to bring the bubbles back.) Anyway, back to the color inquiry, would the darkening be the result of light exposure, age, and is incandescent light a threat???

Date: Fri, 14 May 93 8:49:37 CDT  
From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: PET and GC

In regards to the recent discussion of the use of PET (2 litre soda) bottles and the proper filling thereof, I would think that one should fill them the normal amount (0.5" headspace). You would not want to compress the bottle before filling because then the CO2 formed would go towards reforming the bottle to its normal volume, not carbonation (flat beer). Also, at the pressures involved with naturally carbonated beverages, the expansion of the PET would be miniscule. As a side note, I would mention that a homebrew kit sold by Price Club in California last winter (I don't remember the brand, but it came with Cooper's extract) came with plastic caps for PET bottles. I do not know where one would buy these, as my local homebrew shop (Brew and Grow) doesn't carry them, but I would think that one of the larger mail order supply houses would carry them. I'm not sure if one would want to reuse them or not (you can't boil them, because they will probably deform, and the seal inside may be porous enough to absorb some of your sanitizing solution. Also, the clarity of the material is worrisome if you do not store your beer in the dark.

Do any of you scientists out there know about measuring components in beer by gas chromatography? I am wondering about the following:  
Will the unfermented sugars in the beer crap out my column? If so, after how many injections?  
What kind of column should I use? Polar or non-polar? (My guess is polar, like a PEG column?)  
Has anyone determined the proper settings for temperature and flow? Ramping? What are the probable RT's for common components (EtOH, DMS, DMSO, diacetyl, etc?)

I could put the effort into determining the above, but right now time is at a premium and I would hate to reinvent the wheel if someone else has done the work. If there isn't anyone who has done this before and I do invest the effort, how many of you would be interested in my results? Private e-mail please.

From: "Westemeier\*, Ed" <westemeier@pharos-tech.com>  
Subject: Blindness again

There has been enough comment about blindness being caused by improper distillation of alcohol recently, without any definitive answers, that I'm beginning to suspect we're dealing with an urban legend.

So, FWIW, here's my "data" point:

My grandfather had several friends who produced and sold a considerable quantity of distilled spirits during Prohibition. He once told me that the conventional wisdom of the time was that the blindness often mentioned was caused by improper chilling procedure.

Specifically, many amateur distillers used automobile radiators as heat exchangers. As the wort (or whatever, I'm not an expert) went through the coils of the radiator, it picked up contamination from the lead solder used in its construction. Lead is the cause of so many other health problems related to lead poisoning in the blood that I'm inclined to believe this may be the actual source of the story.

Now, if you'll excuse me, I have to dry off my cat in the microwave.

> Elaine

TNCJOHB is The New Complete Joy of Home Brewing, by Charlie Papazian, which many of us (especially we neo-brewers) find helpful, although evidently there are quite a few texts out there. Although TNCJOHB does have ~some~ recipes, a larger source is The Cat's Meow on sierra.stanford.edu in the homebrew directory. I haven't made any of them yet, though, so I can't vouch for them. I have been happy with all the recipes I've made from TNCJOHB (in addition to the Dark Sleep Stout and the Sparrowhawk Porter, last year I made the Palilalia India Pale Ale), and I would make any or all of them again.

As for a list of acronyms, I think there's a general list of internet acronyms somewhere at Info-mac (sumex-aim.stanford.edu), but that won't include specialized HBD acronyms. BTW, what ~does~ TIA mean?

Yours in Brewing,

I suspect that something else was wrong with that batch. I've made a number of spiced beers using the zest of up to 4 or 5 oranges and never had any trouble. There's even one classic beer style, Belgian Wit (or White), that's traditionally spiced with coriander and orange.

I've also made raspberry, blueberry, and cherry beers, and I'm sure other folks can recount experience with even more adventurous ingredients. I usually just weed out any truly fuzzy fruits, rinse them in a bisulfite solution, then puree and add to the secondary (and watch the yeast go bonkers with all that sugar!). I've never had an infection problem this way. As long as the rest of your sanitation technique is good, you should have no problems.

Subject: All About Beer

I have a question I hope to get some help with. I have been subscribing to All About Beer for a couple of years. For Christmas, I decided to give a gift subscription to a friend and to augment my subscription to include Suds and Stuff. The problem is despite repeated calls to Mike Bozak, none of my subscriptions have started coming. I even spoke to a representative at the Boston Brewers Festival, and still nothing.

Since I have not been charged for the issues, I suspect they have not received my order, but each time I call, I am assured that they have it in the records and all is well.

Questions:

- 1) Does anyone out there think either of these magazines are worth the trouble?
- 2) I subscribe to American Brewer too, and like it a lot. I just wish it came out more than once a quarter. Does anyone recommend other magazines to use in place of AAB?
- 3) Are there any beer related magazines that are more east coast?
- 4) Are the newspapers like Yankee Brew News worth the subscription?

Thanks for your help,

Joe Gareri

From: kensiski@nas.nasa.gov (David L. Kensiski)  
Subject: where have all my fermentables gone???

Last week my brew partner and I made a batch of Winky Dink Marzen, as described by Pappazian in TCJOHB (page 164 in the first edition). Everything seemed to be going fine. It had a starting gravity of 1.043 and fermented happily away at room temperature, peaking at about a burble every two seconds.

At least everything was OK until last night when we racked to the secondary for lagering. When we opened the fermenter, the beer smelled funny. I might describe it as a skunky smell, but I've not got a terribly keen nose for these things. I thought it tasted alright, though my parner claimed he could "taste" the smell in his mouth.

Another oddity was that the specific gravity had dropped to 1.004! There is no sugar left in this stuff! Those yeast must have sure had a good time in that brew!

So that leaves me with a couple of questions. First, what could have caused the smell? Will it go away over time, or are we going to be stuck drinking this batch with our noses plugged? Second, what about the lack of sugar? Is it worth lagering the beer if there's nothing left for the yeasties to eat? Should we just go ahead and bottle it?

Our current strategy is to lager the beer at about 48 degrees for a couple or three weeks and see what we have then. Any other ideas?

Howdy Ho!

I threw together a kind of strange brew last night and need a suggestion.  
The beer so far is:

1/2 pound 40 L crystal  
1/2 pound 110 L crystal  
1/4 pound Black Patent Malt  
1/4 pound Roasted Barley  
1/4 pound Chocolate Malt  
1 pound Dark spraymalt (William's)  
6 pounds Oatmeal Dark extract (William's)  
1 cup Dark Brown Sugar  
1 tsp Cyanne pepper  
1/2 tsp Ground Ginger  
1/2 tsp Corriander  
2.5 oz Northern Brewer pellets  
No finishing hops  
Ale yeast

I was going to add some blackstrap molassas, but I think the jar  
of molassas I have has "gone off" so I did not add any. I would  
like to use molassas to prime this (I will buy some new stuff) but  
I do NOT know how much to use.

Anybody out there primed with molassas before? How much did you use?  
How was the carbonation level? How long did bottle conditioning take?

One additional note: After I had cooled the wort, I opened the  
kettle to put the wort in the fermenter. Inside the kettle,  
floating on top of the wort was....

\*\*\*\*A TUFT OF CAT HAIR\*\*\*\*

So now it is a battle between yeast and cat hair bugs. By this morning  
the beer had gone out of lag and smells fine. Of course I am NOT  
worrying. I only worry about important things, like what kind of  
beer to have next!

Any comments appreciated.

From: garetz@brahms.amd.com (Mark Garetz)  
Subject: More Anchor

Jim Busch says he doesn't recall any open fermentation at Anchor.

All of the primary fermentation is done in open tanks. The steam/porter tanks are shallow (approx 2.5 ft deep) and maybe 8x20 feet (just an estimate). The ale tanks are square (about 12x12) and maybe 10-12 feet deep. The secondary fermentation and conditioning is done in closed stainless tanks. This may be what Jim remembers seeing. I have pictures of all three (and a shot of the copper mash tun and boiler in the morning light hung on my office wall!).

Frank responds to my response:

>You are correct about what dial I was reading: the one on the pipe where the water and grain are mixed. Is it therefore reasonable to assume that this puts a maximum on the actual rest temperature?

I don't know if it's reasonable to assume anything. The tun is heated (by steam I believe) and controlled by a programmable temperature controller in the back room. Don't forget that they do upward infusion mashes. I assume that the reading on the dial would only be accurate if there was a grain/water mixture flowing through it at the time the picture was taken (odds are against it).

From: weissborn@dfwdsr.SINet.SLB.COM  
Subject: 1st batch problem(?)

Tuesday evening I cooked up my first batch and am having a problem that I hope someone can help with.

First, the recipe:

6lbs of light dry malt extract  
1.5lbs of Wildflower honey  
1oz Northern Brewer hops  
4oz of fresh ginger  
2.5 cups of 20l Crystal Malt

Method:

Boiled 2 gals of water. Cooled and poured into 5gal carboy.

Put 3 gals of water into pot, Added crystal malt and brought to a boil. Boiled for five minutes (as per the local brewstore instructions) then strained out the crystal malt.

Brought the liquid to boil again, added the DME, stirring to make sure it didn't stick, added the ginger and the hops. Boiled for about 45minutes. Cooled to about 90dg farenheit.

Poured this into the carboy via a funnel in order to add O2.

Added 1oz of EDME dry yeast. Added a blow-off tube and placed in bathroom('cause it is dark and cooler than anywhere in the house).

Got some bubbling in about an hour and through out the night but no real foaming or high activity as I have heard others get using EDME. By Wednesday, afternoon, no more bubbling. Went back to the brew store and they suggested that I re-pitch. This time I used Nottingham dry ale yeast. Pitched this Thursday afternoon but no noticeable activity by Friday Morning.

So, my question is: "What happened?" and can I salvage this first batch?

BTW, for what it's worth. A Coleman campstove makes a pretty good cooker. I can bring 3 gals to a boil in about 20mins and if it boils over, all I have to do is hose it down to clean it up. My wife was glad I didn't use the stove in the house 8-)

Anyway, any help will be greatly appreciated.

Subject: Re: Belgian souvenirs

Mark asks:

>1) Whats the duty rate on alcohol over the duty-free limit (and for  
that  
> matter whats the duty free limit)?

I got a lot of different replies when I asked this question last year.  
I brought back 12.5 liters of beer with no problems.

>2) Is it best just to pack the beer carefully and carry it on the plane  
> as extra luggage or to ship it?

I boxed the beer up with my dirty laundry as padding. Most of the  
bottles  
were wrapped in newspaper and then shoved into the legs of levis. The  
box  
went as checked luggage and arrived undamaged. A friend of mine did have  
some homebrew leak in his luggage once, so you may want to consider  
lining  
the box with a plastic bag.

>3) Does anyone have any particular recomendations about Belgian beers  
not

>long lag times. On my last batch with Nottingham I used to packages  
>of yeast and the lag time was 48 hours. Could this be due to a low  
>percentage of viable yeast cells?

I've used these two yeasts on quite a few batches and have found that rehydration at around 104-110F is very important to get a short lag time. Also, storage is a big factor in viability. I store my dry yeast in the fridge along with the liquid yeast. Even if you store your dry yeast in the fridge, does your retailer? Do they have a week's worth of yeast on the shelf with the rest in the fridge or do they have a year's supply on the shelf? Dried yeast is still alive and has (I believe) about 8% moisture. The Yeast Special Issue of Zymurgy has an article that reports 10% viable dry yeast after 12 months at 68F and 0% viable after 12 months at 100F. Compare this to 80% viable after 12 months at 38F.

Shane writes:

> There has been some traffic regarding adding fruit to the  
>secondary. Aside from concerns over bacteria and wild yeasts,

>citrus fruits), because it will kill your yeast and give you  
>a flat brew. In one of my earlier batches, I added a bit of  
>orange peel to "liven up" the end product. Complete failure...

I disagree. I've not only made nearly 100 gallons of perfectly carbonated fruit beers, but also a very sour pseudo-lambik which was well carbonated. No, something may indeed have killed your yeast, but I doubt it was acidity. Did you use campden tablets to sanitize your fruit? Did you let all the SO2 evaporate before adding the fruit to the beer? The SO2 released by the campden tablets not only kills wild yeasts and bacteria, but can also kill your cultured yeast.

From: WESTEMEIER@delphi.com

**Subject: Cleveland competition mystery**

The SNOBS Sampling, a sanctioned competition held at the Great Lakes Brewing Co. in Cleveland back in February, was a lot of fun.

Unfortunately, things seem to have collapsed after the judging. We have a number of unhappy brewers in this area who have never received their score sheets (I haven't found anyone who DID receive a score sheet).

Moreover, when I talked to the AHA yesterday, I found that they have apparently never received an organizer's report, so those of us who judged in this comp haven't received any credit for it.

I know that there is a lot of work involved, and I don't know the state of volunteer help in Cleveland, but if anyone has any information as to what happened, it would sure be appreciated.

Subject: Draught packaging; hop growth

In HBD 1139, Jim Busch comments on the effect of the new draught packaging on Guinness:

[stuff cut]

>I can attest to absolutely GREAT canned Guinness.

I can, too. I have had it in the bottle and the old can and thought it was utter trash. When I finally got to taste it on tap, I really liked it. I was very surprised when I tried the draught packaging to find that the new canned version was about as good as on tap. I got my first taste of this a couple of years ago when a friend brought some back from the UK. It is just now showing up here in the USA. Of course, if one does not like draft Guinness from the tap, then this can won't change ones mind.

Recently, I got to try another brand packaged this same way. This new batch is called Flowers Draught. It is one of the best UK ales I have tried, including many available on tap. I doubt, though, that this packaging would do anything for Bud.

It might, however, do a treat for Baderbrau, which is already great from the bottle!

HOPS

For those people growing hops for the first time, here is another "hop report:"

The hops are doing fine. Nugget is still the fastest of Willamette and Cascade. The Cascade took a long while to get going, is slow-growing by comparison and has a more delicate growth in general (smaller leaves). No bug problems so far. I am fertilizing with general-purpose organic fertilizer, and they seem to like it fine. My highest vine is about six feet up the twine (this is the first year.)

By the way, the Cascade took a long while to come up out of the ground.

From: dspalme@mke.ab.com (Diane Palme x2617)  
Subject: Chocolate beer and The Hop Report

Howdy all!

(clack. clack, clackety clack: imagine a teletype here) :)

In response to all the the questions about chocolate beer of late, I just thought I would throw in my \$0.02. I made a chocolate porter recently ala TNCJoHB's Goat Scrotum Ale and tossed a full 6 oz. of baking chocolate into the vat. Some molasses went in as well and the results were wonderful! The beer has a \*very\* noticeable chocolate flavor that coats the mouth but is not bitter. Definately something interesting. Some important words of warning for those wishing to replicate this beer:

1. DO NOT SAMPLE THE BEER WHEN TAKING S.G. READINGS!!!!!!  
I am \*totally\* serious about this. I made the mistake of doing exactly this because (to be perfectly honest), we were worrying about the beer. It was the vilest, most horrible, foul, disgusting ilk ever to pass these lips. Worse than liver!!!! :-) The first time it was even remotely close to beer was when I put the stuff in the bottle. This was about 3 weeks after brew day. Ok. I'm better now. Whew.

2. Be sure you are not operating heavy machinery when drinking this beer. It is \*very\* potent. Time for more honesty here, I don't know what the initial or final S.G readings were because we were \*sure\* this beer was a gonner. :( Little did we know this was going to be the best beer we have ever brewed! Go figure.

Now that I have imparted what little wisdom I have...on to page 2

(clack, clack, clackety clack clack... RRRRRRRRIIIIIIPPPP)

Now for the hop report. Thanks again to all of you who wrote to me telling me not to worry about the little guys. They are all above the ground now and doing great. The Hallertau was the first up, followed closely by the Cascade and bringing up the rear, the Tett. I am very pleased with their progress and plan to do some fertilizing now that they are visible. Is it harvest time yet???? :)

Subject: Hops growth in the N.E.

Well, I don't know why my hops are doing so well, but I'm not complaining. My Nugget vines are at 16', Cascade at 15', Hallertauer at 12' and Mt. Hood at 8'. The first three have reached the tops of the cages they're in so they're going no higher, but the Hood is climbing a string I hung diagonal to the top of my chimney, a hypotenuse of approx. 25'. I'm surprised and pleased with the growth so far. Not bad for a second year in the NY/NJ border area of the country, I'd say. The Hood only gets half the sun the others do, the higher it grows though, the more it'll get. None are with cones, yet.

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: Back from the dead. 1.020 starters.

Greetings to all my homebrewing netbuddies!

First post in about 9 months. Wow!! It's been difficult to even keep up with reading the HBD, much less post, even when you guys have been talking about me.

School's out. Hallelujah!

The big news as far as this forum goes, though, is...every homebrewer's dream came true for me back in November when I became head brewer/consultant at what is probably the World's Smallest Microbrewery--The Tumbleweed Grille and Microbrewery here in Boone, NC. (Cheers!! Clapping!! Thank you. Thank you.)

And how much do we brew? A whopping 60 gallons at a time!! Most of you would get a hoot from seeing the brewhouse. It's nothing more than an upscaled homebrewing operation. We built everything ourselves. Conditions are a little rustic but the beer is pretty good. I'm happy with about 75% of the beers that go out the door. And the other 25% is well-received anyway.

The interesting part of this enterprise is the fact that I've had a chance to put together the numbers for running a microbrewery/brewpub of this size and the results are rather surprising. Even at this scale, the enterprise is commercially viable and we haven't sunk tens of thousands of dollars into the operation.

If there's any interest, I may post my reflections/observations/calculations for this little project. Who knows? I might be able to inspire some of you to give it a shot.

Before closing, let me try to make a worthwhile contribution to a thread I barely followed from couple of weeks ago. (And I apologize if this has already been said. Last time I made a comment about a two week old thread, I got flamed into eternity so be kind...) Didn't see this mentioned so...

RE: why 1.020 wort for starters?

I asked Dave Logsdon this a few weeks ago because we were having trouble with long ferments at Tumbleweed. Dave says 1.020 wort is necessary only from the point of view of efficiency of reproduction of the yeast. Sure you can use 1.030 or even 1.040 wort but the yeast will not reproduce as fast at that gravity.

Good to be back. Hope to be contributing more often this summer now that my schedule is back to normal human proportions.

Subject: Anchor Porter Change Time:8:04 AMDate:5/17/93  
While busily unpacking entries to the 93 NHC the other night I paused for a moment to watch the open primary fermenter in the Ale Room fill. It occurred to me that the wort was pretty dark for any of the ale which they make so I asked the brewer on duty what I was watching. "Porter," was his reply, "we went to ale yeast in the porter about 3 months ago. So now the Steam is the only lager product and it is the only one put into the shallow primaries." I quickly retired to the tap room to sample this new version. I must confess that I had already had my tastebuds cascaded with Liberty so my palate was not in top form, still the porter seemed to be a little less robust than in the past. I'll try it again tonight.

From: gilling@quaver.urbana.mcd.mot.com (Harry Gilling)  
Subject: soda pop

With summer coming soon, I'd like to make some root beer or ginger ale suitable for kids to drink. I've seen the extracts in the stores which contain all sorts of additives including food coloring. I'd much prefer to make something from scratch if I could find some recipes. Does anyone know of a source for recipes?

I understand the the soda made from the extracts results in a drink with about .25% alcohol. Is the reason why this is so low compared to beer is because you bottle it immediately and the yeast stops working before it has time to convert much of the sugar?

-----

Date: Mon, 17 May 93 10:09:25 CST  
From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: re: Sugars

One thing I find amazing about HBD is how adamantly one's opinions are presented as fact! Perhaps this has to do with the relative anonymity of e-mail. Any psychologists (pseudo or real) care to comment?

Anyway to the matter at hand. The e-mail I received after my last "sugar" posting has left me with, yes, \*more\* questions.

Piloncillo (sp?) -- some sort of mexican brown sugar. Anybody heard of and/or tried brewing with this?

re US Brown sugar -- several people said they thought by FDA requirements sugar had to be fully refined. Therefore brown sugar is actually refined sucrose with molasses added back after refining. Can any of you FDA types confirm this? If so is there any reason to use brown sugar. Why not just a smaller amount of molasses?

re Inverted -vs- non-inverted sucrose: Can anyone move the following statements from my opinion list into my fact list:

- a) Sucrose must be broken into glucose and fructose before it can be assimilated by yeast.
- b) Yeast have the ability to break sucrose into fructose and glucose.

If b is true why is inverted sucrose "preferred by brewers" (Rajotte\_Belgian Ales\_).

Caramel -- How does the process of caramelizing change sugar? Can glucose, sucrose, fructose, and maltose all be caramelized? Is molasses caramelized to some extent or does all its flavor come from other stuff in sugar cane and/or sugar beets used to make sucrose?

Maltose -- Is this a simple sugar?

Just trying to learn, WAK

Date: Mon, 17 May 1993 12:09:51 -1100  
From: Kirk\_Anderson@wheatonma.edu (Kirk Anderson)  
Subject: Bud, Wyeast, clear beer, Miller ale

In HBD #1141, Shane writes:

While in Bonn last October... I noticed a restaurant across the street called (I kid you not) "The Chicago Pizza Pie Factory." On their menu, I was appalled to not only find that scourge of American zymurgy, Budweiser, but to also discover that it was more than TWICE the price of fine local brews like Bitburger (it was DM6.90 a glass, about \$4.00!) My friend Eberhard explained that the locals sometimes like to pretend they're Americans...

Purely a novelty item. There's a "Chicago Pizza Pie Factory" in Paris too I believe. What worries me a lot more is AB's effort to acquire the real Budweiser in Bohemia. Does anyone have recent info on this? Is there any reason to hope that the whole world won't be eating and drinking the same multinational swill before our time on earth is up? They said the French would never buy fast food. Ha! Prediction: all of Europe will be drinking Bud in a very few years.

A couple months ago, I asked HBD readers to tell me why I should go from dry to liquid yeast and got some kind and intelligent answers. Well, my first experience with Wyeast was an attempt at a Belgian ale. When I bottled two weeks ago, I thought the stuff tasted very ordinary. But wait! after only 12 days in the bottle, I snuck a taste, expecting it to be fairly green still. WOW! This is my best batch ever and it's only getting better. There's no way I could have got that characteristic flavor without the right yeast.

All you who predict the fast demise of clear beer because it tastes lousy, I hope you're right, obviously. But what did you say when lite beer hit the market? It hasn't gone away, has it? Remember what HL Mencken said about the taste of the American public?

Finally, where and when can I get that new Miller ale (sic) that js was raving about the other day?

Kirk

From: Sean.Smith@LUNCH.TRUST.CS.CMU.EDU  
Subject: West Virginia Brewpub

Thought I'd let you know about a little discovery I made this weekend:

Sometime since last summer, a microbrewery has opened up in Morgantown, West Virginia (home of West Virginia University). The ONE ONION BREWERY AND BISTRO---allegedly ``West Virginia's First Brewpub'---is located in the downtown section, down by the river. The menu didn't look too exciting, but my wife and I had a couple of pints and thoroughly enjoyed them. The Scottish Stout had an especially nice flavor. Talking with the young bartender (who was reading Papazian when things were slow) revealed that the owner is apparently an avid homebrewer who decided to go big-time. They do their own mashing, but apparently don't use a secondary...

For those keeping track of this sort of thing:

WEST VIRGINIA, Morgantown. The One Onion Brewery and Bistro.  
1291 University Ave. (304) 296-BREW

Cheers!

From: Eric Wade <ericwade@CLASS.ORG>  
Subject: PET bottles, sankey kegs, Brewing Techniques, etc.

Finally caught up with my HBD reading after two weeks vacation and thought I'd add my \$0.02 plus ask a few questions.

Re: PET bottles. Some time ago I mentioned that my brother was trying to mail some Hook Norton beer that he brought back from England. Well, it arrived safely and in addition to the pint (glass) bottle of Old Hookey, he also sent me a 2 litre PET bottle of Hook Norton Bitter. The bottle, BTW, was the same brown color as the glass.

Stainless is good, aluminum is bad . . . Can anyone fill me in on the use of the "new" sankey kegs, the type with only one tap hole in the top center and the handles. I've heard that they are aluminum with a stainless coating. Is this correct? How durable is the stainless layer?

What's happening with Brewing Techniques? I understand it is due this month so I shouldn't get too impatient. Just wondering if anyone has any news on its progress.

Cooler mashing and step infusion. Does anyone have instructions on step infusion and picnic cooler mashing? I've been successfully doing single step infusion in my cooler tun but was wondering what the numbers might be for attempting step infusions (i.e., Step 1: x gal H2O @ y deg. F/lb grist, Step 2 add x gal H2O (boiling?), etc.)

Finally, its easy enough to get kegs of beer at most liquor stores here in the U.S. Can the same be said for England. I'm at the early stages of planning a birthday party for my father two years from now. We'll be staying in a private house in southwest England. I'd like to be able to get ahold of a keg of cask conditioned ale. Anybody have any knowledge of what I might have to go through? How long in advance would I have to get it for it to be in serving condition? Would I need to do anything to it? What about a tap?

Many thanks,

Eric Wade <ericwade@class.org>

From: rcristad@weber.ucsd.edu (Riccardo Cristadoro)  
Subject: Thanks for all of the help with my bitter

Last week I posted a request for help with my next batch, a bitter. I was very pleased with the numerous responses that I got, all of them very helpful. I really appreciate the help, and the information that I get from this board. I feel that the quality of brewing advice is outstanding. In any event, I want to share my latest creation from the basement of Pirate ALE:

8 # British 2-row  
.5 # British crystal malt  
.5 # Wheat Malt  
.5 # Golden Brown sugar  
.75 oz Willamette (60 mins)  
.50 oz EKG (60) ----I had to use up some hops  
1 oz EKG leaf hops (60)  
1 oz EKG leaf hops (30)  
1 oz EKG leaf hops (5)  
Irish Moss  
Wyeat #1098 (British Ale) started two days before in a starter

My O.G. was 1.046

There are a few questions I wanted to ask.  
This is my second All-grain brew. Is a starting gravity of 1.046 sound about right for 9.5 pounds of grains/sugar? I was reading Fred Miller's book and he seems to get these amazing o.g.'s with 6 pounds of grain. Also, I mashed at a slightly higher temp (154-155). I was told that I would get more body in the brew by elevating the mash temp. What are the drawbacks of the extra few degrees? Is it a good idea to use .5# of Wheat malt to help with head retention? I got suggestions for Wheat malt and cara-pils. Lastly, one suggestion was to dry hop in my keg. I like the idea of that, but will whole leaf hops (EKG of course) clog my cornelius keg??  
Once again, thanks for all of the help. I'll give you a taste test report in a few weeks.

-----  
Hello all,

While cleaning out the freezer the other day I uncovered four pounds of cranberries. Since Thanksgiving is way off I thought maybe I could use them in a brew. Does anyone have any recipes that use cranberries, if so would you care to enlighten me?? Thanks.

I was reading Eric Warners Wheat book the other day, specifically the section on single decoction mashing. Since I haven't done a decoction yet I have two questions, is it OK to boil the grains for 30min?? And how much liquid do you put in the pot with the grains. Any info would be helpful.

Subject: Brewing Cookbook

I currently use a brewing cookbook that I made using a database program. It is full functional cookbook type of program. It offers customized printing, IE: ingredients or brewing process or complete recipe or any combination, detailed recipe instructions, brew ingredients via table choices of free form entry, sorting, and many more features.

There are many types of these programs available, like SUDS. My question is, is there a need for another program like this? Would you be interested? I'd like your comments.

Please reply to brucek@isg.sni-usa.com

Cheers,

Bruce

From: jay marshall <marshall@pat.mdc.com>  
Subject: fruit beers

In HBD #1142 Jeff Benjamin and Al Korz mention their experiences with fruit beers. Would you guys briefly describe your process - i.e. when you add the fruit (boil, primary, or secondary), whether or not you use a sanitizing procedure such as campden tablets or (as Jeff mentions) a bisulphite rinse, and how much fruit it takes to get a noticeable flavor. Also, I would be interested in knowing what kind of hopping rates are good to use with these beers.

I have tried one beer in which I added 2 qts of pure black cherry juice to the secondary and, while it was very tasty, it didn't have as much cherry flavor as I had hoped it would. It seemed that most of the stuff that makes cherries taste so good fermented away in the secondary.

thanks,

BREW VIDEO ANNOUNCEMENT:

Starkirk Productions has just released a video training video giving information on opening your own micro-brewery or brewpub. We traveled to: Boulevard Brewery (Kansas City MO), Walnut Brewery (Boulder CO), Breckenridge Brewery (Breckenridge CO), Salt Lake Brewing (Salt Lake UT)

,  
Sierra Nevada (Chico CA), Grant's Brewpub/Brewery (Yakima WA), Capital Brewing (Middleton WI), Broad Ripple Brewing (Indianapolis IN). We interviewed the owners and/or brewmasters of these successful operations. They gave us tons of info on opening and operation of brewing establishments. The video comes on two tapes and runs approx 2:45. It sells

for \$24.95 plus \$5 P.H. For info contact me Jim Kirk 70403,3157 on CompuServe or send to: Starkirk Productions, Inc.

From: tom@kalten.bach1.sai.com (Tom Kaltenbach)  
Subject: Light-struck beer again

I have an addition to the recent discussion on light-struck beer. Andy Hoffmann, a friend of mine who reads the digest off-line, brought an article to my attention last week. For those interested in the chemistry of light-struck beer, look up the following:

Vogler, A. and Kunkely, H. "Photochemistry and Beer",  
Journal of Chemical  
Education, vol 59, no. 1, Jan 1982, pp. 25-27.

The article is written by a couple of German chemists, and describes the chemical reactions that occur when beer is exposed to various wavelengths of light. It also discusses the effects of brown and green bottles on the light-struck flavor, and gives absorption spectra for brown and green glass.

It also provides 27 references for those brewers interested in more detail.

Hope this helps.

From: SMUCKER@UTKVVX.UTCC.UTK.EDU  
Subject: BREWING TECHNIQUES

I had the good luck the other day to see a new magazine at my local homebrew store, BREWING TECHNIQUES. All I can say is WOW! this leaves Zymurgy in the dust. This new magazine is designed to bring technical information to the small scale brewer. As I read it it is intended for both the homebrew and the brewpub / microbrewer. The first issue (volume 1, number 1, May / June 1993) has articles by Fix, Schiller, Haunold, and Nickerson. I especially like the article by George Fix on Belgian Malts. It has a column on trouble shooting by Dave Miller and another on beer styles by Roger Bergen. The content is great and each article includes references if you want to follow up on more information (although I am impressed with the depth of the articles). The presentation is very professional and well done. With luck this magazine may do for brewing what Fine Woodworking did for that hobby, take it beyond the amateur world in to a expanding advanced amateur / small profession world. With good solid technical information this magazine can build the growth of both the users / suppliers just as Fine Woodworking did.

BREWING TECHNIQUES is published 6 times a year for \$ 30.00. But a charter subscription is available for \$ 24.00. Their address is BREWING TECHNIQUES, P.O. Box 3222, Eugene, Oregon 97403, Tel. 503 / 683-1916, Fax 503 / 687-8534.

One of the things I like best about this magazine was not once did it tell me to not worry, since most of us type A, technical types worry one hell of a lot and that why we make damn good beer. Just for the record I have no connection what so ever with BREWING TECHNIQUES, I was just very impressed and it was very much worth the \$ 5.00 I paid for it. (The copy I got was likely a free one that my homebrew supplier got as a sample, but so what it was worth the money.) The only two things I found wrong with this magazine was that it was too short and didn't yet have as many advertisers as I would like to see, but I bet these both change with time.

From: <geotex@engin.umich.edu>  
Subject: Beer Disaster <PLEASE HELP!!!>

AAAAAAHHHHHHH!

Yesterday, I followed Charlie Papazian's recipe (The New Joy of HBing) for so imperial stout. Call me a beginner, but, it was my first intermediate brewing attempt. i.e. I used grains to add color etc, to a malt extract, boiled the whole mess (after sparging the grains out) and ending up with some nice looking wort. BUT! The recipe called for 1-2 packages of ale yeast, and I added 2. Today it began to ferment about 12 hours after pitching the yeast. When I got home about 8 hours after fermentation began, the thing was going nutty. I mean it is all bubbling out through the fermentation lock on onto the floor. I am talking a lot of the mixture is gushing out. What went wrong? Too much yeast? Too warm (its about 75)? So is the beer which cost me about \$30 to make ruined? What is a novice to do? I poured some out (gasp), and I am thinking of moving the fermenter outside where it will do minimal damage. I am hoping the cool weather may slow down this out of control process.

Any suggestions are greatly appreciated. If at all possible, e-mail me at geotex@engin.umich.edu. I would like to know ASAP what to do!

Thanks  
Alex

Latest Zymurgy has a very interesting (and amusing) story about this:  
(I am plagiarizing, go ahead and sue me, Charlie.... MAKE MY DAY!!!)

"LOW ALCOHOL OR NO HOMEBREW.....

According to All About Beer magazine, to get a license to brew beer in Japan you must make a minimum of 2 million liters annually. Obviously, this makes homebrewing illegal. Mr. Yamanaka, head of the Japan Association for the Promotion of Homebrewing, is Japan's only importer of homebrew kits. How does he get around the law? In Japan, beverages containing 1 percent or less alcohol are exempt from the law. So Mr. Yamanaka went to Edme Ltd. in England and asked them to make a beer kit with instructions to make a 1 percent alcohol beer. The instructions say to use 40 liters of water and no [additional] sugar, and brewers are warned that deviating from the recipe is illegal. When the tax collectors started asking questions, Mr. Yamanaka told them to find someone else to harass. He hasn't heard from them since."

I wonder HOW MANY poor, unsuspecting Japanese homebrewers actually FOLLOW the directions?! YUCK!!

Re: (R)HOMEBREWING-JAPAN&KOREA

A couple of thoughts about Far East Brewing... I suppose that homebrew ingredients are available at least from mail order (probably just extracts, because grains might be too similar to agricultural stuff, and be prohibited. The Japanese are extremely anal about importing agricultural stuff). Yeast slants are a toss-up. If you wrap them well to eliminate the smell, then they should go unnoticed. If you think you can down grade, you may just want to switch back to dry (gasp!!!).

If I were going to go, I'd make a care package to send to myself. Pack

two 6.5 gal buckets w/ lids, and in them put: a bunch of tubing, a couple airlocks, all the homebrew chemicals, stoppers, a well-wrapped hydrometer, etc. Essentially send a basic homebrew kit. Wrap up another box with many cans/bags of malt extract, etc. Get friends and family to mail you new stuff for birthdays, Christmas, etc.

If all else fails, the Japanese make some pretty damn good brew. They copied the Germans in this just as they copy us in everything else. Michael Jackson was fairly impressed.

Subject: Commercials

>From: Jim Kirk II  
>Subject: Beer Video

I can't wait to read all the flames this one generates. Considering the fact that it is far more commercial than my video announcement several years ago one would expect Jim to be trashed till at least the turn of the Century.

Hopefully, we and the Digest have all matured a little since then and will be a bit more accommodating this time.

New product announcements are one of the most useful aspects of this forum and should not be discouraged. However, they (as all of mine have been, in spite of the thrashing I have received) should be announcements and not advertisements as this one clearly is.

I suggest the following guidelines for NPA's:

1. Details limited to the name and function of the product.
2. Pricing and ordering information should NOT be included.
3. Readers should be directed to private mail for additional info.

I think if we follow these guidelines on the Digest, NPA's will be looked forward to and well received.

BTW, "Brew It At Home", a JSP video on home brewing basics is selling briskly. It has been particularly well received by the public library community. I regularly get calls from people all over the country who have checked it out on a whim and now, can't wait to get into homebrewing.

I would be happy to send additional info on this video to anyone who emails for same.

From: greenbay@vnet.IBM.COM

Subject: Half and Half

I've seen a 'trick' where you have a liter of beer half being Harp and the other half being Guinness stout. The bottom of the liter is Harp, the top of the liter, Guinness stout.

I was reading The New World Guide To Beer yesterday and saw a bottle of my stout and one of my light ales standing side by side and thought "Hey, I know what I should try!" Well, it didn't work for me, didn't matter which I poured in first, or how slow I poured. It all mixed together, black as night. Does anybody know how to do this correctly.

Also, after reading all these happy hop reports, I've a sad one. My hops fell victim to Scott's Weed and Feed. They put up a good fight for five or six days, but on Sunday they just started withering away. The culprit has given themselves the name "Hop Killer."

Bob (funeral arrangements pending . . . )

Date: Tue, 18 May 93 12:44:47 EDT  
From: drose@husc.harvard.edu  
Subject: Let's try this again...

Hello:

I tried to post this yesterday but something happened.

First: I have a question about bittering hops. My understanding has always been that with long boils (60' or more), the only character imparted to the wort is bitterness; volatile oils are boiled off, and so other flavors/aromas are lost. If this is the case, then why do I see recipes (e.g. some Winner's Circle recipes) that use combinations of hops for 60 minute boiling? If nothing survives but bitterness, why not just buy the bitterest hops you can get, use an appropriate amount, and save your Cascades for flavoring/finishing/dry hopping? Is there actually a subtle (but detectable) flavor/aroma contribution from hops boiled for 60 minutes?

Second: There has been much discussion about alternative sugars, such as golden syrup, treacle, etc. I do a lot of Indian cooking and use an unrefined cane sugar called jaggery. It has a molasses-like flavor but is milder and, I think, more complex. It comes as a rather wet brick. Has anyone heard of its being used for brewing? Similarly, I brewed a cream ale this weekend and used 1# or Pakistani Basmati rice. Basmati has a very different flavor from conventional rice, so I thought it might be interesting, besides it was all I had. Anyone tried this one? Keep pushing back the frontiers....

d.

Date: Tue, 18 May 93 12:44:10 EDT  
From: gkushmer@Jade.Tufts.EDU  
Subject: cranberry beer!

I made a cranberry beer last year with just about that amount of cranberries (~4 lbs.)

I took a recipe in the Cat's Meow II and pretty much followed that with the lesser amount of cranberries. In a nutshell, it's an extract with

5 lbs. Light Malt Extract  
1 lb. Sugar (Don't worry about cidery flavors with this one)

I don't remember the hops, and for this one I actually used dry yeast for my first time.

The way I used the cranberries was this way: keep them frozen and then puree them in a blender. Make the wort as you normally would and at the very end, just before you'd add a wort chiller and immediately after you turn off the heat, dump the whole lot in.

The frozen berries bring the temp right down, and you get it in the wort with some bouquet and flavor.

Good luck and let me know if you try something different. I gave them away for X-mas presents and the demand couldn't have been higher for next year!

**Subject: sankey kegs (again)**

Well just read my posting and realized that one of my questions was incomplete. What I really wanted to ask was about the use of sankey kegs as brew kettles, mash tuns etc. Are they aluminum, stainless, a combination, etc.? If they are coated, how thick is the stainless coating and how durable is this over time? Will it withstand repeated boiling and scrubbing?

Thanks,

Eric <ericwade@class.org>

Subject: Kegging

Sorry for the barrage of postings here, I've been busy and I'm just catching up now.

I just kegged for the first time - a weissbeir made from an extract recipe. No problems getting the brew in the keg, etc. However, yesturday I poured a brew and it came out w/ a head, but nothing too big. When I tasted the brew, it was kind of flat - that is, after it settled for about 2 mins, no more bubbles were floating to the head of the brew. So, I checked the pressure in the keg and it was around 5 PSI or so. Thinking that was the problem, I cranked it up to 15 PSI and poured another. Bigger head after the pour, but the same sort of flatish brew once it settled. So, I pumped the keg up to 20 PSI (w/ C02) and decided to let it sit (it is in my fridge; it has been in the keg 1 wk - I primed w/ 2/3c DME).

What am I doing incorrectly?  
Or, is this just the way it works in a keg?

Subject: Chapel Hill Brewpub

My brother lives in Chapel Hill NC. Nice place, but, you'll find quickly that the south has a big appetite for 'American' beers - bud, miller, etc. Some places will sell decent brews, but, they are not all that common, at least compared to Boston.

They do have one Brew Pub - the name is escaping my mind at this time. It has sort of French-ish sounding name... It is near the biggest CD (compact disc) store in the Durham area - they boast 30k titles. I had to ask around (strangers on the street) and I did find it. They were closed, but we did get in to check things out (the doors were open). Sort of an evening place.

Good luck,  
JC ferguson

>Anybody out there primed with molassas before? How much did you use?  
>How was the carbonation level? How long did bottle conditioning take?

I have. Charlie Papazian's book makes a reference to using molasses as primer. Basically, you prime at the rate of about 1/2 of what you would use using DME (dried malt extract). Typically, for 5gal, I use about 1 1/3c of DME, so, for molasses, that would be 2/3c, dissolved in about 1 1/2c of H2O.

I actually screwed up when I did this and used too much molasses. I ended up dealing with some over carbonation and I had to trash a few bottles of my stout.

Give it 2 weeks to condition.

Subject: bad beer

This is a followup to a posting I made several weeks ago regarding some peculiar looking bubble "colonies" that I noticed in my secondary fermenter with a particular batch of ale. It's been in the bottle several weeks now (I followed the advice of several of you out there who advised against its summary dispatch into the Mississippi) and can now say that... It's definitely awful and undrinkable. There is a flavor that I can only describe as "soapy" :( I do not know if this is merely coincidental to the appearance of the strange bubbles or not, but I am wondering if any of you out there have experienced such a taste and if it from an infection. The only other sources that I can blame would be a) soap residue from the primary, but I have always washed it in the same way ( a little bit of Joy and fastidiously rinsing it with hot water no less than 3 times) and have never had this taste before. Also the intensity of the flavor seems to me as if it would take at least a 1/4 fluid oz for the 5 gallon batch for it to be this bad. Another possibility (other than infection) is b) the use of a different malt extract, hopped Northwestern Golden, but I usually use NW malts and have always thought them to be of excellent quality. I really wonder about the possibility of infection.....

Subject: Bad smelling primary fermentation

Hi,  
I've made about 8 extract batches, and each time the beer in the primary smelled, well, like beer. A nice sweet smell. However, my last batch, (which kept fermenting for 2 weeks) smelled terrible. kinda like a mens bathroom afer a keg party. Anyway, is this what you call "infected beer"? Would the smell/taste have changed after bottle conditioning? The beer was still cloudy in the carboy at two weeks. I ended up dumping the stuff down the drain.

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: sour mash, yeast propagation questions

Greetings,

I'd like to hear from anyone with experience making sour mashes. I read Papazian's appendix on sour mashing yesterday, thinking I might try to make a Guinness-style stout that way.

It seems to me, however, that I wouldn't want to use the whole batch of sour mash (Papazian says to boil up 5 or 6 lbs. of malt extract in 1-1/2 gallons) in a stout - I seem to remember that Guinness adds a \*small\* amount of sour mash to their otherwise "regular" wort.

My question: what proportion of sour to "regular" is advisable in this case? And, if I were to brew up the whole sour mash as Papazian suggests, and just use some of it in a brew, how should I store the rest of it and how long will it keep?

Another question: Charlie says to brew it up in a food-grade bucket with an aluminum foil seal inside its lid. If I have an extra plastic or glass fermenter sitting around, shouldn't I just use that and seal it with an airlock?

On to yeast propagation: I am going to try the parallel-propagation method. After I make my gallon of master starter and split it up into six sealed beer bottles as has been described in previous HBD's, I recall that it will keep well under refrigeration for a considerable time. Is this right? If I do this now, can I count on healthy, hungry yeast in September when I resume brewing?

Brew on,

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: bisulfite solution, fruit beers

A couple of folks had questions about making fruit beers. Here's the procedure I've used successfully in the past:

1. Brew a low gravity, lightly hopped beer as a base. I like to use a wheat beer for a base, OG about 1.040 with maybe 1 oz of mid-alpha hops. Goldings and Hallertau work well. Remember that the fruit will add a lot more sugar, so you'll end up with a stronger beer, and that a lot of bitterness will probably detract from the fruit flavor.
2. Let the beer run its primary ferment as normal (I usually go 5-7 days), then rack. Leave in the secondary for another 4-5 days before adding fruit. This allows time for the yeast to get established and for some alcohol to get produced, possibly preventing nasties from the fruit from infecting your beer. Allowing the base beer to ferment out also lessens the CO2 production, so the fruit aroma won't be scrubbed out as much by the fermentation.
3. Sanitize fruit however you wish, puree, and add to the secondary. I just use a sulfite rinse on the whole fruit and don't worry too much about it. Boiling is not recommended as it sets the pectins in the fruit. I don't have any experience with campden tablets.
4. When the renewed fermentation has completed (airlock glugs maybe once or twice a minute), rack off the fruit for a couple of days before bottling. This will allow the beer to clear, and for any residual sugars to get eaten up, preventing gushers. Prime and bottle as usual.

Plan on using a lot of fruit. I typically use 1 or more pounds of fresh fruit per gallon of base beer to get a good flavor and aroma. You could economize by using pure fruit juice; I'd suggest trying about 1 qt per gallon of base beer.

Expect the ferment to go bonkers when you add the fruit. The yeast tend to go nuts with the addition of all that new sugar. Keep an eye on your blowoff tube to make sure it doesn't clog.

Now that it's spring, fruit will start arriving in stores before too long. Making a fruit beer isn't really that difficult, just a little more time consuming (and expensive, if you use store-bought raspberries :- ( ).

From: "Tom Childers" <TCHILD@us.oracle.com>  
Subject: Raspberries in beer

In HBD 1143, Brett Charbeneau asks about raspberry beers...

I've been playing with raspberry wheat beers for a few months now, and am drinking my third batch. You don't need to go all-grain, but you do need to  
sanitize the fruit somehow. There are two main choices:

- Add the fruit to the hot wort after the boil, when the temp has cooled to

perhaps 170F, and keep the fruit/wort at 160-190F for at least 15 minutes

to sanitize the fruit. If you let the temp get too high, or boil the fruit, then you will set the pectin in the fruit and get very hazy beer.

This method works well for frozen fruit, which has generally been turned

to mush by ice crystal formation.

- Sanitize the whole fruit with a food-grade sanitizing solution (perhaps

by soaking in Everclear or 100-proof cheap vodka?), then add the fruit to

the secondary and strain out during the priming/bottling process.

I use the first option, which has the advantage of being easy and pretty bullet-proof. The disadvantage is that you lose some of the aromatic qualities of the fruit by heating it.

Here is my current wheat-raspberry recipe (many thanks to Kathy Henley of Austin, TX for getting me going in the right direction). Sorry, but I don't take specific gravity measurements.

#### Wheat Berry

5-1/2 lbs light dried wheat malt extract  
1-1/2 oz Hallertauer or Northern Brewer (boiling), 7 HBU  
1/2 oz Hallertauer Hersbrucker (finishing), 2-3 HBU  
24 to 36 oz frozen raspberries  
16 oz frozen blackberries  
1 tsp vanilla extract  
Belgian ale yeast (Wyeast 1214)

Boil 2-1/2 gallons of water, add malt extract and boiling hops, and boil for 55-60 minutes. Turn off heat, add finishing hops, cool to 190 F and add the frozen fruit and vanilla. Let sit covered for 20 minutes, maintaining temperature at about 170 F and stirring occasionally. Cool to below 100F, add to carboy pre-filled with 2-1/2 gallons of water, straining out and pressing the fruit to extract most of the juice. Pitch the yeast, ferment at 70-72F, transfer to secondary after two days, then ferment completely out (about another 7 days). Prime with 3/4 cup corn sugar and bottle.

24 oz of raspberries gives a fairly subtle beer, with a mild tart raspberry underpinning that all of my friends loved. 36 oz of berries give a more assertive, but not overwhelming, raspberry flavor. Note that Belgian ale yeast will give stronger "clove" overtones when

fermented at temperatures of 75-78F, and milder flavors at 70-72F.

>pleased with the clarity of my beer to date.

I recommend dryhopping only for the last 7 days before bottling. Anything longer and you'll begin to lose more aromatics to the atmosphere than you are gaining from the hops into the beer. I've had beers spend 6 months in the secondary, but these were pseudo-lambiks, so not a good datapoint. I've had one beer (an Orval clone) spend two months in the secondary and it won a few awards. The Orval yeast is very slow-going -- the current batch has been in the primary for about a month and is still doing a bubble every 15 seconds.

>2) Does anyone have a good half-batch all-grain recipe? I tried

Just take a regular recipe and cut all but the yeast in half. You can pitch a half-gallon starter into a 5 gallon batch and still not overpitch.

>darkening be the result of light exposure, age, and is  
>incandescent light a threat???

I don't believe that light exposure will darken a beer, but oxidation will. I suspect that it was oxidation that caused the darkening. Incandescent light is much less of a threat than sunlight (because sunlight is considerably more intense) and less of a threat than fluorescent because there's a lot less violet-UV in incandescents). However, light-struck beer has a skunky smell, so use your nose to decide if it's had too much light.

The brewstore is giving bad advice -- boiling the crystal malt (or  
any grain for that matter) will extract tannins from the husks. In  
addition to giving you astringent flavors in your beer (like chewing  
on a grape skin) but you may also have some chill haze (the beer will  
get cloudy when you chill it) which is the reaction of the tannins  
with proteins in your beer.

>Brought the liquid to boil again, added the DME, stirring to

>back to the brew store and they suggested that I re-pitch. This  
>time I used Nottingham dry ale yeast. Pitched this Thursday  
>afternoon but no noticeable activity by Friday Morning.

You didn't tell us the temperature at which you were fermenting.  
If the temperature was 75F, then there's a good chance that the  
Edme did indeed finish fermenting all the fermentables and the  
beer was done. If it was 65F, then I'd say it should not have  
taken such a short time. One thing that can make yeast prematurely  
stop fermenting is a sudden drop in temperature (say, 20 degrees).  
I believe that Edme is quite a bit more fermentable than Nottingham  
and the Edme would have used up all the oxygen, so I'm not surprised  
that the Nottingham did nothing -- there was no O2 or sugar left  
for it to eat.

>So, my question is: "What happened?" and can I salvage this first  
>batch?

If you have a hydrometer, check the gravity. If it's below about  
1010, I'd say it's done -- bottle it. If it's above 1010 -- give  
it some more time. If you don't have a hydrometer, just let it sit  
for a week and see if it starts to ferment again.

Not at all! All the beers that I've brewed in the last year have been  
extract + specialty grain (my new business has be too busy to set aside  
even 8 consecutive hours). If it's Lindeman's or Timmerman's Framboise  
that you tasted, you'll have trouble duplicating the intensity -- I  
suspect that they use syrups and pasteurize to keep them sweet. However,  
you can make some very tasty beers with fruit. You need a lot, though..

read on. [By the way, with a name like Brett, Lambiks should be right  
up your alley... you see, one important contributor to the flavor of  
lambiks are the yeasts Brettanomyces Lambicus and Brettanomyces  
Bruxellensis,  
which we pseudoLambik brewers affectionately call, "Brett."]

>rates are good to use with these beers.

The two best fruit beers I've made have been my 1992 pseudoKriek made  
with 13lbs of cherries and 3.5 gallons of homemade pseudo-lambik and  
my nuptial ale which was made with 10 gallons of 15 IBU light ale  
which was put on top of 15 pounds of cherries and 15 pounds of

raspberries in the secondaries. To sanitize the fruits in both batches, I froze the fruit and then blanched it in boiling water for 1 to 2 minutes.

The raspberries completely disintegrated, so I had to add the 1 gallon of water along with them in to the fermenter. The cherries held together.

It's *\*VERY\** important to use a large blowoff tube (I use a 1.25" plastic hose right in the neck of the carboy) and to only add the fruit when the primary fermentation is done -- otherwise the delicate aromatics will be scrubbed out by the CO2 being generated by the primary ferment. A lot of CO2 will still be created, but it's best to minimize the scrubbing action.

By the way, the 13 lbs of cherries was very good but not great -- I think that about 16 or 18 pounds would have been better (and is what I'll use this year).

**Subject: cold plate**

Taking the advice of several HBDers, I bought a cold plate from Superior Products (of my own free will). The cold plate does an adequate job of chilling beer from room temp (~75 degrees) to about 55, which is about right for the ales (bitters and stouts mostly) that I've brewed up to now. The only problem is a tendency for the hose connections to leak, which is not too big a problem since everything is inside a small cooler. However, I would like to be able to leave all my connections hooked up, without having to disconnect between quaffing to slow down the wastage (sic). I currently using 3/8ths inch OD tubing to connect to both sides of the cold plate with hose clamps on both connections. Is there anything else I could use or be doing to stop these blasted leaks?

Thanks for the help

Subject: Fruit/Cooler step mash

Re: Raspberries in beer

My experience with making extract beers with fruit has been good. I am an all-grain brewer who occasionally brews an extract beer with fruit. These have turned out to my liking and have consistently done well in contests. My experience suggests that the yeast culture has a marked effect on the product.

On May 1 BURP, the Washington, DC homebrew club, sponsored the "Spirit of Free Beer" homebrew contest. I was the judge organizer for this contest with 189 entries. As a BOS judge along with Steve Hamburg of CBS, Randy Paul of BURP, and Bill Manger of NYC we selected a Peach Lambic as BOS. Now, I am prejudiced against strange beers for BOS. BOS should be judged on a beers stylistic merits: Which beer best epitomizes its style? Compared to commercial examples this Peach Lambic, made by George Griffith of Hay Market VA, was much better! This beer was made using 100% extract, 5.5 lbs peaches per 5 gallons, and the culture from a bottle of Cantillon Lambic. This beer was better than any of the Cantillon products I have had.

So, fruit beers using extract? You bet!

Re: bisulfite solution

When making fruit beers I rinse the fruit lightly and put it into the secondary. I do not feel that it is really possible to sanitize/sterilize fruit without irreparably damaging the characters that you are looking for. I have had a few beers get a bit "Belgian" on me. But, that's ~fun.

Re: Cooler mashing and step infusion.

The problem with step mashing and coolers is that it is very hard (impossible?) to have the appropriate malt/water ratio and the appropriate temperature steps.

What do I do? For ales I do a protein rest at 122F for 30 minutes with 1 qt H2O/lb of malt. I then take 1/3 of the mash and bring it to 175F. I then add up to 1/3 qt boiling H2O /lb of malt to bring the temperature up to the chosen starch conversion temperature. For lagers I do a double decoction with a strike at 122F, and steps to 144F-155F and 168F.

Cheers, Rick (rgarvin@btg.com)

Subject: foreign american brews

Hi all

I just read Shane's post about finding Bud while in Germany. It reminded me of a funny situation while I was in London a few weeks back.

I was in a pub somewhere in London (don't remember which one, there were so many its all a blur now). Who should walk up next to me at the bar but a couple of southern American boys (since I too am southern, I can talk about southern boys without fear of reprisal). Apparently, they had just come from McDonalds (with their Hard Rock Cafe bags in hand), and were suprised at the number of foreigners in that place. They were parched, and just had to get them a nice cold one. So, they just had that bartender bring them up a Bud (it cost them about \$3 each) to quench that thirst. With horror on their faces, they realized this wasn't the nice cold one they wanted, by gawd, it was HOT!. Well, lots of moaning and groaning went on, until the barkeep gave them some ice to pour their Buds over. I could hardly contain myself. Well, it was funny at the time. I guess you had to be there.

Subject: sour mash, yeast propagation questions

Jonathan Knight asks how long the bottled cultures are expected to last in the parallel yeast propagation method:

I can't say anything definite about what will happen when the cultures are refridgerated since I always kept them at cellar temp. Although this may not hold for ALL the Wyeast strains, I've had no problem with the Irish, German, and British strains keeping for a number of months. Refridgeration may help them keep even longer. What I do is I always decant a starter when I bottle up the cultures so that even if all the bottles were to prove unviable, I will have at least got one batch of beer out of the Wyeast package. This way, you risk nothing by propagating.

As the bottled cultures age and their viability decreases, you can always use two bottles to make up a new starter. In any case, the process can't be any worse than making up a starter from the dregs from Chimay or SNPA as some posters do. There's alot more sediment than in a bottle conditioned beer, and you've had control over the storage conditions from day 1.  
Cheers,  
Rick C.

Subject: Proper amount of spices?

According to Randy Mosher, who has a lot of experience making strangely spiced brews, the best way to add cinnamon is to make a "potion". Soak some cinnamon in vodka for a week or two, then add the potion gradually to the finished (but not yet bottled) beer until it tastes right.

From: phil.brushaber@u2u.lonestar.org (Phil Brushaber)  
Subject: Racking after Pitching

I have read many Homebrew texts but only recently got Dave Miller's Complete Handbook of Home Brewing. Some of what Miller suggests is contrary to my current practices of all-grain brewing. One area is racking the wort off the trub after the cold break.

After the wort chill Miller suggests... "At this point you have two choices, depending on how cold your wort is. If it is down to fermentation temperature (48 to 55 F for lagers) you should pitch your yeast immediately.... Close the fermenter and move it to your fermentation area. The wort should be racked off into a secondary fermenter about 8 to 12 hours later, to separate it from most of the hot and cold break material which will settle to the bottom of the vessel. Also remember that, before pitching, the wort must be aerated."

I find this interesting. The advantage Miller suggests is that after the proper hot and cold break that you don't have to syphon off the clear wort from the boiler, just strain it into the fermenter. But my concern lies in the area of racking (and aerating) the beer again after it has been sitting for several hours, but before fermentation begins. Also there is the inference that the yeast starter should be at the same cold (50 degree F) temperature as the chilled wort. Is anyone else doing this for lagers? I have been pitching my room temp starter into about 70 degree wort, then putting the fermenter into the refrigerator and bringing the temp down to 50 degrees.

Any thoughts?

Date: Wed, 19 May 93 10:50:43 EDT  
From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re beer bread

My landlady did this with the dregs of most of my batches. The crud in the bottom of the carboy is pure yeast if you've racked off the trub or if it comes from the secondary (modulo dryhopping), and a slurry of this will work well (doesn't matter if it turns into soup--you need some liquid to make bread anyway). But her preferred technique was to take whatever was left over from bottling (e.g., incomplete bottle which could otherwise oxidize) and mix it with enough flour to make a sponge. Unless you've lost all your yeast (which you'll find out when your beer doesn't carbonate) the sponge will start rising in a small number of hours and can be filled with flour to the proper consistency for bread dough.

This isn't quite like medieval recipes which call for taking a volume of working beer, foam and all (probably even more effective with true top-fermenting yeasts), but it does give a good flavor to the bread--  
--  
enough that you can taste it even with whole-wheat flour.

Subject: Re: Half and Half

> I've seen a 'trick' where you have a liter of beer half being Harp and the other half being Guinness stout. The bottom of the liter is Harp, the top of the liter, Guinness stout.

I've never seen this done this way. Around Boston, a lot of bars serve Black&Tan, but that's Guinness on the bottom. (It's the only Black&Tan the hypernationalist Irish-Americans around here approve of.) Since this doesn't mix when swirled gently, I suspect the available Guinness (very different from what you'd get in Dublin) is denser than Harp, which isn't surprising. I never watched closely when they were poured, so I can't give direct tips, but in generally you can layer a thinner liquid on top of a heavier by pouring gently (especially at the start) down the side of the glass.

>make a  
>Guinness-style stout that way.  
>  
>It seems to me, however, that I wouldn't want to use the whole batch of  
>sour  
>mash (Papazian says to boil up 5 or 6 lbs. of malt extract in 1-1/2  
>gallons)  
>in a stout - I seem to remember that Guinness adds a \*small\* amount of  
>sour  
>mash to their otherwise "regular" wort.

I've tried making sour-mashed p-guinness before and also making it  
by adding sour beer to the boil, and the latter works much better.  
The sour mash leaves somewhat of a raunchy flavor to the brew, whereas  
simply adding to the boil a bottle or two of beer from a previous batch  
that has acquired a lactic infection produces a crisper, cleaner  
sourness.

How much to add is always subjective. To get you in the ballpark - if  
you can smell the soured beer a mile away, add 1-12 oz bottles in 5 gal.  
If you can actually drink it w/o throwing up, add 3 or 4 bottles.  
If you got lucky and the soured beer actually tastes funky-lambic-like  
sour, add a gallon.

The boil will kill anything in the sour beer, but make sure you clean  
the bottle up and anything outside the kettle that you may have splashed  
with the sour beer well before the boil ends.

P-Guinness

8 lbs PILSNER malt  
1 lb roasted barley  
1 lb barley flakes  
4 oz. black patent  
1.75 oz GOLDINGS ~5% AA hop plugs  
1-6 bottles of soured beer

The whole idea is to keep the protein in the beer, so you start with  
Pilsner malt & don't do a protein rest. Mash using you favorite  
technique,  
but keep it short - 1hr or so. Sparge w 170 F water (acidified). Do not  
recirculate excessively. The short mash and the pilsner malt will help  
avoid a stuck runoff. Bring the wort to a boil as quickly as possible.  
Normally I boil 30 min to coagulate the protein before I add hops, but i  
in this case, add the hops right at the start of the boil, or even  
before.

Use Goldings.\* Add the soured beer - preferably soured from a lactic  
infection.

Boil 1 hour, or 45 min if you used hop pellets instead of plugs. Cool &  
pitch Wyeast 1084 Irish ale yeast starter. SG should be 1.045-1.050 or  
so,  
unless you get spectacular extraction rates (I don't). Ferment 60-65F.

Now if you bottle, use 3-4 oz corn sugar and let condition. If you keg,

you've got an added element in how you imitate guinness: Chill the beer to 50F, & turn the pressure up to 10-15 PSI & Serve.\*\* Do not agitate the keg.  
The beer will have a head, but very little carbonation in the beer itself,  
just like guinness.

bb

\* Cascades will give that funky american hop taste, if you desire, but taste unlike guinness. Any German hop is right out. Fuggles don't give that sharp bitterness. Maybe N. Brewer...

\*\* Normally, to get carbonation in the beer itself, you would chill to < 40F, turn up the pressure to 20-25 PSI, then agitate or else let sit 1 week at that temp/pressure. This means not disconnecting the CO2 supply, since the beer will slowly absorb the CO2 in the headspace and more CO2 is needed to keep the pressure high.

>P.S. I went to this fest last year and it was great!

I would like to make a correction. Beebop and Brew will be on SUNDAY, May 23rd not Saturday. Arcata is located on the coast approximately 300 miles north of San Francisco. Tuck and Patti will be the headlining group.

The following breweries will be in attendance:

Oregon:

Deschutes Brewing Co. - Bend  
Full Sail Brewing Co. - Hood River  
Pizza Deli and Brewery - Cave Junction  
Portland Brewing Co. - Portland  
Rogue Brewery - Ashland  
Umpqua Brewing Co. - Roseberg

Northern California:

Anderson Valley Brewing Co. - Boonville  
Etna Brewery - Etna  
Humboldt Brewery - Arcata  
Lost Coast Brewery - Eureka  
Mad River Brewing Co. - Blue Lake  
Marin Brewing Co. - Larkspur  
Nevada City Brewing Co. - Nevada City  
North Coast Brewing Co. - Fort Bragg  
Sierra Nevada Brewing Co. - Chico

Central/Southern California:

Anchor Brewing Co. - San Francisco  
Bison Brewing Co. - Berkeley  
Butterfield Brewing Co. - Fresno  
Devil Mountain Brewery - Benicia  
Golden Pacific Brewing Co. - Emeryville  
Monterey Brewing Co. - Monterey  
Pete's Brewing Co. - Palo Alto  
St. Stan's Brewing Co. - Modesto  
Tied House Cafe and Brewery - Alameda

I had this discussion with another fellow a few months ago. I believe  
that  
our consensus was that it was correlated with Whitbred Ale yeast. Now,  
the soapy flavor may be due to an infection of the yeast, or perhaps to  
strange and "unique" esters from the yeast themselves. Who knows.

Can you contribute another data point and let us know what yeast you  
used?

Troy

ps. Personally, I don't believe your malt is at fault. (hey! That's  
somewhat  
poetic)

From: Stewart Evans <stewart@sco.COM>  
Subject: cherry ale destroys carboy!

Last weekend I bottled a cherry ale. I started with a basic ale, very lightly hopped. I bought 6 24-oz. jars of sour Morello cherries from Trader Joe's; they were packed in light syrup, most of which I poured off, so the total was something less than 9 lbs of pitted cherries. I put the cherries in the secondary and racked the beer over them, and left them for about 3 weeks until all the cherries had sunk to the bottom. When I took a sample off the top of the carboy, I noted some tartness but very little cherry aroma/flavor. I decided to bottle anyway. When I tasted the leftovers in the bottom of my bottling bucket, I was surprised to find a distinct cherry taste! I wonder if somehow the flavor was not evenly dispersed through the beer initially, but got mixed in by the racking process. Anyway, it looks like it's going to be a very nice summer beer.

After bottling, I rinsed out my carboy and stuck in my bottle-brush to scrub out the krauesen ring. Suddenly I heard a CRACK! like a rock hitting a windshield. The carboy had fractured almost all the way around the base. There was no pressure on the carboy at that point. Weird! Perhaps earlier handling had produced some kind of stress in the glass? It's a pain to lose a \$12 carboy, but at least it happened AFTER I got the beer out of it!

Yes. I suggest you get the Hops special issue of Zymurgy. With  
experience,  
you can tell the difference between hops by aroma, although some are  
quite  
close. Unfortunately, I can't explain how to do this in words -- you  
have  
to just practice. The one aroma that is quite recognizable and  
definable,  
is grapefruit -- Cascades and Centennial (CFJ90) have the most of this  
grapefruit aroma, but I've noted it in Willamette to a lesser extent.

Yes there is, I feel. Among the more subtle, lower-alpha hops, there is  
less difference, but the harsher, high-alpha hops, I feel that there is  
a difference. For lack of a better word, "harshness" is a component that  
is added to the bitterness -- in the back of the throat, not just on the  
back of the tongue, as in smooth bitterness -- when you use high-alpha  
hops. All I can really say is to try some small, pilot batches and see  
if you feel the difference is important enough for you.

That smell you describe is indeed a bacterial infection. It's unlikely that it would have righted itself in the bottle. The cloudiness is another indication that there was an infection. I suspect that more and more reports of infected batches will be cropping up now that the warmer weather is here. It is still possible to brew in the summer, but you must be extra, extra, extra careful about your sanitation -- what worked in the cold of winter may not work in the summer. Open windows, damp basements, warmer tapwater (for wort chillers) and active, airbourne microflora are some of the reasons that summer requires much more stringent sanitation techniques.

From: Pierre Jelenc <rcpj@Panix.Com>  
Subject: fruit, sugar,

Several people have asked recently about sanitizing fruit for fruit beers. I recommend using a solution of potassium permanganate. It has been used traditionally in countries where vegetables, salads, etc are a bit dodgy. Make a frankly purple solution of permanganate in water, and soak the whole fruit for 5-10 min. If the purple color fades (the stuff found things to chew up), add a couple of drops of concentrate and let soak a while more. Drain and rinse with boiled water.

About sugar, again from several posts:

Sucrose is broken readily by yeast into fructose and glucose. The yeast must do that before using it for food. While it can do it, yeast is lazy and will not balk if the job is done for it, hence the use of invert sugar.

Caramel: all simple sugars caramelize upon heating. The reaction is a complex set of thermal dehydrations that produce short polymers and cyclic compounds.

Maltose: it is a disaccharide like sucrose, except that it is made of two glucoses.

Golden Syrup: my local supermarket in NYC at Broadway and 115th has it routinely on the shelves, as well as several other Tate & Lyle specialty sugar products. I saw treacle downtown a while ago, maybe at the South Street Seaport mall.

Jaggery: It is partly refined sucrose from the sap of a palm tree.

Subject: Equipment?

Hello All

I'm very new to homebrewing, only four extract batches. I'm looking for some basic equipment at low prices (Since I'm a college student). I need a couple of glass carboy's and bottles. I have seen bottles with there own tops, look like a little porcelain stopper with a rubber washer on it. I don't know what they are called but look like they would work well.

Could some of you out there help me to find a mail order shop or anybody willing to sell there equipment. The local pseudo homebrew shop wants \$35 for a glass 5 gal. carboy, this seams high to me. Also what are those bottles called and do they work?? Any other helpful hints on any brewing subject welcome.

Please email me at wilsonrs@vax2.winona.msus.edu

The bottles Rob is referring to are Grolsch bottles, a beer made in Holland.  
I was lucky enough to obtain about 400 of these once and it was one of the reasons I began homebrewing. I never liked the beer and I got the bottles empty, but they are excellent for bottling homebrew. They hold 16 ounces, are dark brown to keep out light, are very thick and sturdy (I haven't broken one yet) and are a joy to cap. Just a flip of the thumb and they are capped. No need for a special capper. Most of the original rubber gaskets are still in good shape and the few that were dried out or covered with crud and/or beer mold were replaced. Several homebrew supply stores and mail order catalogs have them both in white and red. I boil the gaskets for 5 minutes to sterilize them before bottling.

The 16 oz. size is nice since I can pour 2 mugs of beer with a good head from 1 Grolsch bottle and still leave the yeast sediment in the bottle. An interesting thing I have noticed while soaking off the original labels is that the older bottles were marked as 16 oz. on the label and as time went on, the labels changed to 15.8 oz. and 15.2 oz. Probably at the same price, but at a savings to the brewery. I'm in the process of measuring the volume of each of the 3 differently marked bottles, but I'll bet that they are all the same. They just put less beer in them when they were bottled.

A typical 5 gallon batch will yield between 35 and 40 Grolsch bottles. I place a removable 3/4" round Avery label on the cap and write the batch number on it using a yellow label for lager and brown for ale. I make my own front and back labels for each batch on a laser printer and glue them on to the bottle with Elmer's white glue. I have no idea where to get more of these bottles. Try a bar that serves Grolsch in these bottles.

Subject: sanitizing Stainless Steel

Al Korzonas writes:

\*\*\*\*\*

JC writes:

>I'd caution everyone against using bleach to clean stainless steel vessels.

>I'm under the impression that bleach will pit stainless steel.

I agree. Iodine-based sanitizers are recommended for sanitizing stainless steel.

- - - -

OK, here's a silly question. I'm using my stainless keg as a cooker, so it'll be sterilized by the boil, right? So, as long as I get it CLEAN, and rinse it good, that should be clean enough, right?

I never bothered sterilizing my wort chiller, because I just put it in the wort when I'm boiling it, so the kettle shouldn't be any different, should it?

How about the ladle? I just leave it hanging inside the keg, during the boil, so I can stir the wort without worrying about putting a non-sterile instrument in it. Is having it sit in/just above the boiling wort enough to keep it from contracting nasties?

\*\*\*\*\*

Hint of the day...I've been pitching my yeast into a quart of starter wort, and I get much quicker starts this way. I just took 1lb. of dry malt extract in a gallon of water, boiled for about an hour, and canned it. Now, when I want to brew on saturday, I pop my wyeast pack on thursday, pitch it into a gallon cider jug when it's ready, add the quart of starter wort, shake the heck out of it, and let it go. By saturday or sunday, it's ready to go (nice 1/4" of froth on the surface), I make my batch, shake up the starter, and pitch. Starts have been within 12 hours regularly, I was getting 24 hour+ starts by just dumping the wyeast pack into the fermenter.

It's definately worth the minimal effort it takes, in my opinion. If you aren't making a yeast starter, I'd say it's not a bad idea to do. The higher cell count you start with, the quicker it'll get fermenting, and crowd out any infections that happen to be there.

Any suggestions on refinement of this technique?

I can think of two reasons for doing this (note: my reasons are more geared for extract brewers):

1) xfr'ing the brew to the 2ndary helps separate the sludge from the brew, and hence, if done right, will produce beers that are more clear.

2) buys you time. bottling is time-consuming; once you have the brew in the 2ndary (carboy), you can let it sit in there for a while (months) until you find a good time to bottle.

From: greenbay@vnet.IBM.COM  
Subject: RE: Half and Half , NA Beer

It worked! Pouring the Guinness into a spoon resting on the top of the bottom beer effectively separated the two. Actually, I only got it to work with Old Milwaukee on the bottom and my stout on top (Old Mil cold, stout warm.) I tried it with one of my lighter colored beers, but the stout mixed in. Maybe in that case the stout should have been on the bottom.

I'm also interested in producing an NA beer. One idea I had would be to just use crystal malt or some other malt for the flavor and body of the beer but not use anything that would contribute fermentable sugars. Then you could boil in the hops cool it down, add yeast and priming sugar and bottle it. This would be restrictive on flavor, style, and whatnot, but would it work?

Thanks for all of the help,  
Bob

SUBJECT: A new half-n-half

Since we have fresh, tasty Celis White available locally on tap, we make  
a  
concoction called "Cream of Wheat." It is a bottom layer of Celis White  
and a  
top layer of draught Guinness. Whenever you take a drink the whole  
boundary  
layer sloshes from one side to the other, but there is surprisingly  
little  
mixing. Very fun to watch and equally fun to drink. The Celis White adds  
an  
interesting spicy-fruitiness to the drink, while the Guinness is  
roasty-creamy. I highly recommend it to those who are brave enough to  
try.

A note about pouring: I believe that the bartender pours the Guinness on  
a  
large spoon held just above the Celis or the rising layer of Guinness.

FROM: Dennis B. Lewis <dblewis@jscprofs.nasa.gov>  
SUBJECT: Lyle's Golden Syrup and Black Treacle

I have access to both Lyle's Golden Syrup and Black Treacle. A one pound  
can runs about \$2.50 for the Golden and \$2.25 for the Treacle. As far as I  
can tell, the Golden Syrup adds a small amount of flavor (slight caramel  
taste) and not much in the way of fermentables (maybe 25-30 ppg). The Black  
Treacle, used in sparing amounts of 2-5% provides an "Old Peculiar" taste to your  
brew according the All-Grain Zymurgy special issue. I haven't used it yet,  
but I tasted it and Theakton's Old Peculiar is right on the money. It is  
similar to molasses, but the taste is noticable different.

Is it really true that Lyle's Golden Syrup and Black Treacle are no  
longer imported? If so, then I'll run out and clean out the store of their  
stock.

Subject: RE: Racking after Pitching

Hi All,

In HBD#1145, STOREY@fender.msfc.nasa.gov posted a funny story about beer culture shock in London.

Reading it reminded me of the last time I was at O'Hare in Chicago. I had a couple of hours to kill waiting for my flight, when I spotted an airport bar that served Guinness Extra Stout. The bar was lined with people drinking the Budmilloors swill, appropriately served ice-cold in order to numb the palate. When I ordered a Guinness, a few people looked up. The bartender apologized, explaining that he couldn't serve me one as he didn't have any cold. \*Everyone\* looked up when I told him that was OK, I liked it warm. I spent the next two hours blissfully sipping room temperature Guinness, to the utter revulsion of the Budmilloors crowd seated around me. I could not have been more pleased :-).

\*\*\*\*\*

Brian Bliss posted a recipe for sour mash Guinness:

>\* Cascades will give that funky american hop taste, if you desire, but  
>taste unlike guinness. Any German hop is right out. Fuggles don't give  
>that sharp bitterness. Maybe N. Brewer...

>Ignore the comment about N. Brewer in my previous note - It is  
>a relative to Hallertau, which does not work in stouts (I've tried  
>it).

I've used Bullion in my stouts with good results. Give them a try.

>sitting for several hours, but before fermentation begins.

One of my brewing buddies, who is a firm believer in the gospel according to Miller, racks his wort from the boiler, then allows it to chill to 45F overnight. Next morning, he racks off the settled cold break into a second carboy and pitches. His lagers come out great. However, I'm not sure he re-aerates during the second racking, I think he treats it like a racking to secondary, i.e., minimal splashing. Lee, care to comment?

I also chill my wort to about 48F before pitching, but I don't bother racking off the cold break. My understanding is that the yeast won't bother with the trub while they have other food available, so off flavors from fusel alcohol production is not a problem during primary fermentation.

My lagers come out well, too. Comments??

>Also there is the inference that the yeast starter should be

>at the same cold (50 degree F) temperature as the chilled  
>wort. Is anyone else doing this for lagers? I have been  
>pitching my room temp starter into about 70 degree wort, then  
>putting the fermenter into the refrigerator and bringing the  
>temp down to 50 degrees.

>Any thoughts?

It is important that the starter and the wort be about the same temperature at pitching time. I read somewhere (Miller? Noonan?) that sudden, severe temperature shock will kill a large percentage of the yeast.

In your case Phil, I'd say temperature shock shouldn't be a problem, as your starter and wort are about the same temperature. However, pitching lager yeast at 70F will cause elevated levels of diacetyl in the finished product. Pitching when the wort is 45F-50F will sufficiently reduce the amount of diacetyl produced during primary fermentation, so that a 1-2 day diacetyl rest after primary will reduce the diacetyl below threshold level.

Of course, a side effect of pitching into chilled wort is increased lag time. I've had some success compensating for this effect by growing large yeast populations in a 1/2 gallon jug. I start 7-10 days in advance of brew day, let the starter ferment out, pour off most of the liquid leaving just the yeast sediment, and re-feed with fresh sterile wort. After two feedings, I typically have about a 1 inch thick layer of yeast sediment. When the wort is properly chilled, I again pour off most of the liquid, and pitch the slurry. Using this method, fermentation starts in 12-18 hours, even at the reduced temperatures.

Cheers,  
Jim

From: Bryan Kornreich <bkornrei@pennsy.med.jhu.edu>  
Subject: secondary fermentations and fruit

Hey there,  
geotex@engin.umich.edu wrote that he was unsure about the purpose of racking to a secondary fermentation container. If anyone knows, please tell us all. I've been wondering about it for years and have never, ever gotten a straight answer. I've heard all sorts of reasons ranging from:  
-It helps clear the beer  
-It makes the yeast happier to work in a cleaner environment, so they take the fermentation further  
and -"What do you mean 'why'? You have to do it! Everyone does it"

Me personally, I've done it and I see no real benefit--maybe a bit of clearing, that's all; but then, I don't particularly care too much about the color of my beer--taste and aroma mean everything to me.

-----  
I have some questions for all you fruit beer brewers out there:  
1. How on Earth do you press your fruity wort (to get the juice out of the pulp) with any hint of sterility. I've always wanted to do a fruit brew, but I am most afraid of this messy procedure.  
2. In yesterday's Wheat Berry beer recipe, would it be a good idea to puree the raspberries and blackberries before adding them in order to avoid the pressing step? And would skipping the pressing be OK, or would too much juice be left in the cellulose matrix of the fruit?  
3. Does anyone out there have a good recipe for a banana beer? And do you have to sterilize a banana before use? (I'm guessing no!)  
4. What sorts of yeast leaves a nice banana taste in a beer (a regular beer, not a fruit beer)? Sort of like the Austrian EidelWeiss (is that the right beer I'm thinking of?)  
thanks,  
Bryan

Far be it from lowly me to say that Dave Miller is wrong... but the research I did last year for a presentation at the AHA national conference proved to my satisfaction (and my own experience has backed it up), that racking wort off the cold break was entirely a waste of time. Somewhere back a few months I posted some direct quotations from DeClerq and from George Fix, but in essence the point is that once the cold break has been created properly (by adequate chilling) it will NOT be reabsorbed into the wort unless the temperature of the wort is raised considerably above any conceivable in a brewery fermentation area.

It is important to get the wort off the hot break material, but this is a relatively simple thing to achieve when drawing the wort out of the kettle.

When I made the presentation (3 times! best believe the AHA gets their money's worth out of you), I said that I had never seen a brewery that worried about racking wort off the cold break -- one fellow from (I think) Chicago said that I was wrong! (oooooooooooh!) and that such and such brewery there did so. Well, that's one. And I suspect Dave Miller's brewpub is another.

I ain't no lager expert, by a long shot, but the procedure you're following is the same recommended to me by Dave Logsdon of WYeast Labs and he does make great lagers. So...

=====

On 1/2 and 1/2 (or, more properly "arf 'n arf")

I was taught to make these while tending bar at the Horse Brass, Portland's "authentic" British pub. I think it's pretty tricky from the bottle, and haven't a clue how to start. But with the proper taps, it's pretty easy. If you'll notice, Guinness is dispensed from a unique faucet that comes down to a small tip, and has a little knob on the side to control the flow. If you put the ale (not Harp, yuck!) in the bottom of the glass and then sloooooooooowly run the Guinness in on top (you have to open the knob up just at the very end to allow a rush of nitrogen/carbondioxide in for the head) you will end up with the heavy Guinness on top of the thinner ale. Naturally, this is an unstable condition and the two beers will quickly mix -- but it does make a nice presentation.

In general, I refused to do any other mixed beers, being a hard-core traditionalist. Arf n arfs I could live with, but some of the waitresses spent a lot of time coming up with cute names for mixes of various microbrewed ales -- they had to find another bartender to do them (whoops! "find another bartender to mix them").

Incidentally, the most beautifully presented drink I ever saw was a Tequila Sunrise at Henry Africa's in San Francisco. The bartender would put the grenadine on the bottom, then the assorted other goodies on top, and finally put a swizzle stick all the way to the bottom and quickly pull it up: the Grenadine would follow up the center of the glass. It was the only time the drink's name ever made sense to me.

There are a number of good reasons for it. One of the simplest is that it leaves the cold break (trub, etc.) on the bottom of the first carboy. This means that (a) you can harvest pure yeast from the 2ndary and (b) that you will end up with much less garp(TM) in your bottles.

There are decoders around that will allow you to read .gif or .jpg files. I'm using Aldus PhotoStyler, which is supposed to be able to read .gif files, but frankly it doesn't work worth a ... Anyway, I've recently received some updates (which won't fit on the damn drive ...) that supposedly will deal with .gif and .jpg (a compression format) -- but I haven't much faith.

I also have some shareware called Graphic Workshop which reads these files (and many others) and converts back and forth. It isn't a Windows program but does run under Windows.

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Bitterness

In this Wednesday's HBD drose@husc.harvard.edu asked about bittering hops, specifically whether there was any reason to be picky about what variety we use for >60 min. boils. I mean bitterness is bitterness, right?

>From the back of the room comes a resounding \*NO\*

While it is true that boiling hops for greater than an hour or so gets rid of the volatile essential oils (for the most part), these oils are not the only compounds that give a hop its unique character. The quantity and proportions of the various alpha and beta acids are different for each hop variety. High alpha varieties typically have an alpha/beta ratio of 2-4 while noble hops' alpha/beta commonly is below 1. In addition the cohumulone/humulone ratio also varies widely, hops with high cohumulone levels are thought to contribute a harsher bitterness to beer and negatively impact head retention.

The big brewers, under the assumption that bitterness was bitterness, funded most of the development of high alpha varieties in the last 20 years. They found that their taste panels were able to distinguish between beers bittered with noble varieties and high alphas and preferred the former in most cases. Today a lot of their research money is being spent developing higher yielding noble-type aroma hops (like Mt. Hood and Liberty and soon to arrive Tettnanger and Saaz triploid varieties).

The best way to demonstrate this is via test brews. Add the same amount of alpha acids to each beer but make one Chinook (~12% alpha) and make the other Saaz (~3-4% alpha) for example. Make sure you boil the hops for >60 min. and don't add flavor/aroma hops. Then ferment, finish, and taste the difference.

Email me with your snail mail address for my catalog which discusses hop varieties, hop chemistry, bitterness calculations, and of course, where to get fresh, whole hops. (Sorry for the commercial, but Jack said it was OK:-)

From: "Steve Kurka - BMC West, Boise, ID" <kurka@bmcw.com>  
Subject: The Sanitation subject again - Recent studies on water nasties

Sanitation and the homebrewer:

Recently, I have noticed more comments on sanitation due to summer's return.  
As a backcountry camper and a homebrewer, I have many concerns about what is "growing" in the water. Some of the water treatment practices of camping be applied to the disinfecting process of brewing:  
For those that read the REC.BACKCOUNTRY postings, you will know what affect Chlorine and Iodine have on microflora, bacteria and the like. If you are interested and do not read RB, I can forward a summary on water treatment.  
It contains reviews on water filters and chemical effectiveness from recent scientific studies and research. (Or look under REC.BACKCOUNTRY for a 1400 line posting on Sunday May 9.)

Now for a few quotes:

1.  
>Without getting too technical, one can gain some appreciation of the  
>problem by understanding a few of the variables that influence the  
>efficacy of chlorine as a disinfectant.  
>  
>1) Water pH: at pH values above 7.5, the disinfectant capability of  
> chlorine is greatly reduced.  
>2) Water temperature: the warmer the water, the higher the efficacy.  
> Thus, chlorine does not work well in ice-cold water from mountain  
> streams.  
>3) Organic content of the water: mud, decayed vegetation, or other  
> suspended organic debris in water chemically combines with chlorine  
> making it unavailable as a disinfectant.  
>4) Chlorine contact time: the longer Giardia cysts are exposed to  
> chlorine, the more likely it is that the chemical will kill them.  
>5) Chlorine concentration: the higher the chlorine concentration, the

...

The post on water treatment is very extensive. Recommended reading for  
anyone who is Paranoid about infections, and the like. Boiling (Heat)  
still looks like the Safest way to disinfect things.

We as brewers do have the advantage of Alcohol production to kill  
nasties.

Isn't this why most countries brew, and say "Don't drink the Water"?  
The brewing process normally will render the water drinkable with  
and excellent flavor ;-) Steve

From: Mark Taratoot <SLNDW@CC.USU.EDU>  
Subject: Beer Bread

Greetings.

Mark S. Hart mailed me and requested my beer and pretzel method. I tried to email him directly (several times) but it kept bouncing. So, I will give a brief summary here. The original post can be found in the HBD archives by anonymous FTP from SIERRA.STANFORD.EDU.

Bread making can be time consuming, as can beer making. But if you make bread on a day that you will be around the house for several hours doing other things, it really is not much of a time drain, nor is it difficult. And the result is oh so yummy. Here is how:

NOTE: Do not use the yeast cake from primary fermentation unless you rack before fermentation gets underway (ie if you get the wort off the trub). Use the cake from a secondary fermenter.

Do NOT use the yeast cake from a beer that has been dry hopped. The beer will not spoil, but it will not taste good.

After you bottle/keg/spill-all-over-the-floor your beer, swish the carboy around to get the yeast cake into a slurry. Pour this slurry into a jar (or bowl if you want to get started right away). Pour some more liquid into the carboy and swish again (you can use dregs from the bottoms of recently emptied bottles, bottles that did not get completely filled, water, vegetable stock, whatever). You can close the jar LOOSELY and keep it in the refrigerator for a week or so. When you get ready to go, you can either decant off most of the liquid or pour it in (I pour it in).

To the slurry, add 2 cups flour (whole wheat preferably) and just a bit of sugar or honey. This is the sponge. Let it sit for 30-60 minutes. If the yeast slurry has been in the refrigerator, it will take longer to rise, so keep this in mind. If you prefer, you can stick the sponge in the fridge and use it as a "sourdough starter."

When the sponge has risen, add:

1/4 cup oil or melted butter (I like butter)

1/4 cup honey or sugar (mmmmmm. Honey.)

1 tsp salt

1 beaten egg (optional. Will help rise and increase protien).

"STUFF" (some, all, or none of the following)

Bulgar wheat (1 part bulgar and 1 part boiling water pre mixed)

sunflower seeds, crushed nuts, wheat berries, rasins, dates,

oats, millet, rye, spent grains from brewing, etc...

AND... more flour, 1/2 cup at a time until the dough has reached the proper consistency. NOTE: if you use a lot of "STUFF" then you may need to add some high gluten flour.

Knead for 15 minutes. Put in oiled bowl and allow to rise until doubled in bulk.

Knead for 15 minutes. Make loaves (I like braids and round loaves, but loaf pans will work too). For ronds and braids, put on

trays that have been sprinkled with corn meal or sesame seeds. Allow to rise until doubled in bulk. Brush top of crust (or all of crust for round loaves and braids) with one of the following for desired results:

Butter (yum) for a soft crust (if you use butter, put some more on right after the bread comes out of the oven)  
Beaten egg for a shiny crust (nice for braids)  
Milk for a nice brown crispy crust  
Nothing (simplicity)

Bake at 350 for 45 minutes or until bread sounds hollow when thumped. If you are using pyrex loaf pans, bake at 325.

Let the bread cool 20-30 minutes, slice, and enjoy with a nice glass of your favorite homebrew!

\*\*\*\*\*PRETZELS\*\*\*\*\*

Pretzels are easy too.

Take the yeast slurry or sponge, 1 tsp salt, a tiny bit of oil, egg if you like, and enough flour to get the dough a nice consistency. Knead for 15 minutes. Put in oiled bowl and allow to rise until doubled in bulk. Knead again. Roll into snakes and shape the snakes into pretzels.

\_\_At this point, I have been told you can increase the final "chewyness" of the pretzels by dropping them one by one into boiling soda water (1/4 to 1/3 cup baking soda in a pot of water). Supposedly they will sink, then rise back to the top when they should be removed\_\_

Put the pretzels on greased trays. Brush with beaten egg (or not, it makes a mess of the trays) and sprinkle with salt (optional) if you need to increase your blood pressure. Bake for ??15 minutes?? at 400?? degrees (take them out as soon as they start to get brown, each oven cooks differently, and when I have made pretzels in different ovens, the times and temp can vary.

As soon as they come out of the oven, spread fine mustard on one and devour it with a glass of fresh homebrew. Pretzels don't save very well, so make them when you have friends over.

Actually, it is easy as pie. (Hmmm. Beer pie... Nah.)

Have fun with these. If anyone has comments or suggestions about these, please contact me SLNDW@cc.usu.edu. I always love to get new cooking tips.

I concur. I believe, also, that Randy recommends filtering the potion through a coffee filter. I did this on a few beers and it worked quite well (however, the judges liked my Curry Beer much more than I did!).

For those of you that haven't had the opportunity to try Randy Mosher's odd beers, they are some of the most creative and interesting liquids I've had the pleasure to taste. My favorite is probably still the Chantrelle (sp?) Mushroom beer. Wow!

\*\*\*\*\*

Brian writes:

>P-Guinness

>1 lb barley flakes

>4 oz. black patent

>1.75 oz GOLDINGS ~5% AA hop plugs

>1-6 bottles of soured beer

>

>The whole idea is to keep the protein in the beer, so you start with

>Pilsner malt & don't do a protein rest.

Yes, but there are big proteins and small proteins. The protein rest will break the big proteins into smaller proteins and amino acids. I'm pretty sure that any really big proteins that are left by the time you are boiling will turn into hot break and do your beer no good anyway, so I don't think that skipping the protein rest will actually significantly increase your protein levels in the final beer. Comments?

\*\*\*\*\*

Brian also writes that he found some Black Treacle a few months ago.

Yes, but I spoke with (as far as I know) sole wholesaler of the stuff and he said that their current stocks had run out and that was it for a while.

From: Tim LaBerge <LABERGE@kuhub.cc.ukans.edu>  
Subject: brewkettles and carboys

Hi all,

I've been on an equipment binge lately, but I've run into some good prices that I'd like to pass along. I found 5 gallon glass carboys for \$9.00 at a factory outlet store that sells cookware, etc. I also found a 9.5-10 gallon stainless steel brewkettle(used) at a restaurant supply store for \$40.00. Moral of the story: shop around and you can find some bargains. (The brewkettle was dented and covered with baked on grease, but it all came off with elbowgrease.)

Date: Thu, 20 May 1993 11:38:08  
From: garetz@brahms.amd.com (Mark Garetz)  
Subject: Hops, Fruits

Brett Charbeneau asks about Raspberry and extract brewing:

HopTech sells a line of 100% natural fruit extracts that make brewing fruit beers easy. No pectins, sugars or preservatives to compensate for, and no problems obtaining fruit out of season or sterilizing it. Flavors available are raspberry, blueberry, peach, pear and cherry. They are added just prior to bottling or kegging so all the fruit flavors stay in the beer. For a light fruit ale, we recommend 30% wheat. Since the extracts contain no sugar or much "sweetness" associated with the fruit, we also recommend using malt extract high in dextrins or adjusting your mash accordingly to get a sweeter brew. For more info, leave a message at 1-800-DRY-HOPS (379-4677) or fax 1-510-736-7950. Catalogs mail 1st week of June.

Steve Boxer asks about leaf hops clogging the keg lines:

You want to put the hops in a "hop bag" and add some weight (Leaf hops tend to float). We also sell hop bags and weights, but these kind of bags are readily available from most homebrew shops. For weights, ours is made of teflon so it won't scratch and is inert to beer, but you can also use clean copper pennies, marbles etc. Hint: "Wet" the bag and hops before adding. It helps make sure the beer gets to the hops (learned this trick from Anchor). By the way, our bags are 100% cotton and even work with pellets!

"Joe" asks if you can tell the difference between hop varieties by flower, scent or growth habits:

Yes to all. However, it ain't easy. The oil components and their ratios can be used to identify a species, but it takes an HPLC to do it! The combination of the cone shape and the leaf style can be used (with practice). But I don't know why it matters. The easiest way to tell is to read the label on the package :-).

"drose" asks why it matters what hop variety is used for long boils, since the aromatics will be lost:

True. The aromatics are lost. But it is wrong to assume that there is only one bittering source. There are many alpha acids, beta acids and oxidation products that make up the overall bitter "character" of a certain hop variety. Each hop variety has all of these in varying proportions, hence the differing bitter characters. The number on the hop package is a total alpha acids number - the ratios of the various alpha acids is variety specific. (Did I mention I'm writing a book about hops?)

Anthony Johnston asks about a "soapy taste" in his beer:

I wonder if that beer was dry hopped? Sometimes this can cause a "soapy" flavor. Some palates are more sensitive to it than others. It is caused (my theory) by the fatty acids in the hops. It is also my theory that this is a "stage" of the oil on it's way to another compound because the flavor will go away in another week or two. (Same beer given to neighbor in week 1

- "YUCHH! Undrinkable. Tastes like soap!" in week 3 - "Hey this is great!

Got any more?" Recently had another brewer friend ask me about an astringent taste after dry hopping with some Tettnang. Same deal (not a fatty acid, but some other hop compound on it's way to something else). I told him to wait a few weeks. Now the beer is "Fantastic" according to him.

Date: 20 May 93 18:05:49 EST  
From: Matthew Mitchell <IEKP898%tjuvm.bitnet@TJUVM.TJU.EDU>  
Subject: bottles, caps, and kegs

From: Matthew Mitchell

Bottles: I recall drinking Watney's Red from a 2 liter brown PET bottle I bought at a packy in Nantucket. they also were kind enough to sell me a six of Ballantine's IPA for the price of regular Ballantine Ale.

.. "Uh...I think I'd better get three more six-packs..." 8^) !

Bottles: Who said they were lucky enough to have stubbies| I wish I had kept the Ortlieb's stubbies I used ten years ago. We used a different bottle for each of our brands: pounders for the lager, kings for the malt liquor, green for the stout, clear for brown ale, and stubbies for special brews. We also used A-Treat soda quart returnables "Party size": wonderfully convenient when the biggest pain is cleaning and capping bottles. (We get 12 oz painted A-Treats here too)

Caps: Rather than putting labels or initials on caps, you may find it smarter to put a batch serial number. (e.g. The batch 13 stout didn't carbonate as well as the batch 16) You can compare brew to brew, and note at a glance through the hole in the top of the case how long a case full have been aging.

Another good idea is to take a handful of caps, place them on a newspaper, and spray-paint them, color-coding by brand or recipe again. This also has the benefit of covering the previous stuff on the caps. (Cheaper to buy the overrun caps than plain ones)

and Kegs:

David's keg with two valves is called the "Golden Gate" keg, which has not been in common use for a decade. I think they're pretty good though.

I remember drinking gravity-fed Bud one evening after a softball game when the pump of our tap failed| You may have a hard time finding a tap to fit.

and BTW: I noted that McGillin's Old Ale House in Philadelphia advertises "Real Ale" Is this REAL ALE as the CAMRA think of it (cask-conditioned and hand-pumped) or is it just real ale instead of faux ale like Molson Golden?

Howzat!?!

From: Matthew Mitchell

Stoudt's Black Angus will present the Second Great Eastern Invitational Microbrewery Festival, June 11 and 12 in Adamstown, PA (between Lancaster and Reading)

Dates: Fri. June 11 6-10pm and Sat June 12, 2-6 pm  
Tickets: (they suggest you purchase in advance: last year sold out)  
\$15.00 per day (specify day) check or MO payable to  
Black Angus Ltd., PO Box ???, Adamstown, PA 19501

Phone: 215-484-4385

Breweries expected:

Dock Street, Philadelphia  
Arrowhead, Chambersburg  
British, Lithicum MD  
Wild Goose, Cambridge MD  
Oldenberg, Ft. Mitchell KY  
New England, Norwalk CT  
Old Dominion, Ashburn VA  
Buffalo  
Pennsylvania (Penn Pilsner), Pittsburgh  
Otter Creek, Middlebury VT  
Sam Adams Brew House, \*Philadelphia\*  
Vermont, Burlington  
Boston Beer Co (C)(R)TM and all those other reserved rights  
Hope they don't sue me for using their name in the post|  
New Haven  
and of course, Stoudt's

Price of admission includes souvenir tasting glass and food  
They say there will be fifty tasting tables and that all the breweries  
will have at least two beers available.  
This is not a competition, so expect a relaxed atmosphere, with the aroma  
of malt, hops, and brots, and probably German music, too.

If you're bringing along someone to drive, she or he may be interested in  
spending time among all the antique dealers on the Route 252 corridor  
while you drink beer.

Prosit|||

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: purl recipe

Hello All,  
Someone asked for a recipe for Purl a while ago. Well, after rooting around in my note books I found one copied by a book on brewing in London, by Thomas Thrale (aka Thrale) ca. 1800. He was at the time one of the biggest London brewers, with an annual output a little more than Whitbread, so presumably he knew his stuff. I found the book on microfische at the Management Library of UCLA. But that's all I noted down. Anyway, here it is:

Thos Thrale's Purl (ca. 1800)

Take Roman Wormwood, two dozen,  
Gentian root, 6 lb,  
Sweetflag root, 2 lb,  
Galanga root (galingale?), 1-2 lb,  
horseradish, 1 bunch,  
Dried orange peel from the Indies (Curacao?), 2 lb,  
Juniper berries, 2 lb,  
Seville orange seeds, dried, 2 lb,  
Cut and bruise all the ingredients, put in a butt,  
(capacity 126 US gallons) and top up with pale or mild ale. Store for one season.

Notes:

Gentians are protected flowers in Europe;  
Sweetflag is a type of Sedge;  
Galanga, to the best of my knowledge is galingale,  
for which I have as yet to find a source;  
The orange peel is almost certainly the Curacao  
peel, still used by some Belgian brewers;  
The ales appear to be normal in all respects;  
I have no idea what 2 dozen of Wormwood refers  
to (bunches, roots?).

Happy experimenting!  
Rob Thomas.

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: sparging

Hello all,  
I've just been reading a two volume book on brewing by  
Hough, Stevens and a couple of others, in which they say  
that in Europe (mainland) decoction mashing is often  
followed by batch sparging. That is instead of sparging with a continuous  
spray of water, the sparge water is dumped on in batches, the whole  
lot stirred, and the washings run off completely before repeating.  
For a 1055 beer they say that 3 such washes will give >99percent  
extraction. As the gravity goes up, so do the number of washes required.  
Any views? I noted in the equipment summary at Sierra.Stanford.Edu that  
some of you out there are also doing this. Has anyone done direct  
comparisons between the two methods?

Intrigued, Rob Thomas.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: why secondary?

Some more reasons:

1. If you're going to do a long fermentation, or you can't bottle until next month, then it gets the yeast off the trub. Left on the trub too long, the yeast will start to produce nasty tasting stuff.

Umm..... Well, I think that's the main reason, anyway.

I'm not a botanist, but I play one on the net:-) But seriously, my understanding is that each hops "variety" (cultivar) is genetically a single individual that has been propagated vegetatively. (As are apples.) If you have a random hop plant that came up from seed, then the odds are about 99 billion to 1 that it is NOT a recognized variety. So trying to identify it is a lost cause. However, if you know that the plant is a known variety, but not which one, then you have some hope.

> I wonder if that beer was dry hopped? Sometimes this can cause a  
"soapy"

I've noticed that dry-hopping often results in a "grassy" or "herbal" taste that diminishes quickly with time. Sort of like chewing on raw hops.

Subject: Re: Secondary and Fruit

Why use a Secondary fermenter?

The reasons have already been mentioned, but I usually add a little explanation:

- 1) It gives the beer some time and a place to settle a little. If you aren't real careful about how much trub gets in your primary, you may have some trouble leaving it all behind (especially when there is more than an inch or so). When I rack to the secondary, I am real careful, but don't care *\*that\** much if some cloudy beer gets through. When I am ready to bottle, there is usually very little sediment left, which means that my beer in the bottling bucket is very clear and there is little noticeable sediment in the bottles.
- 2) Adding extra ingredients. Any subtle ingredients, such as hops or spices or fruit, will lose more aroma during a vigorous primary fermentation than later on. Adding them to a secondary is a good way to increase the amount of aroma that remains.
- 3) Time. If you travel, or have children, or any other demands on your time, you may not be able to bottle the week or month your beer is ready. In that case, leaving the beer on very little sediment in the secondary is *\*much\** preferable to leaving it on the trub in the primary for that extra week or month. Even without any of the other reasons, this reason alone is enough for me.

In summary, if you don't need the extra clarity or time or whatever, you don't need to use a secondary. There is no magic. Plus, you can go wrong with a secondary if you aren't careful about sanitizing or air-free racking.

Fruit:

I always put my fruit in the freezer overnight, supposedly to break down cell walls. I find this much preferable to pureeing or the like. I always get good aroma and flavor using this method.

Subject: Re: sour mash guinness

Brian writes:

"Ignore the comment about N. Brewer in my previous note - It is a relative to Hallertau, which does not work in stouts (I've tried it). But then I seem to remember Jackson saying that Guinness used N. Brewer. I haven't used much N. Brewer. Hmm. The recipe works great with Goldings."

I find (British) N. Brewer works great in stouts; it definitely provides flavour as well as bitterness when boiled an hour, unlike Hallertauer. Better, if you are partial to fruit stouts, consider some Bullion for their blackcurrant character. Unfortunately, these are being phased out here, and I don't know of a suitable replacement. I actually find that if I use enough of our cruddy, local Goldings, I also get blackcurrant. Conclusion? I am either being sold mislabelled Bullion (unlikely, as they have Goldings aroma), or the two varieties have something in common.

"The whole idea is to keep the protein in the beer, so you start with Pilsner malt & don't do a protein rest. Mash using you favorite technique, but keep it short - 1hr or so. Sparge w 170 F water (acidified). Do not recirculate excessively. The short mash and the pilsner malt will help avoid a stuck runoff."

Hmmm. Our anonymous lager malt (which admittedly isn't the same as pilsener malt) shows more tendency to set the mash than ale malt. I'd also be interested to hear more about the effects of mash duration on viscosity; mine seem to get more fluid with time. Unfortunately, I can detect lager malt in even the most aggressive stout (sulphur?), which is why I don't follow Miller's advice. Some wheat malt is well worth considering, however.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: My Brown Ale

Last night, I tasted the brown ale that I bottled just last Sunday. Wow!  
!  
I'm in love! It's not clear yet, but it's already carbonated, and  
delicious!  
Maybe y'all can comment on the authenticity of the recipe:

CHUCK'S BROWN ALE  
Ingredients for 4.5 US gallons

4 lb Alexanders Malt Extract  
0.5 lb Chocolate Malt  
0.8 lb Turbinado  
~2 fluid oz. Honey  
2.2 oz. Cascade Pellets (5.5% AA) 45 min  
1 oz Cascade Pellets, dry hop in secondary  
0.5 t. Irish Moss  
Yeast  
OG ~1.042  
FG 1.010

The choc. malt was steeped in 65'C water for 20 min and then sparged (and removed). The yeast was made from the dregs of 10 bottles of beer (that got dumped due to excessive aluminum leaching) that had been in a starter for 3 days before hand. The yeast for that batch came from the dregs of several bottles of stout, which was made with WYeast Irish Ale. (I think I could make beer from the dregs of the brown ale, but that might be one to many generations!) Temperature of fermentation was 60 - 70'F, 6 days in primary, 9 days in secondary (with dry hops).

I can't describe the taste so well, but it certainly is one of the best that I've ever made. The hop nose is wonderful! I ran across the tubinado in a health food store, and thought why not? I believe that is added some residual sweetness to the beer. I hope that I can duplicate this one some day.

Chuck

From: Tim Murray <MURRAYT@WSUVM1.CSC.WSU.EDU>  
Subject: Imported Beer in Ireland

Reading the thread about Bud in Germany and England reminded me of an experience I had in Ireland last year. While traveling out to the countryside by train one Sunday morn, we stopped at a station across from a train of Irish football fans coming into Dublin. Having been in the country for about a week, I had already fallen in love with draught Guinness, Smithwick's, and Harp, so I was shocked to see the tables of the adjacent train littered, not just a few - piles, of Bud empties. The Irish natives told me that AB had put-on quite an advertising blitz and that Bud was becoming more popular. How anyone with ready access can choose Bud over the other wonderful beers is still beyond me.

Incidentally, the Irish natives also told me that the best Guinness is draught (no surprise there), and that the next best thing is Guinness in the can. They also firmly believe that the way a pint is "pulled" has alot to do with how it tastes.

Looking forward to another Irish foray, I am! tm

Subject: Sources of Cornelius Kegs

I'm sure this has been discussed many times before, but does anyone have any good general sources for soda kegs? Does the retailer who uses these pay a deposit on them? If so I might be able to talk some user out of some empties. My local homebrew store has them for \$20 each, but I thought I would try the low cost route first. Any suggestions would be appreciated.

BTW: has anyone tried the closed system pressurized fermentation method that Teri Fahrendorf wrote about in the 1992 special issue of Zymurgy?

Subject: RE: Equipment/Grolsch Bottles/Labels

Two comments regarding Tom's note (tmr1@hotmailg.att.com).

Grolsch bottles are great, another good similiar bottle is from Fischer D'Alsace. I like their bitter, but most importantly, they use 22 oz 'Grolsch' bottles. They are very handy, heavy, and have the dark brown bottles. And that reminds me, I've never seen dark brown Grolsch bottles, all of mine are green.

Secondly, Tom mentions that he uses Elmer's glue to affix his labels. I don't know how good/bad that works, but I do know that Glue Sticks work great. I just put about a half inch strip on each side of the label and it sticks great. Then, when you clean the bottle, a couple hours of soaking and the label falls right off. It great.

Anyway, got to run,  
Bob

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Evaporative Cooling

Recently read some threads on using evaporative cooling for summertime brewing. The consensus seemed to be it was worthless in humid areas like Austin (where I live). Since none of the posts had any data I decided to get some. Here's the first data point.

Setup: 7 gal glass carboy w/5 gal of beer placed in shallow (4" deep) pan. Cotton towel wrapped around carboy and secured w/diaper pin (my son helps out around the brewery). Towel is soaked w/water every other day or so. About 1/2" water is kept in pan; capillary action keeps the lower 2/3 of the towel wet but the top 1/3 will dry out if it isn't rewet every other day or so. No fan or force ventilation around carboy.

Data: House is airconditioned. Average temperatures in brewery (aka den). Dry-bulb, 75 F  
Wet-bulb, 66 F (measured w/old fashioned sling psychrometer)  
Which from standard psychrometric tables yields a relative humidity of 62%.  
Beer in carboy, 69 F

So w/a passive evaporative system (no fan or force air around carboy) I got about 2/3 of the wet-bulb temperature depression. If a fan is used to blow air around the carboy I don't see any reason one could not reach the wet bulb temp in the carboy (my next step).

For those who think you have to live in Albuquerque to have effective evaporative cooling, take a look at the following truncated psychrometric table.

Dry-Bulb

| Temp F | Wet-Bulb Depression, F |    |    |    |    |    |
|--------|------------------------|----|----|----|----|----|
| //     | 5                      | 6  | 7  | 8  | 9  | 10 |
| 60     | 73                     | 68 | 63 | 58 | 53 | 48 |
| 65     | 75                     | 70 | 66 | 61 | 56 | 52 |
| 70     | 77                     | 72 | 68 | 64 | 59 | 55 |
| 75     | 78                     | 74 | 70 | 66 | 62 | 58 |
| 80     | 79                     | 75 | 72 | 68 | 64 | 61 |

<- Relative Humidity (RH)

Note that for ambient temps of 70 - 80 F:  
RH of 70 to 80% allows wet-bulb temps 6 to 8 F below dry-bulb  
RH of 60 to 70% allows wet-bulb temps 8 to 10 F below dry-bulb  
Or if your basement is at 60 F w/73% RH you should be able to reach 55 F--getting down to lager temps!

So let's quit guessing and get some more data points!

From: Lee=A.=Menegoni@nectech.com  
Subject: Racking off the trub

Jim DiPlama recently posted and asked about the process I used when racking off the trub with particular regard to aeration.

Short answer: I airate as I rack off the trub , which has settled from 4-12 hours, into primary.  
I also pitch a large yeast population as starter.  
Remember starter size will be determined by the amount of fermentables used not simply the volume.

WARNING\*\*\*\*\*CAUTION\*\*\*\*\*WARNING\*\*\*\*\*CAUTION\*\*\*\*\*WARNING\*\*\*\*\*CAUTION\*\*\*\*\*  
I only use this process in the fall, winter and early spring when the outside temp is below 55 and the pollen count is extremely low.  
I do all my brewing except for the mashing outside.  
I also pay careful attention to sanitation.  
WARNING\*\*\*\*\*CAUTION\*\*\*\*\*WARNING\*\*\*\*\*CAUTION\*\*\*\*\*WARNING\*\*\*\*\*CAUTION\*\*\*\*\*

DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*  
\*\*\*\*\*

This process works for me.  
If you don't like this please constructively flame me on the HBD.  
If your normal process yields an occasional contaminated batch do not do this.  
DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*\*\*\*\*DISCLAIMER\*  
\*\*\*\*\*

I chill the wort to about 45-50F with my immersion chiller.  
I then use a sanitized stainless steel frying basket to scoop out hops and what ever break material it picks up.  
I then pour the wort into a sanitized glass carboy, which is on a table taller than the primary fermenter the wort will be later racked into, and cap.  
For ales I move the carboy to my 65 degree basement.  
Depending on weather (outside temp) and time of day/night I let the trub settle for as little as 4 hours or overnite. The longer I wait the more compact the trub layer gets and the less wort I "waste".  
After the settling period I rack into the primary and airate and pitch.

I then pour the "waste" trub layer into a 2 gallon carboy like bottle which I topoff with cold tap water. I have an in line charcoal filter on the tap.  
I let this settle for a few hours and rack off the 1/2 gravity starter wort which I boil and bottle.

When I brew I target 6-6.5 gallons out of the brew pot and plan on losing a gallon to trub. My goal is to get 5 gallons into a keg.

For lagers I use the 4 hour or so settle period since I do not want to raise the wort temp. For ales I go overnite since I want the wort temp to rise closer to pitching temp.

Using this method requires strict sanitation.  
If your normal process yields an occasional contaminated batch do not do this.

When I began brewing 3 or 4 years ago I found the Miller book a better resource than Papazian. I was really turned off by "don't worry", Ostrich don't worry. Through subscription on HBD I have modified my process over time and no longer consider myself a " Miller Dividian".

This rack off the trub thing may be a "momily". During recent brew pub tours the brewers mentioned that they would chill, settle for 15 - 30 minutes, centrifuge and transfer to fermenter. This would represent some degree of wort trub separation particularly when they chill into the 30's or low 40's.

My current understanding of racking off the trub is that one should pitch into the chilled wort and rack a few hours later. This gives the yeast the opportunity to use some component of the trub which it needs in the beginning stage of fermentation and not provide the materials that the yeast uses later in fermentation to produce fusel alcohols. I tried this but was not pleased with the lag time, this from a guy who leaves unpitched wort overnight. I think I left a lot of yeast behind when I racked so I went back to my old method.

What do other brewers think and do about trub and why. Please post to the HBD.

Subject: bittering hops

Re: the thread on flavor contributions of different varieties of bittering hops, I stumbled onto a combination I really like a couple of years ago and repeated it again this year also with yummy results. Namely, in a pale ale type brew, I use BULLION for bittering and CASCADES for aroma. Keep the bittering level around 10-12 HBU, use a full-bodied light extract (or whatever that translates to in all-grainese) and dump in maybe 3/4 lb. of amber crystal. This last time I used about 1/2 oz of cascades for finishing (I'm doing this from memory) and Wyeast "American" ale yeast. This brew was great after just a week or two of bottle conditioning, and provides a "big" flavor with a bracing hop bitterness and aroma. Yum!

Point is, I haven't gotten quite the same results with other, similar brews that used Cascades for finishing (or dry-hopping) and a bittering hop other than Bullion. And, since by general agreement/conventional wisdom/whatever, Bullion hops are often referred to as "coarse," it might not spring to mind as first choice for a pale ale in the 1042 S.G. range. However, I like the results I've gotten and I plan to try the same thing at some point with an I.P.A. where the S.G. is high forties to low fifties.

Bottoms up!

>it'll  
>be sterilized by the boil, right? So, as long as I get it CLEAN, and  
>rinse it  
>good, that should be clean enough, right?

Right. I don't even use soap on mine -- just a non-stick-safe scrubbing  
pad (more gentle than a scouring pad) and elbow grease. The only things  
in there are a little scortched malt and some Beerstone -- if it gets  
really  
bad, maybe I'll use a bit of cola (for the acid) or if one of my batches  
of  
pseudo-lambik goes super acetic on me, I'll use it for scrubbing the  
kettle  
(that's what the lambik brewers do!).

>How about the ladle? I just leave it hanging inside the keg, during the  
boil,  
>so I can stir the wort without worrying about putting a non-sterile  
instrument  
>in it. Is having it sit in/just above the boiling wort enough to keep  
it  
>from contracting nasties?

Anything that's mechanically clean and spends more than 5 minutes in the  
boiling wort or water is going to be sanitary. However, I still would  
not  
use a wooden spoon on cooled wort even though you used it to stir the  
boil.

\*\*\*\*\*

Bob writes:

>but would it work?

Nope. Crystal malt has fermentables in it. Email to Jack for his NA  
beer made by heating regular beer. I've tasted it and it wasn't too  
bad -- not a prize-winner, but not bad.

\*\*\*\*\*

Jim writes:

> It is important that the starter and the wort be about the same  
>temperature at pitching time. I read somewhere (Miller? Noonan?) that

yeast.

You read it here... in the HBD!

> In your case Phil, I'd say temperature shock shouldn't be a problem,  
as  
>your starter and wort are about the same temperature. However, pitching

>lager yeast at 70F will cause elevated levels of diacetyl in the finished product. Pitching when the wort is 45F-50F will sufficiently reduce the amount of diacetyl produced during primary fermentation, so that a 1-2 day diacetyl rest after primary will reduce the diacetyl below threshold level.

I agree that the elevated temperature may cause a bit more diacetyl to be produced, but a bigger problem is with esters. Remember, this is supposed to be a lager. I pitched Wyeast 2308 at 65F and let it sit in a 57F crawl for 12 hours, then in a 50F cooler for 3-4 days then down to 45 for a few months (primary and secondary). The resulting beer was deemed "too fruity for a bock" by judges I respect highly. I can't bring myself to entering as a Porter, although I've been told it's a potential prize-winner. Only four bottles left -- think I'll keep them for myself.

\*\*\*\*\*

Bryan writes:

>geotex@engin.umich.edu wrote that he was unsure about the purpose of racking to a secondary fermentation container. If anyone knows, please tell us all. I've been wondering about it for years and have never, ever gotten a straight answer.

The reason for it is to get your beer off the trub (hot break, cold break and dead yeast). However, I only use 2ndaries for lagers (which will spend a long time on the trub) and fruit beers (because I need to make more room for the fruit and because the 2ndary ferment will mean that the beer will spend longer on the trub than in my standard one-week ale).

>  
>I have some questions for all you fruit beer brewers out there:  
>1. How on Earth do you press your fruity wort (to get the juice out of the pulp) with any hint of sterility. I've always wanted to do a fruit brew, but I am most afraid of this messy procedure.

Freezing breaks open the fruit juice "sacks" in the fruit. I only mash the cherries -- not the raspberries -- freezing turns them to mush anyway.

I use a stainless bowl, sanitized with boiling water and a sanitized potato masher, bought just for this purpose, sanitized with boiling water and never washed with soap.

>2. In yesterday's Wheat Berry beer recipe, would it be a good idea to puree the raspberries and blackberries before adding them in order to avoid the pressing step? And would skipping the pressing be OK, or would too much juice be left in the cellulose matrix of the fruit?

I theorize that freezing will make enough room for the yeast to get in - the raspberries that I put in my psuedo-lambik were not mashed and they have grown very pale in the last 6 months.

>3. Does anyone out there have a good recipe for a banana beer? And do you have to sterilize a banana before use? (I'm guessing no!)

Unless it's damaged, I think not. However, bananas are the wrong consistency for fermenting -- too pulpy -- I suspect you'll have a very cloudy beer.

>4. What sorts of yeast leaves a nice banana taste in a beer (a regular beer, not a fruit beer)? Sort of like the Austrian EidelWeiss (is that the right beer I'm thinking of?)

Well, Red Star Ale yeast is notorious for making banana esters, but in the past, has had problems with wild yeast and bacterial contamination. I've heard, from a very reputable source, that Red Star has some new products coming and that they seem to be a big improvement over past products. Some Weizens are bottled with the primary culture (most are filtered and then bottled with a lager yeast which tend to be more stable) -- if you can find out which ones are which, you can culture yeast from the Weizens that have that ester you like.

\*\*\*\*\*

Jonathan writes:

>Pardon my ignorance: what is meant by "P-Guinness"?

I think this evolved from the Lambik digest. It stands for Pseudo-Guinness.

It has been used mostly with pLambik or pKriek or pFramboise in respect for the appellations (names). True lambiks are made via spontaneous fermentation

in a small region of Belgium called the Zenne (Senne in French) valley. We

respect this fact and therefore use p-<name> to distinguish our versions made with various cultured yeasts and cultured bacterias.

\*\*\*\*\*

There has been a proliferation of advertisements on the HBD lately. Could we please try to keep this forum non-commercial? I wouldn't mind some free advertisement too, but I have been resisting the temptation.

Al.

From: bill@oilsystems.com (Bill Vaughan)  
Subject: Sour mash

Jonathan Knight asks about sour mashing--

I have done numerous batches of sour mash stout; I seem to be hooked on the stuff. I'll give you the recipe and procedure I've settled down to over the last three years, but note that this brew isn't to everyone's taste.

SOURDOUGH STOUT -- mash/extract, makes 10 gallons

MASH: 7# pale malt  
2# barley flakes  
1# rolled oats  
2# wheat flakes  
1.5# roasted barley  
0.5# black patent malt

Mashing procedure: upward infusion with acid rest and protein rest, saccharify at 155 deg F. The acid and protein rests are really feeble attempts to break down all the gums in the flaked barley and oats. Maybe next time I'll try a decoction. Mash-out at 170 deg F for 5 min or so.

Do not sparge the mash, instead cool it to 95 deg F.

Now add your lactobacillus. There are several ways to get lacto but the one I like best is to use good old L. Sanfrancisco, AKA Sourdough starter. I make a starter a week in advance by mashing a pound of pale malt in a quart of water and adding the packaged dry sourdough starter.

Add the starter to the mash at 95 F and stir. Keep it at that temp until it begins to ferment. I do this by putting the mash back in the insulated box; it holds the heat just fine. It will take quite a while to begin to ferment. When the grain starts to float to the surface and you can begin to smell it, you can start checking pH. I like to ferment the mash down to pH 3.9 for a relatively tart beer or 4.3 for a sweeter brew. Watch out - the pH drops FAST at the end of the fermentation. (This whole thing takes about 12 hours, give or take a lot. If it gets too cool it will slow down and take forever. Put a heating pad under your mash kettle in that case.)

When the pH is right, raise the mash to 170 and sparge it out. That will take a long time because it is so damn viscous. One of these days I will lick the viscosity problem, sooner if anyone has any suggestions.

Since the mash is so acid, I can sparge out as much wort as I want without ever getting any husk astringency, so I just sparge until I have 12 gallons of wort.

Now add: 12# amber extract  
14 HBU hops (I like Eroica for this).

Boil down to OG 1.072, cool to pitching temp, pitch Wyeast Irish Ale yeast.

I think it is #1084, but won't swear to it. (I am playing back this recipe from memory; I am at work and my notebook is at home.)

I like to let this brew sit on the yeast for about a month at cool temp. When it is done it should have FG around 1.020, so it is quite strong. The acid, alcohol, hops and malt play well against each other. This is NOT a session beer but I am quite attached to it.

- --Bill Vaughan

Date: 21 May 1993 21:20:01 -0400 (EDT)

From: NULL0TROOPER@delphi.com

Subject: fruit, brewing, a sidenote

My apologies for poor routing, but I understand that there has been a question about sterilizing fruit before adding it to beer. I've made a few batches of citrus wines and fruit-based liquors and would add the following suggestions:

1. blanching the fruit may be sufficient to knock down most bacteria, and is used in some home canning/freezing methods.
2. for larger fruit, combine hot water and scrubbing before pitching to a hot wort. With wine, I use bisulfite after adding sugar to the must, the day before adding the yeast. (with oranges aging in your living room and an allergy to penicillin this is NOT optional :(

I've found that fermentation often lowers the acidity of a wine must, though this should be less pronounced with beers and ales (I haven't tried it, yet). Flavor extraction from fruit can proceed slowly even at 80 proof - so producing an extract beforehand might not be a bad idea if you want a pronounced flavor.

Subject: NHC round 1 entries arrived in Denver

Whew! The unpacking is done in Denver. We have our work cut out for us; there were 840 entries logged. Not counting broken bottles and other problem entries (about 20 in all), the breakdown by category is:

|    |                 |    |
|----|-----------------|----|
| 1  | Barley Wine     | 32 |
| 2  | Belgian         | 47 |
| 3  | Brown Ale       | 32 |
| 4  | English Pale    | 56 |
| 5  | American Pale   | 58 |
| 6  | Bitters         | 36 |
| 7  | Scottish Ale    | 11 |
| 8  | Porter          | 52 |
| 9  | Strong Ale      | 15 |
| 10 | Stout           | 56 |
| 11 | Bock            | 48 |
| 12 | Bavarian Dark   | 19 |
| 13 | Dortmund/Export | 14 |
| 14 | Munich Helles   | 14 |
| 15 | Classic Pils    | 48 |
| 16 | American Lager  | 23 |
| 17 | Fest/Marzen     | 39 |
| 18 | Alt/Kolsch      | 22 |
| 19 | Fruit           | 26 |
| 20 | Herb            | 21 |
| 21 | Speialty        | 41 |
| 22 | Smoke           | 9  |
| 23 | Cal. Common     | 27 |
| 24 | Wheat           | 31 |
| 25 | Trad. Mead      | 12 |
| 26 | Flavored Mead   | 29 |

We advance only the best three from each category regardless of how many were entered. So if you entered in this region, you now know how much competition you'll have in passing round 1. Good luck to all!

There is plenty of room for extra judges. Judging will be Saturday and Sunday, June 5-6 at the Wynkoop in Denver. Two sessions each day will begin at 9:30am and 1:30pm. If you want to be involved in judging and have not contacted me, I need to know by May 25. Registration is required for judges and stewards. People who just show up on the judging days will make things more complicated for me, and I'd prefer to avoid the last-minute shuffle.

Subject: bleach and SS/treacle

the best and most complete source of info on the reactivity of various acids, salts, bases and whatever with various metals, plastics, rubbers is in the back of the Granger catalog.

for example, household bleach does not react with 304 and 316 stainless. however, no info is available on 302 and 440 although its very unlikely you will find pots or kegs made with these.

there are many other interesting items. e.g,. BEER doesn't react with much of anything (thank god) except a little with brass and polyethylene, a little more with silicon and quite severely with cast iron and polypropylene.

Now you are probably wondering about BREWERY SLOP. relax. it does not react with any of the materials tested.

honestly, the table is an array about 400x30.

tate and lyle black treacle can often be found at your fancy-pants food stores. for example, here in austin it is available at simon and david which has other stores around the country, fiesta supermarket, and also st. pat's of texas.

i have also seen treacle on the shelf of safeways in california a couple of years ago.

Subject: Re: Bottles/labels

Here's an input for you, I pick up Kulmbacher malt beer bottles. They are imported from Germany, are brown, have the porcelain tops. I buy them empty from a local German restaurant. I have about 200 now. The gaskets work for many batches, but I have 300 new ones when the time comes. (\$5-6 per 100). I boil them before bottling.

I use labels unlimited for creating great labels with graphics. I have been scanning in beer related stuff for a variety of graphics. I print using a laser and colored paper. It's easy to tell a batch by the label color. Glue stick is the easy way to go, it holds tight, and the label comes off under a minute of hot water rinse! (got to rinse the yeast anyway).

Cheers, The Braumeister in Layton, Utah

>The only problem is a tendency for the hose connections to leak, which is not too big a problem since everything is inside a small cooler.... I currently using 3/8ths inch OD tubing to connect to both sides of the cold plate with hose clamps on both connections. Is there anything else I could use or be doing to stop these blasted leaks?

You need to find out where the leak is. Maybe the fittings are not tight in the cold plate. There is nothing different about these devices as regards leaks. Mine has never leaked a drop since first setting it up. I use the same hose and clamps.

>From: bliss@pixel.convex.com (Brian Bliss)

>\* Cascades will give that funky american hop taste, if you desire, but taste unlike guinness.

Would someone kindly elaborate on this. It may be the root of my problem in trying to make a beer that "tastes like ale". Most of the homebrewed ales I have tasted have a flavor that I had written off as "extract tang" but upon tasting a few made from all grain, I began to have my doubts.

The new Miller Pale Ale has this "funky?" taste. Is there some connection?

>From: gummitch@techbook.com (Jeff Frane)

>I said that I had never seen a brewery that worried about racking wort off the cold break -- one fellow from (I think) Chicago said that I was wrong! (ooooooooooh!) and that such and such brewery there did so.

I pondered the same point and called up Ken Pavichavich at Baderbrau while producing my video and was convinced that the use of a fermenter with a conical bottom and drain, easily provides the function of removing the cold break and old yeast. This step can be resorted to at will.

I also suspect the whole discussion is irrelevant to those of us using imersion chillers as the hot/cold break is conveniently left behind in the kettle when the chilled wort is drawn off.

>From: <ferguson@zendia.enet.dec.com>

>I'm in the market for the smallest fridge that will accomodate 2 5gal  
soda  
kegs. Typically, these are about 5 cu ft of storage. of the ones i've  
seen,  
the inside is big enough if you include the freezer space. but, with  
the  
freezer in place, typically there is not enough room.

That is one of the reasons that makes a chest freezer so much more  
suitable  
for use in the homebrewery. Not only do you not have to deal with the  
freezer compartment but refers have as much useless space above a keg as  
useful space below it. Freezers are all the same height no matter how  
many  
cubic feet the capacity and the height is just perfect for kegs and  
carboys  
with air locks. There is little wasted space.

Just so happens that I bought and instaled a 14 cuft unit last week and  
have  
a PU clone fermenting in it now. Unfortunately, until my Hunter Airstat  
arrives, I is one. (The Airstat is a simple controller that makes a  
freezer  
think it is a refer.) Mine is a bit big for your apartment but just for  
reference, it holds 4 kegs, 2 carboys and a 10 gallon stainless  
kettle/fermenter and a couple cases of bottles.

>From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
>Subject: Evaporative Cooling

>Recently read some threads on using evaporative cooling for summertime  
brewing. The consensus seemed to be it was worthless in humid areas  
like Austin (where I live).

>Data: House is airconditioned.

Not so minor detail. An airconditioned house is not "humid areas like  
Austin", it is a dry environment where evaporative cooling works just  
fine.

However, I would suggest that if you have air conditioning, it would be  
far  
more effective and simple just to place your fermenter in front of the  
A/C or  
air duct.

Subject: Klages Malt/ Banana Beer

Hello:

I am an all grain brewer who has recently switched, for reasons of cost, from British Pale Malt to American 2-row. The supplier says that the american is a mixture of Klages and Harrington, and that it works well with a single-step infusion mash. The bag I got actually is labelled "50# Whole Klages". Anyway, I was concerned that the malt may not be sufficiently modified, so I have done some batches using a protein rest. This has generated the following questions:

1. Do people think that one needs to do a protein rest with Klages or Klages/Harrington? How well-modified are these malts?
2. If a protein rest was called for and I did not do one, what would be the result? Cloudiness? Poor yield? What?
3. When I do a protein rest, my sparges are very slow, as long as two hours. Are sparges usually longer with a protein rest, or with a long mash at any temperature? Traditionally I have had shorter sparges than some people (notable Miller) think I should have. Does the fact that I do single step mashes, combined with the fact that Miller loves lagers and protein rests, explain this discrepancy?
4. How do you pronounce Klages anyway? Is it German, suggesting Kla-gus? Or something else (Kla-jus? Klay-gus? Klay-jus?) This is what happens when you get all of your information from print media.

Also, someone recently asked about recipes for banana beer. My greatest success (failure?) in this area was with what was intended to be a trappist ale. I started with miller's recipe, yielding a high gravity wort, and pitched cultured chimay yeast. Since miller states that high fermentation temperatures are used to enhance ester production, I fermented near (but not, I though, TOO near) a radiator. The resulting beer was absolutely redolent of banana ester. It was completely undrinkable...almost. I am always very reluctant to throw out beer I have already payed for. Anyway, the banana-ness got a little mellower over time, but it wasn't a favorite, and I haven't tried a trappist ale since. If you do try this recipe, you might want to serve it as a black and tan with some of the chocolate stout some was discussing recently. Or with a big dollop of peanut-butter....

dave.

From: tima@wv.MENTORG.COM (Tim Anderson)  
Subject: Trip Report.

Reading of Bud in Germany, England and Ireland is enough to drive a person to drink. So I took a drive this past weekend and drank (in that order)

I live in Portland, Oregon, where good beer, including REAL ALE, is readily available. I try to do my part in keeping the supply fresh.

I had to go to La Grande, a small town in Eastern Oregon, to see my daughter perform in a play (she was spectacular, a Tony would be inadequate). I lived in La Grande for several years, and its remoteness was the main reason I left five years ago. It is 260 miles from Portland and 200 miles from Boise, Idaho. I tried to tell the locals about the signing of the Magna Charta, but nobody would believe me. When I lived there, the classy taverns had Michelob on tap, and all had varying flavors of Schludwiller and Schludwiller Light.

I had dinner at the bar in one of the better places. There was a tap labelled Portland Ale and another labelled Widmer Hefeweizen! In the cooler there were proudly displayed bottles of Sierra Nevada Pale Ale, Bridgeport Blue Heron and Guinness Extra Stout! Over in a dark corner Rod Serling was smiling at me. Well maybe not, but this good beer thing was very disorienting. My first inclination was to plant myself for the evening, but then the thought occurred, "What else might be out there waiting for me?" So after downing a pint of Portland, I decided to do a little survey. I wandered down to what had been an ordinary neighborhood tavern, dark and nondescript, but with a beautiful old cherry wood bar. I had fallen off several of its stools in years past. Surprise! A sports bar! I think they were trying to be Cheers. To their credit they had Full Sail Golden Ale and Widmer Hefeweizen on tap. I ordered a Full Sail, which came with a lemon slice (Yuck, the lemon ruined it. Made it completely undrinkable, down to the last drop.) They also had many bottles worth opening.

At this point I decided to really put the trends to the test. A couple blocks away is (dramatic pause) Marge's Tavern. Marge's would be illegal in most Third World countries. The restrooms were last cleaned in 1922. My faith in rednecks was restored when I asked what kind of beer they had on tap and

was told "We got these." The bartender pointed to three taps labelled Bud, Hamms and Bud Light. I proudly ordered a Hamms and paid my 85 cents (this is true). I drank it (this is also true). They had nothing in bottles, lot's of Industrial Swill in cans.

Well, to make a short story long, this remote backwater of a redneck town has decent beer on tap, and more importantly, people are drinking it. I believe that when Joe Six-Pack starts buying good beer, good beer is here to stay. Perhaps we'll see the day when people will be coming to the U.S. for a decent pint, and we'll be looking down our noses at those Bud-swilling Germans.

Subject: CAMRA in the USA?!

CAMRA for the USA?!

Is the US ready for a REAL grass-roots beer lovers' organization?  
We are about to find out:

Mr. Steve Hindy of the Brooklyn Brewery and some New York homebrewers have invited Steve Cox, the Campaigns Manager of CAMRA UK, to New York City on June 3-4. The subject of the meeting will be how US beer lovers can most effectively start an organization similar in scope and purpose to CAMRA in the UK.

The working meeting will take place Thursday, June 3rd at 6pm at the Marriott/Financial Center, 85 West Street, in Manhattan, just a few blocks from the World Trade Center.

There will be a beer-tasting the following day - Friday, June 4th, at the Kingston Ramada Inn in Kingston, NY at 7:30pm.

ALL interested people are actively encouraged to attend!! If this organization is to succeed, it needs a VERY broad base of support!

From: Mike Peckar 24-May-1993 1509 <m\_peckar@cscma.enet.dec.com>  
Subject: Phenolic brews --> Lambics

I've now had the opportunity to twice rescue bad batches from the jaws of the almighty disposal. For some reason -- maybe some of the more chemically active minds out there can explain this one -- Fruit juice neutralizes (or at least masks) the phenolic taste in beer which has had the pleasure of associating with one too many E. Coli.

Both times The beers were light golden ales; I think that was important. In both cases, I had waited a couple of months in hopes the off-flavors would dissipate, but to no avail. I don't remember what yeast's I used originally, but I think that is important here for several reasons

The first one was an attempt at a pilsner-like Ale. I'd just popped open a bottle and mix in two parts beer to one part Cranberry Juice. The results were quite impressive, though nothing like a real lambic. Still it was much more drinkable Sam Adam's poor excuse for a Lambic, with not even a hint of the off tastes.

The second one was much more interesting and produced a Lambic that is remarkably reminiscent of the real belgian stuff. I had left out a bottle of Cherry Juicy Juice for a while. This is a commercial juice from concentrate which is made up of Cherry, Apple, and White grape juices not necessarily in that order. The bottle had autopitched from the ether, and fermented to a slightly carbonated state. By itself, it had a wonderful champagne mouth, and a creamy taste, with all three fruits prevalent, but cherry dominating. What I did was decant this into my bottling bucket and then I added about a dozen or so 16 oz bottles of my bad brew, leaving behind as much of the dormant/dead yeasts as possible and tasted until the proportions were o.k. I also added some unfermented Cherry Juicy Juice from a fresh container to spark off fermentation again. My hopes were the less dormant natural yeasts would overpower the longer-dormant ale yeasts. Also, I stirred the carbonated beer to release as much CO2 from solution as possible without excessively aeration. My guess is about the same ratio of beer to juice as I had done before (2-1).

The results, after only four days were remarkable: A real good lambic without 6 months of conditioning, without messing with real fruit, and with wild yeasts!

Subject: soot on Stainless steel pot problem

I just got a "King Kooker" propane burner. As many of you have also found out, a home gas stove makes it difficult to get 7 gallons of wort to a boil. My problem is that after the wort boils and I turn the cooker down to maintain a nice rolling boil, the flame is very yellow (presumably because the gas/air mix is off) and soot forms on the bottom of my expensive new Stainless steel pot.

Have any others experienced this problem and is there a good solution?

- --Tony Verhulst

From: bill@oilsystems.com (Bill Vaughan)  
Subject: Decoction mash

I tried my first decoction mash yesterday and would appreciate comments on the procedure. When I'm trying something new, I always make my baseline "plain jane all-grain" brew, because I know how it comes out with various strains of yeast & hop varieties. Grain bill:  
10# 2-row pale malt  
4# light Munich  
2# wheat flakes

(This is for 10 gallons, and yes, I know it's not reinheitsgebot.)

I normally use a 1.25 quart/pound ratio in my mash (learned this from George Fix's book), but this time I doughed the grain in with 8 quarts, let it sit ten minutes, and added eight more quarts. (All water is preboiled and conditioned.) I was aiming for a strike temp of 122-124 deg but missed it and wound up at 120 degrees, probably because the mash cooled more during the dough-in than I had figured on.

Now I had to pull out the "heaviest third" of the mash for my first and only decoction. (Noonan) So how do I measure a third? Must be volume, because there isn't a heaviest third by weight. But my mash tun isn't calibrated in quarts, so I had to figure out how much was in it. Noonan claims that grain has the same heat capacity as water but only takes up 60% of the volume. (At least this is how I translate his mish-mosh of arcane -- nay, alchemical -- terminology.) So I figured I must have had 21 qts in my mash tun. Using a strainer I pulled out 7 qts of mash -- wet grain, really -- and dumped it in my decoct kettle. Now here is where I really varied the standard procedure. Knowing I wanted another 4 qt water for my normal mash, I just added it to the decoct kettle, so it wouldn't stick and scorch while boiling. This resulted in a mash that felt a little thin, but not very. It converted just fine in 10 minutes at 158 deg, then I boiled it for 15 min and put it back in the mash tun.

I was looking for a conversion temp of 153 deg but only got 146, so I had to look-look the mash tun back onto the stove and heat it to 153, whence it went in the insulated box for an hour, converted just fine, and up to 170 for mash-out. Sparge worked wonderfully well. Just the right speed. I always acidify my sparge water with lactic acid to pH 5.0, so I can sparge out as much wort

as I need without getting husk astringency. I wanted 12 gal wort but after collecting 10.5 gal there was no more sugar left in the mash, so I just topped up the brew kettle with 1.5 gal of treated water.

I added a total of 12.5 AAU of hops as follows:  
start of boil: 1/2 oz CFJ4 (8.5% AA)  
1/2 oz Spalt (4.5%)  
1 oz Saaz (3.7%)  
+30 minutes: 1 oz Spalt (4.5%)  
+50 minutes: 1/2 oz Spalt (4.5%)  
end of boil: 1/2 oz Saaz leaf hops (compressed plug)

The boil was 1 hour -- actually the propane began to run low so the last 10 minutes was more of a simmer than a boil. I let the leaf hops sit in the hot wort for 10 minutes before adding the wort chiller, chilled to 70 degrees, collected a hair over 10 gallons of cool wort and pitched Wyeast 2007 "pilsen" lager yeast. OG was 1.048, for a net extraction efficiency of 30 points/lb. This morning, one carboy had started up, but the other one (which has a couple quarts more beer in it) had not. But at least it was producing positive pressure in the blowoff hose.

I expect to ferment this beer at about 60 in my garage -- assuming the Bay Area weather turns cold as it ought to. I do not intend to dry hop. The color was pale -- no darker than my infusion mashed plain-jane, but maybe a little more orange colored.

BTW, can someone tell me what the actual specific heat and density of grain are? I guess I can measure the density myself, but measuring specific heat is beyond my abilities, and nothing in the world will convince me that it is really 1.000 as Noonan says. (except, of course, the collective wisdom of HBDers.)

Subject: New kid/local brewpubs/local suppliers

Hi-di-ho neighbors. I am a newcomer here. I just brewed my first batch. I chose an Irish Stout as I have grown fond of dark beers. I bottled it Saturday, and I am going to let it age until my baby's christening. Kind of a double christening I guess. Babies due around June 7th, so that should givvve it plenty of time to age. Side question, Would I be breaking any trademark rules if I put my name, Croft, on the label? Is Croft still brewing? Regarding brewpubs, I live in southern Massachusetts, anyone know of local brewpubs in that area? I'd like to try some other types of beer before I try to brew them. How about supply houses? I got my first kit from a supply shop in New Jersey. Just wondered if there was anything closer. One last comment, regarding Tim Murray's post about AB in Ireland. Kind of ironic, don't you think? Over in Ireland they are getting turned on by AB and here I am in America getting turned on by Guinness Stout. Oh well.

dipalma@banshee.sw.stratus.com (James Dipalma) writes:  
> I've used Bullion in my stouts with good results. Give them a try.

yep, but they definitely leave a taste that you won't find in guinness.

After a one hour boil, I can detect hop flavor from bullion, hallertau, or cascades and fuggles, and its not in line with what the real stuff tastes like. Just from taste, goldings seem to get me nearest real Guinness.

While were on the subject, I forgot to emphasize that it is important to resist the temptation to add a second dose of hops later in the boil or to dry hop.

- -----

Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU> writes:  
>Thanks to Brian Bliss for his interesting response to my question about  
>making sour mash for Guinness clones.

>  
>Pardon my ignorance: what is meant by "P-Guinness"?

Pseudo-Guinness. Just as a P-lambic is not a lambic, neither is this real Guinness.

>Also, Brian, how do you introduce the lactic infection into the bottled  
>beers?

Nature care of that one for me. Save some of your next soured batch. Beware of exploding bottles, though. By the nature of the infection (sour but not rancid, appearing late in the fermentation, more attenuative that the brewing yeast) I assume that it was lactic.

- -----

Al K (originator of the P-lambic moniker) writes:

significantly  
>increase your protein levels in the final beer. Comments?

Maybe you're right, but the technique doesn't hurt, saves times, and aids filtering during the sparge. The stuff IS too damn clear, though. (sometimes it's hard to get things backwards!) Maybe if I go back to a high-gravity boil...

>interested to hear more about the effects of mash duration on viscosity;  
mine  
>seem to get more fluid with time. Unfortunately, I can detect lager  
malt in  
>even the most aggressive stout (sulphur?), which is why I don't follow  
Miller's  
>advice. Some wheat malt is well worth considering, however.

As far as the DeWulf Cosyn's malt goes, the pale ale definitely drains  
slower  
that the Pils. My experience with mash viscosity vs. time contradicts  
yours; I also would like to hear empirical evidence on the subject.

Does anybody know for sure exactly what Guinness is hopped with?  
Is this in Jackson's book (World Guide to Beer)?  
The next batch will utilize N. Brewer & wheat malt... Maybe some of  
the wheat malt could be sparged separately, with extra hot water.  
The wheat malt has no husk to contribute to the astringency, and  
the hotter water will make any protein more soluble.

- - - - -

Tim Murray <MURRAYT@WSUVM1.CSC.WSU.EDU> writes  
>Incidentally, the Irish natives also told me that the best Guinness is  
draught  
>(no surprise there), and that the next best thing is Guinness in the can.  
They  
>also firmly believe that the way a pint is "pulled" has alot to do with  
how  
>it tastes.

It should be poured turbulently to allow the carbonation (and N2) to  
escape  
and form the creamy head, then the pressure reduced as it is topped off.  
There should be a creamy head, but little carbonation left in the beer  
itself.

To answer this question, I have actually performed a blind tasting, and  
had  
it performed on myself. The results: the Guinness poured turbulently had  
a  
much creamier head. The taste was the same.

whew!

**Subject: Fridge Question**

In stead of a fridge look for a small chest type freezer.  
They work great with a external thermostat. You maybe  
able to find one that will just hold 2 to 3 kegs. Chest type  
freezer also don't spill the cold air the way a fridge does  
when you open the door. Hunter makes a room air  
conditioner thermostat that many homebrewers have used  
to control a freezer to fridge temperatures

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Hops, Fruits/Racking off the trub/London bottle shops

Spencer writes:

"I've noticed that dry-hopping often results in a "grassy" or "herbal" taste that diminishes quickly with time. Sort of like chewing on raw hops."

I actually find this more with large amounts of certain bittering hops; Hallertauer in particular. My best guess is that this could be due to chlorophyll content, which is responsible for the green colour. My home dried hops (at room temperature) go brown without seeming to lose their aroma, presumably because I use neither forced drying nor sulphur dusting.

Lee writes:

"My current understanding of racking off the trub is that one should pitch into the chilled wort and rack a few hours later. This gives the yeast the opportunity to use some component of the trub which it needs in the beginning stage of fermentation and not provide the materials that the yeast uses later in fermentation to produce fusel alcohols."

This is a perennial issue and I don't have the definitive answer either. However, my understanding of the chemistry is that many fermentation byproducts, such as fusel oil and esters, are produced during the yeast respiration phase. At this point, the yeast requires oxygen to reproduce, most homebrewed worts contain suboptimal levels of dissolved oxygen, so it's a reasonable bet that the yeast will attempt to extract oxygen from the trub, and produce fusel oil in the process. Whether it will show more or less preference for the trub is one of HBD's great controversies. For the yeast to metabolise trub during the secondary requires it to switch from anaerobic to aerobic fermentation (yes?), which strikes me as unlikely under normal conditions.

Does anyone know of any decent bottle shops in London, specialising in imported beers? E-mail responses might be best.

I'm not sure about this. Putting the fermenter in front of the A/C, you get a blast of cold, followed by warming, followed by a blast of cold, .... Sitting in the corner with a wet T-shirt on, you get continual gentle cooling. (Of course, the difference may be irrelevant, given the thermal mass of 5 gallons of beer.)

Brewmasters Pub proudly announces the 3rd Annual Southport Beer Festival. The festival is to be held in the Bier Garten at Brewmasters Pub on June 19th between 2:00pm and 9:00pm. Brewmasters is located at 4017 80th St in

Kenosha, WI (Phone: 414-694-9050), for directions send private email. The purchase price is \$14/advance or \$16/door (advance purchase guarantees

commemorative mug)and includes unlimited beer tasting. For those requiring

solid nutrition you will be happy to know that a pig will be roasted. The following list of breweries are to participate (there may be some last minute changes):

Adlerbrau ----- Appleton, WI  
Boston Beer Co.(tm) --- Boston, Mass  
Brewmasters' ----- Kenosha, WI  
Broadripple ----- Indianapolis, IN  
Calumet Brewery ----- Chilton, WI  
Capital ----- Middleton, WI  
Cherryland Brewing ---- Sturgeon Bay, WI  
Chicago Brewing ----- Chicago, IL  
Lakefront ----- Milwaukee, WI  
Sprecher Brewing ----- Milwaukee, WI  
Water Street Brewery -- Milwaukee, WI  
Weinkeller ----- Chicago, IL

For anybody wishing to stay overnight a list of hotels is available, send request via private email.

From: Bud and European drinkers 25-May-1993 1011 -0400 <ferguson@zendia.enet.dec.com>

**Subject: The rise of Bud in Ireland**

There has been a lot of talk about the rise of the popularity Budwieser beer in Ireland and europe in general. I've been to Ireland twice recently

and Germany/Austria recently as well and this is the way my Irish friends have put it. When the warmer weather comes, the Irish look for brew that is lighter, and Bud has that appeal. Many Guinness drinkers switch to Bud

for the summer, and when the cooler weather returns, back to the Guinness.

When the Irish workers get home at 5:30pm, they still have 5 hours of day light left! The sun finally sets around 10:30pm or so. On the other hand,

in the winter it is light by 9am and dark by 4pm (November anyways).

Perhaps

this extended light period during the summer has an effect on the choice of brew too.

From: roman@tix.timeplex.com (Daniel Roman)  
Subject: Manhattan Brewing Company

I've recently been made aware by a friend that the Manhattan Brewing Company has reopened (last week?) under entirely new management (it closed in 91). They produce up to six different types of beers and ales on premises and the theme there is beer. Even the food makes extensive use of beer in the recipes and/or is used to compliment the different beer styles. The address is 23 Watts St., between Thompson and Broadway I believe.

I have not been there yet but I know someone who knows the Manager so this info is 2nd or 3rd hand. I hope to get there soon, anyone work in the Canal St. area of NYC willing to do a scouting mission?

Also, does anyone have the address of the fellow who keeps the publist file on sierra? I seem to have misplaced it. I'd like to make sure he gets this updated info.

From: man@lcwdwl.att.com  
Subject: Sparge efficiency relative to flow rate

Subject: Re: efficiency and sparge rate

This past weekend I experimented with my sparge rate to see if speeding it up would result in reduced yield. I normally make 12 to 13 gallon batches in a converted keg mash tun with stainless false bottom. I always have to control the flow with a valve or I would sparge 15 gallons in 20 minutes. I usually restrict the flow to force the time to 2.5 to 3 hours. At this rate, my yields were generally 27-30 pts/lb/gal. I used a tried and true recipe for a session beer - Neshanic Bitter (1.039). This time the sparge lasted only one hour to claim 15 gallons. I boiled it down to 13+ with a OG of 1.040. My yield was 29.7 which I am quite pleased with. I will continue to experiment with this sparge rate.

For the recipe hungry:

Neshanic Bitter (Recipe for 13 gallons)

16.0 lbs DeWolf-Cosyns Pale Ale  
.9 lbs DeWolf-Cosyns Cara Munich  
.6 lbs DeWolf-Cosyns Wheat  
8.5 gal mash water @ 175 F (a little to hot for this much grain, try 5 F less)  
1 Tbsp gypsum in mash. Mash for 1 hour. Recycle 1 quart.  
8.5 gal sparge water @ 180 F. Acidified with 10cc 88% lactic acid.  
75 min boil  
22.4 AAU Northern Brewer Whole Hops (60 minutes)  
Counter-flow chilled  
Wyeast Chico (second generation)  
Fermenting @ 65 F.

Misc:

Grains weighed on Hobart deli scale.  
Grains cracked in roller mill.  
SG derived from refractometer, confirmed with hydrometer.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Brewing Techniques

My issue of Brewing Techniques came yesterday. Looks pretty good, I think I'll spring the \$24 to help keep it in business. In this issue:

"Factors affecting hop production, hop quality, and brewer preference," A. Haunold and G. Nickerson

I haven't finished this one, but it includes some gas chromatograms showing "hop oils" in a few varieties.

"Belgian malts: some practical observations," G. Fix

George does test batches. Includes charts with color, diastatic power, etc. Conclusion: the specialty malts are unique, the regular malts are very good, with slight flaws.

"Reinheitsgebot and the fifth ingredient," M. Schiller

Bacteria and how to keep 'em out.

"Thinking about Beer Recipe Formulation," D. Richman Darryl describes how he put together his award-winning "Bock Aasswards" recipe.

(Side note: it claims here he has a Bock book coming out soon.) I would like it if this became a (semi-)regular feature, probably with various contributors. (Hint: send in your contributions. I've seen some HBD postings that would do nicely in this slot.)

"Spreadsheet for Recipe Design," K. King

Haven't read it yet.

Articles are classified as "Feature" (cover story, 1st above), "Technical Articles" (2 & 3 above), and "Brewers' Forum" (4 & 5 above).

Columns (and therefore regular features, I assume):

"The troubleshooter," D. Miller

The obvious thing, but more in depth than the "prof" in Zymurgy.

"Brewing in Styles," R. Bergen

(This column will feature "guest brewers".) This month is American Wheat Beers. Talks about mashing & sparging techniques, as well as stylistic points. Some points aimed specifically at the professional (microbrewer) audience, e.g., reference to lauter tuns with rakes.

The letters section, "Technical communications," looks very much like some of the better articles in the HBD (and includes a couple of HBD regulars in this issue).

All in all, a good effort. This single issue has almost more information content than a whole year of Zymurgy! Well, maybe I exaggerate. And Zymurgy has its points, too: a profusion of recipes, a chatty style, and lots more ads. (I assume this will change.)

Brewing Techniques has a much sparer, cleaner, more professional "look" to it, which is appropriate to a publication of this sort. It's very readable, and shows good attention to look as well as content. Of course, there were a few typos, but not nearly as many as some other brewing magazines I could mention.

[Imagine standard disclaimer here.]

Actually, immersion chillers do not give a well-defined cold break due  
to the more gradual temperature drop.

Subject: Re: efficiency and sparge rate

Inm HBD #3321 you write:

>Is there a relationship between extraction efficiency and  
>sparge rate. I seem to remember some previous  
>dialog on this but don't remember what the concensus was.

Chuck: I have sparged a 5 gallon batch (collected 6.5 gal) from less than 20 minutes to over 90 minutes. I have not noticed much difference in the efficiency. Now, however, with a poor crush or poor lauter geometry I have seen wide variations in my sparge efficiency. Actually, I don't know much about geometry other than I typically get 100% of the expected extract with my two rigs (false bottom plastic bucket with drum tap, and a 1/2 bbl keg and a 8" slotted copper ring for the filter - that is my new, fancy, 10 gal brewery). I do have experience with poor crushes: ones done by a coffee grinder (lots of whole grains and flour) lauter middling ok, but poor extract, ones done by a roller mill set too close: lots of flour, incredible slow sparge and excellent extract. A proper crush with a roller mill (or corona) lauters very fast and I still get 100% extract. BTW, the corona will give you more flour and a slower sparge, but other than that does a very credible job of crushing grain when set properly.

If you have poor extract rates and suspect your geometry you can try the technique (I can't remember who tried this first, I think maybe Martin Lodahl) where you drain the first runnings, add all the sparge water, stir, let settle and drain again. that should remove any geometrical considerations (channeling, etc.)

Cheers!

From: gummitch@techbook.com (Jeff Frane)

**Subject: Re: Galanga**

Lord knows why anyone would put Galanga into a brew, but... As has been pointed out, galanga is used in southeast Asian cooking, primarily Thai and Vietnamese. It is a relative of ginger (so it is NOT a root, but a rhizome), but it is MUCH MUCH more expensive. It is available fresh in any Vietnamese grocery store, but the odds are a beverage recipe really requires dried, powdered galanga. In this form, it's more likely to be called "laos" (like the country). Although related to ginger, it doesn't taste at all like it, and ginger really wouldn't be a substitute.

And, come to think of it, dried galanga/laos isn't all that expensive, just the fresh stuff.

And while you're in there rooting around, try to find me a supply of kaffir lime peel (dried).

>Have any others experienced this problem and is there a good solution?

I learned this trick in boyscouts while backpacking.  
Cooking on an open fire seems to ALWAYS accumulate soot on the  
bottoms of your pans. The solution? Place a thin film of dish  
detergent on the pan bottom. Although, the soot still  
accumulates, it washes off easily with water. (Of course you  
are going to have to scrub real well with steel wool or something  
similar to remove the soot that has already accumulated... but  
after that, if you use this method, its easy street.)

From: Ulick Stafford <ulick@davinci.helios.nd.edu>  
Subject: Bud in Ireland

In hbd1147 Tim Murray mentioned seeing lots of empty Bud cans on a train being drunk by Irish Football fans. There is much that should be known about this. Firstly, anyone who has travelled by train anywhere knows that the selection of beers can leave a little to be desired (it is interesting to note that the selection improves alot when crossing the Canadian border at Port Huron/Sarnia, but that is another story). Secondly, Budweiser produced in Ireland (by Guinness at the Smithwicks plant in Kilkenny) has been acclaimed by Americans who have drunk it as tasting like a beer (as agianst how it tastes here). It is produced to normal Irish strength (4.3% - a bit weker than here), which probably improves its balance. Thirdly. It is normally priced (in cans anyway) the same or cheaper than other lagers, and it is possible it was being drunk because it was cheap.

Subject: SS reactivity

Don writes:

>the best and most complete source of info on the reactivity of various  
>acids, salts, bases and whatever with various metals, plastics, rubbers  
>is in the back of the Granger catalog.

`Fraid not Don... a more complete source of reactivity is in the back of  
the Cole-Palmer catalog, but I won't go so far as to say that it is the  
most complete source.

>for example, household bleach does not react with 304 and 316 stainless.  
>however, no info is available on 302 and 440 although its very unlikely  
>you will find pots or kegs made with these.

According to the Cole-Palmer reactivity chart, both "Chlorine Water" and  
"Sodium Hypochlorite (<20%)" are listed as "Moderate Effect" for 316 and  
304 Stainless Steel and "Severe Effect" for 440 Stainless Steel. While  
we're at it, it also says that there is a "Severe Effect" with "Cast  
Bronze,"  
"Cast iron," "Aluminum" and "Carbon/Ceramic". Copper is not listed, but  
I strongly suspect that it, too, is reactive with both "Chlorine Water"  
and  
"Sodium Hypochlorite (<20%)."

>there are many other interesting items. e.g,. BEER doesn't react with  
>much of anything (thank god) except a little with brass and  
polyethylene,  
>a little more with silicon and quite severely with cast iron and poly-  
>propylene.

Strange, in the Cole-Palmer chart, "Beer" has "No Effect" on  
Polyethylene,  
Silicon or Polypropylene.

>honestly, the table is an array about 400x30.

Honestly, the Cole-Palmer table is about 550X40, but it still is not the  
most complete I've seen -- just the most complete I have here at arm's  
length.

From: boomer@sylsoft.com (Richard Akerboom)  
Subject: Death of Rumor--There is NO Bud in Germany

There is NO Anheuser-Busch Budweiser in Germany. A message a few weeks ago started this rumor, but the author was confusing the original, Czech Budvar (called Budweiser in German because of the German name for the city) with the cheap imitation we get here in the states. I emailed the author to find out, and he now realizes his mistake. This also explains the high price he quoted.

If Anheuser-Busch were to import US Bud, they would have to change the name, as the Czechs have the rights to the name in Europe. At least until A-B buys them out, which I hope never happens.

>  
> Have any others experienced this problem and is there a good solution?  
>  
> - --Tony Verhulst

Looks like you were never in the Scouts, Tony 8-) The soot problem can  
be  
solved  
by dampening a bar of soap and then rubbing it over the bottom and sides.  
When  
you cleanup 95-100% of the soot will come off since it is "stuck" to the  
soap  
and not to the pot.

Thanks to all who replied about my 1st batch problems. At the suggestion  
of  
several folks I took another gravity reading. The O.G. (@90f) was .1112  
the reading I got a few days ago was .1042(@74f) (I wish I could find my  
temperature adjustment chart). The feeling at the local brew shop is  
that it  
is close to finished although it still tastes a little sweet. I am  
planning  
to take another reading tonight and will probably bottle tomorrow.

Thanks again for the advice.

From: John Cotterill <johnc@hprpcd.rose.hp.com>  
Subject: Fermenter Geometry/Sierra Nevada

- 1) I have been doing some experiments fermenting in 5 gal glass carboys and 5 gal SS soda kegs. I have found that the beers in the soda kegs all take much longer to ferment out. I think it is do to the geometry. Has anyone else noticed this? I have heard of some people fermenting in Sankey (sp?) kegs. I dont know what a Sankey keg is, but I am guessing that is is a regular beer keg. If so, how in the heck do you make sure they are clean? I want to use SS especially since I can use pressure to transfer the beer instead of syphons. And a standard beer keg has a geometry similar to a carboyu. Anyone have any experience fermenting in Sankey/beer kegs?
- 2) I have spent the last year trying to make a Sierra Nevada PA clone. I really have not even come close although the attempts have resulted in some mighty tasty beers. I have a pretty poor sense of taste which is complicating my efforts. It seems to me that Sierra Nevada Pale Ale uses lots of flavoring hops with low bittering hops - just an un-educated guess. Can anyone shed some light on the hop profile for SNPA and perhaps even suggest a recipe.

Thanks!

**Subject: Soot on stainless**

Here's a little trick I picked up in Boy Scouts many years ago. To make soot easy to remove from the outside of pans that have been used over a campfire (or a yellow flamed Cajun Cooker), coat the outside of the pan with soap. You can either coat it in liquid dish detergent or rub a bar of soap all over the outside. The soot will simply rinse off with the soap at cleaning time.

From: Paul Boor <PBOOR@beach.utmb.edu>  
Subject: kegs in fridges

In reference to fridges or freezers and the cold air falling out when you open the door, I finally broke down and installed a stem tap through the door of the keg fridge. It is the thrill of a lifetime, drilling a hole through the fridge door! It was so much fun (and the tap looked so much more professional than fumbling inside with the hoses) that I sprung for two more. I justify the cost by the electric I will save during the 10 month Galveston summer, not opening the door to draw a beer.

From: jdg@cyberspace.org (Josh Grosse)  
Subject: Sparging efficiency

In HBD 1148, chuckm@pbn73.cv.com asked about the relationship between sparge time and extract efficiency.

My answer using English 2-row pale malt:

45 minute sparge = 27 pts / gallon.

2.5 hour sparge = 34 pts / gallon.

I've been using a grain bag in a BruHeat as a combined mash/lauter tun. I have found that I get the clearest run-off and slowest drain rate by lowering the level of wort until the grain bed compacts. Recirculating before this happens has no effect. Once the grain bed has compacted, it clears the runoff almost instantly. Then, I recirculate. With a compact grain bed, it takes a long time for the sparge to complete. I pre-acidify to 5.5-5.7 with 88% lactic acid.

Last fall, Spencer Thomas and I got 33 pts / gallon using a recirculating mash system. I don't have the money for such a system myself right now, so I'll read a book (or catch up on a week's worth of HBDS) while sparging.

Subject: Beer Bread with Machine

Kim Kiesow asks if anyone has made beer bread with a bread machine:

Yes. My wife makes it all the time. She just substitutes some of my homebrew for the water in the recipe, but she microwaves it first. This is mainly to warm it up because the machine wants warm water (although I have yet to figure out why because you can delay the bread start for 12 hours or more). The type of beer to use depends a lot on the type of bread you want. But very bitter beers will make the bread a bit bitter. My favorite has been a dark rye made with Porter. To make the rye dark, she adds cocoa powder.

Subject: Sweetport recipe and Hoegaa

Subject: Sweetport recipe and Hoegaarden recipe help.  
Hi fellow brewors!

A couple of quick questions for you all. Has anyone brewed up Mike Ligas's recipe "Sweetport Porter" from The Cat's meow II, 5-45? The recipe says it is for six gallons, but the comments state that the author generally is an all grain dude. So... does this mean mix up six for a full wort boil that boils down to apx. five, or does it mean the actual volume of wort after the boil is six gallons??

Also... I have grown quite enamored of the coriander-orange peel flavor of Hoegaarden "White" from Belgium. The current fruit beer thread has me really itching to brew up something very similar. I have seen Papazian's recipe in TNCJOHB but it is all barley malt based, and my memory is not what it used to be, but I'm sure that Hoegaarden is a wheat beer. I have seen "Grand Cru" kits from Brewferm, but the kit thing makes me a little sceptical so any advice on reproducing this lovely brew would be most appreciated.

Thanks... Steve Lovett

Date: Tue, 25 May 93 18:24 EDT  
From: tom@kalten.bach1.sai.com (Tom Kaltenbach)  
Subject: Porter recipe

As a result of a private request by Keith Schwols, I am submitting the recipe for a beer that won first place in the Porter category in last month's AHA-sanctioned competition held by the Upstate New York Homebrewers Association (Rochester, New York). I've included my brewing notes, just for kicks.

"Independence Porter" by Tom Kaltenbach (5-gallon recipe)

6.6 lbs Munton & Fison amber malt extract  
0.5 lbs Munton & Fison light dry malt extract  
0.5 lbs chocolate malt, crushed  
2.5 oz Cascade hops pellets, boiling (55 min) (note: for 2 oz, alpha = 5.4; for 0.5 oz, alpha = 4.7)  
0.5 oz Hallertauer hops pellets, finishing (steep during chilling)  
2 tsp gypsum  
1 pkg Whitbread dry ale yeast

Brewing notes:

The chocolate malt grains were crushed and added to approximately one gallon of water and slowly heated. Before a boil was reached, grains were removed and sparged through two strainers, (one coarse and one medium). The malt extract, gypsum, and boiling hops were added and boiled for 55 minutes. About 15 minutes from end of boil, yeast was rehydrated by standard method [note: standard method consists of removing 1 ladleful (approx. 1/4 cup) of boiling wort and diluting to 1 cup with cold water in a sanitized 2-cup Pyrex measuring cup. It is then cool enough to add the yeast immediately. The Pyrex cup is covered with plastic wrap, sealed with a rubber band.] At end of boil, immersion wort chiller was placed into brewpot, the finishing hops was added, and the brewpot was removed from the heat. The pot was immediately transferred to the sink and the chilling begun. The brewpot lid was placed over the chiller and the gap between pot and lid was sealed with plastic wrap. After chilling for approximately ten minutes, the wort was transferred to the primary, straining out the hops pulp in the process. Wort was diluted to five gallons with jug-aerated water. [Note: jug-aerated water refers to the following: cold tap water is added to the fermenter 1/2gallon at a time to make 5 gallons. Each 1/2 gallon is shaken vigorously for 30 - 60 seconds in a sanitized plastic gallon jug to aerate. This may also help dechlorinate the tap water.] Some cold tap water was blended with warm to produce a final temperature between 65 and 70 degrees in the fermenter. The yeast was pitched immediately. The original gravity was measured to be 1.060 at approx. 67 degrees --> 1.061 corrected. Fermentation was carried out at approximately 62 degrees. Primary fermentation continued to 18-Nov-92, when beer was racked to the secondary fermenter. Batch was kegged on 7-Dec-92; final gravity: 1.015 @ 60 degrees --> 1.015 corrected. Alcohol content was computed to be 6.0375% by volume, 4.83% by weight.

From: "Tom Childers" <TCHILD@us.oracle.com>  
Subject: secondary fermentations and fruit

In HBD 1146, Bryan Kornreich asks

> How on Earth do you press your fruity wort (to get the juice out of the pulp)  
> with any hint of sterility.

I keep my (large wooden) spoon and strainer in the pot during the end of the boil to sterilize them. Since the Wheat Berry recipe used a partial boil, you can just take the implements out, set the strainer on the funnel, and start pouring the wort. When the strainer fills with hops and fruit, I press it with the spoon to extract the last bit of fruit juice, then toss the strainer contents and repeat the process until all of the wort is in the carboy. Then I slap a clean cork in, let it sit for a few hours to get to pitching temperature, and add about a quart of yeast starter.

By the way, I find that sterility is not a huge issue when I use big yeast starters. You can never maintain sterility in your cool wort - bacteria are falling into the stuff at the rate of hundreds or thousands per minute. Eventually, the yeast will crowd the bacteria out. However, if you pitch a small yeast culture, then the bacteria have enough time to create off-flavors before losing the race. I build up a very active starter, and primary fermentation is generally in full swing within a few hours.

(Of course, I do keep things very clean, and sanitize the fermenter, siphons, bottles and caps before using them. I haven't had a pedococcus infection yet, knock on wood. Remember, people have been making beer for thousands of years...)

> would it be a good idea to puree the raspberries and blackberries before adding them in order to avoid the pressing step?

Pureeing the fruit should work fine, although you may get a cloudier beer from all of the little pieces of fruit skin in suspension. You might want to thaw the frozen berries first :-)

From: des@pandora.swindon.ingr.com (Desmond Mottram)  
Subject: Czech Budweiser

In HBD recently Richard Akerboom wrote about Czech Budweiser. This is IMHO

one of the world's finest beers. Richard adds:

>  
> If Anheuser-Busch were to import US Bud, they would have to change  
> the name, as the Czechs have the rights to the name in Europe.

Not in all European countries. In many cases A-B got there first. Here in the UK both companies can use the name.

> At least until A-B buys them out, which I hope never happens.

It will happen, make no mistake. A-B are out to get the Czech company. I believe they already own 30% and are continually on the look out for ways to increase their ownership. You can try lobbying A-B but do you really think you will get anywhere? They will mouth all kinds of platitudes, but when they get it they will kill the beer. So enjoy it while you can, it really is a SUPERB beer and it won't be here for ever.

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Re : Racking off thee trub

Yesterday, I wrote this:

"However, my understanding of the chemistry is that many fermentation byproducts, such as fusel oil and esters, are produced during the yeast respiration phase. At this point, the yeast requires oxygen to reproduce, most homebrewed worts contain suboptimal levels of dissolved oxygen, so it's a reasonable bet that the yeast will attempt to extract oxygen from the trub, and produce fusel oil in the process."

This relied on memory and is inaccurate; apologies for the confusion.

With further reading, precursors to these byproducts are formed, during both the lag and respiration phases. Yeast does not extract oxygen from trub, it uses the unsaturated fatty acids as an alternative to oxygen for growth. The net effects of this alternative pathway remain controversial.

From: G.A.Cooper@qmw.ac.uk (Geoff Cooper)  
Subject: Guinness, Starter OG, wine acidity

Conn Copas <C.V.Copas@lut.ac.uk> writes:

>I find (British) N. Brewer works great in stouts; it definitely provides  
>flavour as well as bitterness when boiled an hour, unlike Hallertauer.  
Better,  
>if you are partial to fruit stouts, consider some Bullion for their  
>blackcurrant character. Unfortunately, these are being phased out here,  
and I  
>don't know of a suitable replacement. I actually find that if I use  
enough of  
>our cruddy, local Goldings, I also get blackcurrant. Conclusion? I am  
either  
>being sold mislabelled Bullion (unlikely, as they have Goldings aroma),  
or the  
>two varieties have something in common.  
...  
>...Unfortunately, I can detect lager malt in  
>even the most aggressive stout (sulphur?), which is why I don't follow  
>Miller's advice. Some wheat malt is well worth considering, however.

Brian Bliss <bliss@pixel.convex.com> asks:

>Does anybody know for sure exactly what Guinness is hopped with?

Although Guinness might have used bullion in the past, bullion has not  
been  
produced commercially in the UK since the 1987 crop, and is no longer  
available (if someone in the UK sold you some recently they were old). As  
a  
data point: when I last enquired (two years ago) Guinness were using  
Target  
hops, a high alpha (10%-12% depending on season) hop which doesn't seem  
to  
give too much aggression with its bitterness. It has a respectable aroma  
also  
and is gaining popularity with many commercial breweries. The choice by  
Guinness is based on the price per unit of alpha acid - that is, it is  
cheaper to obtain their bittering by using that hop rather than others;  
If  
another hop were cheaper they would use it (assuming it didn't adversely  
affect the flavour). No altruism on their part.

Further data: the 1992 UK hop crop, in Zentner, for some varieties was  
Target 47,396  
Challenger 12,866  
Northdown 11,977  
Goldings 8,965  
Fuggles 8,124

Northern Brewer was in 10th place with 347 Zentner, and the total  
production  
was 96,417 which is fairly typical (1991 was exceptional with 120,333)

I also recall that Guinness use a high proportion of 'lager malt' in  
their  
grist for reasons of economy too (I can't find my notes confirming this  
so

don't take that as gospel yet). It is simply that lager malt is cheaper than pale. In the small quantities that I purchase, lager malt costs 405.00 per tonne and pale costs 415.00 per tonne (crystal 425.00 per tonne, Roast Barley 385.00) - prices in pounds sterling.

\*\*\*\*\*

On the subject of Guinness, I shall refer back to the discussion about their thingy in the bottom of the draught guinness in cans. Al K. finally scotched this momily but his description was not quite complete. In fact the plastic chamber, which has a little hole in it, is totally empty when it is put in the can. (No I don't meean a vacuum, I mean gas at atmospheric pressure OK?)

The system works because the pressure in the can exceeds atmospheric pressure (remember the pssst when you pull the ring?). The can is filled with beer that is cold enough (0C to 1C) to retain sufficient condition and an oversize can (440ml beer in 500ml can, say) is used. They also "dose" the beer with extra nitrogen (less soluble and finer bubbles). Once the lid is on, (and the beer warms up) gas comes out of solution to create the pressure in the can. The pressure in the can and inside the chamber reach equilibrium forcing beer (and gas) into the device through its little hole. Once the can is opened, the resulting drop in pressure forces this beer back out of the chamber through the tiny hole. The shock of passing through this tight constriction creates small stable bubbles which rise through the liquid acting as centres where other bubbles form.

Clever really. The last remaining problem was finding a way to purge oxygen from the whole system (hence, or otherwise, the nitrogen momily?).

\*\*\*\*\*

Talking of momilies, Jack S. descibed me as 'a momily buster in the bud'. Now that we have been told what a momily is, I know what I was being accused of. But then again if Jack knew me better he probably wouldn't think of me as being 'in the bud'.

The above happened when I asked about the rationale for using starters with SG 1.020, which appears to be the received wisdom on this digest. I agreed to summarise the responses, but unfortunately I have little to report. The most promising response was from Kinney Baughan (quoting Dave Logson as) saying that it is "necessary only from the point of view of efficiency of reproduction

of the yeast."

Perhaps I shall carry on looking at this one for a while, but lets have a few data points. In my descriptions for making culture media, only two values seem to appear; if you are to use (hopped) wort agar one uses SG 1.040 (hopped) wort with 1.5% agar; if you choose to use MYGP (or similar) broth/agar then (I calculate) the SG is about 1.005.

\*\*\*\*\*

Bruce <NULL0TROOPER@delphi.com> writes

>I've found that fermentation often lowers the acidity of a wine  
>must, though this should be less pronounced with beers and ales (I  
>haven't tried it, yet).

On the contrary, under normal conditions fermentation increases the acidity (and lowers the pH) of wine must. This increase is typically of the order of 1 ppt (as Tartaric). The exceptions are when the must is extremely high in acid at the start (eg >12ppt), or if there is a high proportion of malic acid present and the particular strain of yeast being used can ferment malic acid. There are only a few of those strains available to the home brewer and it is very unlikely that one will be used (and then they only use about 20-25% of the available malic acid)

As for beer, one might expect a pH drop from 5.5, say, to below 4.5 (after which the activity of a number of bacteria is inhibited - fortunately for us)

\*\*\*\*\*

And finally, I was recently in central Florida and suffered the shock in the supermarkets of finding that they had yards and yards of chilled shelving all containing the same beer - they just had different names: Bud, Bud Dry, Bud Lite, Michelob, Michelob Dry, Miller, Miller Lite, Coors, Pabst ... etc. I was attempting to overcome the experience, when I spotted an oasis in the corner - there were a couple of six-packs of Carlsberg Elephant. A beer I know and I selected that one without hesitation - no choice really. If you haven't tried it I suggest you do, if you come across it.

Regards  
Geoff

From: Michael\_Genier.Wbst139@xerox.com  
Subject: An easy fix for soot on Stainless steel pot

"soot forms on the bottom of my expensive new Stainless steel pot. "

Dear Tony Verhulst

This problem is best solved by a very simple method that I learned while a Boy Scout. The problem of soot and the burnt outsides of pots and pans is epidemic on a campfire. The method is to gingerly wipe on ordinary dish soap on the outside of your pot. On a camp fire may be half way up the pot, but in your case maybe just the bottom. The soap forms a non flammable barrier, that attracts the soot. When you clean your pot, the soot will come off with very minimal scrubbing. P.S. don't forget that the soap is on the bottom of the pot and set it on your counter space, in the woods it dosen't hurt the dirt.

Good Luck --Michael Genier

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: California Common Beer

I just bottled my first attempt at a California Common or "steam" beer yesterday and I noticed a definite DMSO odor in the beer (the cooked corn type odor). Will bottle conditioning help to reduce this over time or will I just have to get used to it. What causes this (I've heard that this is generally due to slow wort cooling, but as this was an extract recipe which normally is cooled rapidly as it is transferred to the carboy containing cold water, I doubt that the cooling is any different from my other extract recipes.)

The effect is not extremely unpleasant, just unwanted.

Thanks,

Anthony Johnston

P.S. In response to the current controversy of racking off of the trub, I have recently made two batches of beer (stout and steam) where I did rack mostly off the trub, but went ahead and pitched the gallon or so remaining with the trub to see if there would be a difference. All 4 beers are now in bottle, so I will report results in a few weeks.

From: pascal@netcom.com (Richard Childers)  
Subject: Lambics - Is Belgium Unique ?

Quoting a recent thread on lambic production ...

"From: Mike Peckar 24-May-1993 1509 <m\_peckar@cscma.enet.dec.com>  
Subject: Phenolic brews --> Lambics

"The second one was much more interesting and produced a Lambic that is remarkably reminiscent of the real belgian stuff. I had left out a bottle of Cherry Juicy Juice for a while. This is a commercial juice from concentrate which is made up of Cherry, Apple, and White grape juices not necessarily in that order. The bottle had autopitched from the ether, and fermented to a slightly carbonated state. By itself, it had a wonderful champagne mouth, and a creamy taste, with all three fruits prevalent, but cherry dominating. What I did was decant this into my bottling bucket and then I added about a dozen or so 16 oz bottles of my bad brew, leaving behind as much of the dormant/dead yeasts as possible and tasted until the proportions were o.k. I also added some unfermented Cherry Juicy Juice from a fresh container to spark off fermentation again. My hopes were the less dormant natural yeasts would overpower the longer-dormant ale yeasts. Also, I stirred the carbonated beer to release as much CO2 from solution as possible without excessively aeration. My guess is about the same ratio of beer to juice as I had done before (2-1)."

"The results, after only four days were remarkable: A real good lambic without 6 months of conditioning, without messing with real fruit, and with wild yeasts!"

"From: bliss@pixel.convex.com (Brian Bliss)  
Subject: defending my recipe

">Also, Brian, how do you introduce the lactic infection into the bottled >beers?

"Nature care of that one for me. Save some of your next soured batch. Beware of exploding bottles, though. By the nature of the infection (sour but not rancid, appearing late in the fermentation, more attenuative that the brewing yeast) I assume that it was lactic."

I am curious ... has anyone ever tried to induce a lambic in the Bay Area, or any other area which is known to harbor a particular type of yeast in the air ?

Are 'lambic' bacteria distinct from 'lactic' bacteria, and if so, how ?

The Bay Area, for instance, and California in general, was where  
sourdough  
was evolved, and I have been given to understand that the cause of sour-  
dough's sourness is lactobacillus acidophilis. So, making an intuitive  
leap  
here, I have to wonder ... has anyone tried this ?

Where would I get a pure lactobacillus acidophilis culture to experiment  
with ?

Is the sourdough made in Alaska different from that made in California ?

Is there a potential for an explosion of lambics along the West Coast ?

Comments, corrections, feedback, welcome, as always.

Date: Wed, 26 May 1993 10:12:20 -0500 (CDT)  
From: tony@spss.com (Tony Babinec 312 329-3570)  
Subject: snpa revisited

Here is some info and speculation on Sierra Nevada Pale Ale and how one might try to clone it. SNPA is surely worth emulating, yet it has an elegance of flavor that is a bit elusive. I can't claim to have cloned it, but am iterating toward it!

Note that Sierra Nevada Draught Ale is SG 1.048 while Sierra Nevada Pale Ale (bottled) is SG 1.052. The Draught also tastes a bit sweeter to me than the bottled.

Malts used are U.S. 2-row, dextrin malt (U.S. cara-pils), and crystal malt. I don't know the proportions used at Chico, but it seems to me that you shouldn't be too heavy-handed with the crystal malt, as I don't find a pronounced caramel flavor in SNPA, in contrast to, say, Mendocino's Red Tail Ale.

Hops are Perle for bittering and Cascade for flavor/aroma. Perles are a fine general-purpose medium-alpha bittering hop, while Cascades are signature hops in SNPA, Liberty Ale, and other American pale ales.

Yeast is Wyeast "American" ale or bottle-cultured SNPA.

An all-grain recipe for a 5-gallon batch goes as follows (your mileage may vary):

8 pounds U.S. 2-row pale malt  
1 pound U.S. cara-pils  
0.5 pounds crystal malt 80L

0.8 ounces Perle (alpha 6.5) at 60 minutes  
0.5 ounces Cascade (alpha 6.3) at 30 minutes  
0.5 ounces Cascade (alpha 6.3) at 2 minutes  
0.5 ounces Cascade final addition (see below)

yeast is Chico yeast

In the mash, aim for a starch conversion temperature of 153 - 155 degrees F for some residual sweetness in the beer. As for the hop schedule, factors such as hop freshness and vigor of boil will affect the final beer. To my palate, SNPA is a medium-bitter beer, not high-bitter beer, so something like 35 IBUs seems to be a good target.

Regarding that final hop addition, I believe that Chico runs the hot wort through a hopback with some fresh hops in it, so you might rig up a homebrewer's gadget equivalent of a hopback. Or, you might add the final addition at flame off and let the hot wort sit for 10 minutes with the lid on before chilling. Or, you might try dry-hopping. I'm not claiming that these will produce an equivalent effect, but they are all attempts to give the beer some of the requisite hop flavor and aroma.

From: bliss@pixel.convex.com (Brian Bliss)  
Subject: SN

There have been a few request for Sierra Nevada Recipes the past two days. I pulled this off the hbd last December - it's one of those articles worth saving. Jack Schmidling asked about elaborating on "american hop flavor". My advice is to go out and buy a 6 pack of assorted SN beers, and see if you can pick out the ones made with cascade finishing hops and/or dry-hopped:

- -----

#### Summerfest

alcohol content: 3.5% by weight  
starting gravity: 11.5 plato (about 1.046)  
ending gravity: 2.7 plato  
yeast: lager  
bittering hops: perle  
finishing hops: hallertauer  
malts: 2-row barley malt, dextrin malt

#### Pale Bock

alcohol content: 5.2% by weight  
starting gravity: 16 plato (about 1.064)  
ending gravity: 3.7 plato  
yeast: lager  
bittering hops: perle  
finishing hops: mt. hood  
malts: 2-row barley malt, dextrin malt

#### Pale Ale

alcohol content: 4.4% by weight  
starting gravity: 13 plato (about 1.052)  
ending gravity: 2.8 plato  
yeast: ale yeast  
bittering hops: perle  
finishing hops: cascade  
malts: 2-row barley malt, dextrin malt, caramel malt

#### Porter

alcohol content: 4.7% by weight  
starting gravity: 14.5 plato (about 1.058)  
ending gravity: 3.5 plato  
yeast: ale yeast  
bittering hops: nugget  
finishing hops: willamette  
malts: 2-row barley malt, dextrin malt, caramel malt, chocolate malt, black malt

#### Stout

alcohol content: 4.8% by weight  
starting gravity: 16 plato (about 1.064)  
ending gravity: 4.5 plato

yeast: ale yeast  
bittering hops: chinook  
finishing hops: cascade  
malts: 2-row barley malt, dextrin malt, caramel malt, black malt

#### Celebration Ale

alcohol content: 5.1% by weight  
starting gravity: 16 plato (about 1.064)  
ending gravity: 3.9 plato  
yeast: ale yeast  
bittering hops: chinook  
finishing hops: cascade  
dry hops: centennial and cascade  
malts: 2-row barley malt, dextrin malt, caramel malt

#### Bigfoot Ale

alcohol content: 10.1% by weight  
starting gravity: 23 plato (1.092)  
ending gravity: 6 plato  
yeast: ale yeast  
bittering hops: nugget  
finishing hops: cascade  
dry hops: centennial and cascade  
malts: 2-row barley malt, caramel malt

From: "Tom Childers" <TCHILD@us.oracle.com>  
Subject: Hoegaarden Replication

In HBD 1149, Steve Lovett asks about reproducing Hoegaarden Grand Cru with wheat malt. A few months ago, I posted a barley malt extract wit beer recipe, and promised to try the same with wheat malt. Well, the first wheat malt batch finished a couple of weeks ago, and my friends and I are quickly wiping out the results. The wheat "bite" is great. This beer has a somewhat higher FG than Hoegaarden Grand Cru, so you may want to cut back the malt and/or honey to try and emulate Hoegaarden accurately.

Tamalpais Wit, v2.0

4-1/2 lb light dry wheat malt extract  
2 lbs orange honey  
1 ozHallertauer/N. Brewer  
7.5 HBU boiling hops  
1 ozHallertauer/Hersbrucker  
3 HBU finishing hops  
1-1/2 oz crushed coriander  
1/2 oz dried orange peel  
Belgian Ale yeast (Wyeast 1214)

Bring 5 gallons of water to a boil, then add first three ingredients. Boil 45 minutes, then add 3/4 oz. coriander. Boil 10 minutes, then add remaining coriander and orange peel. Boil 5 minutes, and add the finishing hops for a final 2 minutes. Chill immediately to 75 F, areate into 5 gallon carboy, and add yeast. Ferment using blow-off method, then prime with 3/4 cup corn sugar and bottle.

The keys to making this beer are (1) use belgian ale yeast, (2) crush the coriander yourself, so it is nice and fresh, (3) use orange honey, and (4) use the best Hallertauer hops you can find. Papazian's basic recipe is very flexible; I've made 5 different beers so far by changing the malt combinations, and I've liked them all. I like this one the best so far.

Subject: Cleaning stainless steel

In HBD # 1147, Al (korz@iepubj.att.com) writes re cleaning stainless steel vessels:

>Right. I don't even use soap on mine -- just a non-stick-safe scrubbing  
>pad (more gentle than a scouring pad) and elbow grease. The only things  
>in there are a little scortched malt and some Beerstone -- if it gets  
really  
>bad, maybe I'll use a bit of cola (for the acid) or if one of my batches  
of  
>pseudo-lambik goes super acetic on me, I'll use it for scrubbing the  
kettle  
>(that's what the lambik brewers do!).

What about using a copper "Kurly Kate"-type scrubbing pad? If copper is softer than stainless steel (and I assume it is) then it shouldn't be a problem. Or is it? Also, how about baking soda?

From: garetz@brahms.amd.com (Mark Garetz)  
Subject: Yeast vs. Trub, Materials List, SNPA Hops

Con Copas talks about racking the wort off the cold break vs. yeast performance:

Let me throw this in: A brewer friend (who also happens to be the winemaker at a major Napa Valley winery) ran some controlled experiments on the performance of yeast in wort where some of the break material had been left in the fermenter, and where the break material had been completely filtered out. His results showed that the yeast definitely needed something from the break material. The "pure wort" did not ferment well at all. Both were oxygenated, the yeast was pitched from a starter (lab cultured) and the tests were conducted in the mini-lab of this winery. Sorry I don't have the details on what he meant by "didn't ferment well at all" but it doesn't really matter. The point is not to worry about getting rid of all the trub before pitching.

Al Corzona throws another chart into the ring....

After seeing Don's post, I was particularly concerned about the "severe effect on polypropylene" because HopTech is making a Hop Back out of polypropylene because of its excellent high temperature characteristics. I hauled out my Grainger's catalog and had a look at the list. Sure enough there it was polypro=severe effect with beer (with a note that beer is OK at less than 72F). Now a hopback really doesn't work with "beer" but wort. The list also contains "cane syrup" but it also got a severe rating with polypro. Anyway, I was concerned. Turns out Grainger's reprinted the list from the Little Giant Pump Co. (this reference is actually printed in the Grainger's catalog). So I called TLGPC. They didn't know squat about the list and told me it was provided by Phillips 66. So I called Phillips. After being bounced around to about 12 divisions, I finally found the one that deals with polypropylene (they make it). BTW, \*no one\* at Phillips ever heard of the list and they guess it must have been done a long time ago. Anyway, after a few minutes of begging that I should be connected to a materials engineer (not a sales "engineer") I got some helpful folks in one of their labs. Turns out the guy who knows the most about polypro is also a homebrewer! Well it was certainly a relief not to have to spend 1/2 hour explaining what a hop back, wort etc. were! Bottom line: The chart is wrong as regards to polypro. Beer won't hurt it or react with it (neither will wort). This guy said that polypro's barrier properties weren't that good and thought the chart might have been inferring that you wouldn't want to store carbonated beer in it for long periods because it would go flat. However, carbonated water is "OK" for polypro on the chart. We couldn't

figure it out. Now I know why Grainger's has a disclaimer as to the chart's accuracy right up front. For what it's worth...YMMV.

JC asks about the SNPA recipe:

I'm not sure what they use for bittering (I think Galena but don't quote me). For finishing and aroma they use Cascade. Lots of it late in the boil. And then they run the wort through a hop back charged with even more Cascade. They do not dry hop this beer. If I were trying to get an SNPA, I would do something like this:

8 lbs Pale Malt  
.5-1 lb 40 degree Crystal  
Optionally a pound of carapils for more body.  
40-45 IBUs of Galena, Cluster or Cascade, boiled 90 minutes  
1 oz Cascade 10 minutes  
1.5 oz Cascade 5 minutes  
2 ozs Cascade in a hop back (or steeped if no hop back)  
SNPA yeast cultured from a bottle, or Wyeast Chico Ale

Personally, I'd use a single infusion mash at 150-153 degrees.

Mind you, this is off-the-cuff and merely a guess.

Subject: Re-using yeast & commercial beer storage

Message Creation Date was at 26-MAY-1993 14:32:00

Greetings,  
I have some questions in two basic areas. Any insight would be appreciated.

1. I'm lazy. I would like to re-use my yeast as opposed to propagating multiple yeast colonies. I rack my beers to 2ndary fermentors and usually use polyclar on my lighter colored beers. Should the yeast cake I save come from my primary or secondary fermentor? I see problems with each:  
a. Primary will have more cold-break, dead yeast, and hop residue than secondary.  
b. Secondary will have plastic particles due to the polychlar. (Should I use isinglass, instead?)

2. I've a couple questions regarding the storage of commercial beer (You know - that stuff ridiculed in the HBD). Based upon the assumption that the vast majority of commercial beer is filtered and pasteurized is there any problem with storing the beer in an 80 degree dining room versus a 60 degree basement (assuming light is not a factor)? How about a 100 degree attic?  
Also, if I keep one 6-pack in my 65 degree basement as a control and then daily rotate a second 6-pack between my 35 degree refrigerator and my 80 degree laundry room will any differences in taste result? Will the rotated beer deteriorate more quickly? Will a commercial beer which is constantly changing in temperature by as much as a 50 degree delta deteriorate more quickly than beer constantly sitting in a warm room?  
Finally, how different would the test results be if I chose to also sacrifice (shudder!) a 6-pack of home-brew in this experiment?

I appreciate the help & information.

From: "Anton Verhulst" <verhulst@zk3.dec.com>  
Subject: soot: take 2

I'd like to thank all who responded to my cajun cooker soot problem. I was gratified at the response - 8 to 9 people sent me email with suggestions.

First of all, I was a boy scout :-)) and I know the soap trick. I was not clear in my posting - it's not the cleaning of soot from the pot that is my problem. The cleaning is easy. After chilling the wort, I put a large strainer over my primary and pour the wort directly from the 10 gallon brew kettle into the primary. This usually means that I get soot on my hands and clothes. THAT's my complaint.

Two people wrote to me suggesting that a possible solution was to reduce the size of the hole in the gas jet from 5/64" to 1/16" (when will the U.S. move into the 20th century and use metric?). I did this and noticed an improvement in flame quality at low gas settings. I'm planning to brew a batch this weekend and see if the improvement is enough or if I'll be shopping for a new cooker.

Drew Lynch sent me a nice summary of different types of propane cookers which I'm happy to include (with Drew's permission):

"In my search, I found three types of burners.

The "real" cajun cooker (what you have) has a single flame. It has the benefit of the highest total heat output (as high as 200,000 BTU!), and the detriment of no real adjustability. They also are very inefficient gas-wise at the "simmer" setting. There is no mixture adjustability. This is the cause of your soot problems.

The "stove" type burner has ~100 individual flames. It usually has the lowest output (~20,000-40,000 BTU) and the best adjustability. It is very gas efficient. The mixture need not be adjusted on these.

The King Kooker company produces a hybrid of the two types (which I have). It has approximately 30 individual flames, 145,000 BTU and decent adjustability. The efficiency is in between the two listed above. To get an ideal burn, the mixture adjustment plate would be moved when you switch from "nuke" to "simmer". In practice, the wide open setting seems to work well enough all the time, and I get minimal soot marks on the bottom of my brewkettle.

I am very happy with the model I have. For a given batch, I heat 5 gallons of mash water to 178F, 5 gallons of sparge water to 180F, heat the mash from 156F to 170F, and do 90 minute boils of 5-7 gallons. I get about 4-6 batches from a single propane tank (20lb?). I would return the burner you have, if you can, and try to procure the more adjustable version.

I have a local (Los Altos, Ca.) source for the King Kooker of the

"right" type: Fermentation Frenzy, (415)941-9289. Where are you located?"

Thank you Drew.

Tom Stolfi wrote that he has a \_Camp Chef Cooker\_ "stove type" burner with 35,000 BTUs that will boil 5 gallons of cool water in about 20 minutes and gets NO soot on his pot at all. He also mentions that the same company makes a 135,000 BTU unit.

Well, that it folks. I wish I'd known the above info before I bought my cooker. I'll report the results of boiling with my modified King Kooker next week.

Good brewing,

Tony V.

>dont have any DME to make it with. Can I just use a corn sugar/water  
>solution. If so how much water and corn sugar. Also is it true the more  
>sugar the higher the yeast count. I use dry yeast, does this take longer  
to  
>start? How long do you leave the starter before pitching?

I suggest you get some DME and then first re-hydrate the dry yeast in  
104-110F sterile water for 15 to 30 minutes before adding it to a 1020  
DME starter for a day or two. Starters made from corn sugar have proven  
to make for a sizable yeast mass, but that the yeast subsequently has  
difficulty fermenting mixed-sugar (glucose, fructose, maltose, etc.)  
wort.  
It's best to start on wort. There are arguments on whether it's better  
to  
start the yeast on a 1020 OG starter or on a starter that is more like  
the wort they will be fermenting. I use a 1020-1030 OG starter. I've  
found that the yeast starts faster in lower gravity starters (this is  
in-line with Wyeast Labs' findings and recommendations). I believe that  
the ideal situation would be stepped-gravity starters -- first 1020, then  
1030, then 1040, finally pitching into the wort, but I don't go through  
all that trouble.

> anyone else noticed this? I have heard of some people fermenting in

DeKlerk wrote that fermenter geometry is an important factor and says  
basically that a short, wide fermenter is better than a tall narrow one.  
I know that George Fix ferments in 1/4 barrel kegs partly for this very  
reason.

\*\*\*\*\*

Paul writes:

> In reference to fridges or freezers and the cold air falling out when

Galveston  
>summer, not opening the door to draw a beer.

I had considered this also, but backed-off when I read that some people  
have  
problems with mold in the faucet. I've found that if I don't drink from  
a  
particular keg for two weeks or so, a big glob of mold forms in the  
faucet.  
This, despite the fact that I have my faucets INSIDE the fridge at 54F.  
If you use the faucets every day, you shouldn't have any problems.

This implies that you pour hot wort through a strainer. If this is true,  
then you are aerating the hot wort (Hot-Side Aeration or HSA) which is  
causing a considerable amount of oxidation of the wort. George Fix has  
a great article in a recent Zymurgy on Hot-Side Aeration, which explains  
in detail the problems with HSA.

Al.

From: jdsgeoac@osg.saic.com (Karen Jdsgeoac Hyrum GEOACOUSTIC)  
Subject: RE: Fridge Question

JC Ferguson asked a few days ago how to modify a double dorm fridge to fit 5 gallon kegs. I did this a few years ago as follows:

The U shaped freezer was attached to the top of the fridge with 4 clips. Remove these clips. The freezer/cooling plate is now supported by the incoming freon line. I carefully pushed the U shaped freezer down and back so that the large part of the plate was parallel to the back of the fridge. This operation is tricky since there is some danger of crushing or splitting the freon line. I however had no problem, and the fridge has been working fine for about two years like this.

From: Hugh R Bynum <Hugh\_R\_Bynum@ccm.hf.intel.com>  
Subject: More soot on pots...

A number of articles in HBD 1149 suggested the tried-and-true Boy Scout method for easily removing soot on SS pots. Keep in mind that if your propane cooker is burning with a yellow flame and making enough soot to be a problem, it's also generating some carbon monoxide. CO is generated when hydrocarbons (e.g., propane) don't burn completely due to insufficient oxygen. It's colorless, heavier than air, and highly poisonous. In nonlethal amounts, prolonged exposure can leave you with nausea and a splitting headache.

If you want to solve the problem and not just the symptom, try adjusting the damper plate on the gas inlet to your cooker. On my "Superior"(tm) propane burner, it's a slotted disk that fits over the air intake on the cast iron part of the burner, just behind the gas inlet valve. Fully open, there's enough air to blow the flame off the jets; closed down, it burns bright yellow. With a few tweaks, I was able to get it adjusted for a clean blue flame through the full range between a simmer and full throttle. While the Superior burner is rated at 35,000 BTU, I would guess that the 200,000 BTU King Kooker is fairly adjustable through its full output range as well. Good luck!

From: Paul\_Szabady@DGC.ceo.dg.com  
Subject: Ferment too quick?!?

Message:

I was wondering if anyone out there in HBD-land has tried the recipe for Armenian Imperial Stout from TNCJOHB. I just brewed a batch using this recipe this past sunday night. I pitched the yeast (that came with the "M&F Old ALe Kit" first thing monday about 6:30am. By about 8pm, I had a nice ferment going. Tuesday am, I switched from an overflowing airlock to a hose and pan of water due to an extremely vigorous ferment. Wed at about 1am I switched back to my airlock and was pleased with a "once every 15sec glug". By noon on wed, I seem to have practically stopped fermenting. I've been making homebrew for about 6 years now and have never seen a recipe with this amount of malt (almost 11 lbs - \$33.00 for supplies!!!) finish soooo quick. Barely 54hrs. I'm thinking maybe I should've spent a little more and got a better yeast. Any suggestions/comments???? Should I pitch more yeast??? I broke my hydrometer a while ago and haven't replaced it yet so I don't have any sg readings.  
Email direct or post...TIA ps

Date: Wed, 26 May 1993 23:18:49 -0500  
From: donald oconnor <oconnor@ccwf.cc.utexas.edu>  
Subject: bleach and ss

i'd like to clear up some confusion evident in al's post yesterday. al's confusion is significant, although understandable.

al is confused regarding sodium hypochlorite, chlorine water and bleach. bleach is a dilute, about 5%, aqueous solution of sodium hypochlorite. chlorine water is water with hypochlorous acid. sodium hypochlorite is the sodium salt of the acid. i doubt that anyone is using either sodium hypochlorite or chlorine gas for sanitizing their SS pots or kegs. although the reactivity of chlorine water and sodium hypochlorite with SS is mildly interesting and contained in both the cole-parmer and granger catalogs, it's not pertinent to the issue. as i mentioned earlier, the table in the granger catalog suggest there is no reactivity between 304 and 316 ss and bleach. curiously, the cole-parmer table al has is in perfect agreement on this point. it's under "chlorox (bleach)".

my own experience agrees with the data in al's coleparmer table and the granger catalog. i used to use about 1 teaspoon of bleach per gallon of water in sanitizing kegs (304 ss) and have observed no effect whatsoever with exposures typically of 30 minutes to 1 hour. it is best to be cautious however. it's easy to confuse aluminum for SS and the granger catalog suggests bleach is reactive with aluminum. curiously, the cole-parmer catalog says that bleach does not react with aluminum. these tables are only guidelines. no details as the conditions of the test such as length of exposure are given.

al is also confused about the nature of silicon and silicone. the one with the 'e' has a long 'o' as in conehead. although they are spelled similarly, the difference between silicon and silicone is similar to the difference between graphite and plastic. al's confusion led him to erroneously state that there is no reactivity between beer and silicon. closer examination of the cole-parmer table will reveal that there is no reactivity between beer and siliconE. as i said earlier, the granger catalog indicates that beer is reactive with silicon but who cares.

From: driscoll@curacao.dartmouth.edu (Jim Driscoll)  
Subject: Manhattan Brewing/Bud in Europe

Danial Roman asked for a scouting reported from the newly reopened Manhattan Brewing Company ("New York's Working Brewery & Restaurant", 42 Thompson Street, New York, NY 10013, (212) 925-1515, Fax (212) 925-7051, Opens at 5:00pm for dinner, with lunch hours to be added soon.)

Up from the street level a flight or two, you find an open space with 2 large (~100 BBL) copper kettles dominating a small dance floor, a bar with hand pumps, some table seating in the center, and above the bar additional table seating. On tap are 5 ales, from which I sampled the Brown Ale, India Pale Ale and their Amber Ale. Mixed drinks and wine can also be had from the bar, but there is no evidence of any beer other than those house brewed. I didn't stay for dinner, but the menu, along with everything else, seems hardly changed from its previous incarnation.

You might find Garrett Oliver running around in a white lab coat with a patch marked MBAA (for the Master Brewers Association of the Americas), which readily identifies him as the brewmaster. Garret was the former assistant brewer at Manhattan and he was kind enough to take me up a floor and show me their brewery. They have a 7 and a 12 BBL steam jacketed kettle with agitation. They mash in the M&F malt in the kettle and do a temperature program mash (Michael Lewis of UC Davis derides the term step-infusion mash as ``homebrew language'') and then pump the mash to the lauter tun with a v-wire mesh false bottom. They use only whole hops in the boil. Fermentation takes place in open fermenters with top fermenting yeasts. From the open fermentors the green beer goes into one of their 15 or so 7 BBL grundyds in a cold room where it undergoes a secondary fermentation and is racked to a serving grundy which dispenses to the bar below under pressure.

Garrett is an enthusiastic brewer and mentioned some exciting and unusual brews that he plans on producing once the new operation settles down a bit. When in the NY metro area you should support the local brewers by checking this place out as well as Zip City (Manhattan) and Mountain Valley Brewpub (Suffern, NY).

- - - -

Richard Akerboom notes that AB would have to change the name of Bud in Europe since the Czechs have rights to the name Budwiser there. This is in fact what they do. If you grab a long neck ``Bud'' here the label says Budwiser, but in Europe when you grab a ``Bud'' the label says just that: Bud. I guess they want to be their Bud too. (Actually, the only place I have personally seen this Bud was in a specialty beer store in Mechelen, Belgium.)

Subject: re-using yeast

Due in part to things I've read here re; yeast culturing, I decided to try an experiment with my last batch. A couple weeks back, I took a 3 gal. keg of SNPA-clone pale ale to a picnic. It occurred to me that, since the beer was clean (and tasty) and had yeast cultured from an SNPA 6-pack, why not just let the dregs sit in the keg under pressure at room temp until I brewed again (last Saturday) then simply pop the lid, add 1 cup sterile cool water, swish it around, and dump directly into the primary. Fermentation started within 12 hrs and smells clean. It's a slow ferment as are most that I do with SNPA but smells clean. Questions:

- can anyone see potential problems or drawbacks with this method
- how long might clean yeast be held under pressure this way before it loses viability.

One other question.... I recently bought WYEAST packs for both british ale and Lonmdon ALe (forget the #'s). Can someone tell me what the difference in these yeasts are based on their experiences, and which styles of ales they might match up best with.  
Thx

Subject: New Orleans Brewpubs

Mary Dabney Wilson asks about brewpubs in New Orelans:

Mary,

I was just in New Orleans and there is a new(er) brewpub there called Crescent City Brewhouse. The place is very nice and the beer isn't bad either. There's also an oyster bar and live entertainment. I especially enjoyed the Weissbeer they had. They also have a Marzen they call Red Stallion. If I recall correctly, you can get a sampler of all of their current brews. You can see the copper mash kettles on the first floor and the stainless holding tanks on the second, but they don't give any brewery tour (like Goose Island does in Chicago)

Be sure to check out the t-shirts. I like the logo and the stallion on the back. I bought one right away!

It's located between St. Louis (for sure) and Tolouse (I think) right off the waterfront (Decatur?).

Don't get confused about the Jackson Brewery (Jacks), it's just a shopping mall conversion of a real brewery. The only thing at Jacks is Budmilloors.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Close brush with disaster

I'll set the scene:

Here I am at work, hustling to get things wrapped up so I can head off tomorrow (Friday) for Belgium. I'm looking forward to lambic hunting, while my friends over there are combing the countryside for rare and unusual brews made in farmhouses, basements, garages and what have you for our week of overindulgence. I'm packing up two sixes of my own beer for field testing, and bringing along several bottles of Celis for presents. In other words, all is nearly ready for a peak snob beer experience. Now it's time for lunch.

I walk out the door and down the street to our usual lunch place and walk straight into.....a Bud Lite commercial! There they were...camera crews, mountains of equipment, people trying to look important, cases and cases of the vile stuff, workers everywhere hanging neon Bud Light signs where there'd never been any before, and a gathering tribe of bimbos and guys named Biff.

During lunch it turned out I'd sat down next to the crew, who were reviewing takes from their recent shooting in Baltimore. Must've seen the Bud Light truck drive by Baltimore's Washington Monument at least twenty times. Lots of in-bar photos of guys named Biff touting Bud Light. Babes named Gina and Tiffany, touting Bud Light. Dogs, touting Bud Light. My lunch companions and I (NOT the crew!) could not contain our amusement and got some nasty looks.

That was close, though. What would the homebrew world think if my face showed up in an ad for this pathetic stuff? It would be almost as bad as being in a Sam Adams commercial! (Of course, nobody here knows what I look like, but...)

Looking forward to better things,  
Phil Seitz  
PSEITZ@MCIMAIL.COM

P.S. On second thought, perhaps I could infiltrate their evil organization, swap some bottles, and change history?

From: sxs32@po.CWRU.Edu (Subbakrishna Shankar)  
Subject: Rot on hops leaves?

I've noticed some yellow/brown rust like discoloration on the lower leaves of my hops vines recently and am concerned (not worrying) that it might be a symptom of a fungal infection. This is the second year in the ground for these rhizomes, and the vines are already at 12-15 ft and growing vigorously. Last year we had a cold, wet summer here in Cleveland, so the vines reached 10 ft only by the end of the summer and failed to produce any flowers. I also found plenty of slugs and aphids. This year the weather has been warmer and drier, and I have not seen any slugs or aphids. I have of course watered and fertilized the plants.

Has anyone else seen this discoloration? Is it a lack of a certain nutrient or is it indeed a disease? How can I safely get rid of it? Thanks in advance for your help.

Subject: Beer in Japan

Hey all,

Firstly, I want to thank everyone who responded with their opinions on the importance of secondary fermentations and with hints on obtaining banana ester formation in beers.

I was wondering if anyone knows any place to obtain real beer in Japan. I have heard all sorts of horror stories about the big 4 brewers over there hiding knowledge of real beer from the Japanese public. All I have ever seen there in the past are a small variety of American Pilsner clones. Pretty gross; it actually drove me to drinking lots of sake--

not necessarily a bad thing, but this summer I'm going to be over there for two whole months, and I don't know if I'll make it without a true ale, bock, or stout to tide me over until my return. If anyone knows of a nice

brewpub, or even any sort of place with good beer in Tsukuba (where I'll be) or Tokyo (not too far away)--I'd really appreciate it.

And if anyone who gets this list is in Tsukuba or Tokyo now, or will be this summer, drop me an E-mail, and maybe we'll be able to set out in search of beer together.

Thanks,  
Bryan

>

The only brewpub I found when I was there last month was the Crescent City Brewpub, and I hate to be negative, but I must say I was singularly unimpressed. I only had a weiss beer (actually about a half of a weiss beer, I was unable to bring myself to finishing it.) A group of 7 friends gathered there, and no one was interested in going back. In all fairness, I had just finished a rather wicked hurricane when I got there, so my taste buds (not to mention my vision, my sense of balance, or my speech) were not in top form.

One positive recommendation: drink Abita beer while you are in New Orleans, especially Abita Turbo Dog. And if you get outside of the city, try to visit the brewery. Good people; wonderful beer.

Subject: Ferment too quick?!?

Message:

I was wondering if anyone out there in HBD-land has tried the recipe for Armenian Imperial Stout from TNCJOHB. I just brewed a batch using this recipe this past sunday night. I pitched the yeast (that came with the "M&F Old ALe Kit" first thing monday about 6:30am. By about 8pm, I had a nice ferment going. Tuesday am, I switched from an overflowing airlock to a hose and pan of water due to an extremely vigorous ferment. Wed at about 1am I switched back to my airlock and was pleased with a "once every 15sec glug". By noon on wed, I seem to have practically stopped fermenting. I've been making homebrew for about 6 years now and have never seen a recipe with this amount of malt (almost 11 lbs - \$33.00 for supplies!!!) finish soooo quick. Barely 54hrs. I'm thinking maybe I should've spent a little more and got a better yeast. Any suggestions/comments???? Should I pitch more yeast??? I broke my hydrometer a while ago and haven't replaced it yet so I don't have any sg readings.  
Email direct or post...TIA ps

-----

Well the first thing i would do is get a new hydrometer, how quick the batch appears to finish is not accurate enough. i have seen batches of stout become extremely vigorous, coming out the top of the fermemnter then after dropping about 0.10 to 0.20 in 48 hours to a slow steady drop over a period of up to 5 days! This of course is somewhat dependent on the yeast used, but before doing anything but waiting, BUY A NEW HYDROMETER!

First of all this is not true. The Czech company does not "own the rights in Europe." There is no such thing as a European patent office. Rights to trademarks are secured in every country. And this being the case, Anheuser-Busch products are widely available in a few countries here. In this country, Sweden, one can get US Bud (in all 3 strength classes - the least of which allowing it to be advertised on tv), Schiltz, Michelob, Sam Adams (arggh!), Anchor Steam, and various temporary products. But you can also get the superior Czech Bud... which happens to be the cheapest class 2 beer (up to 4.5%/vol)... By the way, the better Czech pilsner (IMHO), Pilsner Urquell (also given a german name - as if that was a good thing) - is the cheapest class 3 beer sold here (up to 5.6%/vol)...

From: Kurt Swanson <Kurt.Swanson@dna.lth.se>  
Subject: European Bud...

[I don't know why my previous post didn't make it, but here's the gist of what I attempted to say before]

There is NO European trademark office. Each country has its own, and thus has the right to decide a difficult question - who has the right to the name "Budweiser". Here in Sweden, both products are sold - with no difference in name. In other countries US Bud is "Bud." But it is certainly not an equivalent situation in all of Europe. In any case, I read in a recent issue of CAMRA's "What's Brewing," that AB and the Czech firm have come to an agreement in terms of marketing, so that both products would be marketable in all countries...

P.S. Besides BUD, we in Sweden can buy Schlitz, Michelob, Sam Adams (arggh!), and Anchor Steam, as well as a few other temporary products...

From: pgs@ai.mit.edu (Patrick Sobalvarro)  
Subject: litmus papers, Cambridge (MA, USA) water

I made my first partial mash last weekend, and ran into a problem. I was following the instructions in Miller's "Complete Handbook of Home Brewing." My problem was with the litmus papers I found at the local brewing shop (The Modern Brewer). I thought that the range was appropriate (4.6 -- 6.2), but according to the chart and also to my own results, the variation in color over the range was quite narrow -- tan to a rather light brown. The result was that I had a very hard time telling whether my mash pH was in the right range. So here is my question:

Does anyone know a retail source of good litmus papers that have a greater variation in color over this range, or perhaps a range of only 5.0 -- 5.5? A shop in the greater Boston area or a mail-order house would be best. The Cole-Parmer and Edmund Scientific catalogs I have don't have litmus papers -- only pH meters.

Speaking of pH meters, the cheapest ones do not have detachable electrodes. Can someone with experience in these matters tell me how long I might expect the electrodes on these meters to last if one is only using them in brewing, where only mildly acidic solutions are encountered?

Next topic. Because my local brewing shop didn't have this information, I thought I would post for interested homebrewers in the area the assay I got from the Cambridge Water Department. I didn't actually get to talk to a chemist, so I wasn't able to get anything about seasonal variation from them, but this is interesting all the same. Miller's book leads me to believe that the number listed as "Alkalinity" refers to the total amount of both carbonate and bicarbonate.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinass)  
Subject: Dubbel, Steam

A double batch of Belgian Dubbel Ale and Steam (tm) (a trademark that deserves one, btw) Beer, fermented at high gravity and diluted at keggling:

5 lbs. light Munich  
2 lbs. light Vienna  
1.15 lbs. crystal (60L ?)  
10.35 lbs. M&F 2-row  
2 lbs. turbinado sugar

1 oz. Centennial whole hops (90 minutes boil)  
2 oz. Saaz whole hops (added at end of boil, steeped while chilling)

2 tsp Irish Moss (15 minutes)

Single-step infusion by mashing in with 20 qts. water at ~170 degrees. My notes have "17" with no 3rd digit, but it's commonly 170-172 degrees. Conversion at 156 degrees for 4 hours (probably done much sooner; I was busy). Pour mash into 10 gallon cooler lauter-tun. Top off with boiling water. Stir. Let settle 30 minutes. Drain, recirculate 2 gallons. Boil 90 minutes, leaving about 8 gallons at 1.070 (not measured).

Rack ~5 gallons onto slurry from a previous batch of Belgian ale. The yeast had been cultured from bottle of Chimay.

Rack the remainder (~3 gallons) into another carboy. Pitch with Wyeast California Common (aka Steam) slurry from a previous batch.

Ferment the Belgian at 60-70 degrees. Yes, that's a wide fluctuation. I tried to keep it warm by surrounding the carboy with gallons of hot water. It works, but eventually the cool cellar temps win out.

Ferment the Steam at 55-58 degrees.

No secondary fermentations.

Keg the Dubbel after 16 days. Had to add 3/4 gallon of boiled/cooled water to fill 5 gallon keg. FG: 1.012 (before adding water). Fruity, but no bananas. Some bubblegum. More spice/clove. Did I say fruity? Very fruity, in a very nice way. Strong, alcoholic, rum flavors/aromas, maybe from the t.sugar. Dark brown. Stayed cloudy until just recently. A unique and delicious beer; I've taken to drinking it from a wine glass.

Keg the steam after 37 days. Had to add ~ 2 gallons of boiled/cooled water to fill 5 gallon keg. FG: 1.014 before adding water. At the time it tasted sulphurous with a homeperm(!) aroma. Something happened as it carbonated, though, because within a couple of days those off flavors and aromas were gone, replaced by a Steam beer fruitiness (not at all like the Belgian though), and a nice Saaz aroma, not noticeable in the Belgian.

A little too light body maybe, but perhaps only in comparison to the very big body of the Dubbel. Neither beer is very bitter, though the Steam reveals the bittering hops better. The Steam is a crystal clear light brown color. An excellent summer beer, if I do say so myself.

So, a grand and very successful experiment. If your brewing time is limited and seldom, I highly recommend this double batch/high gravity/dilution brewing approach.

Chip Hitchcock asks in a private email:  
>All right, I'll bite. What's a Zentner? Teribu, perhaps?

I was afraid someone would ask that. Well, its a unit for measuring hops  
in,  
isn't it. Aka a big sack full :-)

I think it's 50Kg of hops (but not absolutely certain).

\*\*\*\*\*

I said that I recently had a bad experience with beer in Florida, but in  
fact  
with the help of a few HBD contributors, I found a couple of brewpubs  
that  
sold some very pleasant beers. May the brewpub concept prosper and  
flourish.

And what about American cheese? Is there any chance of a Campaign for  
Real  
Cheese being started over there? I got the impression that the mega-  
cheeseries  
had done the same to your cheese as the mega-breweries have done to your  
beer.  
Plasticity, bland, virtually no variation in flavour or texture. Where did  
I go  
wrong?

I found the good beer in Florida by asking your advice, maybe next time  
I'm  
on your side of the pond I'll ask for advice of sources of cheese too.

Geoff

"A riot is an ugly thing... and it's about damn time we had one."

- "Young Frankenstein"

Phil Seitz's post about infiltrating the evil empire of A-B and substituting a homebrew for a bud light, possibly changing the course of history, is a step in the right direction. Radical activism is like farting during the church sermon. Its a barbarous act in the face of entrenched hypocrisy.

Here in Chicago we're currently being bombarded by a wave of Samuel Adams billboards. It's not enough that the Chicago tollway system is the cheapest parking in town. To add insult to injury you have to stop in front of one of these billboards. Sitting in traffic for a half hour, staring at a monstrous Sam Adams advertisement? I still have nightmares.

During one of my more recent tollway camp-outs, I tried to avoid staring at one of these billboards. I did this by admiring the architectural design of the billboard structure itself. I was amazed with the precision with which the welder had mounted the ladder rungs. These rungs marched all the way up the pole with military precision. It looked like a step ladder was necessary for the billboard painters to reach the rungs from the ground. I became amused with the idea of donning a ninja suite, climbing the billboard and painting the word "boycott" in huge black letters in the foam of the billboard pint. But alas, the traffic started to move again, the daydream vanished and common sense soon returned.

Although I consider myself to be a Question Authority type from way back and a student of the Arf School of Agnosticism (ASA), I decided that this was something I wouldn't try. Not because of being scared of heights. Not because of my history of brewing-related accidents. The real reason is that I can't tolerate the I-told-you-so's while stuck in a full-body cast.

Subject: AHA National Conference In Portland

All,

For those interested in going to the national conference this year, I would like to know if there is something special that the HBD crowd should organize while there? Perhaps it is customary for this group to identify themselves by a characteristic identifier (scarlet letter, black armband..).

I would like to meet the faces behind the e-mail addresses and I thought maybe our own activity might be a thought. Many things come to mind but some possibilities might be:

1. A brewpub night for the HBD crowd.
2. A preconference HBD get together.
3. A postconference HBD get together
4. your proposals here.

I would be happy to help organize something but would like to know if there is any interest. No doubt that we will see each other anyway but some kinship may be just the thing.

If you would like to e-mail me directly and save airtime that would be fine and I could then just give all responders the dump.

Frank Dobner

PS: I have my plane tickets, conference registration and hotel arrangements already made. I am staying at a place up the street and saving a bit of money

>Subject: bleach and ss

>  
>curiously, the cole-  
>parmer catalog says that bleach does not react with aluminum. these  
>tables are only guidelines. no details as the conditions of the test  
>such as length of exposure are given.

Aluminum has some pretty unusual properties which are probably relevant here. It is unstable in the presence of oxygen, water, acids and bases, BUT it is normally covered with a layer of oxide which prevents these corrosives from reaching the actual metal. If you manage to amalgamate a bit of mercury with the surface of a bit of aluminum this oxide coat will not stick. The piece of aluminum will corrode in air, right before your eyes (this makes a very impressive demo)

The relevant point is that in a strong oxidizing solution, such as concentrated bleach, the oxide coat is stabilized and the aluminum is not attacked. If you dilute the solution too much though, the alkalinity will overcome the oxidizing strength, and at some point the aluminum will get attacked (I don't know the figures here). The same phenomenon allows concentrated, fuming, nitric acid to be transported in aluminum containers. God help you if you get any water in there though!

Personally I wouldn't mess with aluminum for beermaking, because it's corrosion properties are so tricky.

From: woessner@psych.purdue.edu (Leo Woessner)  
Subject: keg party

I want to make a keg of homebrew and have a summer keg party, but I cannot afford to buy a co2 system. I can easily get a stainless steel beer keg since I live in a college town. It will be the type with a ball in the top

I want to prime the keg to get it carbonated.  
Question #1: How do I prime the keg (amount of sugar, DME etc)  
QUESTION #2: How do I get the ball out of the keg?  
Question #3: Will the ball seal the keg without pressure behind it?  
Question #4: If not how can I get the ball to seal without a co2 system?

I don't think the ball will seal without pressure behind it, so I have been thinking of using a magnet to hold the ball in place while the keg is conditioning. Anyone with experience, knowledge, hearsay, guesses, etc. please send e-mail. When I make the keg I will write a summary of my experience.

Thanks in advance

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: Spontaneous Fermentation

In HOMEBREW Digest #1150, Richard Childers speculated:

> I am curious ... has anyone ever tried to induce a lambic in the Bay Area,  
> or any other area which is known to harbor a particular type of yeast in  
> the air ?

We're headed here for an Avernus of terminological confusion. By definition, a "Lambic" is Belgian, which is why those of us experimenting with homebrewing in the style usually call our efforts by some other name. And yes, quite a few of us have experimented with spontaneous fermentation. In some cases, the results have been vaguely similar to Lambics, but it would be asking quite a lot to have enough similarity between the microflora of the Senne valley and that of, say, Mill Valley to produce a beer that in any way resembled the "real thing." The more promising experiments have been those using cultures of the organisms identified as having the greatest effect on the Lambic flavor profile.

> Are 'lambic' bacteria distinct from 'lactic' bacteria, and if so, how ?

Yes, they're quite different, for the most part. Most Lambics have a Lactobacillus component in their makeup, but it's relatively small and completely overshadowed in its flavor effects by the bacterium *Pediococcus damnosus* (nee *P. cerevisiae*) and the yeasts *Brettanomyces bruxellensis* and *B. lambicus*. The balance of these last two seem to vary depending on how close to Beautiful Downtown Brussels the brewery is, with *B. bruxellensis* dominating in town and *B. lambicus* dominating in the country. Main alcoholic fermentation is carried out by wild *S. cerevisiae* and *S. bayanus*, and there's a wide spectrum of others that get into the act at one time or another. A simplified summary can be found in "Lambic", by Jean-Xavier Guinard, from the Classic Beer Styles series, Brewers' Publications, 1990.

> The Bay Area, for instance, and California in general, was where sourdough  
> was evolved, and I have been given to understand that the cause of sour-  
> dough's sourness is lactobacillus acidophilis. So, making an intuitive leap  
> here, I have to wonder ... has anyone tried this ?

I haven't tried it in the Bay Area, but I'd guess that while a tray of wort left out overnight and then fermented without further encouragement would produce something, but I really doubt you'd recognize it as a Lambic. One of the reasons I say that is that if you want a good idea of what a spontaneously-fermented beer made in a given location will taste like, just consider the smell of standing water. In Brussels, puddles and gutters have a sharp, Lambic-like "tang", instantly recognizable.

From: pohl@unixg.ubc.ca (Derrick Pohl)  
Subject: Wheat Beer Recipe

In HBD #1150, Steve Boxer wrote:

> I'm getting the ball rolling on my next brew---A Wheat Beer. I would  
> appreciate tips and recipes for a real wheat beer with lots of clove  
> aroma and taste. I would appreciate an all-grain (infusion) recipe.  
> What hops should I use (Hallertau)? Also, I plan to use Bavarian  
> Wheat #3056 yeast, what is the correct temp to ferment? Thanks in  
> advance for all of the help.

Here's an all-grain recipe for a lovely wheat ale I brewed last fall  
which  
uses Wyeast's Belgian Ale yeast rather than the Bavarian Wheat, with  
plenty  
of nice clove aftertaste resulting. It is a light, refreshing beer,  
perfect for summer (pretty good for winter, too, which is when I drank  
it).

Belgian Wheat Ale  
-----

For about 23 l:

1 tsp. Gypsum in mash water  
6 lb. Pale Malt (British highly modified variety from Baird's)  
3 lb. Wheat Malt  
1/4 lb. Crystal Malt (light)  
2/3 oz. Bramling Hops (boil 50 min.)  
1/3 oz. Bramling Hops (boil 10 min.)  
1/4 oz. Centennial Hops (boil 1 min., then steep for 15 min.)  
Wyeast Belgian Ale yeast

S.G. 1.044

Two-stage mash: 50 deg C. for 30 min., then 66 deg C. for 45 min.

The two-stage mash is because of the wheat malt component.

Fermented at cool room temperature (around 16 deg C.).

That's it. The light hopping is to let the wheat and yeast flavours  
shine  
through, and they do, very nicely. Although this is an ale, I found it  
tasted best well-chilled. It also needed a little while (about a month)  
in  
the bottle for the yeast and hop flavours to reach an optimum balance.  
Enjoy!

The AHA conference is rapidly approaching. I will be making the trip from Washington, DC. While looking over the materials I was trying to find the value added by a partial registration vs buying tickets to the social events. I got three speakers for \$30. I got the partial anyways.

I will be going out Friday before and checking out the local culture (haha).  
Anyone who will be out early also let me know and we can get together.

I am trying to convince John Mallet at Old Dominion Brewing Co to ship homebrew kegs with his product that will be in the Oregon Brewers Fest. He has yet to agree. Otherwise, I think I will ship a case of my brew to the hotel. That way I can hand carry a case too.

Cheers, Rick

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Celis - Part 2

Laurie and I did get into some really detailed discussions with Peter Camps and Kimberly Blackmon concerning the yeast they are using. Except for Pierre-Xavier Guinard's fantastic book, and my good fortune to be able to talk with experts like Martin Lodahl, I have not been able to find detailed and reliable information about the strains that are preferred for Belgian Ales. Peter is a native of Belgium, and Kimberly has taken a course in brewing microbiology there, so this was a opportunity that could not be passed up.

The White and Grand Cru are fermented from the same ale yeast, a strain that originates from Belgium. A special strain of lactobacillus is also added to the White, hence the intrinsic characteristics of their Belgian ale strain is best seen in the Grand Cru. One will note a honey like taste and smell in this beer. While some of this comes from "special ingredients", honey is not added, and I feel the flavor note is primarily a fermentation product (2,3-pentandione). How well it serves this beer! I brought some fresh bottles of the Grand Cru to the Beer Fest at Temecula, Ca. for Martin Lodahl to taste. He gave it high marks for both authenticity and overall quality. Comments Martin?

The White has been highly praised in this forum, and both Laurie and I concur with this opinion.

Whitbread ale yeast is used to ferment the Pale Bock (Belgian Pale Ale). I had extensive discussions with Kimberly about this strain. Based on this plus investigation of her working slants, I conjecture that it is one of the single strain versions in the Whitbread yeast collection, and not the 3 strain version. Peter tells me that the Whitbread yeast have found wide acceptance among Belgium's ale brewers, and indeed their strain was obtained from Belgium.

They brew a very fine lager called Golden, which is not widely available outside Texas. It is cold fermented (10C), and well aged. The total cycle time for a brew is 8 weeks. The yeast used is definitely a mixed strain. One is a lager strain which originates from Czechoslovakia, and the other is a Belgian ale strain. Two distinctly different colonies can be seen on their working slants, and both are inoculated during propagation. Given the fermentation temperatures used, it is likely that the lager strain is the major player, however the ale strain likely introduces subtle effects in this tasty brew. Peter tells me that such mixed strains have found acceptance among some Belgian lager brewers.

Perhaps the most impressive thing we found at Celis is that everyone seems to love their job and would not want to be doing anything else. Who can blame them!

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Celis - Part 1

It was my and Laurie's good fortune to be able to visit Peter Camps (Head Brewer at Celis) and Kimberly Blackmon (their QA Director). What terrific people! Pierre Celis was out of town the day we visited, and we therefore did not get a chance to meet him. Rumor has it that he is a class act as well.

We were told that over 12 million has been put into the plant, but it looks to be worth five times that. Words like "attractive" and "tastefully done" seem to apply to everything from the building to the brewhouse. Those familiar with the special requirements of closed looped systems used in commercial brewing will immediately recognize that some world class process engineering went into this facility. It also impeccably clean.

Peter was besieged at the conference in New Orleans with questions about how to brew White Beer, so we decided to spare him and keep the conversation on a general technical/scientific level. Nevertheless, the following points emerged:

1. They brew four 100 hl. batches a week which go into two 200 hl. fermenters. All of the yeast is pitched with the first brew, and the fermenter is filled to its working capacity with the brew from the next day. They are currently using two vessels, a combined mash/lauter tun and a brew kettle. There is a second brew kettle in place, but is not as yet in operation. When it goes on line, they will be able to do two brews a day. These vessels are copper, and were built in the 1930s. They are indeed gems!

2. Cascade, Saaz, and Willamette hop pellets are used in different amounts for each of their beers.

3. The White is 50% unmalted wheat and 50% pale six-row malt from Belgium. Their other beers use a pale two-row malt from Belgium as a base. The six-row with its high DP is needed to convert the large unmalted grain fraction in the White.

4. A domestic caramel malt is used, but this may soon be replaced with one from Belgium.

5. After the fermentation all their beer is sent through a centrifuge. I estimate that this is roughly equivalent to a filtration at the 8-10 micron level.

6. All of their beers, except the White, are given a DE filtration at the end of storage.

7. All of their beers are flash pasteurized before packaging.

8. Their Pale Bock is really a Belgian Pale Ale, and is fermented at 22-24C. Its alcohol content is under 4% by wt., and because of a (really stupid) Texas law can not be called an ale.

9. Iodophor or sometimes paracetic acid is used for sanitizing; caustic solutions are used for cleaning.

Subject: The Hop Source

It has come to my attention that Glenn Tinseth, a person who has been on HBD, has opened a new hop outlet. The address is the following:

The Hop Source  
11886 Paradise Road NE  
Silverton, Oregon 97381  
503-873-2879

I do not know Glenn personally, but I am aware of his background. He was trained as a chemist, both on the undergraduate and graduate levels. His current full time job is with Dr. Gail Nickerson's research lab at Oregon State. Those who saw the feature article in the first issue of Brewing Techniques will recall that name. Dr. Nickerson is one of the leading figures

in hop research, and the labs at Oregon State are world class in every sense.

In fact, I think it is fair to say that Oregon State is to the hop industry

what MIT and Stanford are to the computer industry.

In any case, Glenn's prices seem right. For example, he has an impressive list of imports which sell for \$18.18/lb. I recently purchased 3 pounds (one each of East Kent Golding, Styrian Golding, and Czech Saaz), and plan to get more when the new crop comes out next fall. He also sells all the major domestic varieties for \$9.45 to \$11.85 per pound.

My major interest in Glenn's operation is his ability to give us "as is" alpha-acid data rather than values measured at harvest. For some of the low alphas (most notably Saaz), this is important. I am also going to urge Glenn to provide other services like doing IBUs on samples of homebrew sent to him. Analysis like that is a piece of cake given the type of lab he is in. There are going to be some charges for such services, for among other things Oregon State is going to overhead on the use of their equipment. Given the elementary nature of the assays, I hoping the charges will not be too expensive.

Glenn deals only with whole hops, but he will not get any complaints from me for that. Also I have no financial interest in this operation. I am simply a very satisfied customer.

Subject: Homebrewed Clear

Hello:

With all the talk of Miller Clear recently, I became curious. How do they do it exactly? Of course, a more pertinent question may be "WHY do they do it?" That notwithstanding, I set out to make my own clear on a very small scale, not in the interest of good beer, or even acceptable beer, but out of plain curiosity. I work in a yeast lab. We routinely treat amino acid solutions with activated charcoal to remove contaminating nucleotides. A byproduct of this treatment is that the solutions go from yellow (before filtration) to completely clear (after). Hmmmm. Could this simple observation be applied to the world of brewing? I did the following experiment: I took 1 ml samples of three beers I have fermenting at present: a dark lager, a cream ale, and a pale ale. All yeast and hop particles were removed by centrifugation. Then I added a small amount of activated charcoal powder to each tube, mixed for a while, and then removed the charcoal by filtration. The result: three tubes of absolutely colorless liquid! But appearance is not everything; had I really succeeded in reproducing miller clear? I took a tentative sniff; there was the distinctive aroma of ABSOLUTELY NOTHING. A small taste: again, the very soul of NOTHINGNESS. There was a slight alcohol flavor, but I am sure that I can tone that down in subsequent batches. In short, the experiment was a complete success, and I will begin large scale production soon, beating miller into the Massachusetts market and becoming fantastically wealthy. Of course, when I design the packaging for this unique product, I must avoid using words like "Boston", "beer", "the", and "and", thereby inviting the ire (and lawsuits) of the venerable Jim Koch. Perhaps a totally blank white label would be appropriate (Jim has already aquired the rights to red, blue and silver); when people walk into their neighborhood tavern and say nothing, they will be served a frosty mug of ""!  
dave.

Subject: AHA Conference in Portland

There were a couple of posts today in reference to the AHA Conference here in Portland; I suspect there will be many mor in the days to come. With luck, we shall get a big Internet crowd there, along with plenty of people from the CompuServe Beer Forum. Last year, Russ Wigglesworth provided everyone with little red computer stickers for their nametags so that we could pick out fellow computer beer/nerds from the crowd. With luck, someone else will do the same this year.

Someone (Rick?) said that he was buying a partial membership, leaving out the social stuff and paying for speakers. A suggestion: You've got it backwards! From my experience at last year's conference, the "lectures" are the least interesting part -- hanging out, eating and drinking with other homebrewers, that's the real fun...and the most educational. I say this as one of last year's speakers! There were a couple of really interesting presentations, but the high points for me were meeting George & Laurie Fix, having dinner next to Charlie Olchowski, finally meeting Martin Lodahl in person, and doing a walking tour of Milwaukee with Russ, and... oh, yeah, that beer. And judging in the 2nd round. And Fred Eckhardt's cheese and beer tasting. And...

Speeches? We don't need no stinkin' speeches.

There are two JamBeery nights. HBD could host a table. I beleive that there is a \$35 fee. We are doing one for BURP (Brewers United for Real Potables) the Washington, DC club.

Otherwise, I will be out there with some other HBD participants and enjoy a session. I thinks a brewpub trip would be a crowd pleaser.

From: John Cotterill <johnc@hprpcd.rose.hp.com>  
Subject: EASYMASH & MALTMILL

My experiences brewing this last weekend are note worthy.

I usually use a slotted copper tube manifold and cooler as a mash tun. My grain is roller milled by the local brew shop, generally about a week before

I get around to brewing. I do a single step mash. My extraction is generally around 24 pts/lb/gal with an efficiency of about 70%. Sometimes it heads up closer to 75%. I have been happy with this level of extraction and just add a little extra grain to compensate.

I am working on a RIMS system. I have a SS pot with a fitting welded near the bottom. I have not brewed in it yet since the RIMS is not done. It seemed like such a waste to have this pot collecting dust when there was some brewing to be done.

I just purchased the world famous MALTMILL (had not used it yet). I have a false bottom for the mash tun, but my experiences using a mash kettle on the stove with a false bottom have been poor. I decided what the heck, I'll make an EASYMASHER and see what happens. Well, my extraction was 31.2 pts/lb/gal with an efficiency of of over 91%!! I could run the sparge as fast (or slow) as I desired. I did, however, have to recirculate about 1 gal to get a clear beer, but that is much better than the copper manifold (about 3 gal). I did have a relatively thin mash (1.4 qt/lb), so that may have something to do with it.

I gotta say, the system really works. I am impressed by the results. I need to brew a few more batches to say for sure how repeatable things will be. But I expect little difference on future batches. I suspect the gains are a combination of both the MM and the EM.

My only complaint is that I did not expect such a high extraction. Instead of a 1.054 pale ale, I got a 1.070 strong India pale ale!

Subject: pH Testing

>From: pgs@ai.mit.edu (Patrick Sobalvarro)

>Speaking of pH meters, the cheapest ones do not have detachable electrodes. Can someone with experience in these matters tell me how long I might expect the electrodes on these meters to last if one is only using them in brewing, where only mildly acidic solutions are encountered?

I have no idea but I suggest that anyone on a tight budget contemplating the purchase of a pH meter, borrow one and try it a few times. I have used mine on about 10 batches since purchasing and no step in the process has varied from nominal by more than the measurement error.

The only reason I continue to use it is because it is humiliating to think I got sucked into buying something I have no use for.

What bugs me even more is finding out that it is even more useless for wine making because pH is not a useful measurement of acidity in wine. One must measure titratable acidity with an arcane process that makes the pH meter look like something from Star Wars.

> city, try to visit the brewery. Good people; wonderful beer.

A recent selection from Beers Across America was Abita Bock. This stuff was good! I didn't do a formal evaluation of it at the time, so I'm relying on memory:

Style: Helles Bock

Appearance: golden, nice rocky head, good clarity.

Aroma: malty/sweet.

Flavor: Malt predominates, hops bitterness evident, no apparent hops flavor/aroma, sweet, but not overly so.

Body: medium. Appropriate.

Overall impression: A very nice beer, true to style, and very drinkable. I want more!

I'd give it around a 40 (out of 50), I think.

Too bad it's not available in Michigan...

From: dra@jsc-ws.sharpwa.com (Darren Aaberge)  
Subject: Spruce beer

I have a spruce tree growing in my front yard and I have been wondering about using some of the fresh spring growths in a brew. Does anyone have any experience using spruce in beer? Papazian has a recipe for using it and there are a couple of recipes in the cats meow, but they are all a little vague on how to use it. So far my plan is as follows:

10 lb 2-row pale malt  
1/4 lb crystal 401  
1/3 lb chocolate  
1.5 oz Cascades (boil for 60 min)  
1 pint of spruce clippings  
American ale yeast

My biggest question right now is when to add the spruce. Should I boil it for 60 minutes or should I add it at the end of the boil? Any suggestions or comments would be welcome. I don't want the spruce to be overpowering, yet I want it to be evident along with the hops.

Darren

Subject: Converting a freezer to a fridge

When I moved into my new house, a large (as in 20 or 22 Cubic feet) freezer was included. I have no use for it in its present form. Does anyone know of a way to convert it to a fridge. I know there are thermostats you can buy and hook to a fridge for more precise temperature control. But, I don't want to spend the \$\$, if it is impossible for a freezer to be kept at a temp. above freezing. If it would work, the size would be great. It would probably fit a couple of carboys and a case or two.

Email me directly or post if you think there are others who are curious.  
Thanks for any responses.

blah...

>This month they sent 2 porters. I found both of them-- Catamount and  
Boulevard

>to be so roasty/burnt that I don't really enjoy them.

I, for one, was happy.

I received a bottle of boulevard "Bully" porter 2 years ago from  
a friend, and remembered it as being somewhat watery. When the  
package came, I was delighted to see blackened friends awaiting  
me. I tried the bully porter at room temp, and it was anything  
but watery - smooth & delicious. Upon refrigerating the rest in  
a too-cold fridge (I like my milk COLD and my keg fridge was full),  
the somewhat watery (by my taste) mouthfeel returned.

IMHO, Bully porter is a much better beer at warm temps.  
(and exhibits more of a taste change with temp than most beers).

The literature that came with it (or was it the bottle?) claims  
that it is made with roasted barley and chocolate malt; it is  
more a stout (and a fine one at that) than a porter.

From: sag5004@yak.ca.boeing.com (Ford Prefect)  
Subject: Another data point

Hello,

I am busy brewing for my upcoming wedding. And have made a couple observations that some people might be interested in. If not, I apologize in advance (AIA :-).

Basic recipe:  
19 lb Klages  
3 lb Munich  
1.5 lb Crystal  
1 lb Wheat

2oz Tettenanger, 2oz Centennial (for 60 minutes)  
2oz Cascade (5 minutes)

\*(NOTE: I am not sure about the Centennial but I am sure it is one of those 'C...' types of hops)

I have made this four time recently, had an OG from 1.054-1.058. This makes ~11 gallons (one 5 gallon, and one 6 gallon carboy). I do a single step infusion mash, with a mash out up to 175 and hold for 15 minutes.

Experiment 1: Make two batches in a row pitching whitbred dry in one, and wyeast 1214? (belgian) in the other. The dry yeast had a bit of a bite that is mellowing out as time goes by. The only thing I can say about the liquid is I like in more than the dry.

Experiment 2: This was an accident. Having scotch/irish genes, I decided to stretch the next packet of 1214. I put a 2 quart starter in a gallon jug and let er rip for 3 days. Brewed, pitched 2/3 into the carboys, and 1/3 into some settled, cool wort from this batch. (monday) On friday I brew again, and had the fastest start I have ever seen. eg. 1:30 pitch and clean up, and by 4:30 foam city.

Everything smells and tastes "normal". I will hopefully, have enough for the wedding (I probably will if I don't drink it all myself first :-).

Just a data point, PS What style catagory would this beer fit into?

From: rstya@mda.ca (Roy Styan)  
Subject: dusty, dry beer

I was racking my beer a few weeks ago and found there was an extra two liters or so. Can't waste good beer so I found a two liter bottle and racked into it. During all that mucking about the yeast got quit stirred up and a lot ended up in the bottle. So its experiment time. What does beer taste like after spending a couple of weeks on a couple of cm. of yeast?

The quick answer? Yech.

This stuff was as dry as a popcorn fart. One sip and all the moisture in your mouth gets sucked down with the beer, leaving nothing but dustball for you to choke on. And bitter? Not the nice hop bitterness we all know and love, but the bitterness one gets from biting into a tree root (y'all chew tree roots down there, don't you?).

The main batch, on the other hand, has the nice malty aroma and taste I was looking for (its an english brown), and slides down leaving a pleasant roast aftertaste. Yummy.

What I found interesting is that all the elements of the dry, bitter batch were in the main batch, but they had not be accentuated. Rather, they had blended with other elements leaving a well balanced and rounded beer.

Woof.

You're probably sanitizing it in bleach solution, right? Don't soak it longer than 10 minutes and rinse with "clean" water immediately and it will not turn cloudy.

\*\*\*\*\*

donald writes:

>al is confused regarding sodium hypochlorite, chlorine water and bleach.  
>bleach is a dilute, about 5%, aqueous solution of sodium hypochlorite.

I re-checked my 1991-1992 Cole-Parmer Chemical Reactivity charts and there was no mention of Chlorox (bleach). There was no confusion on my part as to the difference between bleach and sodium hypochlorite. I was quoting the "Sodium Hypochlorite <20%" entry because it was all I had to work with. I've just gotten off the phone with a Cole-Parmer Applications Specialist, who took my order for the 1993-1994 catalog and verified that "Clorox (bleach)" has been added to the 1993-1994 catalog. Indeed, the table now shows no effect between Clorox Bleach and 304 or 316 Stainless Steel.

However, as don says himself:

>these tables are only guidelines. no details as the conditions of the test  
>such as length of exposure are given.

I've read reports in the HBD of pitting (especially on the welds) in Stainless Steel kegs after repeated use of Bleach solution in the kegs. I trust the cumulative experiences of homebrewers well beyond what I read in a table and I've taken don's report as a single datapoint.

Furthermore, I'd like to point out that don's wife is the owner of St. Pat's of Texas (brewing supply) and they do not stock Iodophor rather they stock a chlorine sanitizer.

Finally, don has, in a newsletter, questioned the quality of the DeWolf-Cosyns Belgian Malts (another item not stocked by St. Pat's of Texas) while on the other hand, St. Pat's of Texas turns out to be the sole distributor of Breiss malt in the area.

I've yet to find the reasoning for don's tirade on yeast a few weeks ago, but I'm sure that his ulterior motives will surface eventually.

Please note that this is not a flame. I'm simply posting data that I've collected and am not personally attacking anyone.

A1.

>sterile cool water, swish it around, and dump directly into the primary.  
>Fermentation started within 12 hrs and smells clean. It's a slow ferment  
>as are most that I do with SNPA but smells clean. Questions:  
> - can anyone see potential problems or drawbacks with this method

Repeated re-use could favor a mutant strain and I recommend not re-using yeast too many generations for this reason. Typical problems with mutant yeast are the loss of the ability to ferment certain sugars and the loss of the ability to re-absorb diacetyl.

> - how long might clean yeast be held under pressure this way before it  
>loses viability.

The pressure probably won't make much of a difference. Temperature does. You are better off storing it at around 40F, but letting it warm up to pitching temperature slowly before use. At 40F, I believe that your yeast would have a sufficient percentage of viable yeast for at least a month, but this is dependent on the health of the yeast at pitching time, the level of oxygenation of the wort, etc.

>

>One other question.... I recently bought WYEAST packs for both British  
>Ale and London Ale (forget the #'s). Can someone tell me what the difference  
>in these yeasts are based on their experiences, and which styles of ales  
>they might match up best with.

British is very similar to the old, three-strain Whitbread yeast, whereas the London Ale is very similar to Bass and Co's Whiteshield yeast. I haven't used the British (Wyeast #1098) but I've read that others have reported a spicy, tart flavor profile. Wyeast's London (#1028) is one of my favorites and I use it often. It has a woody profile but otherwise is quite neutral.

>might be a symptom of a fungal infection.

Did the leaves first turn light green between the veins, then yellow, then rust-colored? If so (and maybe also if not), you may have a Magnesium deficiency in your soil. I did and I could stop what you reported by dissolving two tablespoons of Magnesium Sulfate (Epsom salts -- at your

local drugstore) in a couple of gallons of water and then splitting this between my four hills. I don't know if this is the best way to add Mg to your soil, but it worked for me. I had to do this about every 2 to 4 weeks to keep the leaves from turning. Any other suggestions for increasing soil Magnesium? I know that hops are one of the few plants that require Mg, but a tablespoon of MgSO4 a month!?!

From: jpgareri@acs.bu.edu (Joseph Gareri)  
Subject: EDME Brewcraft Barrel

I recently purchased an EDME Brewcraft Barrel. The first batch I put in was not great. The main problem was it was terribly flat. The barrel is 6 gallons with the CO2 injectors and a release valve that is supposed to keep pressure up to 10 psi.

The batch was about 3.5 gallon wheat recipe from the Cat's Meow. The recipe itself was very weak, but that's another problem.

I primed it with 1/4 cup corn sugar dissolved in 1.5 cups boiled water. There was some gas build up, but the beer never got terribly carbonated, so after 2 weeks, I primed again with the same amount. This didn't seem to work either. Is it because there was too much air space, so the CO2 did not remain in the beer? The directions from EDME say it is not necessary to use one of the CO2 injectors for conditioning. Any thoughts?

I am currently in the secondary with Tom Childers "Wheat Berry", and would not want to spoil a batch that seems to be coming along nicely (thanks Tom for your tips). Should I prime with the 3/4 cup corn sugar as Tom recommends for bottling or should I reduce the sugar as is recommended for kegging? I can't figure if this system is more like bottling or kegging.

Any help would be greatly appreciated.

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Iowa Beers

Just thought I'd share a pleasant experience I had this weekend. While visiting Cedar Rapids, I dropped down to the Amana Colonies (19 miles south) and was pleasantly surprised to find in addition to several small wineries.... a brewery! Millstream brewery is in Amana (Main Amana) and has 3 beers on tap and in bottles; their Schild Brau was the best IMHO, amber in color and not too hoppy. They also had a very nice wheat beer. Their lager however could stand some improvement, no one in my group really cared much for it.

And while I'm on the topic of Iowa, has anyone out there been to the microbrewery in Alden, Iowa? Any idea how far it is from C.R. and if it is worth the trip. Private email please.

Date: Tue, 1 Jun 93 11:58 CDT  
From: korz@iepubj.att.com  
Subject: DMS/Lambiks/Hoegaarden

Anthony writes:

>I just bottled my first attempt at a California Common or "steam" beer  
>yesterday and I noticed a definite DMSO odor in the beer (the cooked  
>corn type odor). Will bottle conditioning help to reduce this over time  
>or will I just have to get used to it. What causes this (I've heard  
>that this is generally due to slow wort cooling, but as this was an  
>extract recipe which normally is cooled rapidly as it is transferred to  
>the carboy containing cold water, I doubt that the cooling is any  
>different from my other extract recipes.)

DMS (Dimethyl Sulfide) is the chemical that give the cooked-corn aroma.  
DMSO (Dimethyl Sulfoxide) is oxidized DMS. Some DMSO can break down to  
DMS during the ferment by the yeast. Most of the DMS that is created  
during the boil, cooling and ferment gets scrubbed out by the CO<sub>2</sub>, so  
you need to have very high levels of SMM (the precursor of DMS), DMS  
and DMSO to have some spill-over into your finished beer.

There are primarily two sources for DMS, bacteria and the malt. The  
bacteria that generates DMS is called *Obesumbacterium Proteus*. You  
may have had wort infected with this bacteria all along, but since  
this bacteria's activity is mostly during the earliest stages of  
fermentation, when the pH of the wort is greater than 4.5, a longer  
lag time on this particular batch may be all that was needed to get  
the DMS in the final beer above the 30ppb human detection threshold.

Another source for DMS is from the SMM that is created when malt is  
germinated. During the kettle boil, virtually all DMS that is created  
is boiled-off. If you cover the kettle or if the boil is not a rolling  
boil (just a simmer) you can retain enough DMS to detect after  
fermentation.

Also, as you mentioned, fast cooling is essential to minimizing DMS  
in the wort because when you take the kettle off the boil, DMS still  
continues to be produced until you cool the wort below 140F, but is no  
longer being boiled-off.

\*\*\*\*\*

Richard writes:

>Are 'lambic' bacteria distinct from 'lactic' bacteria, and if so, how ?

Lactic bacteria are only one of many bacteria that contribute to the  
flavors and aromas of Lambiks. *Pediococcus Cerevisiae* and *Lactobacillus*  
*Cerevisiae* are two of the lactic acid producers, but certain types of  
(all?)

Pedio also create diacetyl, for example, but only God knows what the  
other  
microbiota in Lambik wort do with the diacetyl since I have yet to taste  
a Lambik with a noticable diacetyl character. In addition to the Pedio  
and  
Lacto bacteria, Enteric bacteria play a role in the flavor/aroma of  
Lambiks.

Brettanomyces yeasts, *B. Bruxellensis* and *B. Lambicus* give the  
characteristic  
"horsey" aromas as well as contribute to the flavor. Many "wild"  
*Saccharomyces* and *Brettanomyces* yeasts combine to produce the intense  
fruitiness found in many Gueuze Lambiks, so much so, that I've often had

to look back at the bottle to make sure I hadn't been served a fruit lambik!

So you see, there's a lot more to Lambiks than just a lactic sourness. Note that recent bottles of Timmerman's Framboise that I've tasted have had a more pronounced Brett (horsey) character than I recall. Perhaps this is simply a batch-to-batch variation (lambiks, more so than any other beers, vary quite a bit from batch-to-batch and even bottle-to-bottle!) or perhaps Timmerman's is trying to blend more towards a traditional flavor (I hope so).

Mark writes:

>ago. Anyway, after a few minutes of begging that I should be connected to a materials engineer (not a sales "engineer") I got some helpful folks in one of their labs. Turns out the guy who knows the most about polypro is also a homebrewer! Well it was certainly a relief not to have to spend 1/2 hour explaining what a hop back, wort etc. were! Bottom line: The chart is wrong as regards to polypro. Beer won't hurt it or react with it (neither will wort). This guy said that polypro's barrier properties weren't that good and thought the chart might have been inferring that you wouldn't want to store carbonated beer in it for long periods because it would go flat. However, carbonated water is "OK" for polypro on the chart. We couldn't figure it out.

I expect that a materials engineer at Phillips 66 should have been able to figure out that the reason that Polypropylene is not acceptable for long-term storage of beer is not only because of CO2 permeability, but O2 permeability! According to the Cole-Palmer catalog, the O2 permeability is  $25 \times 10^{-10}$  (cc-mm)/(sec-cm<sup>2</sup>-cmHg), which is 2.5 time higher than HDPE (high-density polyethylene) which is widely known to be too oxygen-permiable for long-term beer (or hop, for that matter) storage. Long-term storage in oxygen-permiable plastics will, of course, oxidize your beer (or hops).

By the way, why does every post by Mark sound like an ad for his business?

I, for example, have yet to mention that my store/mailorder house, Sheaf & Vine Brewing Supply, sells hops stored in a special, proprietary plastic that is food-grade, yet is an oxygen-barrier and that the pouches are CO2-purged before vacuum sealing... but you don't see \*me\* running shameless ads in the allegedly non-commercial HBD ;^).

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Hop Utilization and clarifications

In a recent Digest, Mark Garetz petitioned the readers for info regarding Jackie Rager's alpha acid (AA) utilization numbers in his article in the Zymurgy Hop Special Issue. I am currently in the middle of a fairly good sized research project into this exact subject.

As George Fix mentioned in a recent posting, I am fortunate enough to be able to work in Gail Nickerson's USDA hop lab where I have the glorious title "Official Volunteer Hop Grinder and Sample Prepper" in exchange for the use of their equipment. In addition to running alpha and beta analyses on my hops, I am studying AA utilization vs boil time and AA utilization vs wort gravity. Both my early findings and an extensive literature review indicate that there are problems with Rager's numbers. Typical util vs boil time curves look nothing like Rager's numbers and max. util % numbers range all over the place in the literature, from 10-50% in the finished beer (Rager gives a middle of the road 30% for a 60 min boil).

It is still too early for me to give some definitive answer to the util question. I know how unsatisfying it is to hear that something is wrong without hearing the right answer but I am afraid that we (myself included) are stuck with Rager's numbers for a while longer, at least until I get a few more test batches in bottles and run through the spectrophotometer. Is this "Vapor-data"?

Also, for everyone I promised a catalog to, they come from the printers tomorrow, and will be in the mail the same day! Sorry for the delay but the response to my previous posting surprised me (a good surprise:)

Subject: Litmus Papers

Actually, nowadays just about nobody uses "litmus" papers any more. The old fashioned "litmus" came in two types, red and blue, and you had to use the correct one for measuring acid or basic solutions. The modern equivalent is referred to by various names, but in our lab we just call them "pH papers". If you can't find the right stuff in your catalog, look under "test strips" or "test papers" or "pH" rather than "litmus". Modern test strips are much better than "litmus". The ones I like best (NOT the cheapest BTW) are known by the trade name ColorpHast, and come as single use strips of plastic with patches of colored indicator at the business end.

Just thought all the pH-concerned out there might like to know... P.

From: Nick Zentena <zen%hophead@canrem.com>  
Subject: Belgian malts in Brewing Tech

Hi,

I got my copy of Brewing Techniques this week and I've got some questions.

The article on Belgian malts by Prof. Fix stated that the test mashes were conducted using distilled water and 30grs of calcium chloride. Is this enough in the way of minerals? Would this very soft water profile cause the results to differ from real world mashes? I assume that the distilled water was used to give some sort of a standard.

Also the article gives the following:

Pils malt -linter 105 able to convert 15-20% adjuncts  
Pale ale malt- linter 60 able to convert 10-15% adjuncts

In comparison I think Canadian 2row is 120-130linter and capable of converting 50+% adjuncts.

Are the adjuncts numbers given for the Pils just conservative? Would it be able to convert a high adjunct mash like a normal p-lambic?

Finally is Brewing Techniques going to be review books other then those available from the AHA?

Thanks  
Nick

I agree, the partial registration includes all social events and some  
of the lectures. I have been to a few of these conventions and I have  
trouble sitting in a wonderful place like Portland in a hotel for 8  
hours a day. Plus, getting up early after Brew Pub hopping.

Cheers, Rick

From: tmr1@hotmailg.att.com  
Subject: Re: Cloudy hoses/Bleach and SS

I also suffer from the "cloudy hose" syndrome. I left mine soaking overnight in a water/bleach (20:1) solution and it is permanently(?) cloudy. Will this impair the use of the hose for racking? Will the bleach leach? Can I do something to get the hose clear again? Maybe boiling in water will do something to it.

Any suggestions are welcome.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: iodine

I'm sure this has been covered before, but here I go again....

The last batch I made, I did the iodine test two ways: 1. I drained a little out of the spigot at the bottom of my mash/lauter tun (Gott cooler with copper-pipe manifold). This tested completely starch free after 20 minutes (the first time I tested it). 2. I pushed the spoon into the top of the mash and let some fluid run into it. This never tested clear, even after 1.5 hours.

So which one should I believe? I got a great (for me) extraction rate of 31 pts/lb/gal, with wonderfully clear sweet wort, so it would seem that conversion was indeed complete (maybe at 20 minutes).

A related question: Foster suggests (in Pale Ale) that you should mash for 1.5 hours for flavor development, even if conversion is complete sooner. Any comments on this?

Subject: Weissbier available: Elkton MD

From: Matthew Mitchell

On the way back from the NCAA lacrosse finals (Syracuse 13, NC 12 in what is arguably the best tournament game ever-see it on CBS Sunday at 3:30 ET)

I took a detour off I-95 to avoid traffic, toll, and poor PA state liquor stores.

I discovered that my favored shop: State Line Liquors in Elkton, Maryland (between I-95 and Newark, Delaware on MD route 279) has an excellent selection of Weissbier, and a number of Belgian beers, all available as singles. Selection of US microbrews is fair to middlin': there is SN and Pete's and a few other more common varieties, but I've seen better at other places.

They have an 800 number (I think it's 800-345-WINE, but please check first!) The booze prices are significantly better than most neighboring states, and their wine selection is decent (if you can afford it, the

Latour and Palmer is right out on the shelves, but of recent vintage rather than classic) So if you are traveling 95 south, exit northbound at MD 279 or southbound at DE 896 (then turn left at the football stadium and left again on 279) You'll save more than the toll!

No connection of course: just a satisfied Pennsylvania refugee!  
Howzat!?!

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Stainless Steel

As one the people who raised concerns on HBD about the use of chlorine with stainless equipment, perhaps a few additional remarks might be helpful.

The two alloys which are most relevant to brewing are the following (shown with their % concentrations):

| type | Cr    | Ni    | C    | Si | Mn    | P    | S    | Mo  |
|------|-------|-------|------|----|-------|------|------|-----|
| 304  | 18-20 |       | 8-12 |    | .0812 | .045 | .030 |     |
| 316  | 16-18 | 10-12 |      |    | .0812 | .045 | .03  | 2-3 |

The 316 alloy differs from 304 by its 2-3 % molybdenum (Mo) content. It is the latter which gives this alloy complete resistance to chlorine. However, 316 is very expensive, very difficult to cold work, and not used to make 5 gallon soda pop kegs. The best of the latter are made from 304. This alloy has some resistance to chlorine, but not like 316.

Studies

done with brewing in mind concluded the following:

1. The relevant parameter is the concentration of the free available chlorine (FAC), independent of its source (bleach, chlorine powder, etc.).

2. At room temperature (and a normal pH), 304 is resistant to chlorine as long as the FAC is below 250 mg/l.

Since our standard 1 oz. bleach per gallon gives a FAC of 100 mg/l, one could conclude that chlorine bleach can be used to sanitize ss kegs. Careful brewers will reject this conclusion. The factor of 2.5 is cutting it too close. More to the point, the studies were based on a one time application of the chemical to the metal, and does not take into account the effects of long time use. I use boiling water or iodophor simply because I am not prepared to gamble with ss equipment that I hope will be with me in the long run.

I am not against taking gambles in other aspects of brewing, like taking ones standard Vienna formulation, doubling the hop rate, and sending a few bottles to Jeff Frane. Actually a much bigger gamble, and one I may live to regret, is \*\*\*not\*\*\* doubling the hop rate and sending some to Jeff! Gambles like this are done everyday, but hopefully not with valued equipment.

There is, in addition, a completely different aspect to these issues. My grandfather was a brewer who like many of his generation absolutely detested "chemical" cleaners and sanitizers. For him it was hot water, 18 hr. brew days, and maybe some vinegar and wet steam. I do not fully agree with this viewpoint, but recalling some excellent homebrews I have judged at various points in the past that have been ruined by residual chlorine, there are some merits to this point of view. That is way I was initially excited about peracetic acid. However and alas, the version Diversity and others is producing for the brewing industry is not for us. Even a drop or two of their concentrated solution on our hands would turn them white as snow. These products were produced with closed CIP systems in mind, and not the way we do things. It would therefore appear that boiling water or iodophor are our best options for ss. If the latter

is used I would also recommend rinsing before use with water or sterile beer, although there are many successful brewers who do not rinse.

From: Jamie Ide 02-Jun-1993 1044 <ide@studio.enet.dec.com>  
Subject: EasyLauter

My last six batches have included partial mashes of 4-6# malt, which gets combined with extract for the boil. I've found partial mashing to be easy, once I got the hang of it, and I can taste the improvement it's made in my beer.

The only problems I've had with the process have occurred during sparging. Up until my last batch, I'd been using a cylindrical water cooler (it came with my house, you can't fight destiny) with a grain bag, which sat on a vegetable steamer, as a lauter tun. I got lousy extraction with this method -- the one time I carefully measured gave me 17 points! -- and I had to recycle 1 gallon (out of 2.5) of runoff before it cleared. The poor extraction may have been due to my grain bag's mesh sides and a poor crush. I quickly grew tired of going through the extra work of mashing and then having to add 6 lb. of extract to get a reasonable SG, so it was time to look for a Better Way.

In the grandest tradition of science, I appropriated someone else's idea. Jack Schmidling's EashyMasher (tm?), sounded, well, easy and cheap to make. I decided to adapt the idea to my lauter tun. I poked around the hardware store and found a PVC connector which would screw onto my valve (the plastic one with the red lever, though it may fit a drum tap too). This connector ended in barbs which fit 3/4" plastic tubing. I attached a couple of inches of that to extend the pick-up tube, and fixed a few inches of rolled up screen, cut out of a broken window, on with a hose clamp. Total cost was about \$4.

I've tried it on one batch and it performed impressively. The runoff cleared after only two cups! I couldn't calculate my extraction because I ran some extra off for canning yeast starters, but I hit my target gravity which I'd predicted using 25 point extraction. A big improvement, though I think a better crush will improve it further. Not having to recirculate a gallon saved me some time, and clean-up was easier. An unmitigated success.

I recommend giving this a try if you're currently using a grain bag or a Zapap system. Almost every brewer has a bucket with a valve on it, and for \$4 you can convert it to an EasyLauter tun.

Jamie Ide ide@studio.enet.dec.com

Disclaimer: I only know Jack through the HBD and the EasyLauter is too cheap to sell.

From: Jamie Ide 02-Jun-1993 1046 <ide@studio.enet.dec.com>  
Subject: Wort Chiller to Sparge Heater

I'll be going all grain soon, and I have an idea for heating sparge water. I don't have a second large boiler to heat the water, and I collect the runoff of my partial mashes in my boiling kettle, so I can't use that. What I was thing of doing is running my immersion wort chiller (aka that coil of Cu tubing currently sitting in my basement) backwards.

That is, immerse the chiller in a pot of hot (boiling?) water and run tap water through it to heat sparge water. By playing with the flow rate and the water temp., I ought to be able to get it up to temp. easily.

This would also give a couple of advantages:

I could stop the flow when the runoff sg dropped and not have any leftover water. With practice, I could even use the water that the chiller sits in.

I could easily hook up a "showerhead" to the hose output and get a nicely distributed flow over the mash.

Has anyone tried this? Any opinions?

From: "UARS::COOK"@CDHF1.GSFC.NASA.GOV (Chris Cook)  
Subject: Spruce and Oak Additions

Darren Aaberge asked about adding spruce clippings to his beer.

I've made a number of spruce beers and I enjoy the flavor a lot. I started with Papazian's Goat Scrotum Ale and have stayed close to that style, adding spruce to a rich, dark base for my spruce beers. Unfortunately, given that I don't have a spruce tree, I've depended on spruce extract, so my experiences may not translate completely but they may still be useful.

For the first few spruce batches, I threw in a bottle of essence at the beginning of the boil. This was a lot, and I think compares to about a quart of new spruce growth. The house smelled wonderful and, when the beer was done, the spruce flavor was smooth and rich without being overpowering. Keep in mind that I was making a Spuce Beer, so I wanted spruce to be one of the major flavors.

After a few batches, I got to wondering that wonderful aroma when I boiled meant that I was boiling off the aromatics. For the next Spruce Beer batch, I waited until just before the boil ended to add it. I knew the flavor would be stronger, so I added half as much as usual.

This beer was, to be kind, different. The flavors were too bold and too harsh, without the richness I'd expected. This might have been an artifact of the essence, and may not apply to fresh spruce. There may be no bad beers, but this was certainly not a good beer, and I ended up dumping the last half.

Darren said that he didn't want the Spruce overpowering the hops, so a pint sounds about right. I'd use a quart, but then I'm already a convert. Not knowing, I wouldn't worry about bruising the branches; just throw them in whole at the same time as the boiling hops.

[A side note: I hold off the boiling hops until I've gotten a good, obvious hot break - about 10 minutes after the boil starts. If I don't wait, I don't seem to get as much hops bitterness. Someone said once that the uncoagulated proteins coat the hops, limiting hops utilization. I don't have much hard evidence of this, but I've been following the advise.]

As a counter-example, I've also used oak chips and oak essence in IPAs. (I know that it's not in style any more, but I like it as a subtle addition.)

In this case I added the chips or the essence to the secondary. The batches with the oak chips were good; the batch with oak essence wasn't good at all. It had something like the real oak flavor, but with harsh, strange overtones that were unsuitable; eventually it had to be tossed.

Let us know how things work.

I think you probably mean Adel, Iowa which is west of Des Moines. The  
Old  
Depot brewpub just open there in 1991. My wife and I just went there a  
couple  
weeks ago. They make 3 or 4 beers(I think an ale, lager, porter and  
something  
else) and 1 or 2 beers of the month. When we were there they had a  
Weisse and  
an IPA which were both really good. I talked to someone who went there  
earlier this year and had a good Irish Red Ale. The food there is also  
very  
good. The restaurant is not what you would probably think of a normal  
brewpub  
though. Its a new, modern-looking building which is separate from the  
brewery. I would recommend going there if you're in the area.

Subject: clorox and stainless steel

Al (korz@iepubj.att.com) writes:

>I've read reports in the HBD of pitting (especially on the welds) in  
Stainless  
>Steel kegs after repeated use of Bleach solution in the kegs. I trust  
the  
>cumulative experiences of homebrewers well beyond what I read in a table

(here here, didn't one of those tables say that grape juice ate teflon?:  
-)

Here's yet another data point (YADP)

I believe that problems may arise when brewers use a bleach solution that  
is  
too concentrated. I started keging in 1978 using cornelius style kegs  
and  
1980 with SS 1/2 barrels. I still have those same kegs. They have been  
sanitized with bleach solution every time and believe me these kegs have  
seen a  
lot of activity:-) I have yet to see any wear of any kind on these  
lovelies,  
beyond the occasional need to replace the O rings and brass wing nuts on  
the  
cornelius's, and the bungs and figure 8 gaskets on 1/2 barrels. I had  
bartending experience prior to the use of these kegs where I learned  
about  
chlorine test strips to determine the sanitizing power of the solution. I  
use  
in the ballpark of 50 ppm as determined by these strips and I havent had  
any  
problems with the results.

When I work with newer brewers, one pretty common trait is to watch them  
splash  
horribly (to me anyway) concentrated solutions of bleach water over  
everything  
associated with the brewing process. I usually take some of my test  
strips  
along and show them that they are using solutions that are 'off the  
scale' of  
the strips capacity (it only reads up to 200 ppm). Its easy to believe  
that  
'more is better', but when it gets to the point where you may sustain  
damage by  
contact to yourself, it may be time to examine your technique. I always  
wear  
eye protection/gloves but at ~50 ppm I dont get too worried about burning  
holes  
in my lab jacket or brief skin contact - or eating holes in Stainless  
Steel.

Dont get me wrong, I'm not knocking idophor (I used it all the time when  
I was  
doing hospital OR work), but bleach is inexpensive (esp. when you dilute  
it

properly), easily available, effective, and pretty safe when used properly.

>60 minutes or should I add it at the end of the boil?"

I have no experience in using spruce clippings in beer or anything else,  
but the terpenes responsible for much of the characteristic aroma are  
fairly volatile, and I suspect they would steam distill out during a  
prolonged boil. I'd add them at or near the end of the boil.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: Iowa beer, Scottish Ale

Anthony Johnston wrote commenting on Amana beer and asking about a microbrewery in "Alden."

I'm relatively new to the state (4 years), and my spouse and I have been procreating since we arrived. The rug rats, unfortunately, keep me from getting around much. However, I concur with Anthony's appraisal of Amana beer (good amber, not-so-hot-but-not-too-bad-either lager) which I have been able to get frequently on tap locally and in bottles. (I have my first trip to the brewery itself planned in a couple weeks - provided we can get a good babysitter.)

But I'm confused about "Alden." Do you mean "Adell?" (It's entirely possible that there is a place called Alden that I haven't heard of - please correct me if so.) Adell is on Route 6 just West of Des Moines, and no I haven't been there either. I've heard they have a very interesting menu, and their beer is available locally in bottles. I've only had a chance to sample the porter, which won't knock your socks off, but I found it very pleasant. The name of this beer is "Old Depot." If I ever get over there I'll post a review.

- - - - -

David Hinz posts an enthusiastic report of his Scottish Ale brewed to Papazian's "style guide" specs. David, would you care to share the specifics of your efforts? I'm an extract brewer, but I'd still like to see your grain bill if you did an all-grain recipe, so I can try to approximate with extracts, and I'd be curious about your choice of hops and yeast as well.

Jonathan Knight  
Grinnell, Iowa

P.S. speaking of Iowa beer etc. - Tom Calahan, my e-mail reply to you bounced. Are you still on the net?

or  
>comments would be welcome. I don't want the spruce to be overpowering,  
yet I  
>want it to be evident along with the hops.

I've brewed two batches of spruce beer: one a dark ale similar to the  
recipe you propose, and the other a light lager. I used about 100g (~4  
oz.) of green spring Sitka spruce growth in each one, boiled for about  
one  
hour. Personally, I preferred the light lager, but the dark ale was OK  
too. The flavour lent by the spruce surprised me. It wasn't at all like  
a  
tree, or a forest, or sap, or anything else one might associate with a  
spruce tree. Instead, it's a sweet, almost berry-like taste, with a bit  
of  
sourness thrown in. I can see why Papazian thought it tasted like  
Pepsi-Cola. It's subtle, yet distinct. I have also found that it  
dissipates fairly quickly in the bottle. My spruce lager has been in the  
bottle for a little over a month now, and the spruce character has  
subsided  
considerably, which is OK because it was a bit much at first.

Whether you go the ale or lager route, keep the hops light to bring out  
the  
subtle spruce flavour, and you should probably use a little extra spruce  
in  
a darker recipe.

To brew, perchance to dream....

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Stainless Steel - Part 2

Shortly after sending my post on stainless to HBD I started to worry that my phrase "boiling water or iodophor" may be misinterpreted as one and not

two alternate procedures. In particular, one should \*\*\*never\*\*\* add an iodophor to water at an elevated temperature, since potentially toxic fumes can result. The version of iodophor I use is called Accord II, and is made by Diversity. This is the version that has the iodine bound up in phosphoric acid; the other versions have it bound up in detergents.

Diversity

states that their product if applied at 110 F can be used to clean. I tried

this once and the smell was not pleasant. The point where it would be dangerous is much higher, but I bet it happens below 212 F.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: My Swollen Head, and Book Reviews

My goodness! HOMEBREW Digest #1153 seems to have been the Martin Lodahl Commemorative Issue! Prof. George Fix called to mind a truly delightful afternoon:

> I brought some fresh bottles of the Grand Cru to the Beer Fest at  
> Temecula, Ca. for Martin Lodahl to taste. He gave it high marks  
> for both authenticity and overall quality. Comments, Martin?

Sure! I can't imagine a better antidote for an 11-hour drive than to sit sipping beer and talking brewing with G. Fix and D. Richman! And I can't remember when I've had a beer that delighted me as much as that Celis Grand Cru. It's solidly in the Belgian Strong Ale tradition, delightfully smooth and complex, different flavors arriving in succession. Before that, the White was the only Celis product I'd tried, and was delighted with it both bottled and on draft. One of these days I'd very much like to get to that brewery, and try the rest of the line!

By the way, I would have been perfectly happy with just that afternoon, but as an Extra Added Bonus there was the Southern California Beer Fest put on by the Barley Bandits and the Maltose Falcons, in Temecula. It was truly superb.

In the same issue, Jeff Frane was speaking of last year's AHA Conference, and said:

> ... the "lectures" are the least interesting part -- hanging  
> out, eating and drinking with other homebrewers, \_that's\_ the real  
> fun...and the most educational. I say this as one of last year's  
> speakers!

And one of the better ones, at that! I very much enjoyed Jeff's presentation on wort chillers. I also agree with his priorities -- the people were certainly the best part.

> ... There were a couple of really interesting  
> presentations, but the high points for me were meeting George &  
> Laurie Fix, having dinner next to Charlie Olchowski, finally  
> meeting Martin Lodahl in person ...

That guy, again!

> ... and doing a walking tour of Milwaukee with Russ, and...  
> oh, yeah, that beer. And judging in the 2nd round.

Where Jeff got to meet Eric Warner's to-die-for Weizen.

> And Fred Eckhardt's cheese and beer tasting. And...  
>  
> Speeches? We don't need no stinkin' speeches.

Fortunately, in HOMEBREW Digest #1154 Nick Zentena restored my perspective (I may some day be able to find a hat that fits, again) by asking:

> Finally is Brewing Techniques going to be review

> books other than those available from the AHA?

As the author of the book review in question, I have to tell you that BT didn't ask me to write it. They asked me to write something, leaving it pretty much up to me what I wrote. I like that particular book (Jean-Xavier Guinard's "Lambic"), I've read it a number of times, and so I thought I could review it without doing it (or BT) too much violence. As far as I know, there's neither a connection nor is there antagonism between BT and any part of AoB, including the AHA and Brewers' Publications. So the answer is yes, there's no preference at all being extended towards any one publisher, in BT's reviews.

From: tony@spss.com (Tony Babinec 312 329-3570)  
Subject: oktoberfest recipe ideas

Most German Oktoberfest beers have a starting gravity of 1.052 - 1.055, which puts them more in line with the AHA "Vienna" style. These beers are amber-colored (aim for 10L - 12L), malt-accented lagers. From the point of view of recipe formulation, you have the choice of using crystal malts, munich malt, or some combination.

In their book, George and Laurie Fix present recipes using crystal malt. Depending on your setup and extract efficiency, for a 5-gallon brew you might use a grain bill such as the following:

8 - 9 pounds pilsner malt  
6 oz crystal malt 10L  
6 oz crystal malt 60L  
6 oz crystal malt 120L

The above grain bill specifies pilsner malt, and you should use the finest German or Belgian pilsner malt. Lacking that, use a good U.S. 2-row pale malt. The crystal malt blend gives the beer the requisite color, body, and sweetness.

In subsequent articles and postings to HBD, George Fix has reported using mixes of DeWolf-Cosyns Cara-Vienne (20L) and Cara-Munich (80L) malts. In the first issue of Brewing Techniques, it appears that George Fix has settled on a mix of Cara-Vienne and Special B. Using the BRF program, the following grain bill should produce a color in the desired range:

9 pounds pilsner malt  
1 pound Cara-Vienne (20L)  
1.5 ounces Special B

As an alternative to the above grain bills, one could explore the use of Munich malt, which should give color and malt flavor. As an example, consider the following grain bill:

5 pounds pilsner malt  
4 pounds Munich malt  
1 pound U.S. cara-pils  
1/4 pound crystal malt 40L

Note the high fraction of Munich malt in the grain bill. As U.S. Munich malt can be of variable quality, brewers have raised the concern that the resulting beer will suffer from grain harshness. However, with the availability of DeWolf-Cosyns Munich malt, as well as German Munich malts, surely such a recipe should be tried.

For hops, use fine European Noble hops, and hop to 22 - 25 IBUs (or roughly 6 AAUs). As an example, the hop schedule might be:

0.85 ounces Tettnang (alpha=4.5) at 45 minutes until end of boil  
1/2 ounce Styrian Goldings (alpha=4.9) at 30 minutes until end of  
boil  
1/2 ounce Saaz (alpha=3) at 15 minutes until end of boil

This style is not a bitter style, so total hopping is kept down. Nor are pronounced hop flavor or aroma desired, so the last hopping is 15 minutes before end of boil.

Use a good lager yeast and proper fermentation temperatures.  
Wyeast "Bavarian" lager works very well. Ferment at 50 degrees F  
or so. Rack the beer to secondary, and lager for 4 to 8 weeks.

Subject: How can I protect my stove?

Whoops, sorry about the previous post! I mailed the wrong file!  
(insert sheepish grin here)

I've recently gone all-grain, and I must say I've found the improvement in my beer to be considerable (although I \*hate\* how long it takes to brew a batch). If it wasn't for the HBD, I'm sure I wouldn't have gotten the nerve to try it yet. My thanks to all of you.

However, I still have a bit of a problem. I've been using a 33-quart enameled canning pot over two burners of my (gas) stove. The problem is that the stove top is getting really disfigured from the heat, especially between the two burners. Some sort of brown deposit forms on the white enameled stove surface that is darn near impossible to remove.

Two questions:

1. Is there some method of removing these stains from the stove?
2. Would it help if I lined the stove top with aluminum foil or some other material when doing the boil?

Solutions of The Secret of Alcoholic Fermentation

"Beer yeast, when dispersed in water, breaks down into an infinite number of small spheres. If these spheres are transferred to an aqueous solution of sugar they develop into small animals. They are endowed with a sort of suction trunk with which they gulp up the sugar from the solution. Digestion is immediately and clearly recognizable because of the discharge of excrements. These animals evacuate ethyl alcohol from their bowels and carbon dioxide from their urinary organs. Thus one can observe how a specifically lighter fluid is exuded from the anus and rises vertically whereas a stream of carbon dioxide is ejected at very short intervals from their enormously large genitals."

By Friedrich Woehler and Justus von Liebig.

Subject: California Festival of Beers & Style Question

For those of you unlucky folks who don't live in the central coast of California, you missed an excellent event over the holiday weekend - The California Festival of Beers, held in San Luis Obispo. This event has been annual for at least 5 years and features the majority of California micro-brewers displaying their craft. There were 65 brewies present this year with a relaxed atmosphere and almost no lines anywhere. The exception to this was the line to get into the event, which seemed endless but really moved along pretty well. There were too many beers to critique, but who wants to be critical at an event like this anyway? The afternoon spent in pursuit of great beer and amazing scenery is an annual event that overshadows even my wedding anniversary, which my wife has reluctantly given up the last 5 years running. To anyone within driving distance, go to it. I have a friend who comes in from Phoenix every year for this event. Good time, highly recommended, always held on Memorial Day weekend.

In HBD 1154 Stuart Galt gives a recipe of the following:

```
>Basic recipe:  
>19 lb Klages  
>3 lb Munich  
>1.5 lb Crystal  
>1 lb Wheat  
  
>2oz Tettenanger, 2oz Centennial (for 60 minutes)  
>2oz Cascade (5 minutes)
```

and asks what style it is. Based on the recipe my program, the Brewer's Workshop, predicts the OG to be 1.056, color to be 8 degree lovibond, and bitterness to be about 55 IBU's. This is based on an 11 gallon boil, an extraction efficiency of 70%, and 20 lovibond crystal. By these parameters alone the style would fit an India Pale Ale almost like a glove.

But one must use caution when designing recipes to meet a style. IPA is classically fermented in oak, so the use of oak chips would round out the style. IPA should use british Hops, not German or American. The use of Tettenanger, a finishing hop, in the full boil is also unusual and wasteful in that the excellent aromatics will be boiled off. The bottom line is that there are many beers worth brewing, even if they don't fit a style exactly. Darryl Richman has an excellent article in the new magazine, Brewing Techniques, which deals with the topic of recipe design. Highly recommended to anyone with a casual or better interest in the hobby.

Disclaimer - I wrote and sell the Brewer's Workshop, so my opinions are necessarily biased.

Subject: Using a freezer

I think that this is a good question and if I knew how easy it was to use a

freezer and how cheap used chest freezer where I would have started with a

freezer rather than a fridge. I am sure this information has been in HBD before but I don't think it hurts to add another data point.

Using a freezer works very well. I have both a fridge and a freezer for my beer and the freezer works the best and has the most useable space. This is of course a chest type freezer and not an upright. The Thermostat I use is a Johnson Controls, A19AAT-1C, PORTABLE THERMOSTAT, RANGE 20/80 DEG F, SPST, OPEN LOW, STYLE 1.

I purchased it from the Brewhaus, 4955 Ball Camp Pike, Knoxville, TN 37921.

phone 1-800-638-2437. price was \$ 64.45. It works very well!

Hunter room air conditioner thermostats are also reported to work but are limited to a lower temperature of about 40 der F. You want to go lower for long term storage or lagering. Cost about \$ 40.00

Subject: Stoudt's Fest

Hope to meet any of the fellow HBD'ers at Stoudt's 2nd Annual Event. I don't quite know where I'll be - I've donated my efforts to the cause as I did last year to where-ever Ed & Carol put me. I lived in Philly last year so it was an easy task. This year I'm trekking from Long Island with family in tow. I'll be at every session, so look me up. Just say "Home Brew Digest", I should be able to recognize that!  
>Jim Busch - I hope to meet you - you'll be at Baltimore Brewing, is that right?  
Side note: I had been away from HBD awhile, and while catching up on my reading, I found that what I had done to my Honey Wheat Ale (without knowing) was to get it closer to a "White". It had started out to be a quick, simple wheat beer:  
6.6 lb Northwestern Wheat Extract & 3 lbs honey, Cascades up front with Hallertau to finish. Simple, just rack and can (I'm that 5 Liter Keg guy). But for some reason I hesitated when racking. It needed something... Somehow came up with Coriander and Orange Peel - I must have read it long ago and just filed. Anyway, I can't wait for it (but I will). Question: Does it Clear? or does it stay rather cloudy? Hope I have some to take to Stoudt's.. enough is enough.  
Later.

From: dejonge@tekserv.geof.ruu.nl (Marc de Jonge)  
Subject: Oktoberfest recipe and dirty stove tops

After reading Tony Babinec's post in HBD 1155, I decided to throw in another recipe for munich oktoberfest. This one is so simple it's hardly a recipe but the taste comes out great: Strong malty flavour, might do with a bit more hops, the taste is definitely 'in style' (so the style might do with a bit more hops :)

[recipe for 20 litres]

5.5 kg Munich malt  
40 g Hallertau hops (whole, 5.1% alpha)

yes, that's it

I make this with a 2-stage decoction mash, fairly high temperature (for German beer)

Add strike water to get a temperature of 53C (pH of the mash around 5.4) while 60% is at this temp. do a quick infusion step of 67C with 40% of the mash (20 mins), boil (20 min) and back, (temperature should be around 67C) rest 45 mins, boil 1/3 of the mash for 10 minutes, back and rest 20 minutes (around 72C), sparge

add 30 g of hops at the beginning of the boil, the remainder some 20 minutes before the end

Pitch bottom fermenting yeast, primary at 14C, secondary at 9C, lager at 6C for a month.

OG 1053-1057  
FG 1012-1014

The malts I've used for this recipe are Belgian munich and Munich munich, they come out a bit different (the German version was somewhat darker), but very nice.

On another issue:

Hal Laurent asks about stains on the stove top:

>Two questions:

>

> 1. Is there some method of removing these stains from the stove?

>

a warm cleaning soda (Na<sub>2</sub>CO<sub>3</sub>, not caustic soda!) solution may help, but I'm not sure what that does with your stove top

> 2. Would it help if I lined the stove top with aluminum foil or

> some other material when doing the boil?

Being a sloppy cook, I find it useful to flood the stove with water before I start cooking anything messy, that reduces the cleaning of the stove to mopping up afterwards.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: iodine

Hi All,

In HBD#1155, Spencer W. Thomas writes:

>I'm sure this has been covered before, but here I go again....

>The last batch I made, I did the iodine test two ways: 1. I drained a  
>little out of the spigot at the bottom of my mash/lauter tun (Gott  
>cooler with copper-pipe manifold). This tested completely starch free  
>after 20 minutes (the first time I tested it). 2. I pushed the spoon  
>into the top of the mash and let some fluid run into it. This never  
>tested clear, even after 1.5 hours.

>So which one should I believe?

I'd say believe the first sample. What I think happened is that the sample drawn from the spigot was free of grain husks and pieces of grain by virtue of being drawn through your sparge manifold, while the second sample taken from the top of the mash contained grain material.

IMHO, the iodine test *is* a reliable means of determining starch conversion, but it is absolutely critical that the sample be free of any grain husks (which contain cellulose) and grain chunks (insoluble starch, which will never convert). What is being tested here is the degree of conversion of *soluble* starch to sugars, so it's important to test a sample that is liquid only, free of any particulate matter.

Cheers,  
Jim

X-Sun-Content-Lines: 37

Does the radiation from a standard home microware offer any sanitation or sterilization benefits? I remember reading about a new autoclave design that also used microwave in the process and began to wonder about home microwave ovens.

I just cultured my first batch of wyeast into 4 starters, and was very paranoid about sanitation. Afer soaking the bottles in a bleach solution I decided to boil them. I do not have a pot big enough, so I filled each bottle 1/3 full and stuck them into the microwave to boil the water inside the bottle. As I sat there waiting for the boil, I wondered if the microwaves themselves would kill any of the nasties.

Boiling the water inside the bottles worked well, but I also got to relearn the hazards of superheating water. The bubbles in boiling water need a site to nucleate or the water does not boil at 212F. Typically scratches in pans or glass provide a nice nucleation point. However if there are no scratches, ie a nice smooth bottle or flask, the water will heat above 212F. That is why boiling chips, little pieces of porus ceramic, are put in flasks in chem class. One of my 4 bottles did not boil when the others did. I first thought it was because it was positioned in the corner. When I opened the microware and touched the bottle, the hot water spurted out the top! Thank goodness I was wearing an oven mit. I will continue to use the microware to boil water in the bottle, but plan to put in a scratched glass marble in to act as a boiling chip.

From: donald oconnor <oconnor@ccwf.cc.utexas.edu>  
Subject: SS/dry yeast

Al writes,  
"I re-checked my 1991-1992 Cole-Parmer Chemical Reactivity charts and there was no mention of Chlorox (bleach)."

Better check again Al. Page 1185, item 23 from the top, 1991-92 Cole Parmer catalog is none other than "Clorox (bleach)." It's in the 93-94 catalog as well, page 1465.

Al goes on,  
"Furthermore, I'd like to point out that don's wife is the owner of St. Pat's of Texas (brewing supply) and they do not stock Iodophor rather they stock a chlorine sanitizer."

Wrong again. St. Pat's has never at any time stocked a chlorine sanitizer  
. St. Pat's has stocked both the 4 oz and liter size of iodophor for about a year. We've been using iodophor for as long but I see no reason to run down bleach which, as John Isenhour points out, is inexpensive, readily available and just fine if used properly. It should be noted that my standard dose (1 tsp/gallon) was 1/6 th that suggested by George Fix (1 oz/gallon), i.e., nearly a full order of magnitude below the safe level. If I understand George correctly, he believes repeated use with a bleach solution known to be safe, will eventually cause harm. Poor logic. If we drink a beer a day for 40 years, we won't die from alcohol poisoning.

I recommend Arne's ? wonderful post of a couple days ago about the reactivity of chlorite with aluminum. Its a wonderful example of how useless superficial knowledge such as numbers from tables can sometimes be.

More from Al,  
"Finally, don has, in a newsletter, questioned the quality of the DeWolf-Cosyns Belgian Malts (another item not stocked by St. Pat's of Texas)"

Not true on both counts. St. Pat's newsletters have had only good things to say about belgian malts. Not only does St. Pat's sell Belgian malt, St. Pat's was one of the first shops to do so. In fact, St. Pat's was the first shop to advertise the availability of Belgian malts in Zymurgy (summer '92 Great Fermentations also has an ad in the same issue). My wife Lynne learned of these malts from Pierre Celis during a personal tour of his brewery while it was still under construction. Lynne can testify to Pierre's wonderful nature. He spent an hour or so toting our youngest boy Patrick, 1 at the time, around the brewery.

Al adds,  
"St. Pat's of Texas turns out to be the sole distributor of Briess malt in the

area."

St. Pat's, like Pierre Celis, appreciates the quality of both Briess and DeWolf Cosyns malt.

Al goes on,  
"I've yet to find the reasoning for don's tirade on yeast a few weeks ago,  
but I'm sure that his ulterior motives will surface eventually."

The only two people who have resorted to sophomoric remarks regarding my posts about yeast are Al and George. I believe Al sells dry yeast for a profit and George of course is employed by the distributor of Whitbread. On the other hand St. Pat's gives dry yeast away free because Lynne cannot in good conscience sell it for a profit. I would be more than delighted if George and Al's dream of pure dry yeast were to come true; then Lynne could start selling the dry yeast for a profit.

I found it ironic that in the end George was blaming Lallemand, Al's favorite dry yeast producer, for the problems with Whitbread, the product that George represents. For the record, all Whitbread, the good, the bad and the ugly has been produced under contract by Distillers in England. That particular portion of the Whitbread history seems to have been invented for the purpose of not only deflecting responsibility for the really atrocious batch of a couple of years ago, but also to pass blame on to the competitor, Lallemand.

Best regards,  
Don

Subject: Converting a freezer to a fridge

Thanks to all who responded to my query.

I have found the Hunter Airstat as recommended at Builders Square For \$28. It only has a low end of 40 Degrees. That was somewhat bothersome since one of the reasons I wanted a fridge was to try lagering. The other suggestion, a Johnson Controls Portable Thermostat is sold at my local Homebrew store for \$64.95. This price was somewhat bothersome, but I think it's the one for me. It has a wider range (down to 20 degrees) and the owner of the homebrew store says he recommends it over the Hunter because he knows of some people who used Hunters and had their compressors burn out. It seems the Hunter is a little TOO precise and kicks the compressor on when there is any fluctuation in temperature. The freezer I lucked into seems pretty old, so I guess my decision is made.

Subject: pH Testing

>From: jdg@cyberspace.org (Josh Grosse)

>In today's issue, Mr. S. questioned his purchase of a pH meter, and said he felt he purchased equipment he found to be useless.

>I have one, and I find it extremely useful for three purposes:

You will note that \*I\* found it to be useless, i.e. with MY process, using MY water. I only suggested that before spending the money, one should try one to see if it is needed in his/her case.

If no adjustments are necessary and the water supply is constant, then one need not make the measurements on a continuing basis.

>1) Adjusting the pH of the mash. (pH 5.0-5.5)

I presume you mean that you adjust the water to something so that after adding the malt, the pH is 5.0 to 5.5. I wonder what that something is.

My water is 8.1 and drops into that range. I would be interested in knowing what your numbers are without adjusting.

>2) Adjusting the pH of sparge water. (ph 5.6-5.8)

Again, my sparge water is 8.1 and after sparging 10 gallons, it only raises the total pH of the wort a tenth of a point.

>3) Ensuring I don't oversparge. (ph > 5.5)

It is just as useful to use a hydrometer. If you stop sparging when the gravity falls below 1.008, you will not likely have any problems. It will take tons of a water a few points higher to have any effect on the total wort.

But again, I am only suggesting that one try it before buying. He may find that it only tells him what he already suspected from the quality of the beer produced.

Subject: looking for time saving tips

In HBD #1155 Hal Laurent appreciated the quality of his brews after switching to all grain but complains about the amount of time it takes.

When I read his post I thought he was talking about me! :-). I've got 3 all grain batches under my belt now and they were great (IMHO). Even my wife drinks my beers now - she was indifferent to my extract brews. My best time for brewing an all grain batch is about 5 hours and I'd like to cut that down as much as possible. Some one in a recent Zymurgy issue said that an all grain batch took him 3 hours, including clean up.

My biggest problem right now is that I don't have water ready at the right temperature at the right time and I know that this will be cured by experience. I would like to hear about time saving tips from other brewers.

>A lot of people in my area (Southern MA) are buying Sam Adams. (Course there's  
>not a whole lot of selection in my area.) Is Sam Adams Ale and Lager really  
>that bad, or is it that people just don't like Koch(?). I'm new, so forgive me  
>for not being up on the controversy.  
>\*\*\*\*

The controversy is not the beer produced by SA, it is generally regarded as excellent (with the exception of the "Lambic"). The problem is Ed Koch and his less than above board advertising techniques and litigations. SA has made claims that were not true (winner of the GABF 4 years running), filed lawsuits against micro-brewerys for the use of the name "Boston" in their beer, and generally handled himself in a manner that makes you glad he is not your neighbor.

I've been watching the digest for almost a year now and have found it amusing as to the various controversies that unfold. It's like watching the black sheep of the family, wondering what he's going to do next to screw up.

I personally do not participate in the boycott of SA products. I like his beers, and use them as examples good American beers. I do go on, then, to explain about Koch. I may not like Koch, but its hard to deny that the lager is excellent.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: Lautering

I realize that the variety of methods of sparging are as numerous as people brewing, but I am looking for some general guidelines.

What are the main parameters in sparging? That is, what are the important things that you want to work towards however you are sparging? How important is, for example, the thickness of the grain bed? the temperature of the water? the level of water above the grain bed? the amount of recirculation? water hardness/softness? pH?  
what have I missed? which are irrelevant? which depend on the style of beer the brewer is aiming for? what do people that sparge for two or three hours doing all that time, recirculating or waiting for the grain to "soak" or what?

With that information, what is important for equipment? geometry of the lauter tun?

Several points of view would be great. I think this aspect (along with a poor grain crush from the store) is my main problem with poor efficiency now (and maybe others too). Thanks

- Bryan

I guess I'm asking for a lot of information, so pointers to a good reference would be fine, if one exists.

From: "Robert C. Santore" <rsantore@mailbox.syr.edu>  
Subject: RE: How can I protect my stove?

In HBD 1155 Hal Laurent asks about how to avoid brown stains on his stove.

Hal, I have the exact same set up you described: A 33 qt enameled steel brewpot over two burners of a white enameled gas stove. I get the same brown stains you do. One obvious source of the brown gunk is wort boil-overs or small drips and spills. I've also found that ANY residue on the stove at the start of the brew session will turn into that impossible stain even if it doesn't look dirty to begin with. While starting out with a very clean stove, and cleaning all spill as they happen will help, I have never had a brew session that didn't leave some stain. The solution is to use oven cleaner after you're all done. Let it soak awhile and you should find that the stain wipes right off.

> That is, immerse the chiller in a pot of hot (boiling?) water and run tap water through it to heat sparge water. By playing with the flow rate and the water temp., I ought to be able to get it up to temp. easily.

> Has anyone tried this? Any opinions?

Ah, yes. Great minds do travel the same paths. You just missed my latest new product announcement. The EASYSPARGER (tm) or easysparger (if you make it yourself) does exactly that with a lot less fuss.

It is a small (6 qt) kettle with two barb fittings on it. One goes to a hose and faucet adapter and the other, an inch lower, goes to a piece of stiff tubing that dribbles water into the lauter tun. The kettle sits on the stove and will provide all the sparge water you will ever need with no pre-planning or calculating.

On second thought, there is one significant disadvantage of your approach and that is there is no chlorine evaporation in the wort chiller, whereas in the open kettle, most of it is evaporated before getting to the outflow.

> I could easily hook up a "showerhead" to the hose output and get a nicely distributed flow over the mash.

For the record, a shower head is one of those things that commercial brewers use that have no application in small batches but are so cute that some suppliers just can't resist selling them.

If (as it should be) the water level is maintained above the grain level in the lauter tun, it make no difference where or how the water enters as long as it is not a tunneling downpour.

>From: tony@spss.com (Tony Babinec 312 329-3570)

>Most German Oktoberfest beers have a starting gravity of 1.052 - 1.055, which puts them more in line with the AHA "Vienna" style.

> Ferment at 50 degrees F or so. Rack the beer to secondary, and lager for 4 to 8 weeks.

I got the idea from the Fix's book that the most fundamental difference between the two styles derived from the fact that the Oktoberfest was, by

definition, aged for many months, i.e. March to October.

If you look at the gravity ranges for the two styles, they just about overlap to the extent that the bottom end of one is the top end of the other.

I would think that aging a "Marzen/Octoberfest" for two months would be cheating on the old family recepie.

.....

To clarify a point on an earlier posting, my tap water is around 8.1 and upon doughing in, the pH of the mash drops to around 5.5. The point being that if one buffers their water to this range before doughing in, they may be just kidding themselves.

> tested clear, even after 1.5 hours.

I have been using an identical setup, and have have identical results. My top test did eventually test complete, after 3-4 hours. For a while, I even did overnite mashes to get complete conversion. I ended up with a lot of underbodied, overalcoholic brews. What I have done since then is raised my normal mash temp to the upper end of the range, and stir occasionally. I now get complete conversion top and bottom in less than an hour. The stirring does speed loss of temperature though.

- - - -

My SS keg went to the fabricators today! I am having false bottom supports and a nipple welded into it. I already have the pump, and plan on doing a pseudo-RIMS using my existing King Kooker, the keg and the pump, and graduating to 10 gallon batches as well :-)! Thanks to Rick Larson for all the info!

In the last HBD, Tom Nelson said:  
>The use of Tettenanger, a finishing hop, in  
>the full boil is also unusual and wasteful in that the excellent  
>aromatics will be boiled off.

I beg to differ! The use of "noble", low-yeild hops in the full boil improves your beer. The only "waste" is money, but hops are a relatively small part of our financial investment in homebrewing, so I only use the best.

As has been discussed here at some length before, hops contribute much more than sheer bitterness, even when used early in the boil. The "other flavors" - not all of which are driven off by an hour of boiling - are a vital part of the incredible complex of flavors in a truly great beer. I say, calculate your bittering units, and then throw bales and bales of Tettenanger, Saaz, or whatever, in, if that's what it takes. The extra buck or two will be well spent. Leave those high-alpha hops for the commercial guys who watch the bottom line.

Date: Thu, 3 Jun 93 12:08:08 EDT  
From: Lee=A.=Menegoni@nectech.com  
Subject: OFest Recipe Formulation

Regarding the use of German vs Belgian Pilsner malt for Fest recipes. In George Fix's review of Belgian grains he mentions that the Belgian Pilsner pilsner malt is much lower in SMM, the DMS precursor that is a good indicator of the level of malty/sulphury flavor in the brew, than the German malts. I find this component an important part of the flavor and aroma profile of a fest beer like Spaten Ur Marzen and would consider using German malts as the base malts in addition to the highly praised Belgian specialty malts. I would also do a decoction mash.

My read of George's review suggests that for Chec style Pilsners, Fest and other lagers with a rich malty profile quality German pils malts are a better choice than Belgian. Are there other factors which out weigh the low SMM that make the Belgian a better choice? Did I miss something?

From: djt2@po.CWRU.Edu (Dennis J. Templeton)  
Subject: Iodine testing

>From yesterday's digest:  
From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: iodine

I'm sure this has been covered before, but here I go again....

The last batch I made, I did the iodine test two ways: 1. I drained a little out of the spigot at the bottom of my mash/lauter tun (Gott cooler with copper-pipe manifold). This tested completely starch free after 20 minutes (the first time I tested it). 2. I pushed the spoon into the top of the mash and let some fluid run into it. This never tested clear, even after 1.5 hours.

So which one should I believe? I got a great (for me) extraction rate of 31 pts/lb/gal, with wonderfully clear sweet wort, so it would seem that conversion was indeed complete (maybe at 20 minutes).  
<end>

This point is poorly made in the books, I think, but I remember one text covering it. Iodine will react with powdered husk as well as with starch.

In my experience the starch reaction is the purple color that is usually described, and the reaction with husk particles produces a greenish brown color. In a thick solution, with excess iodine around, the two results can be confusing. If you look closely at the husk reaction, you will probably notice that the color is not in the solution, but in tiny particles, with clear fluid in between.

I have developed the habit to test only runoff that has been pre-circulated a little, as Spencer reports above, and I also dilute it a little, maybe 2:1 with water before adding the iodine.

Good luck,  
dennis

From: ng570@andechs.pnl.gov  
Subject: taste of yeast starters

I have a question concerning how a yeast starter should taste, i.e., whether contamination has occurred or not. The situation is this:

after propagating a Wyeast 1084 (Irish) package into several bottles of about 5 oz each (unhopped, O.G. 1.020, fermented completely out), I took one out last night to pitch into a 1 quart starter so that I could brew this weekend. Well for once I decided to taste it to see if there were any problems. Well it was very clean tasting and the 'beer' was very clear (i.e. not cloudy), however it seemed very acidic. Is this typical for this case or do I have a possible contamination of lactic or acetic acid bacteria? I hate to toss out all of these potential starters if I'm just being paranoid, but I don't want to ruin a perfectly good batch of beer either.

Thanks for the help,

Kirk Peterson

Subject: Micro in Alden, Iowa

HBD;

There has been a small amount of discussion on a micro-brewery in Alden, Iowa, and subsequently in Adel, Iowa.

Well, I did a very small amount of research and called the City Hall in Alden and was informed there was no brewery in Alden. (Dispersed amongst much laughter). Just for reference, the town of Alden is located about 30 miles north of Ames, Iowa off of highway 35 on highway 20. (Not that it matters now.)

Now for something that I DO know for sure. I live exactly 3 blocks from the Dallas County Brewing Company in Adel. The other information supplied by other HBDers is correct. The beer is marketed under the name "Old Depot" in reference to the restaurant which is housed in the former Adel railroad depot.

The 4 beers that are available \_are\_ Lager, Porter, Ale, and a Light. The other beers mentioned are only available on tap in the Old Depot Pub which is part of the restaurant. These beers are touted as "Beer of the Month" and are available on a monthly basis, or until the batch runs out.

As far as the restaurant goes, the menu is very diverse. I have only been there for the lunch which is pretty normal, but the appetizers and dinner entrees are different.

I don't know how most micro-breweries work, but in this case the brewery and the restaurant seem to be separate entities. Which is probably good. I have heard some not-so-great things about the restaurant (ie: service) and since the newness has worn off (The whole thing is only in it's 2nd year.) the parking lot has been sorta empty. At least if the restaurant assumes room temperature, I can still get that beer that I have come to love. :-)

Subject: EDME Brewcraft Barrel/Bleach & SS/St. Pat's of TX correction

Joseph writes:

>I recently purchased an EDME Brewcraft Barrel. The first batch I put in  
>was not great. The main problem was it was terribly flat. The barrel  
is  
>6 gallons with the CO2 injectors and a release valve that is supposed to  
>keep pressure up to 10 psi.

I think the problem may be that these barrels, most of which are made by  
or for English companies, are made for storing and dispensing English-  
style  
ales, which are considerably less carbonated than American-, Belgian- or  
German-style beers. You may be able to modify it to keep the beer at  
a higher pressure, but I think that it would just be better to just store  
English-style ales in it.

\*\*\*\*\*

George writes:

> 2. At room temperature (and a normal pH), 304 is resistant to chlorine  
>as long as the FAC is below 250 mg/l.  
>  
>Since our standard 1 oz. bleach per gallon gives a FAC of 100 mg/l, one  
>could conclude that chlorine bleach can be used to sanitize ss kegs.  
>Careful brewers will reject this conclusion. The factor of 2.5 is  
cutting  
>it too close.

Then John writes:

>cornelius's, and the bungs and figure 8 gaskets on 1/2 barrels. I had  
>bartending experience prior to the use of these kegs where I learned  
about  
>chlorine test strips to determine the sanitizing power of the solution.  
I use  
>in the ballpark of 50 ppm as determined by these strips and I havent had  
any

I put two and two together and thought about what my test strips read.  
Just as another data point, when I use Bleach solution (bottles,  
thermometers, glass carboys, etc.) I use one tablespoon per gallon  
of hot water (and yes, I use only cool water for Iodophor solutions).  
Testing with chlorine test strips, as I do periodically, results in  
a reading of 200ppm at the start, dropping from there (how quickly it  
drops is proportional to how much organic material is stuck to the  
item being sanitized -- bottle that still contained the yeast from a  
previous batch will turn your 200ppm solution to something way below  
50ppm).

Later, George writes:

>The version of iodophor I use is called Accord II, and  
>is made by Diversity. This is the version that has the iodine bound up  
in  
>phosphoric acid; the other versions have it bound up in detergents.

I use an "Iodophor" that is sold under the name BTF or B.E.S.T. (same  
stuff, judging from the chemical composition on the labels). It does  
not contain phosphoric acid, but also does not contain detergents.  
I know there are versions that do have detergents, and these types

are to be avoided for our purposes, but BTF and B.E.S.T. are not of this type and \*are\* suitable for homebrewing use.

\*\*\*\*\*

I must apologise to Lynne O'Conner about posting outdated and incorrect data about St. Pat's of Texas. Without checking, I incorrectly posted that they do not carry Iodophor or the DeWolf-Cosyns malts. I've since been told by two sources that they do, indeed carry these items. My mistake. Sorry.

The whole issue of posting information for possible commercial gains is a tricky subject. Even if we don't identify ourselves as retailers or having commercial interests in a particular item, could we be posting information that tends to bias the buying habits of the HBD readership? I think so. I have done my best to be fair whenever I post on a topic. Sure there's a much bigger profit from a package of Wyeast than a package of Lallemand or Coopers... it's easy to bash dry yeast because many people have had bad experiences with it. Most brewers will believe it. I, personally, have had some good experiences with Lallemand and Coopers and have posted favorably about them. I've had private email which has indicated that recent shipments of Red Star (can you believe it!?) have produced prize-winning beer. I will re-assert myself to continue to try to be unbiased in my posts and urge everyone to do the same.

The HBD is one of the best sources of brewing information in the world. On the Brewing Techniques magazine subscription, you will notice there's a question something like: "where do you get most of your brewing information? Personally, I have to say the Homebrew Digest. Even the questions are often as enlightening as the answers, because they make you think and because they make you put yourself in another brewer's apron re-think something you may have done 250 times and come up with an even better way to do it.

I started to brew because I could not buy English Bitter here in the states. I continued to brew because I love the art and science of brewing.

I opened a homebrew supply store because I have hopes of someday making a living related to brewing. I'm passionate about beer and brewing and have spent hundreds of hours helping brewers not because I hoped to gain their business, but because of my love for the art, the science and the result -- bottom line.

\*\*\*\*\*

-----

40-50 psi; 3) "Shake the shit out of it" for 10-15 minutes (I assume this means periodically over 15 minutes time). I haven't tried this method yet as I have read that this is indeed a way to do it but is more intended for getting beer carbonated quickly; The way I have been going about it is to 1) Chill to below 40 deg F; 2) Crank the CO2 up to 25-30 psi; 3) let it sit for 3-5 days under pressure (with the CO2 valve open). Again this gets me adequate carbonation but gives me the foam problem. Maybe part of the problem might be related to the fact that when I actually go to dispense the beer after letting it carbonate I lower the CO2 regulator to 10 psi and "burp" the excess pressure out of the keg. One guy told me this sudden pressure change may be the problem but I have gotten the same results if I carbonate and dispense at a common pressure of 10 psi.

The guy at the local beer store claims that the "head pressure" has to be pretty much equal to the "pressure" trying to rise up out of solution and that even a difference of +/- 1-2 psi can cause problems. I am hardly a physics expert but I would think that these pressures would reach an equilibrium on their own (over time). I am also thinking if the pressure difference was \*that\* critical, this would be a much more common problem and would therefore be asked more frequently on the HBD. All the people I have talked to say that they have never had a problem with foaming.

Also, this problem of not being able to keep the beer carbonated at low storage pressures and the foam problem at high pressures makes me wonder how people get away with the "demand cooling" approach using cold plates, etc. How can the beer stay carbonated when stored at temperatures approaching and exceeding room temperature and not foam when dispensed? Is it possible the CO2 will re-dissolve back into solution spontaneously in the cooling coils or some such? Once I get my foam problem solved I was thinking about putting one of these things together for portable use.

Lastly, I was wondering how to control bacterial growth in beer dispensing faucets if they were used less frequently (once or twice a week)? Will the mold (or whatever) grow in just the nozzle or will it spread throughout the dispensing hose? Is there a way to prevent or retard this process without having to disconnect and flush the line after each use.

I would greatly appreciate any help that anyone could give on any of  
the  
above questions.

Thanks in advance,

Mark--

While racking my latest concoction, a strawberry ale, into the carboy I splashed the wort around a lot. The problem was that my hoses were all cruddy

so I figured (perhaps mistakenly) that I should just pour the wort through a

filter funnel into the waiting carboy. As the wort was splashing around, something from the deep recesses of my mind remembered Papazian saying something about how doing this was a BAD thing. Does anyone know why this is

so bad? Will my precious brew survive? Thanks,

Daniel Katz, crazed student, homebrewer, armadillo

**Subject: Cloudy Hose and Stainless Steel**

To clear cloudy hose wrap it in a large sheet of clean paper, brown paper or a paper bag is OK. Seal with tape and place in you oven at 200 deg F. for 30 to 60 minutes. Your hose will clear and if you keep it sealed will be ready to use when you break the seal.

On the discussion of stainless steels while 304 and 316 are both used, 304 being the most common, it is very likely that the welds are made with type 308 or 308-L. Corrosion is most likely in the weld or in the heat effected zone next to the weld. Like Fix I don't like bleach in contact with the stainless I pay for and want to use for years.

From: cestes@argos5.DNET.NASA.GOV (Chris Estes)  
Subject: Propane Cooker

Hi All...

We're getting ready to move into our new house next month. My brewing activities have been banished to the basement! That works well, except that I don't relish the idea of carrying 5 gallons of wort down the stairs after cooking. Add that to the fact that the new house has an electric stove and things look grim.

I'd like everyone's input on what kind of propane cooker to get. I only make beer in 5 gallon batches, so I don't need a surplus Saturn V motor up-ended! What's best? What kind of gas do I use? How much should I expect to spend? Can I use it in the basement, or do I have to step out-side on the patio? Will I have to build a stand to hold my brewpot, or will it come with something sturdy enough? You get the idea; I'm totally in the dark on these things!

TIA for everyone's help (I'm indebted to all for similar advice last year on the purchase of my keggng setup. "I'll never wash another bottle!")

Please e-mail directly or post here if you think it'll be of social benefit!

Thanks,

-Chris Estes-

From: gjfix@utammat.uta.edu (George J Fix)  
Subject: Red Star Yeast

The production of Red Star ale and lager dry yeast by Universal Foods of Milwaukee was terminated a few years ago because consumer dissatisfaction with these products. At the beginning of 1993 Larry Noakowski of Universal and Crosby + Baker entered into discussions about bringing these products back with new and improved production procedures. There was general agreement that yeast samples would be tested, and any production batch that did not meet standards would be sent back to Universal. Eventually Dr. Jim Foy of Universal and I came to an agreement about what precisely these standards would be. In particular, they are exactly the ones I gave in my article "Evaluation of Pitching Yeast" which appeared in the 1992 edition of Beer and Brewing.

Dr. Foy decided to start with an ale strain AHY 43391. It is a different strain than was used previously, and my background checks indicate that it possibly may be one of the strains in the Tanner collection. These were used in small and medium sized commercial brewing in the first half of the 20th century.

Two different evaluations were made. The first was on yeast produced in Dr. Foy's lab in Milwaukee, and the second was on yeast from a full production run at Universal's plant in Baltimore. The detailed analysis can be found in reports to C+B. The following is a summary:

1. Lactics - Some rods were detected in the lab sample, but the total lactic count satisfied our criteria of <1 cell per million viable yeast cells.

The HLP analysis of the production yeast showed a nil count. Both Dr. Foy and Larry Noakowski anticipated this result. The production run was done under sterile conditions, while the lab sample was produced in a standard laboratory environment.

2. Viability - This is a strong point of fresh dry yeast. Less than 10% of the cells stained with Rhodamine B, indicating >90% viability. Dr. Foy and I are recommending the following hydration procedure:

a. Use 14 grams of dry yeast per 5 gallons of brew. \*\*\*Rigorously\*\*\* sterilize everything used in the hydration procedure.

b. Add the dry yeast to 1/4 - 1/2 cup of water at 90F. Higher temperatures are not needed with yeast like this which have a high % viability.  
Leave for 15 mins.

c. Combine the hydrated yeast with 1-2 gallons of wort that is as close to the wort to be fermented as possible. I took samples from the main wort at the end of the mash/sparge and rapid boiled and rapid cooled it. This was used for the starter wort.

d. Aerate the starter as much as possible under of course sanitary conditions.

e. Don't forget to properly oxygenate the main wort once it is chilled.

f. Pitch the starter into the main wort once the latter has been chilled to the recommended fermentation temperature (65-68F). Yeast with this type of viability will result in minimal lags. The longest I experienced in my test brews was 2 hrs.

3. Attenuation - Red Star's old ale strain was reported to be a poor attenuator. This is not the case for AHY 43391. One can expect an ADF in the 76-78% range.

4. Flavor - This strain leaves a clean, slightly dry finish with a gentle fruity tone. A German style wheat ale was brewed with it, and entered in the recent competition in Kenosa, Wisc. It took first place in the mixed ale category with scores of 41 and 42. The judges were Cheryl and Jay Schultz (certified). Copies of the score sheets were sent to C+B along with my reports.

5. General Recommendations - I feel this is an excellent yeast for beginning and intermediate brewers. It will not contribute the sophisticated flavors that many strains available in liquid form and slants do. On the other hand, if proper sanitation is used, this strain will not contribute anything ugly or unpleasant either. This is a yeast where the malt and hops used, and the way they are processed, will define the finished beer's flavors.

As I hope was clear from my first post, I am being paid by C+B standard consulting rates to do this work. I also do similar work for others. I am not, however, involved in the distribution, marketing, or sales of this or any other products for that matter. In this particular case, this is actually something I regret. I fear C+B is going to retain "Red Star" on the label. If I had a vote, which I do not, I would call this new strain "Pasteur Ale Yeast" in analogly with Universal's widely used, and indeed first rate, champagne yeast.

I have really enjoyed being on this forum, and I have posted the C+B material because I thought it might be of interest. There are, on the the other hand, some distinctly unpleasant elements on HBD that makes it anything other than fun. Perhaps it is the special nature of this type of communication which brings out these things.

Subject: Sam Adams revisited

Fellow zymurgophiles:

It keeps getting strangerer and strangerer -- a Sam Adams spot heard last week on a local radio station (San Diego, Calif.) had our pal Mr. Koch telling the listeners that his beer had been chosen as the "Best Beer in America" at the GABF, "THREE years running." (emphasis added) Now, I've heard those commercials where he sez "four years...", and even heard one after the 3 yr. promo. Looks like Madison Avenue has got a few ads out that they don't want to pull, and that Mr. Koch has taken some of the uproar to heart... (however, even in the "3 yrs running" spot, he still tells us that Sam Adams is the only U.S. beer imported into Germany).

Subject: A Hop question.

I asked a question recently about a belgium like (I think) style, and some previous bumblings with trying to make a barley wine... Just made me have more questions.

I realise that when the wort first comes to a boil there is no hot break yet. I have been told (or read I can't remember) that adding hops before the hot break will cause them to be coated protein goop and not allow for as much utilization as one might hope for. There also seems to be a debate about the use of low alpha acid hops for bittering. I there any information out there that could tell me if there are any know differences between adding the hops at the start of the boil, and waiting a bit till it really gets going and hot break has occured? Also what properties do the hops contribute to the beer when you add the bitter hops at first boil so they can get all goobered up with the proteins?

I am not paniced, just curious.

Thanks a bunch.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: **Faster all-grain**

In the search for faster all-grain brewing, I'd like to put forth something I tried this weekend. I made two (5-gal) batches of beer, an IPA and a Porter, from a single mash. It worked like this:

Mash-in 20 lbs (turned out to be too much) pale ale malt and a little crystal malt at 67C. Mash for 1.5 hours (on suggestion of Foster in Pale Ale), mash out to 77C, sparge 4 gallons, dilute with 2 gallons, start boiling it. Meanwhile, add .5lb chocolate malt, .25lb black patent, .75lb crystal malt to mash tun, add 77C water as needed, steep 30min. Sparge 6 gal porter while IPA is boiling (60 min boil). Bring Porter to boil, start chilling IPA. Rack IPA to primary carboy, combine 2 smaller pots of Porter into large boiling pot (that had IPA in it), finish Porter boil. Chill & rack Porter. Pitch 1qt yeast starter into each (using same yeast for both, in this case). Clean up. Total elapsed time, from starting mash water heating, to end of clean up, about 7 hours.

Wait, you say, that's a long time! Yes, but I got two batches of beer, so it's only 3.5 hours each. Also, I'm don't consider myself an "experienced" all-grain brewer, and it's only slightly longer than I have taken for my other 5 gal batches. There are some opportunities for making it shorter:

- \* Overlap heating the initial strike water with some other activity. This takes almost an hour on my 11,000 BTU stove burner.
- \* Shorten the mash. 1.5 hours is pretty long.
- \* Get a more powerful burner. This would shorten the initial water heating period and the time to bring the first wort to a boil.
- \* Get a second 8 gal pot. Except I don't know if my stove could really hold 2 of them.

It seems to me that the critical path in this is:

heat strike water-mash-sparge 1-boil 1-chill 1-finish boil 2-chill 2-finish clean up.

Certain things are irreducible: the mash has a minimum length (30 min???)

)  
The boil need to be 60min to for best hop utilization, etc. I don't think it would be too hard to get it down to 5 hours for two batches, though.

How did the beer come out? Well, it's still fermenting. But I did use too much malt: I got an IPA at 1.064 and a robust Porter at 1.060! And I probably could have bottled several pints of starter solution -- the gravity of the wort stream when I stopped sparging the Porter was still 1.025 (temperature corrected, of course).

 From: jlf@palm.cray.com (John Freeman)  
 Subject: Mashing times

I've posted this before, but the question of making mashing more efficient came up again, so...

I drew up this PERT chart long ago to determine what could be done in parallel. I have mashed in as little as 3 1/2 hours - I had no homebrew to drink while I was doing it... With homebrew, it takes a little longer.

I tried to draw this to scale, each column representing about three minutes, each task placed approximately where it belongs in time. The straight line represents the critical path, the things you cannot hurry: heating, mashing, boiling, cooling. One of the best speedups you can make is to sparge into your boiler while applying heat (at J).

- A. Clean mash tun, measure mash water.
- B. Heat mash water.
- C. Assemble grains, scale, grain mill, etc.
- D. Crack grains.
- E. Mash.
- F. Clean up from cracking.
- G. Relax.
- H. Measure and heat sparge water.
- I. Clean and set up sparge equipment.
- J. Sparge into boiler.
- K. Heat wort to boil.
- L. Weigh hops.
- M. Boil wort.
- N. Clean up sparge equipment.
- O. Proof yeast (dry) or take wort sample for yeast starters.
- P. Add hops to boil.
- Q. Clean and set up wort chiller.
- R. Chill wort.
- S. Put hydrometer and thermometer in wort.
- T. Put away materials.
- U. Clean boiler, strainer, etc.
- V. Pitch Yeast.
- W. Clean wort chiller.
- X. Relax. Relax. Relax.

Subject: EASYMASHER vs easy masher

> johnc@hprpcd.rose.hp.com  
>Subject: EASYMASH & MALTMILL

> I decided what the heck, I'll make an EASYMASHER and see what happens.

Just for the record, EASYMASHER (like MALTMILL) is a registered trademark and technically, can not be "made" by any entity other than JSP. However, I encourage you all to make "easy mashers" to your heart's content. What better way to stimulate the need for a mill.

> I did, however, have to recirculate about 1 gal to get a clear beer, but that is much better than the copper manifold (about 3 gal).

As I claim that the runoff runs clear after a few ounces, I thought it was worth exchanging mail with John to see what the "problem" might be.

Turns out the spigot he selected has a 3/8" flow through and the one I use has a 1/8". The flow through is defined as the smallest passage in the system, sort of like Kirchoff's law in current flow.

The smaller opening restricts the maximum flow and seems to be the key to speedy clearing. Even with my smaller flow, I only crack it slightly until it runs clear and then run it at this rate for a while before opening it full. Actually, I open it full just to clear the big stuff and then close it down.

Although a 1/8" flow doesn't sound like much, when several feet of 3/8" hose are connected to the spigot, the rate is about 10 min per gallon and provides a typical sparge rate.

This is not a condemnation of larger spigots, just a suggesting of how to get a clear runoff more quickly when using one. To repeat, open it to clear the big stuff then close it down to a trickle until it runs clear and then gradually open it wider as needed.

From: Lee=A.=Menegoni@nectech.com  
Subject: Lagering with A Hunter Airstat

A Hunter Airstat is a fine device for homebrewers to use for a temperature controlled environment. The 40F limitation really isn't a problem unless one is trying to do an extended lagering near 32F. I generally ferment at 45F, diacetyl rest at 48F and lager at 40F. I really don't have the time or space to do a March to October Fest Bier fermentation. When I need temps near 32F I bypass the Hunter and use the temp control on the fridge which I have marked with the setting for 34F. My fridge happens to have a really good control that goes to eleven. The only time I set it for the low 30s is to clarify beer, both prior to racking to a keg and the first few days its in the keg. One needs to take appropriate caution when doing an extended low temp lagering to ensure that you don't get yeast autolysis. Another important part of producing a lager is proper wort chilling to inhibit DMS production and a wort pitch temp at fermentation temp to minimize production of diacetyl and esters. Low temp lagering is another piece of the delicate puzzle we call lager beer.

From: Richard.Stueven@Corp.Sun.COM (Richard Stueven)  
Subject: Garlic Beer

Due to numerous requests (four, to be exact) here's the  
"recipe" for gak & laurel's Garlic Beer:

We didn't keep any notes on the garlic beer, so here's my best  
recollection:

6# plain light extract syrup (hopped? who knows...)  
2oz Cascade leaf (60 min)  
2oz Cascade leaf (10 min)  
one Big Thing of garlic (maybe half the size of your fist)  
Whitbread dry ale yeast

The procedure is the same as for any simple extract beer. Chop  
up the garlic and throw it into the boil for the full 60  
minutes. If you don't want quite so much garlic flavor, strain  
the garlic bits out before racking (we didn't).

To which I'll add:

Avoid this recipe. It was a particularly nasty beer...simply awful.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: stovetops, fermented black beans

Here's my two bits on cruddy stovetops.

bit #1: it seems to me that a lot of the crud comes not from actual boil-overs, but rather from various kinds of condensation and dripping. I wouldn't be surprised if some of it is simply from goopy steam condensing on the top of the stove (the scientists in the crowd are invited to blast this to smithereens if untrue) - but beyond that, if you just have a regular ole gas stove and you like to boil four gallons or so, as I do, then you have to keep the pot partially covered to maintain a good rolling boil (or is this a momily?). The steam that condenses on the lip of the lid on the side that sticks out over the edge of the pot then dribbles down the side of the pot, into the eye of the stove where it gets nicely cooked!

bit #2: I haven't tried sloshing the top of the stove with water, or with dish soap, prior to brewing. Both ideas have been suggested in HBD and I certainly think they are worth trying. As an alternative to oven cleaner for the top of the stove (AFTER making a mess), may I suggest the more environmentally-friendly (not to mention epidermally-friendly) baking-soda-and-water solution? Just let it sit on the crud for a while, then most of it comes right up. For the worst of it you may need steel wool and elbow grease. But seriously, baking soda works great. I've also used it to clean greasy car batteries, and yes, also ovens!

This is not a beer-related question except that it involves fermentation. I have seen several chinese recipes which call for fermented black beans. I love black beans, and I love fermenting, so I'd like to make my own. Does anyone out there have the slightest idea how to go about this??? T.I.A.

From: Ulick Stafford <ulick@brahms.helios.nd.edu>  
Subject: The stick I buried won't grow and other stories

A few day ago I posted to r.c.b and received no repsonse. Basically I buried a Rhizome an inch deep 2 weeks ago and nothing has peeped up yet. Comments? Is it dead or did I dod something wrong (I planted it horizontally).

Second comment is related, but there is a hop growing article that makes occasional appearence here, and a yeast washing article is often requested on r.c.b. Could these be stored in stanford/sierra/pub/homebrew/docs? If they are in a different directory there, let me know.

Thirdly, js commented about the lack of need for pH meters, but if you have the soft water supply that comes from the large natural reservoir (that is our sewer) that Chicago uses, pH adjustement is not necessary. The hard ground water I use requires considerable adjustement unless around 1.5 lb of black stuff is used in a batch. I will concur that a pH meter (cheapo) is a pain in the butt, and I am happier using those awful cheap 5-6 papers everyone complains about.

Fourthly, I must thank Rafael Busto for his joke. AS the saying goes it was so funny that the first time I heard it, I fell off my wooly mammoth.

 From: mkenny@bcmlg01.attmail.com  
 Subject: RE: Hunter Airstat Modification

In HBD1156 Bruce Ray asks how to modify a Hunter Airstat to maintain temperatures below 40F.

I originally posted this last November and have been using it with the mod very happily ever since. I use the airstat to control a 13cf chest freezer. I put the airstat in a manual "HOLD" mode and simply set the temperature up or down as desired. The airstat is designed to control a compressor driven refrigeration device (a room air conditioner) so it is right at home with a refrigerator or freezer. It turns the attached unit on when it senses a temperature 2 degrees above the setting and off 1 degree below the setting. It has a built-in timer with a 4 minute delay to keep the attached unit from cycling too rapidly. At 45F my freezer runs less than 2 hours total in a 24 hour period and about 3 hours at 35F.

You cannot change the Air Stat range but you can offset the sensor calibration. In other words, performing the following modification will allow you to set the Airstat at 40F yet the fridge/freezer temp will be maintained at 35F.

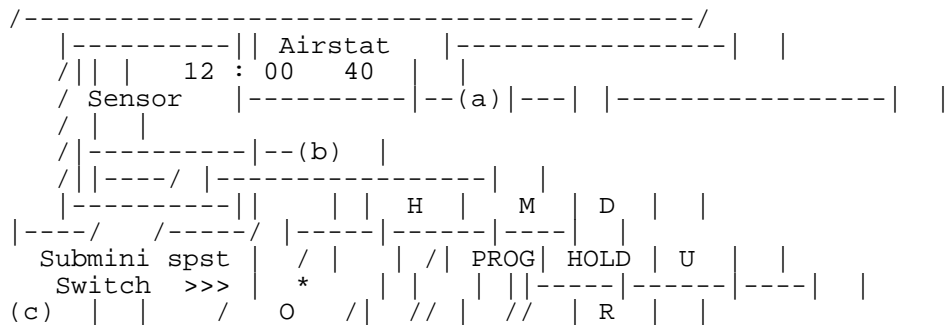

The sensor is a thermister that provides 10K ohms of resistance at 25 degrees C. According to the thermister data sheet, at 32 degrees F the resistance is 27.28K and 22.05K at 41 degrees F. The resistance decreases as the temperature rises so if you make the air stat think the sensor is 22k when its really 25k the air stat will say 41 but the sensor temp will be around 35 degrees F. This is done by simply putting more resistance in parallel with the sensor. Using ohms law,

$$R_t = 22K, R_{th} = 25K \text{ (Thermister), and } R_p \text{ (parallel resistor) =}$$

$$\frac{R_{th} (25K) * R_t (22K)}{R_{th} (25K) - R_t (22K)} = 183K \text{ Ohms}$$

With this resistor in place the the range of the air stat is effectively shifted about 5 degrees lower. Just keep in mind that the temperature reading on the air stat will not match the fridge temp.

The thermisters change in resistance is not linear. It will change about 20k ohms going from -13F to -4F and only 2k ohms going from 68F to 77F. Therefore the desired range of use should be considered before determining the magnitude of offset. Although, in the 12 degree swing between 33F and 45F this should not pose a problem.

| /-----/ |-----| |  
/-----/

180K  
(a) -----////////-----o /o----|  
(c) |  
(b) -----

I installed a 180K ohm resistor in series with a sub-mini spst toggle switch mounted on the front panel just left of the AC outlet and below the pocket that holds the sensor. It is fairly easy to do since the sensor leads are readily accessible. This switch lets me use the airstat normally above 40 degrees when off and down to 34-35 when on. The airstat seems to sample the sensor about every 5-10 seconds and will indicate the change in this timeframe.

Cheers,

Subject: **Garlic in Beer: Not meant to be.**

Greetings.

In HBD 1156, Lou Casagrande asks about garlic beer. Well, I made one (12 oz) bottle of the stuff. I put a peeled clove of garlic into one bottle of a golden amber ale that I had brewed (at bottling time.) We split this beer between 5 people for tasting. After we had all tasted it, there were still 11 ounces left. The stuff was bad. And I LOVE garlic (I usually move the decimal place in recipes calling for garlic so I increase the garlic content by an order of magnitude).

Nobody liked this beer. And 3 of us liked the jalapeno beers we had made previously.

But, by all means, try it. You might like it. Just don't expect too much.

Subject: Temperature Controllers

Steve Septer:

I have a 23 cu ft chest freezer that I use a temp controller I got from William's for \$49. It has a range from 20F-80F with a 4 degree temperature differential. When set to 50F, it will cool to 46F, shut off, then wait for the temp to rise back to 50F before it comes on again. I'm very happy with it.

Subject: sanitizer

I have been using a product called "Starsan" which I obtained from a local brewpub which uses it in sanitizing their stainless equipment on a continual basis. I have to believe that it is not only effective, but also harmless in continuing use to their equipment. I was told that it is a phosphoric acid product, but no mention was made of iodine content. I use it as prescribed, 6 ml per gallon. At this concentration it does not require a rinse and seems to have no taste (I tried it straight, at the use concentration...some people will drink anything!). It's been very effective on bottles, tuns, counterflow chillers, etc. Does anyone know what the nature of this product really is? I can recommend it without reservation based on experience.

Subject: Hunter Air-Stat too precise...

Steve Septer writes (paraphrasing):

>My dealer told me that the Hunter Air-stat was TOO precise, shutting on  
>and off for every little temperature variation... burning out  
compressors...

The Hunter Airstat has a reasonable temperature differential built in to prevent this. After all, it was designed to control a room air conditioner which has the same kind of compressor as a refrigerator/freezer. Its only limitation is that it doesn't go below 40F. Someone else in the last HBD requested posting of a mod to make it go lower. I too, would appreciate that post. BTW, I got my Airstat at Home Depot (a hardware "superstore") for about \$19.75. Home Base (the competition) also has 'em for the same price. One of the advantages of the Hunter vs the Johnson is that the Hunter has a digital temperature readout of the internal fridge temp (as well as the set point). Another is that the sensor is solid state and connected by wires. The other uses a capillary tube and makes it a bit harder to get a good door seal (but this is being real picky). For those that like that type, Graingers has several of these to choose from, starting at about \$37 (if memory serves)

Subject: Iodine test

Personally, I stir my mash at least once to evenly distribute the temperature and enzymes. I used to put a drop of mash liquor on a white plate and then put a drop of iodine next to it and run them together. It was hard to read due to particles or because the beer was dark (porter/stout). Here's what I do now... Put a drop of mash liquor on one edge of the plate and tilt the plate so it runs to the other side. Put a drop of iodine next to the starting point of the mash liquor drop. Run them together and observe the reaction. A single drop spread out that much, you will be able to see particles and the liquid and see the color change. I haven't tried it yet with a really dark beer like stout, but I don't see why it wouldn't work.

Subject: SS kegs, beer fests in So. CA

There is something that I've been wondering, and I've seen this question posted before, but I'm not sure I've seen the answer. I know there are a lot of homebrewers using half of a keg for a brew pot. What I'm wondering is how do you know whether or not the keg is SS? Are they layered metal, Aluminum on the outside, but lined with SS? I guess I've always thought they were made out of Al, but I must be wrong. Are certain kegs made from different materials? And with all of this talk about different grades of SS, is there a cheap/efficient way of determining what grade the keg is made of? I'm searching for the "cheapest big SS brewpot", and cutting a keg in half seems like a decent way to go, but I'd like to know what it is made of.

Sorry to end on a sad note, but I was majorly bummed to learn that there was a beer fest (several?) in Temecula, CA, and I never even knew! Whoa! Imagine a collective gathering over good brews just 40 miles from your house, with some pretty major HBD players attending (see HBD #1154, and 1155 for some of the names), and you missed it without a clue! Are these things annual events? Do you need to be invited? Do I need to get on somebody's mailing list?

Missing the boat,  
John Fitzgerald.

From: jdg@cyberspace.org (Josh Grosse)  
Subject: pH adjustment Qs & As

In HBD 1156, Jack Schmidling asked for process clarifications on my pH adjustments and measurements:

> >1) Adjusting the pH of the mash. (pH 5.0-5.5)  
>  
> I presume you mean that you adjust the water to something so that  
after  
> adding the malt, the pH is 5.0 to 5.5. I wonder what that something  
is.

Correct. After mashing in, I adjust pH downward with gypsum. The amount I need to get my pH in range varies depending on the malts I use in the mash, so it's recipe dependent. I've yet to need to adjust upward, but, if I did, I'd use calcium carbonate.

> My water is 8.1 and drops into that range. I would be interested in knowing  
> what your numbers are without adjusting.

My water supply's pH varies slightly from day to day. They use slaked lime, like many public supplies, but there is some6. sources (ground/river water). Today's reading is 9.54.

On my last batch, my notes show unadjusted pH was 5.9. That batch was 100% Hugh Baird Pale Malt.

> >2) Adjusting the pH of sparge water. (ph 5.6-5.8)  
>  
> Again, my sparge water is 8.1 and after sparging 10 gallons, it only raises  
> the total pH of the wort a tenth of a point.

I adjust to approximately 5.7 using 88% lactic acid. I do this to ensure that I minimize phenols and tannins in my wort. See any Miller book for the how-to's, and see Dr. Fix's book (Principles of Brewing Science) for the whys.

> >3) Ensuring I don't oversparge. (ph > 5.5)  
>  
> It is just as useful to use a hydrometer. If you stop sparging when the  
> gravity falls below 1.008, you will not likely have any problems. It will  
> take tons of a water a few points higher to have any effect on the  
total  
> wort.

I find the pH meter is easy to use; it's already sitting out, and it is a more accurate indicator of phenol or tannin extraction than specific gravity.

Subject: Airstat

>From: LPD1002%NYSHESCV.bitnet@UACSC2.ALBANY.EDU

>I have found the Hunter Airstat as recommended at Builders Square For \$28. It only has a low end of 40 Degrees. That was somewhat bothersome since one of the reasons I wanted a fridge was to try lagering.

I have been trying to "lager" a batch with Wyeast Bavarian yeast for almost 3 months now at 40F and it still is bubbling at the same rate as when I first transferred it to the secondary. It is my not so humble opinion that 40F is plenty cold enough for lagering.

> The other suggestion, a Johnson Controls Portable Thermostat is sold at my local Homebrew store for \$64.95. This price was somewhat bothersome, but I think it's the one for me. It has a wider range (down to 20 degrees) and the owner of the homebrew store says he recommends it over the Hunter because he knows of some people who used Hunters and had their compressors burn out.

I made an interesting discovery several days ago that may be a clue to that problem. While bottling some beer, I noted the compressor attempted to go on but shut down after about 2 seconds. After a delay of a few minutes, it cycled again but went off right away. I have noticed this before but it usually stayed on after several cycles but this time it persisted for over thirty minutes and I decided I had a problem.

The investigation seemed to point to bad advice from the supplier of the Airstat and users on this forum. The instructions say to turn the freezer to max cold when using the remote controller. When I turned the temp controller on the freezer down (warmer), there was a click near the low end and the compressor went on, stayed on and has not exhibited the problem since.

> It seems the Hunter is a little TOO precise and kicks the compressor on when there is any fluctuation in temperature. The freezer I lucked into seems pretty old, so I guess my decision is made.

There could be something wrong with the one you are using because the guard band of the Airstat is 3 degrees. When set at 45 for example, it should go on at 47 and off at 44 and mine does exactly that. Considering my above comments, there might also be a problem if it is set to 40F as this is the lower limit.

Frankly, I think it is a terrific little gadget for the money and a real

testimonial to modern technology. It even gives a record of daily and cumulative usage.

>From: Drew Lynch <drew@chronologic.com>  
>Subject: Re: iodine

> The last batch I made, I did the iodine test two ways: 1. I drained  
a  
> little out of the spigot at the bottom of my mash/lauter tun (Gott  
> cooler with copper-pipe manifold). This tested completely starch  
free  
> after 20 minutes (the first time I tested it). 2. I pushed the spoon  
> into the top of the mash and let some fluid run into it. This never  
> tested clear, even after 1.5 hours.

I get the feeling from this and the followup comments that stirring is  
only  
casually considered as part of the mashing process and two or 3 hours  
mashes  
would lead one to believe that it might even be considered a bad idea.

I stir my mash every ten minutes when resting and almost continuously if  
heating. I get conversion times that agree with the specs for the malt  
being  
used. For example, the Belgian Pilsner converts in just a tad over the  
5  
minutes specified.

I take my sample by simply pulling the spoon out and letting whatever is  
on  
it drip into the sample dish. Not very scientific but I get consistent  
results.

Subject: Stuck Run-off

My first wheat beer coincided with my first stuck run-off during the sparge. I used 5 pounds of 2 row klages and 5 pounds of wheat malt. The malt appeared to be crushed correctly. I have used my lauter tun a few times before and didn't have a problem with slow sparges. If anything, the sparges were a little on the fast side. I should also mention that I used a infusion type mash w/o a mash out. Do I need to mash out when I use that much wheat malt? I'm not even sure what could cause a stuck run-off except for too fine of a crush on the grains.

I use a Phils style lauter tun. Instead of using the Phill's false bottom, I used the lid of my bucket and drilled hundreds of 1/8" holes. There are a few little gaps between the side of the false bottom and the bucket. Any ideas or suggestions?

From: thutt <thutt@MAIL.CASI.NASA.GOV>  
Subject: What differs in American Beers

We all complain about the lack of variety in American beers, and as I was bemoaning this fact to a friend of mine, an excellent question popped into my head. I recently read (forget where) that A.B. has about 17 different beers, all basically the similar, while many European breweries have the same number, but with a much greater, often seasonal variation.

So, the question is, what exactly are the differences between, any two beers made by the same mega-brewery? (eg: Bugwieser -vs- Busch)

And, another observation: It seems to me that Miller is the least resistant in trying new styles of beer. Some good (Amber Ale), some marginal (Reserve) and some questionable (Clear). I would surmise that if these work out well for Miller, you can bet your brew kettle that A.B. & Coors will soon begin brewing a larger variety (with real variation) of beers.

From: P\_LABRIE@UNHH.UNH.EDU (Paul LaBrie)  
Subject: "Thick" dry stouts...why?

This past weekend I attended a local homebrew party where I brought along a Cornelius keg of my latest dry stout (a variant on the Line/Miller recipes which I have been consistently happy with).

The comment I always seem to receive at these parties, whether I'm pouring my own, or an actual Guinness, is that dry stout is "thick". Do beer-tasters (read "willing amateurs") elsewhere also refer to stouts as "thick" or is this just a local phenomenon?"

Note: I'm NOT looking for a diatribe on the tasting abilities of the average American light beer drinker (flame-throwers on stun only). What I am curious about is whether the dark color and strong bitterness of dry stouts actually imparts a feeling of "thickness" to some peoples' minds, even though the body of the beer may be quite thin. "Thick" (to me) implies a comment on texture and body. My stouts (luckily) and their commercial counterparts definitely do NOT have the texture of a syrup or a motor oil so why "thick"? Any taste & aroma physiologists out there? (I'll summarize any private postings).

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: top cropping???

I've got this batch in the fermenter that just won't quit. The yeast has been crawling up-and-out for a week now. Yesterday, I thought it had settled down and switched the blow-off for an airlock, but NO! A few hours later, I took off the airlock and replaced the blow-off. The airlock was half full of "solid" yeast sludge. Seems like, with the proper care, I ought to be able to collect this stuff and reuse it. Does anyone have any hints on doing this in a "sterile" fashion? (I should mention that the blow-off bucket also had about 1/4" of nice looking yeast slurry on the bottom when I switched it out.)

One thought that occurs to me is to do a "2-stage" blow off, where the main blow-off tube goes into a sealed, sanitized container with a second blow-off or airlock. I could collect the yeast in this container, and then save it for the next batch. Does this sound like a reasonable scheme?

Yours in confusion,

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: sparging & manifold design

A while back, there was a discussion about copper manifold sparging designs. A few of us had built in a "down pipe" into our design. This is a pipe that rises from the manifold to a point above the top of the mash, and is open at the top. I designed it into mine with two purposes in mind: to easily underlet mash and sparge water (although this could be done through the outflow), and to act as a "suction breaker" in the case that a sparge through a hose to a lower level was to apply too much suction (by siphon effect) and "set" the mash. Others pooh-poohed the need for such a device.

Well, the other night, I got to see the suction-breaker effect in action. I was (as previously described) trying to make to batches from one mash, and was, understandably, trying to make it go as fast as possible. So I opened the valve full (3/8 OD pipe/tubing) and let it run. At one point, when I glanced over at it, the tubing was full of bubbles, presumably resulting from air sucked in through the down tube. I quickly throttled back the sparge, and the bubbles disappeared. So at least it worked to let me know I was going to fast, and may have helped prevent over-compaction of the mash.

Subject: paulaner salvator ideas

It's a great beer, and so is Spaten Optimator. The premier issue of Brewing Techniques has an article by Darryl Richman where he describes the thinking that went into his first place Bock. The recipe for the beer appeared in Zymurgy. I don't remember the exact amounts, but based on his article and some bocks I've made, I'd suggest lots of Munich malt and some Aromatic malt too. If I remember correctly, Darryl used no pale malt.

More generally, you might consider using proportions of the following malts:

pale malt  
Munich malt  
Aromatic malt  
U.S cara-pils (dextrin malt)  
crystal malt

The starting gravity for your doppelbock should be 1.076. Hops should be multiple additions of Hallertauer. Yeast should be a good liquid lager yeast such as Wyeast "Bavarian" lager.

Doppelbocks do not have to be so dark as traditional bock. Color can be obtained with ample amounts of crystal and Munich malt. Be careful with highly roasted malts. While there is a temptation to use them for color, I don't think a chocolate malt or burnt malt flavor is appropriate in a doppelbock.

From: Robert Schultz <Robert.Schultz@usask.ca>  
Subject: Re: Homemade cooker (and Easymasher)

I have been using a Coleman camp stove and I am not overly happy with the results, over an hour to bring 25 litres to boil. However, if I shroud the pot I'm sure that I could lower the time to boil. On the other hand, I think this is fairly heavy duty work for the Coleman stove and I don't want to start repairing it the next time I go camping....

SO, I am putting in place pieces for a cooker. I got a 120 litre water heater from a friend for the cost of removing it from her basement (it is going to cost me a six pak for the friend that helped me carry it out). I have ripped it apart keeping in tact the base and burner assembly. I have an old portable barbeque which I have scouged the control/regulator and now have to mount to the base. The last item is to get my welder friend to build a rack strong enough to hold 50 litres of brew while applying 35,000 BTU. Total cost should be 2 six paks of brew.

The major obstacle is to determine if I can fire this unit up inside the house? I have used the Coleman stove inside the house (keep the exhaust fans running) with no apparent dangers .. it depends how clean this new unit burns (proper orifice/burner combination).

EasyMasher  
=====

As for the building of trademaked/patented items, I am under the impression that one can build these items for personal use, but you can not sell for profit.

**Subject: Those Black Beans**

Someone was asking about Chinese fermented black beans and how to: well, foist of all, they aren't really black beans. Second of all, I'm pretty sure they aren't really "fermented". There's a problem that arises with translations from Chinese, not to mention the Chinese habit of employing picturesque terminology, especially in reference to food.

At any rate (and completely void of beer references): if memory serves, FBBs are actually produced from soybeans. They are heavily salted, and usually in conjunction with ginger. And as dear old dad pointed out in reference to "fermented bean curd", protein doesn't "ferment", it putrifies. The bean curd and the "black" beans would probably more accurately referred to as "pickled" or perhaps "salted". The beans are available at any decent Asian grocery (don't buy the stuff in jars at your supermarket --fooeey!); the best come in a yellow cardboard tub (can't remember the brand name offhand, could be Pearl River Bridge). As nice as the tub is, the beans will stay moist longer if you transfer them to a tightly closed jar. Use much more than called for in most recipes; they seem to be written for the "American" palate; one of my favorites is beef chow fun made with wide rice noodles, green peppers and LOTS of black beans. Yum.

From: "Westemeier\*, Ed" <westemeier@pharos-tech.com>  
Subject: Wheat beer puzzle: 2 layers?

One of our local club members reported a puzzling result from his latest batch. Since no one here could positively identify what happened, I thought the collective wisdom of the HBD could at least offer some plausible theories.

The situation:

A German wheat beer, about 60% wheat, mashed and boiled normally, and pitched with Wyeast wheat yeast. Fermented at 75 to 80 degrees Fahrenheit to get the most spiciness, and racked to a secondary after 3 days. Fermentation stopped after 10 days, and when he looked at it, it seemed to be in two layers. The top half of the carboy was dark, and the lower half was much lighter. Thinking that it was a case of the yeast simply taking a while to settle out, he peered through the carboy, using a flashlight. No, the top half was definitely much darker, and there was a distinct dividing line in the middle, separating the layers.

He then used a racking tube to carefully take samples from each layer. The top (darker) half was considerably lower in gravity than the lower half. Both layers tasted fine, although the alcohol definitely came through in the taste of the darker, upper layer. He bottled the two layers separately, as best he could, and now seems to have two distinctly different wheat beers from the same carboy.

Has anyone ever seen this effect before?  
Can anyone offer an explanation for it?

From: Bob Konigsberg <bobk@NSD.3Com.COM>  
Subject: Re: Propane Cooker

Posting as a followup to Chris Estes question on putting a propane cooker in his basement.

Aside from the burner size comparisons Chris, I would strongly recommend that you also install a really good exhaust fan WITH a hood.

Boiling that much wort will release a lot of water vapor into the air, and it may well condense in places you don't want, providing a breeding ground for higher concentrations of strange critters that you don't want in your beer, as well as possibly allowing wood rot to set in in your home's structure.

In addition, if the burner is any kind of healthy size at all, depending on its adjustment, you may be risking built up concentrations of Carbon Monoxide (toxic) and Carbon Dioxide (non-toxic, but oxygen displacing).

I decided not to brew in my basement for those reasons (too cheap to put in a good exhaust hood I guess :- ) ).

Good Luck,

BobK

From: Bob Konigsberg <bobk@NSD.3Com.COM>  
Subject: Yucky Stove tops

The nasty stuff on stove tops falls into two basic categories.

1) A Light film of grease/oil which is left over from other cooking,  
and gets burned in place by the heat of boiling.  
CURE: Wash the stove thoroughly BEFORE brewing.

2) Spills that get burned into place.  
CURE: Clean up spills right away, even if you have to turn off the  
heat and slide the pot to the side for a bit. They will never get  
easier to clean up, only more difficult.

>Hi All...

>We're getting ready to move into our new house next month. My brewing  
>activities have been banished to the basement! That works well, except  
>that I don't relish the idea of carrying 5 gallons of wort down the  
>stairs after cooking. Add that to the fact that the new house has an  
>electric stove and things look grim.

No need to carry hot wort. Chilled it and then  
shipon it down the stairs. I brew either in the  
garage or outside. After cooling the beer is  
shiphoned down the stairs using a 1" shiphon hose.  
Works well and is pretty quick.

>I'd like everyone's input on what kind of propane cooker to get. I  
>only make beer in 5 gallon batches, so I don't need a surplus Saturn V  
>motor up-ended! What's best? What kind of gas do I use? How much  
should  
>I expect to spend? Can I use it in the basement, or do I have to step  
out-  
>side on the patio? Will I have to build a stand to hold my brewpot, or  
>will it come with something sturdy enough? You get the idea; I'm  
totally  
>in the dark on these things!

The burner I use is only 60,000btus but has no  
problems with 40-55litress that it boils regularly.  
Since it designed for large scale home canning it  
comes with a very sturdy stand. Many people place  
40gallon drums on it! I don't know if it's available  
outside of Toronto. In my understanding all the  
higher BTU's give you is a faster boil.

>buried a Rhizome an inch deep 2 weeks ago and nothing has peeped up yet.  
>Comments? Is it dead or did I do something wrong (I planted it  
>horizontally).

Assuming the weather is fine and the rhizome was alive when planted the only thing I can think of is that you planted it upside down. Brush the dirt off and check for growth. Depending on type some hops are relatively slower growers. My hallertau plants grow and develop much slower than either the nugget or Mt. Hood.

Subject: Re: Calcium Chloride Source?

In HBD# 1157, Darren asks:  
>Does anyone know a source for food grade calcium chloride?  
>I'd like to use some for water adjustment.

I got my CaCl<sub>2</sub> from "All World Scientific Supply" in Lynnwood, WA. They have an 800 number so you can just call 1-800-555-1212 to get it. I think I paid \$15/500gm for USP grade. You should be able to look under chemical supplies in the yellow pages and find someone local. If not, then All World does ship. Also, since you are at a university, try your local chem student store or ask around the biology section.

Cheers!

P.S. a 55 gal drum of USP CaCl<sub>2</sub> costs only \$.75/lb - quite a mark up for stuffing small bottles and labeling...

Subject: Iodophors

With all the discussion of iodophors I thought I might post the following info from a tome entitled "Disinfection, Sterilization and Preservation" Ed. by Seymour S. Block 4th ed 1991.

Iodophor is a complex of elemental iodine or triiodide with a carrier that has at least 3 functions. (1) to increase the solubility of iodine (2) to provide a sustained release reservoir of the halogen and (3) to reduce the equilibrium concentration of free molecular iodine. The carriers are neutral polymers such as polyvinyl pyrrolidone, polyether glycols, polyvinyl alcohols, polyacrylic acid, polyamides, polyoxyalkylenes and polysaccharides. No where does the article mention the use of phosphoric acid as a iodine complexing agent. I have been told by an industry rep that phosphoric acid is added to maintain a low pH (<9) and aid in cleaning.

Another important feature of aqueous povidone-iodine solutions is that there exists a maximum concentration of 25.4 mg/L of "free iodine" that arises in a 0.1% solution and can never be exceeded. So more iodine is not better and is in fact wasteful.

I suggest this book for anyone who really wants to know about all the sanitizing techniques used by brewers.

GREAT NEWS FOR THE STATE OF MICHIGAN!!!!

Well folks, it's finally happened. Michigan's first brewpub, The Eccentric Cafe, will open its doors at noon, Friday June 11, 1993. Located in downtown Kalamazoo, the brewpub is adjacent to The Kalamazoo Brewing Co. Congratulations and thanks to Larry Bell, president, mover and shaker.

Larry brews a fairly long and interesting, some would say eccentric line of brews that range from the refreshing (Bell's Beer) to the massive (Explorer Stout). I don't have a clue as far as which brews will be offered in the pub. Some of us will be traveling from Ann Arbor to Chicago this Friday for the national competition. Hummmmmmm isn't Kalamazoo on the way? The usual report will follow....

Subject: dry hopping = 100 IBU's ??

Summary:

Hop pellet residue that got into my bottles seems to be making the beer progressively more bitter and undrinkable.

My first try at dry hopping resulted in some suspended pellet material getting into the bottles. At first the beer was delicious, with a lovely fresh hop aroma but 6 weeks later the beer is becoming undrinkable. Is this

likely to be due to continued extraction of bitterness? I am under the impression that hops must be boiled to extract bitterness. Is an infection likely? There's no unpleasant taste, just this very bitter characteristic.

Date: Mon, 7 Jun 93 10:53:23 -0500  
From: gjfix@utamata.uta.edu (George J Fix)  
Subject: Miller Lite and American Lagers

I conjecture that the Miller Brewing Co. uses a high gravity system whereby their beers are brewed at 16 P (SG = 1.065), fermented, and then aged. Following this, it would seem reasonable that they are diluted, filtered, and then in the case of Miller Lite, pasteurized. According to Fred Eckhardt (see page 49 of his TEOBS) the diluted version has an (equivalent) OG of 7.8 P (SG = 1.031), an IBU of 19.5, and an alcohol level of 3.3 % by wt. I believe these are accurate numbers, which means Miller Br. is diluting by a factor of two. What is interesting here is the Miller Lite that is residing in Miller's ruhr storage tanks. It is a 16 degree beer with an IBU of 39, and has an alcohol content of 6.6% by weight (8.25% by vol.). A knockout? You better believe it!

The point of this observation is that the undiluted Miller Lite is what the original American lagers use to be. If one has any doubts about this, then check page 38 of Nugy's book. The latter is reference 12 on page 41 of Fred's book, and reference 6 in my book with Laurie. Nugy's book is full of the older beer formulations. In particular, on page 38 he gives the recipe for one of the best selling lagers in the Northeast in the pre-prohibition era. Here it is:

100 bbl. (3100 gals.) batch  
4775 lbs. pale malt  
1380 lbs. flaked maize  
50 lbs. domestic hops  
38 lbs. imported hops  
OG = 15P (1.061)

The IBU was not cited, but with a .88 pounds per barrel hop rate it had to be as high as the undiluted Miller Lite, and maybe higher. This beer could be distinguished from European lagers because of its use of some unmalted cereal grains. Note that the flakes are used in this formulation as an adjunct in the proper sense of that term; i.e., not as a malt replacement but rather as a specialty grain which is used for special effects. In particular, the flakes give the beer a residual grainy sweetness that was apparently valued in lagers in that period. By the way, although Fuller's ESB is a dramatically different beer, one can still pick up that same "sweetness" in it. Fullers also uses flaked maize as an adjunct, something Laurie and I both directly observed last summer in London.

What is a real irony here is that if any of us were to brew Nugy's lager, and enter it in the American Light category, all \*\$## would break loose. I can just see the looks of disbelief as unsuspecting judges tasted this one! Yet this is exactly the type of beer that originally defined this category.

One final point. It is my belief that Miller Reserve is made exclusively

from malted barley, and in particular no raw barley is used. I would be willing to bet that the phrase "100% Barley" was chosen by their marketing people and not by their brewers. Why is it so lightly flavored? Well folks, guess what submicron filtration gives you!

George Fix

P.S. Many commercial breweries (including a large one in Ft. Worth) use a 5% phosphoric acid solution as a final step in cleaning. It is not too good with organic dirt (caustic solutions are used for that), but it will really put a nice shine on 304 stainless. It is regarded as being natural to beer, and not aggressive to equipment. Rinsings is nevertheless used after its use.

P.P.S. Thanks for all the nice e-mail that was sent. There are a bunch of really great people on this network!

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Re: SS Kegs

Someone queried about differentiating between SS and aluminum in kegs...

There are many entries in the archives regarding this, but the best method is probably to obtain a sample of NaOH or KOH (caustic soda or caustic potash). Put a few drops on the metal to be tested. Within about 30 seconds, the solution will start to fizz and bubble, evolving hydrogen gas, if the metal is aluminum. The solution will have no effect on SS. This should also work with Drano or lye, if you don't have access to a chem lab.

WARNING: THESE SOLUTIONS ARE VERY DANGEROUS. USE ONLY WITH ADEQUATE SAFETY PRECAUTIONS, OR NOT AT ALL IF YOU ARE THE TYPE TO HOLD OTHERS RESPONSIBLE FOR YOUR OWN MISHAPS.

From: Darren Evans-Young <DARREN@UA1VM.UA.EDU>  
Subject: Foam with kegging

In response to Mark Parshall <markus@pyramid.com>:

Mark,

Your problem can be related to both temperature and pressure. I had exactly your same problem. The main cause of foaming is dispensing with too low a pressure. However, since a higher dispensing pressure causes more agitation of your beer, it also causes the CO2 to come out of solution and foam. So the trick here is to increase dispensing pressure but slow down the flow. How do you do that? Use a smaller diameter dispensing hose so that it takes more pressure to push the beer through the smaller hose. I changed all my tubing from 1/4" to 3/16". The out connector and the cobra faucet take 1/4" hose, so you have to have short pieces for connection plus 2 hose unions that change from 1/4" to 3/16".

faucet---1/4" line---union---3/16" line---union---1/4" line---keg  
connector  
6"6' 6"

I use 6' of 3/16" tubing and this has completely eliminated my foaming problems. Another thing that will cause foaming is temperature. At home I have no foaming problems because the keg and dispensing lines stay inside of my fridge. However, when I take a keg somewhere, the lines warm up and the 1st couple glasses drawn are foam until the lines are cooled by the colder beer. At homebrew club meetings, I always watch for someone to get a beer from a keg and then immediately get one after them. They get foam, I get beer.

Dont give up on the cobra faucet. My beers draw just like they do in a bar, nice and slow but with plenty of carbonation and a nice head.

Get you some 3/16" tubing, unions, and hose clamps. Rapids has them.

174-T Trans 3/16" vinyl tubing .35/ft  
RP220C 1/4" X 3/16" Unions .90/each

From: pyle@intellistor.com (Norm Pyle)  
Subject: Batch sparging

Rob Thomas asks about batch sparging. I use this method, out of laziness mostly. It works for me but my efficiency isn't near what is claimed here on the net for many folks. Of course, I only do a single batch, i.e. I dump all of the sparge water into the lauter tun, stir it, let it settle, recirculate a bit, and drain it all off. Once. I get around 24 pts/lb/gal. I expect that could be raised significantly with a couple of batches, even if the total amount of sparge water isn't significantly increased. Of course, as you increase the number of batches, you approach the continuous inlet of sparge water method which I, because of my admitted laziness, am trying to avoid. I may get really ambitious next time and split my sparge water into two batches to check the impact on extract efficiency. Or not.

For those of you using a Bruheat or equivalent as a boiler: I always pull my stove out, crawl back there, unplug the stove, plug in the Bruheat, and proceed to brew with the stove in the middle of the kitchen (don't want to push it back in, might be a bit too much work!). My new plan, soon to be implemented, is to connect a small extension to the back of the stove. It will be connected from the terminals on the back of the stove up to a 220V connector which is mounted on the back of the stove, near the top (much easier to get at). There is no modification to the house wiring, or to the stove, and it can be removed when/if I move. The added benefit of this is that my stove will not be out of action for heating sparge water or something else. The Bruheat will be in parallel with the stove's load but it is small compared to the maximum drain from the stove/oven. If I only use one or two other heating elements at the same time it should be no problem. Another added benefit is that, at most, the stove will only be pulled out a few inches.

DISCLAIMER: Don't do this! Working with 220V (221, whatever) is dangerous and this does not comply with any Electrical Codes that I am aware of. NO NO NO! I do not recommend you do this! It was only a joke (note smileys: ; ) :0 : ) ).

Cheers,  
Norm

From: Bob.Clark@Eng.Sun.COM (Bob Clark)  
Subject: Keg experiences (was Re: Foam With Kegs; Forced Carbonation)

My 3-tap fridge is based on 1/4" tubing, and ball lock cornelius kegs.

Maximum liquid line length from disconnect to tap is about 4 feet.

My artificial carbonation technique is to put the keg in the fridge, and hook up the CO2 at about 30 psi once a day. About half a week of this, and it's carbonated. I'm trying a new technique right now of keeping the keg continuously connected at 30 psi - don't know how quickly this will work.

When carbonated, I just hook the keg up to my fridge CO2 supply, which is somewhere around 8-10 psi, continuously connected (if I don't have any leaks at the time!). Since I have individual check valves for each of the three potentially connected kegs, overpressure in one or more of the kegs is not a problem. I just start pouring, and live with the extra foam until everything reaches equilibrium, which doesn't take too many pints. If I have not sufficiently carbonated the beer, another week or so at my normal dispensing pressure is sufficient to carbonate it properly.

As far as moldy taps go, I just disconnect the liquid line from the keg, and take the tap off. This is easy, since there is a knurled collar and thread system which connects the tap outside of the fridge to the beer shank, which is the pipe that runs through the sidewall of the fridge. I take apart the whole tap, and do a little boiling and a little rinsing to clean out the mold.

I'll clean a tap if it's been a coupla weeks, or if there are some folks coming over. If I get a little lazy, I just never bring up the subject of mold with company, and they've never noticed anything ;-)

Date: Mon, 7 Jun 93 23:28:54 PDT  
From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Boil and New Utilization Table

Someone, sorry but I can't find my note, asked about adding hops before or after the hot break:

I think the most important thing is the boil time, not worrying about when the break occurs. Your utilization will be more affected by the boil time than any supposed break material coating the hops. Besides, it doesn't matter a whit what coats the petals (aka, but wrongly, leaves). It is the stuff in the little yellow lupulin glands that counts. I've never seen any stuff on the petals in my wort anyway. There is also the argument that having the petals and/or hop particles from pellets thrashing around in the boil is helpful in getting a good break to happen.

Bob Jones commented about the work that Glenn Tinseth is up to taking a new cut at Rager's numbers:

Glenn and I have corresponded on the subject relative to incorporating his results in my book. Until the results are in (which could take a while)

I have taken a stab at modifying Rager's utilization chart. My revised figures are based on inputs from many brewers (thanks, BTW, to those from HBD that responded to my request for comments on Rager's numbers), reviews of the literature and my own estimates. The following should not be considered as an absolute (there aren't any in brewing) but more as a "work in progress". The chart is about to be published in my catalog, but in the spirit of Bob's note and the input HBDers have provided, I'm willing to share it with all.

The chart lists Rager's original numbers, and three different columns of new numbers. The first column is Rager's, the second lists numbers for yeast with "average flocculation", the third column for yeast with fast flocculation and the last for yeast with slow flocculation. Besides the boil time and wort gravity, the effect of the yeast on the bitterness is probably the next most important factor and that is why I've included it. The reason for the three figures is that the faster the yeast settles, the less time it will be suspended (duh) and therefore has less opportunity to absorb alpha acids, so the utilization is adjusted upwards. It follows that yeast dropping out slowly will absorb more alpha acids and therefore the utilization should be adjusted downwards. Also, you can see that I've discounted any alpha utilization at low boil times.

| Boil Time<br>Number | Rager's<br>Flocculation | Average Yeast<br>Flocculation | Fast Yeast<br>Flocculation | Slow Yeast |
|---------------------|-------------------------|-------------------------------|----------------------------|------------|
| < 5 min             | 5% 0%                   | 0%                            | 0%                         | 0%         |

| 41-45 min | 26.9%  | 19% | 23% | 15% |
| 46-50 min | 28.1%  | 20% | 24% | 16% |
| > 50 min  | 30.21% | 25% | 17% |     |

I'm sure that I don't have to ask for comments :- ) and of course, YMMV.

BTW, for those who don't know what we're referring to, we're talking about a chart and formulas published in the Zymurgy special issue on hops. Also, the complete formula is published in both Glenn's and my catalogs. And for those that don't know, the original article had a formula error in the gravity adjustment. It should have read:

$$GA = (\text{Boil Gravity} - 1.050) / 0.2.$$

Also, the example shown is wrong. It should be:

$$GA = (1.096 - 1.050) / 0.2 = 0.23.$$

From: U-E68316-Scott Wisler <swisler@c0431.ae.ge.com>  
Subject: Strawberry Ale

After reading all the articles on fruit beers over the past month, I decided to some strawberry ale. Fresh picked raspberries will have to wait for mid-summer. I had a 38 OG, 28 IBU pale ale in clearing in a secondary secondary fermenter. I bottled 4 gal, then added 1.5# of chopped and mashed up strawberries to one gallon remaining in my carboy. After about a week, I strained/racked off the beer with a grain steeping bag stretched over my racking tube. The beer, which was once very clear, now has the appearance of fresh-from-the-farm apple cider (golden brown and opaque). It is now in a one gallon glass secondary in the refridgerator 'clearing'. I have become curious about the absence of strawberrys in the previous HBD discussion, or any brewing literature for that matter. Strawberries are more pulpy than raspberries, but I really never expected the cloudy final product. If anyone else tried this, another data point would be nice.

BTW, I aquired a 3 barrel SS 'vat', for lack of a better term, that overwhelms my small scale. (10 gal takes up 3" in the bottom). It is 36" high by 31" diameter. It has a drain in the bottom with a sanitary fitting, a lid with a slot for a mechanical stirrur, and is on a heavy duty 3 wheel stand. My eyes got a bit greedy before my brain realized just how big it was. Anybody close to Cincinnati interested can private email me.

Subject: Foam with kegging

In HBD #1158 Darren Evans-Young writes the following.

> I had exactly your same problem. The main cause of foaming  
> is dispensing with too low a pressure. However, since a higher  
> dispensing pressure causes more agitation of your beer, it also causes  
> the CO2 to come out of solution and foam. So the trick here is  
> to increase dispensing pressure but slow down the flow. How do you  
> do that? Use a smaller diameter dispensing hose so that it takes  
> more pressure to push the beer through the smaller hose. I changed  
> all my tubing from 1/4" to 3/16". The out connector and the cobra  
> faucet take 1/4" hose, so you have to have short pieces for connection  
> plus 2 hose unions that change from 1/4" to 3/16".

I have been able to attach both the cobra tap and disconnect to 3/16"  
hose  
by heating the end of the hose in hot water. This softens the hose enough  
to get it on the barbed fitting with out too much effort.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: Stuck Run-off

Hi All,

In HBD#1158, Riccardo Cristadoro asks about using kegs as fermenters.

Some time ago, I obtained some free pin-lock kegs from a friend who owns a restaurant. I had an existing ball-lock setup, bought some pin-lock hose barbs and used the new kegs for awhile, but eventually amassed enough ball-lock kegs that the pin-locks fell into disuse. Recently, I've been using them as secondary fermenters for lagers with great success.

I removed the pickup tubes, and cut about 1/2" off the end. Prolonged secondary at 40F produces a fairly thick yeast sediment, shortening the tube allows me to transfer from these kegs without picking up the sediment.

I put a ball-lock hose barb on one end of a short length of pressure tubing, and a pin-lock barb on the other, which allows me to connect a ball-lock keg directly to the pin-lock via the liquid out fittings. When the beer is ready, I put the CO2 tank on the gas in fitting on the pin-lock, and transfer the beer under pressure from the secondary to a ball-lock keg that has been purged of oxygen. The entire five gallon batch is transferred from one sealed, sanitized, oxygen-free container to another sealed, sanitized, oxygen-free container in about two minutes. No worries about starting a siphon, keeping my mouth off the siphon tube, no oxidation, no exposure to airborne micro-nasties.

The best part is that pin-lock kegs take up much less space than carboys, I can fit three batches of lager in the same fridge that won't take two carboys at once.

\*\*\*\*\*  
\*

Also in HBD#1158, Riccardo writes about a stuck sparge:

>My first wheat beer coincided with my first stuck run-off  
>during the sparge.

.  
>I should also mention that I used a infusion type mash w/o a mash  
>out. Do I need to mash out when I use that much wheat malt?

Wheat contains a lot of high molecular weight proteins, sparging a wheat mash is somewhat more problematic than one that contains 100% barley. Stuck mashes are a fairly common occurrence with wheat.

You didn't mention whether or not you did a protein rest, but I would \*strongly\* advise using a protein rest in the future, particularly if you're not going to use decoction mashing. Eric Warner recommends a staggered protein rest in his Classic Style series book, that is, brief rests at 117F, 122F, and 126F. At each of those temperatures, a different class of peptidase (protein reducing enzyme) is activated. The point is to break down as much high molecular weight protein during the mash as

possible, in order to reduce the chances of a stuck sparge later.

>I'm

>not even sure what could cause a stuck run-off except for too fine  
>of a crush on the grains.

Lack of heat in the tun is another classic cause, and this relates to your question on mash-out. When mashing-out, the temperature of the mash is raised to ~170F, and held for 5-10 minutes. Adding heat to the mash not only stabilizes enzyme activity, it is very helpful in avoiding a stuck sparge. Highly recommended for wheat mashes.

One other little pointer. When mashing barley, most brewers use a water to grist ratio of roughly 1 - 1.5 quarts/lb. When I brew a weizen, I use 1.5 qts/lb for the mash itself, as a thick mash protects protein reducing enzymes better than a thin one when the mash is heated. At mash out, I add quite a bit more water than I typically use for barley mashes. Since the mash is finished, enzyme activity is irrelevant, and the extra water thins the mash and helps keep it from setting during lautering.

Cheers,  
Jim

From: "Bill (W.R.) Crick" <heybc@bnr.ca>  
Subject: Microwave for sterilization

Ralph Palmer asked about sterilizing in the microwave.

At a microwave cooking class that came with my microwave, they said DO NOT DO ANY CANNING<, JAMS, or PRESERVES IN THE MICROWAVE. They said stick to boiling it on a canner on the stove. I don't know why, but suspect that there could be an issue with the microwave not sterilizing well enough?

I have boiled wort in the microwave in a beer bottle, with a loose cap, and then capped it while hot, for yeast starters. It seemed to work OK, with no obvious growie things in the bottles after a few weeks in the fridge. The starter I made, and the beer seemed healthy

Bill Crick    Brewius, Ergo Sum

PS: If you have temp probe microwave, you can easily mash a few pounds of grain in the microwave. Just program the temps, powers, and times you want, including a mash out, and go cut the lawn or something. It beeps when its time to sparge;-)

The last I heard (Jan, 93) it still isn't legal in Michigan to brew beer  
and  
serve it in the same place. Maybe I am just picking nits here but a  
brewpub  
it a pub where the brewery is part of the pub, no? Sounds to me like  
Larry  
Bell opened a pub adjacent to his brewery in which he will sell the beer  
brewed  
in his brewery. Not the same thing as a brewpub.

So either the Law in Michigan has changed in the past 6 months and I  
don't  
know about it or what it being described here is not actually a brewpub.  
I would like to know because there is a lot of interest in opening one in  
Traverse City should this law ever be changed. :)

Not at all! A wire brush attachment on your electric drill will do wonders cleaning up a burned-on mess. Of course, you'll have to forego your stove's enamel finish, but you'll end up with a nice burnished steel finish instead.

have fun

From: Cisco <FRANCISCO@lan.ccit.arizona.edu>  
Subject: Calculating Proper Dispensing Pressure

There has been enough talk about dispensing pressures for cornelius keg systems so I thought I'd throw in some logic on how to calculate dispensing pressures. I have been kegging for over ten years and learned a lot by trial and error until I had the luck to run into the individual who sets up most of the draft systems here in Tucson. Believe it or not there is some logic to all this and your elevation from sea level must also be taken into consideration.

Optimum dispensing pressure is 12 lbs. at 36 to 40 degrees. For every 2000 feet above sea level you must add 1 lb. Tucson resides at 2400 ft above sea level so I need to add 1 1/4 lbs to 12 lbs to get a total of approximately 14 lbs(13 1/4) total dispensing pressure. I have a chrome tower draft column which will offset 3lbs pressure, leaving me with 11 lbs(14-3=11) that must be taken up with hose. How much hose will I need to offset 11 lbs? That depends on the inside diameter. A hose of 1/4 id. has a 1 lb drop for every 18 inches, so I would need 198 inches or 16 1/2 feet. That's a lot of hose! A hose with 3/16 id has a drop of 1 lb for every 4 inches, so I would use 44 inches or 3 ft 8 in. This is what I use.

After you have calculated and assembled your system you can fine tune the way your system pours a beer by adjusting the pressure no more than 1 lb above or below the calculated pressure. My CO2 pressure is set at 13 1/2 lbs and I get a beautiful creamy head about an inch thick.

One last point is that you should keep your CO2 tank at room temperature - not in your cooler. If you keep the CO2 tank in the cooler the CO2 can not form a gas and remains in a liquid state feeding into your beer and eventually it will overcarbonate it. Read the dial that states internal tank pressure and when it is stored in a cooler you'll notice that the dial indicator is in the red zone, take it out and let it sit at room temperature and the dial will move above the red zone indicating that the CO2 is allowing gas to form from the liquid.

My draft system is in an old freezer with a Johnson type controller. The Hunter airstat just couldn't get the temperatures I wanted.

The new magazine Technical Brewer is great! Keep up the good work!! The short blurb on dispensing pressures was nice but it left out some of the fine points of calculating proper pressure.

John Francisco  
Francisco@lan.ccit.arizona.edu  
May your homebrew always give you good head!

From: korz@iepubj.att.com  
Subject: Sanitizers

As an offshoot of the Bleach/Iodophor/SS discussion, Ulick and I have exchanged some private email, the last of which had a few points of general interest:

U>I guess that is the best solution. I use bleach for  
U>sanitizing everything - but the only stainless I use  
U>is a spoon. It does corrode my wort chiller (Cu) and steel

A>I have a copper immersion wort chiller and I don't use any  
A>sanitizer on it -- I wash it with water immediately after use,  
A>store it in a large plastic bag between uses and sanitize it  
A>by dunking it in boiling wort for a few minutes.

U>spoons I use for skimming if I leave them soaking a while.  
U>I don't see why anyone would want to use any chemical  
U>when stainless kegs can be boiled anyway.

A>Yes, but the kegs I have, have rubber tops and bottoms, not to mention  
A>the rubber seals throughout the beer path (8 seals if you include the  
A>large one -- I just reconditioned two kegs... I know) which would  
A>probably  
A>survive several bouts with boiling, but would eventually lose  
A>elasticity  
A>and not seal anymore. Boiling water is a good sanitizer, but is also  
A>more dangerous. Bleach and Iodophor only harm you if you get them in  
A>your eyes or mouth -- boiling water will mess you up anywhere it hits  
A>you!

Al.

P.S. This last statement is probably of some general interest. Do you mind if I post the above email? Or you could just post it, I don't care.

Date: Tue, 8 Jun 1993 13:22:42 -0400 (EDT)  
From: Bryan Kornreich <bkornrei@pennsy.med.jhu.edu>  
Subject: Are stouts really thick?

Hi All,

In response to Paul Labrie's comment that his friends labelled his not-so-thick stout as a thick beverage, I think I may have an idea what's going on with them:

When I first started drinking beer--not too long ago, since I'm only 22-- I also tended to call stouts "thick". And in fact, I still call that

Guinness stuff in the bottle (though not so much the draught) "thick".

I guess I can speak from a tiny bit of medical/physiological authority since I'm a medical student, but I don't know if that's necessary. I think the reason is threefold:

1. It has to do with the strong flavor and bitter aromas of a stout in comparison with a pilsner, or even an ale. The burnt chocolate malt and other strong/bitter flavored ingredients give a greater input into the bitter taste receptors of the tongue but especially to the olfactory receptors in the nose. Don't forget--all this burnt grain stimulus is in addition to the bitterness of the hops. And in an ale, the predominant odor is fragrant hop--in a stout, burnt grain/coffee/chocolate odors predominate--and these are bitter aromas. So even though your stout may not taste as bitter as some ales, the bitterness of the stout is multimodal (taste and smell), so it may seem to be more bitter overall. This bitterness may be manifest as a much more potent and "thicker" input to the brain.

It's not at all unlike strong coffee (especially since stouts often have coffee-type aromas and flavors). A strong batch of coffee or espresso will seem thick, even though the liquid itself isn't syrupy--and indeed they are thick, with flavor.

2. The visual cues of a dark stout, (during the cerebral phase of digestion for those picky readers) prepare the mind and the gut for receiving a thick liquid. In nature, dark liquids (eg: mud, honey...) are often thick, so the brain associates dark liquids with thick/viscous liquids, and clear/light colored liquids (eg: water, salt water) with thin liquids.

3. Stouts typically have a thick creamy head, which will make one subconsciously think that the beverage beneath is itself thick and creamy--like a milkshake.

Of course, as experienced beer drinkers, we all know that dark colored beers are not all thick, though some may be thick tasting. Just look at Michelob dark--Michelob with brown food coloring--or here in Baltimore, we have National Bohemian Dark, which is an even poorer imitation of Michelob Dark.

I hope I haven't bored you to death,  
Cheers,  
Bryan

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: "fermented" beans/american beer/headaches

Thanks to Jeff Frane for the info re: "fermented" (not) "black" (not) beans.  
Seems like I'll either have to go to the Asian market in Des Moines or find someone who knows how to make the suckers.

The postings in the latest HBD from George Fix and "thutt" re: American mega-brews reminded me of an interesting experience I had this weekend. A friend of mine (who appreciates my homebrew very much) offered me a Coors Extra Gold to try. So, I said, what the hell. I was actually pleasantly surprised - the stuff actually tasted like it had something to do with malt! So, I had another.

Now, at this point I actually hadn't had a budmilloors in months. So I am wondering if other HBD reader concur with me that this is a slight cut above?  
I suppose I could be enterprising and give myself a blind tasting of megabrews to see if I could pick out the Extra Gold from among them, but hey, let's get real - when there's homebrew around, why should I torture myself?

The other reason I don't want to do this - and the reason I stopped after two Extra Golds - was that I got something I don't remember getting in a long time: a headache! Now, I normally just have one homebrew a night. Helps me sleep well, and makes me get up on time when I have to go to the bathroom. On occasion I have indulged in two or more homebrews at a time, and I have gotten warm fuzzies, or even been a little drunk - but no headaches. (I don't think I can compare my experiences with really "good" commercial beer, because it tends to be so expensive I consider it a waste to overindulge in it - I hardly ever have more than one at a time).

Does anyone else have experience comparable to this? Anyone get headaches from homebrew? Is my non-headachy homebrew due to my use of the blow-off method (that ought to be good for some lively dialogue!) or is it common for homebrew not to cause headaches anyway? Could I be allergic to the preservatives in commercial beer? At any rate, now I remember why back in my youth (creak) I had such a hard time getting drunk on beer. Two or three bumilloorses and that was about all I could stand. Of course, maybe even back then my palate was crying out, "no, not that swill, please -- get me some real beer you dolt!!"

I had exactly the same thing happen with a steam beer. The only common element seems to be the high temp ferment. I never racked off, and after a couple of days I began to dump ice on the carboy because it was getting up to 90 in my apt. Within a few days of starting with the ice two distinct layers developed just as you described. I don't know what caused it, I eventually stirred up the whole mess and bottled it. A month later I flushed 50 bottles of beer down the toilet, which should speak for itself :-). I think you've had better luck.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Dry Hopping 100 IBUs?

Peter Maxwell writes:

>Summary:

Hop pellet residue that got into my bottles seems to be making the beer progressively more bitter and undrinkable.

>My first try at dry hopping resulted in some suspended pellet material getting into the bottles. At first the beer was delicious, with a lovely fresh hop aroma but 6 weeks later the beer is becoming undrinkable. Is this likely to be due to continued extraction of bitterness? I am under the impression that hops must be boiled to extract bitterness. Is an infection likely? There's no unpleasant taste, just this very bitter characteristic.

I suspect what has happened is this: A significant amount of beta acids got into your beer either from the dry hopping or the boil. In the bottling, racking or some other process, you also introduced a lot of oxygen which has caused the beta acids to oxidize. Normally, the beta acids are not bitter, but when oxidized they become bitter.

I would doubt that you have an infection. I would also doubt that the suspended hop particles are the actual culprit, unless we're talking about \*lots\* of them. If there are really a lot, you might now be extracting tannins, which you might be interpreting as bitterness. But this is highly unlikely. Usually you get this effect \*first\* and then it mellows into a nice hoppy aroma.

Next time you should use a hop bag to get rid of the pellet particles and see what you can do about reducing O2 introduction.

> On page 6 of BREWING TECHNIQUES, there is an ad for a 5 liter Mini Keg  
> System.  
> I am not interested in 5 gallon Cornelius keg systems at this time,  
> but there  
> are

I currently "keg" in the 5 litre minikegs. Absolutely unbeatable for ease of use. Simply rinse them, pop them in the oven at about 250 for half an hour, rinse the outside to cool, fill and plug. I have two kinds of tap, a pump, and a CO2 cartridge type. The CO2 tap has a valve to shut off gas flow, and I have found that I can store the tap for two months without losing pressure, simply by turning off the valve. Each cartridge will dispense 1.5 5l cans. I use the hand pump when reasonably sure that the beer will get consumed rapidly. If you are ordering from the place in Pa, they have converted to the smaller US CO2 chargers. I don't know how long they will last.

As I understand it, the outfit in Pa. has a limited supply, as they purchased the leftover stock of a defunct brewery. I am considering going into business selling cans and taps. My cost is about \$5.50 a can, and \$15-\$20 for the tap depending on type. These prices would go down if I was able to order more from the importer. Supposedly, the original mfg of the cans was in the US, but is now exclusively in Germany. It would be great if we could get them made here again.

From: gummitch@techbook.com (Jeff Frane)  
Subject: More on Black Beans (still no beer)

I checked on those fermented black beans last night. As I remembered, they're actually soybeans, and they are first inoculated with a special fungus, then dried, and occasionally salted. These are apparently the oldest form of what we now know as soy sauce (brown bean sauce is the intermediary step in soy sauce evolution). But, anyway, fermented they're not, at least in the sense that we use the term as brewers.

Date: Tue, 8 Jun 1993 20:03:32 -0500 (CDT)  
From: Hi-keeba! <BIRMINGH@FNALV.FNAL.GOV>  
Subject: Miller reserve

Prof. Fix says:

>One final point. It is my belief that Miller Reserve is made exclusively  
>from malted barley, and in particular no raw barley is used. I would be  
>willing to bet that the phrase "100% Barley" was chosen by their  
marketing  
>people and not by their brewers.

I may be able to shed a little light on that subject, actually.  
About two years ago, I took part in a marketing taste test, the  
product  
being Miller Reserve Amber Ale (let's just say that I couldn't avoid  
the guy with the clipboard in the mall, and when he offered me beer,  
I  
didn't want to.)

Anyway, I was given several little cards with the names of beers  
on them, and told to rank them (I could stack cards to indicate that  
I  
thought certain beers were more or less interchangeable.) I forget  
the  
names of all the beers; Samuel Adams was one, the rest were  
undistinguished beers. I don't remember if there were any imports in  
the list, and I wouldn't have recognized most microbrewery products  
then.

After I ranked the beers, I was given a sample of the ale, then  
told to insert it into my ranking. I put it between the 'premium'  
megas  
and Sammy's.

The surveyor then asked several questions, and had me fill out a  
questionnaire. The word "barley" came up several times, but since I  
was  
not yet a homebrewer, the word "malt" did not. I knew about the  
Reinheitsgebot, however, and thought I should stress "barley good,  
corn  
and rice bad."

I'm not saying that I skewed their statistics or anything, but  
considering that I liked the beer and therefore am one of the people  
they want to reach, my words might have been more heavily weighted.  
Also, it's conceivable that there were lots of other people who knew  
that  
barley malt makes good beer, but didn't know how important the  
difference between raw and malted barley can be.

So, anyway, this is possibly part of the reason that the Miller  
marketing types use the phrase "Barley" and not "Barley Malt."

Last week I was in the beer section of the n. Austin Whole Foods Market picking up some supplies for my next batch of homebrew. I came across a package of "victory malt" from St. Patricks. Can anyone tell me what this is, and what style of beer it would be used for?

Just curious -

Wayne

From: Kieran O'Connor <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>  
Subject: William's

I have two of the William's controllers for fridges. I am completely happy with them. Im not sure how the innards work--as requested in yesterday's HBD--but it does an excellent job of keeping the temperature near to what you set.

Actually--it cools the fridge to below the temp you set--4 degrees--then allows it to warm up to the set temp--then cools again.

I've used an indoor outdoor thermometer (the kind with a probe) to check whether the Controller is accurate and it seems to be so.

I tihnk the thing also has a 1 yr guarantee--although I think it might (hope) be lifetime! Anyway--it does have a broader range than the Hunter--the Controller goes from 20-80 degrees F--the hunter low end range is 40.

If any brewers have further questions on this--feel free to e-mail me.

Subject: RE: headaches

Hi All,

In HBD#1159 Jonathan G Knight writes:

>The other reason I don't want to do this - and the reason I stopped  
after two  
>Extra Golds - was that I got something I don't remember getting in a  
long  
>time: a headache!

Yep, same here, one or two Budmillors was always sufficient to give me  
a pounding headache the next morning.

>On occasion I have indulged in two or more homebrews at a time, and I  
have  
>gotten warm fuzzies, or even been a little drunk - but no headaches.  
>Does anyone else have experience comparable to this?

Ditto again, my consumption will vary from just one to several at a  
time, but regardless of consumption levels, I've never gotten a hangover  
from drinking homebrew.

>Is my non-headachy homebrew due to my use of the blow-off  
>method (that ought to be good for some lively dialogue!) or is it common  
for  
>homebrew not to cause headaches anyway?

At the risk of re-starting the blowoff vs. no blowoff thread, I don't  
think  
use of a blowoff system has anything to do with this, as I use 6.5 gallon  
carboys as primary fermenters, no blowoff. IMHO, the reason the mass  
produced commercial swill always gave me such awful headaches was due to  
their use of artificial preservatives/flavorings. There just isn't  
enough alcohol in 12 ounces of ~4.5% beer to account for getting me that  
sick.

On the other hand, homebrew has plenty of nice, healthy yeast in it.  
One  
of the reasons people get hangovers is the depletion of vitamin B that  
occurs as the body processes alcohol. Yeast is a great source of vitamin  
B,  
and I think that's one reason I don't get hangovers from drinking  
homebrew.

Comments? Anybody else noticed a homebrew/no hangover connection?

Cheers,  
Jim

James writes:

"Eric Warner recommends a staggered protein rest in his Classic Style series book, that is, brief rests at 117F, 122F, and 126F. At each of those temperatures, a different class of peptidase (protein reducing enzyme) is activated."

I could use a little more information here. Where does Warner say these digestion enzymes come from, ie, from malted wheat itself, or from any accompanying lager malt (I presume not from either ale malt or unmalted wheat)?  
Secondly, does the mashing schedule differ according to whether one is using malted or unmalted wheat (I presume the latter requires more digestion)?

From: "John DeCarlo" <jad@pegasus.mitre.org>  
Subject: Hops/Hot Break and Strawberries

To add hops before or after the hot break. Good question.

I can't say much about the utilization factor, but I *have* found, on advice from this forum, that if you skim off the hot break you don't have to worry about boilovers. I now do this regularly with great success.

Of course, this means that you add the hops *after* skimming off the hot break (unless you can mechanically figure out a way to leave in the hops floating amongst all this stuff).

++++++

Strawberries:

The flavor of strawberries isn't very intense, IMHO. I have tried using them in beer without any success and suspect you will need on the order of 20 lbs per 5 gallons to get any strawberry flavor. Once the sugar ferments out, the remaining flavors are very subtle.

From: Nick Zentena <zen%hophead@canrem.com>  
Subject: Duties on importing Belgian malts into Can

Hi,

I checked the following out for both myself and because of somebody else question. So I thought I'd pass the info on.

I called customs and got the following info.

chapter 11.07.10.10.00 covers unroasted whole malt [I hope this means pale etc]

chapter 11.07.20.10.00 covers roasted whole malt[RB,black etc I guess]

Duty on belgian malt is \$0.0073[.73cents]per kg. for whole malt. Thats \$0.37 per 50kg bag. If they actually charge you the duty the custom service charges would likely higher.

Crushed malt is 1.1cents per kilogram.

The duties are on belgian malts I didn't ask about US malts they maybe [and likely are] different. Also any local taxes aren't included but at least here in Ontario the items are classed foodstuff and not subject to tax.[cross your fingers and pray on that one]

Nick

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Hop Utilization and temp controllers

Mark posted his "better estimates" of hop utilization. Thanks for a "seat of the pants/back of the envelope" estimate. I don't think yeast flocculation has anything to do with hop utilization. I DO know what your saying and DO understand the resultant effect of yeast flocculation, however lets keep the two seperate. I sure hope Glenn is doing that. I would rather do two separate calculations.

On a different subject... Those that are looking for a temp. controller, I use Honeywell temp controllers (yes they have the little tube connected to them, ie. none electronic). The one I use has a single pole double throw switch in it. This allows me to control either a cooling source or a heating source by flipping another switch mounted in the bottom of the unit. This way I can control warmer temps in the winter for making ales. I use a glow coil screwed into a light socket for the heat source. Works great! The temp controller was about \$22 from Johnstone's (a local parts supplier).

What's the count from all the regional first rounds?

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Clarifying Fruit Beers

After reading the recent thread on fruit beer I decided to give one a try. The batch history (from memory):

For 5 1/2 gal  
5 lbs Briess 60%wheat/40%barley malt extract  
1 lb Briess amber barley malt extract  
7 HBU Goldings (I think it was Goldings)  
OG 1.038  
Chimay Yeast repitched from a recent batch

One week primary fermentation  
Secondary fermentation 4 days  
All fermentation at ~70 F

5 lbs fresh blackberries macerated w/2 crushed campden tablets.  
Allowed to sit in bucket for 36 hours.

Fruit put in 7 gal carboy and beer racked on top. Fermentation restarted in 36 to 48 hours. Slow but steady fermentation for about a week. By then most of the fruit pulp had floated to the top of the beer and had lost most of its color, sort of looked bleached out. I then racked under the floating fruit and over the sediment back into a 5 gal carboy where it has been for an additional week.

The 5 gal carboy is full up to the neck and I can still see little CO2 bubbles forming in the neck. A last check I was getting about 4 bubbles/hour out the lock. SG at final racking was 1.010. There's a yeast sediment at the bottom of the carboy. The beer's a \*beautiful\* pinkish red color. But, its not clarifying. Not a sign of clarification even near the top. It looks like a huge bottle of chilled Celis White (except for the color).

I would like:

- 1) General comments. (Does this read like the way your fruit beers behaved?)
- 2) Specific comments about clarity. Will it clarify eventually? How long should I wait?
- 3) If it isn't going to clarify, how can I tell when to bottle?

Date: Wed, 9 Jun 93 08:34:01 MDT  
From: pyle@intellistor.com (Norm Pyle)  
Subject: IBU, etc. calculations

The last several batches I've brewed were hopped according to a program I received from a fellow hb'er. It calculates the IBU's for a "balanced" beer, based on OG, volume, etc. It also calculates the IBU's that I would achieve with certain hop additions (AA%) at a given boil time, etc. It is very handy, and I've had no problems hitting my hopping rates right on with this program. I typically adjust my IBU's on the hoppy side of "balanced", maybe 10-20% high, and I've been quite happy (hoppy).

The problem is this: it runs on a PC and I only have PC's available to me at work, not at home. Lets just say I get enough of computers during the day. I'd like a list of these formulae on paper so I can run the numbers the old-fashioned way at home, during the brew process. He said he took them out of an old issue of Zymurgy, presumably the hops special issue. Does anyone have this handy and could post a concise list? I could probably go out and find the issue, but I'd sort of like to have it this week. Thanks.

I may just try a type of easysparger in my cooler mash/lauter tun next time (who sez it has to be done in a pot on the stove?). Of course, if my extract efficiency goes way up, my hopping rates will have to be recalculated!

Cheers,  
Norm

>buried a Rhizome an inch deep 2 weeks ago and nothing has peeped up yet.  
>Comments? Is it dead or did I dod something wrong (I planted it  
>horizontally).

Last year I planted a rather sickly looking Cascade rhizome. After several weeks a couple of weak shoots appeared (while the Mt. Hood hops, planted at the same time, were growing vigorously) and grew to a whopping two feet tall. This year, my Cascade hops are still weak looking, but have grown to 5 feet tall.

The rhizome should be planted vertically. The shoots should bud out from the rhizome like branches on a tree. They may travel horizontally and eventually turn upwards.

From: gummitch@techbook.com (Jeff Frane)

**Subject: Those Lite/Light/Lyte Beers**

Some very interesting information about Light beers from Dr. Fix. I'd be interested in tasting a lager like that -- it sounds like it would go a long way toward explaining the popularity of American beers before Prohibition. When I started doing all-grain ales, I used a small portion of flaked maize and the results were as George described. Hmm, maybe we should try that again...

At any rate, when the Blitz-Weinhard brewery developed their light beer, they apparently achieved the lower gravity by Reducing the Amount of Corn Grits! What a concept! And the amazing thing is, the beer is really very good -- at least if you drink it from the taps at the brewery. The flavor profile is definitely improved by cutting down on the breakfast cereal additions.

Now if B-W would only try brewing an all-malt lager of their own...

From: "Bill (W.R.) Crick" <heybc@bnr.ca>  
Subject: re:mircowave mashing

I had a few requests of details on my microwave mashing methods, so I thought I'd post it.

What I do is something like this, but I'm still developing the method.

To mash two pounds of grain in a large plastic bowl.  
Add about 1.5litres of water at 130F to grain to get protein rest of around 122-125F.

Put in microwave with temp probe in middle of mash, supported by chopsticks across the bowl.

Program following on microwave: (Mine is a Panasonic "Quasar")

- o low power 130F  
This will slowly warm it up for a protien rest.  
after about 30 minutes clear program and program following:
- o medlow 160F
- o hold temp 160F 30minutes
- o medlow 170F

Wait for the beep, and then sparge in a sieve, or colander with a litre or two of 170F water, into boiling pot.  
Add extract and boil, Add hops .....

NOTES:If you use too high a power level, the outside heats faster than the inside, and you get uneven heating. Too low a power, and the temperature ramp is too slow.

My microwave cycles temperature in the hold temp program from about 5F below setting to actual setting. IE:for 160F it will go down to 155F , add heat to 160F, cool to 155F ....

This is a good range if you are trying to use a partial mash to add maltiness, and body to an extract beer.  
To change the alcohol, body balance , you could do a 150F step, or use a lower power toramp the temperature more slowly. I usually am going for body, so I sometimes use a 170F water infusion after the protein rest to get to the mash temperature faster, and then only used the microwave to hold the temp, and do the mash out. I forget the amount, but I think it is .75litre of 170F water per pound of grain, assuming there is already .75litres per pound of water for the protien rest.

Bill -nuke it on high for 15 minutes, and then bottle it- Crick

>refridgerator 'clearing'. I have become curious about the absence of  
>strawberrys in the previous HBD discussion, or any brewing literature  
for  
>that matter. Strawberries are more pulpy than raspberries, but I really  
>never expected the cloudy final product. If anyone else tried this,  
>another data point would be nice.

I have brewed a combination of the "Strawberry Beer" From CATS MEOW - II  
and Papazian's "Rocky Racoon Honey Lager". What I did was make a batch  
of  
Rocky Racoon, but used ALE yeast (I'm still limited to brewing Lagers in  
the  
Winter). To the recipe I added 1 lb of Crystal Malt, and then steeped 8  
pints of pureed fresh Strawberries in the Wort after boil.

As the Cats Meow recipe suggested I added a few tablespoons of Pectic  
Enzyme  
to the primary fermenter to aid clearing. I also used Gelatin Finings  
(for the first time) on this batch since it still a little cloudy after ~  
2  
weeks in secondary. It appears to be clearing well in the bottles,  
but has a lot of sediment on the bottom.

The beer did turn out very well, a very pronounced Strawberry smell, and  
a  
pleasant Strawberry flavor. The only problem was the the primary  
fermentation looked really bad with all the chopped up strawberries and  
sludge floating around in it.  
(I received more than a few comments about what it looked like ;^>).

Here's a data point, for what it's worth...

During the 1991-92 Sharks season, the best beer they served at the Cow Palace was Meister Brau. (Insert trendy umlauts as needed.) While it's certainly not the best beer in America (oops, apologies to Mr.Koch and his lawyers) I generally put away four or five or six large cups (at \$4.50 a throw) during a game.

During the 92-93 season, they replaced Meister Brau with Miller Genuine Draft, got rid of the large cups, and sold the small ones for the large price. Half a cup of this stuff gave me a ripping headache, so I drank 7-Up at the games last year.

Next season in the new "Your Company's Name Here Arena at San Jose", we'll be drinking Gordon Biersch beers, which I'll guarantee are headache-free.

Subject: Re: Malt and Hops/Dispensing Pressure/Beers and Headaches \*  
THEORY\*

Chuck writes:

> 1. What is the difference between caramel and crystal malt. When  
> would I use/not use them.

They are the two names for the same type of malt, one that, while still wet from germination, has been warmed into the saccharification temperatures and effectively "mashed in the husk." Crystal (or caramel) malts add some residual sweetness (via the added unfermentable sugars that they provide)

, some caramel-like flavor, some color (depending on the darkness of the malt) add a bit of body and increase your head retention a bit. There are certain styles for which a lot of crystal malt is not appropriate (like IPA) and some that require it (like Bitter). In general, consider the style you are trying to target with a batch and think about whether it has some caramel-like sweetness. If it does, add 1/2 to 2 lbs of crystal malt. Crystal malts come in various darknesses, the lighter ones, of course add less color and caramel flavor, the darker ones more.

> 2. The lower leaves of my Centennial (and Mt. Hood to an extent)  
> hop vines are turning a yellowish color. Can anyone help out  
> here as to what is happening, is it bad, and how do I stop it.  
> I live in the Boston area.

Check a general gardening book (I don't have mine here and I don't recall what yellowing leaves indicates). However, hops are one of the few plants that require Magnesium, a shortage of which will cause the hop leaves to turn lighter green between the veins, then yellow, then eventually brown. I've been using MgSO4 (Epsom Salts) for adding Mg, but I don't know if this is the best thing to use. I've been adding about 1/2 tablespoon to each hill every two weeks.

First of all, I'd like to say, that was great post. Secondly, I'd like to mention that I've had no problems with keeping my CO2 tank in the cooler. Sure, the high-pressure side is considerably lower than if I leave the tank out at room temperature, but who cares if the high-pressure side of the regulator is getting 200psi or 400psi?

As long as the the low-pressure side is at 13.5 or whatever, we're happy.

>  
>Does anyone else have experience comparable to this? Anyone get headaches  
>from homebrew? Is my non-headachy homebrew due to my use of the blow-off

I have a theory on this. Just for the record, the first (and last) time I had Coors Extra Gold, I got a splitting headache. I've never gotten one from my own homebrew. I had thought that certain beers gave me headaches and certain ones didn't. Then, after a long break from a particular Belgian beer that I had often enjoyed without a headache, I had one, just one and I got a headache from it. Beers that have given me headaches include Bud, Lowenbrau (US), Leinenkugel and Samuel(tm) Adams(tm) Boston(tm) Lager (tm).

Here's my theory: Each brand of beer has a considerable amount of ethanol and smaller amounts of higher alcohols, in different proportions. I theorize, that if the human body has not dealt with a particular higher alcohol for a while, it has trouble with it and you get a headache. Once you get used to it, it doesn't bother you, unless you don't have any for a while.

Subject: Headaches from Industrial Brew

In HBD # 1159, Jonathan G Knight <KNIGHTJ@GRIN.EDU> writes about getting headaches from industrial beer of the Bud/Miller (or in Canada, Molson/Labatt's) variety. I can only say yes, yes, yes, I concur exactly.

It's one of the best reasons to go for natural brews, either homebrewed or commercial. Another thing that I find happens with industrial beer is that

I always get stuffed up after a few bottles. Anybody else find that? And of course, there's no comparison in the hangover department: industrial brew is a virtual death-sentence for the morning after a bout of extreme indulgence. I truly do not think these are placebo effects, but I would be

perfectly willing to participate in a properly conducted double-blind experiment if someone is willing to buy the beer!

From: John Cotterill <johnc@hprpcd.rose.hp.com>  
Subject: How Long do Hops Float?

I currently dry hop during secondary fermentation in a soda keg. My hops are placed into a hop bag that is dropped into the keg. I want to get away from using the bag. However, since I do not have a filter in the bottom of the keg, and don't want to add one, I am concerned that the hops will clog the dip tube in the keg. This assumes, however, that they sink to the bottom of the keg during the 7-10 days they spend in the secondary. So how long will they float?

Thanks,  
JC

Subject: Source of Hop Util. Numbers

If I remember correctly, the data given by Rager in Zymurgy (Special Hop Issue) as base hop utilization was actually derived from Eckhart's Essentials of beer Style. Rager merely sketched a line through the three broad ranges of time and temperature given by Eckhart, and said as much in his article. So, really, most of the blame for the current numbers should go to Eckhart. In any event, we still need to have some one get some real utilization data from actual small scale runs.

I don't think the source of the gravity adjustment equation in Rager's article was given, though. Glenn Tinseth's catalog (Thanks, Glenn, nice job!) gives a different equation. The reference gravity is 1.040 vs 1.050, and the adjustment is not a function of the base utilization (boil time) as is Rager's. Maybe Glenn (and/or Mark Garetz) could shed some light on the sources and differences between these adjustment factors.

Also on this subject, I would like to coin a new unit, the EIBU, for Estimated IBU. Since IBU's, strictly speaking, must be measured in the finished product, what we are doing with calculations like the above is estimating what (we hope) the IBU's will be. Presently, recipes which give bitterness in IBU's are stretching the truth a little.

From: jpgareri@acs.bu.edu (Joseph Gareri)  
Subject: Wheat Berry Review

Monday night, I bottled Tom Childers' Wheat Berry that appeared in HBD 1144.

This is one of the nicest tasting beers I've ever had. It has a nice assertive berry taste to it and a good balance with the hop bitterness. The wheat is evident, but is definitely taking a back seat to the berries.

I had to modify the recipe a little because I was unable to get light wheat

DME. For those who missed it, here is the recipe again.

for 5 gallons:

5.5 lb light dried wheat malt extract \*  
1.5 oz Hallertauer or Northern Brewer (boiling), 7 HBU  
.5 oz Halleertauer Hersbrucker (finishing), 2-3 HBU  
24-36 oz frozen raspberries  
16 oz frozen blackberries \*\*  
1 tsp vanilla extract  
Belgian ale yeast (Wyeast 1214)  
\* I used 7lb Briess Weizen extract (65% wheat/35% barley)  
\*\* I used 1 pint fresh blackberries

Thanks Tom again for a great recipe.

Does anyone have any other recipes using fruit? Last summer, Boston (no TM)

Beer Works had a great watermelon ale that I was thinking of giving a try.

I'm considering doing a peach something later in the summer when the peaches are ready. Any recipes would be greatly appreciated.

Joe

Subject: Technical Brewer magazine

Greetings:

Does anyone have an address for Technical Brewer magazine, so that I can get a sample copy? Are there any other magazines out there that people feel are useful or interesting, or possibly both?

Spencer Thomas asked how he could collect yeast from his primary fermenter and keep it sterile or as uncontaminated as possible. I would suggest that he keep his yeast in a plastic container that can be sterilized with chlorine or something. Before he uses it, it can be acid-washed with food grade phosphoric acid. You take the ph down to 2-2.3 by adding acid to the yeast slurry. If you go too low, you can add water to buffer the ph back up again. Leave the yeast like this for two hours and then pitch it. Acid washing seems to be either liked or disliked by people, and can be controversial to some.

Hope that this helps.

>some real beer you dolt!!"

I have very recent experience with this subject. Saturday night I was at  
a  
wedding in Bloomington, Illinois. Nothing but Bud and Miller Lite.  
Believe  
it or not, attendees at the wedding actually had preferences! I had way  
more  
than I usually do (about 7). The next morning when my one year old woke  
up at the usual 4:45 am my head was pounding like a pile driver. Two  
Tylenols  
helped but commercial jiz is what kept me from drinking a lot when I did  
not know any better. I do not always use a blowoff for my homebrew and  
still  
do not get as severe headaches. But I also do not drink 7 usually. Maybe  
the headaches were from the Pirodi cigars we were smoking. Who knows?

The palate pays dearly in this country of ours.

I love homebrew.

From: nexgen!bart@daver (Bart Thielges)  
Subject: Questions for the Oracle

I'm new to this forum, so please accept my apologies if my questions seem ignorant or redundant.

1) Is there an inexpensive source of malt extract in the USA ? Part of what

piqued my interest in homebrewing was the low price of canned malt extract in England (~\$5-7 USD). Prices are about double here. I'd be willing to purchase large (50 lbs. or so) bulk quantities. I realize that mashing from grain is the cheapest, but I'm not ready for that yet.

2) Is there a market for used small scale brewing and kegging equipment ?

I've checked our local newspaper want ads, the local home and microbrew newsletter ("The Celebrator"), and stores which sell used restaurant equipment with no luck. In particular, I'm looking for a used CO2 bottle, regulator, and hoses. Ultimately, SOMEONE must want to get rid of their old equipment.

3) I'd like to experiment with adding different sugars to my wort,

particularly brown sugar or molasses. Has anyone tried these ? Any recommendations on quantities to try ? How about other sugars and their effects ? Anyone tried dissolving a pack after dinner mints into their wort ? Just kidding about the last one !! You can stop grimacing now.

4) I realize that sterility is very important. All of the procedures

that I've read mention that during racking, a siphon should be used to transfer the fermented wort. However, I have yet to figure out how to start a siphon without getting my mouth on the end of the hose. One procedure even specified "suck on the open end of the hose until you get a mouthfull of beer." Even though I brush twice a day, I still worry that I might contaminate through this contact. Is there any way to start a siphon without risking the contamination ? Or am I just being too paranoid ? Will my batch be ruined ? And how do you know that the light in the fridge goes out when you close the door ?

OK, so now it must be obvious that I'm a neurotic miserly penny pinching flake. What variety of beer would best fit my personality ?

My Cascades have reached about 8 feet now, but the Chinook cuttings never appeared. I dug them up recently to find them rotted and full of little white worm-looking things. They were planted in the same soil and received the same attention, so I guess they are either more temperamental or just defective. So when do the hop cones appear?

From: donald oconnor <oconnor@ccwf.cc.utexas.edu>  
Subject: sanitizers part 2

### 3. Ease of use

Both are easy to use but iodophor has two advantages.

Iodophor is colored due to the iodine. Iodine reacts (2 electron reduction) to form iodide ion which is colorless. Therefore its possible to know by the color of the solution when the stuff is spent. However, when used properly, its very difficult because the color is very faint due to dilution.

Bleach has the disadvantage of being unstable. Liquid bleach loses it's oxidizing strength with time after opening.

### 4. Flavor and odor and residue

So why are iodine sanitizers so much more popular than chlorine sanitizers in the food and beverage industry? It's all over the ads and bottles of iodophor.

"TASTELESS" "ODORLESS"

Chlorine can be detected at very small levels. Iodine thresholds are much higher. All of the other differences between the two are miniscule by comparison.

Bleach should be rinsed out to insure removal of the residual flavor.

It is not essential to rinse iodophor, but some do. There was an article in the New Brewer a couple of issues back in which a brewpub detailed their sanitation procedure. They rinse out the residual iodophor.

The two brands of iodophor I use do not contain detergent as was suggested a few days ago. Both are designed explicitly for the beer and beverage industry. Neither leaves a residue which will impair head retention etc.

### 5. Cost and availability

Household bleach costs about \$1/gallon. Iodophor is typically about \$10 per liter. Bleach has 5 times as much sanitizing strength ounce for ounce.

Therefore, bleach is about 200 times cheaper than iodophor.

Bleach is everywhere. Iodophor has much more limited availability.

### 6. Personal safety

Both oxidizers will kill cells including yours and mine. Both should be handled carefully. But bleach is a stronger oxidant so a little more dangerous on this point. More importantly though is the caustic nature of full strength bleach. This poses a more serious risk, particularly to eyes.

Iodophor is a safer product than household bleach.

So pick your poison :-) Both dilute iodophor and dilute bleach can and have been used as effective sanitizers. Bleach is cheaper. Iodophor is

safer to use, more stable, and is tasteless and odorless. Neither poses  
a  
threat to 304 stainless equipment.

And remember, you need less than 1 teaspoon of bleach in the  
entire 5 gallon keg to get the same level of sanitation that iodophor  
provides at its recommended dose.

Hope this clears up some of the confusion.

Best regards,  
Don

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Evaporative Cooling

Here's an inexpensive alternative to those who want to do summertime brewing in hot climates but haven't got the \$ and/or space for an extra freezer w/Hunter Airstat etc.

Since my last post on this subject (See HBD#1147), I've done some more experimenting. This time I used a fan to blow air by my glass carboy wrapped in a wet towel. This allowed me to achieve the full wet-bulb depression in the fermenter.

    Lastest example:

        Dry-bulb temp, 78F

        Wet-bulb temp, 68F

        Beer in carboy, 68F

I use a lot more water than when using the fan. Before, when I used passive evaporation, I would have to add water to the pan every other day or so. Using the fan I have to add about a gallon of water \*every\* day.

As noted in my earlier post, I brew in a house with central airconditioning. The dry-bulb temp inside is generally 76-82F and the relative humidity is about 55-70%. In Austin the peak outside temps now are now 85-95F with relative humidity 75-90%.

Some of you have suggested I simply place the fermenter in front of an air duct and forget the evaporative cooling. I don't do this for two reasons:

- 1) My air ducts are in the cieling, making it difficult to place a 7 gal carboy 'in front' of one.
- 2) During the day my AC runs < 50% of the time and less than than at night. Without some insulating system this would lead to fairly large fluctuations in fermenter temp. Recall the ambient room temp is up to 80F.

In summary: Using inexpensive evaporative cooling to \*supplement\* the normal refridgerated cooling. I'm able to take my 76-82F, 55-70% RH house temps down to 68-72F in the fermenter. High but acceptable temps for ales. Those of you with basements in the low to mid 70s should be able to get fermenter temps down to 60-65F. To those of you with the \$ and space for a chest freezer, I'm jealous.

Subject: Re: Molasses in Beer

> 3) I'd like to experiment with adding different sugars to my wort,  
> particularly brown sugar or molasses. Has anyone tried these ?

I have brewed with a combination of malt extract and Carob Molasses, which you can find in most Middle Eastern groceries. I have used, in 5 gal batches, a 16oz jar of the stuff. Its very dark, and sweet, and ferments out quite well. The carob, which (I think) is a fruit borne by trees does have a distinctive taste in the beer.

I have also used Mate instead of hops. Mate is an Argentinian tea (pronounced Ma tay) and can be bought in Latin groceries. It too has a distinctive and pleasant flavor.

> 4) I realize that sterility is very important. All of the procedures  
> that I've read mention that during racking, a siphon should  
> be used to transfer the fermented wort. However, I have  
> yet to figure out how to start a siphon without getting my  
> mouth on the end of the hose.

I grab a glass from the kitchen cupboard. I stick my siphon hose under the faucet, fill it with water, stick one finger on one end to stop water from running out, stick the other (open) end in my carboy, then drain the water which is in the hose into the sink. As the water drains out, I can see the beer replacing it in the hose. I then take my glass and fill it with a beer, then stick the hose in my secondary or my keg, or the bootles I am filling. No problem! no mess! no contamination!

With my glass-ful of beer, I check the specific gravity, and then relax and drink it all up.

From: gjfix@utammat.uta.edu (George J Fix)  
Subject: Garrett Hildebrand

Please forgive the brief use of bandwidth, but my e-mail to Garrett has been bouncing.

Garrett:

Diversity Chemical usually has a local office in all major cities. Look the one near you up in the yellow pages. It is best to buy iodophor in a gallon jug. Don't let them talk you into anything larger. Accord II was designed for breweries. The version in most homebrew shops (the one containing the detergent instead of phosphoric acid) was designed for dairies. If stored in a cool, dry location it will have a good shelf life. Use 1 oz. per 10 gallons (1 tbsp. per 5 gals.) Diversity claims 2 min. contact time is sufficient. I use 5-10 mins. The diluted solution should display a well defined red/yellow color. If it is white, then dump the solution and start over. This sometimes happens when attempting to sanitize equipment that has been cleaned with an alkaline based agent and not properly rinsed. I would not use iodophor on plastic tubing. Al Korzonas' recommendation to use bleach followed by a water rinse is a good one.

Take care.

George Fix

From: Mark Garetz <mgaretz@hopstech.com>  
Subject: Hop Utilization, Hop Bags

Bob Jones writes that he doesn't believe that yeast affects hop utilization, and would rather see the calculation split into two:

Well, if Bob is strictly referring to the extraction of alpha acids during the boil, then he's part right. I say "part right" because at what point would we measure the utilization? Right after you shut off the heat or after the wort has cooled? The amount of alpha acids in the beer will be drastically different at these two points, since the solubility varies widely with temperature.

But the issue of when we measure is the whole point. IBUs are measured in finished beer, not wort. Utilization is meaningless unless we relate it to the finished product. The point of the whole calculation is to predict what we will end up with in the final beer. So to my mind, it makes no difference whether we combine or separate the calculations for the effect of yeast on the beer. You're going to have to do both sets of calculations before you add the hops. If you really want to separate the two, use the "average" column from the table and then adjust your number up or down depending on your yeast's characteristics. I used a 20% adjustment factor, up or down from average, in the table.

John Cotterill writes that he wants to get rid of the bag he uses for dry hopping and wants to know how long the hops will float:

Firstly, I have never seen the hops sink if added loose, but some brewers have told me they will. I think that CO2 bubbles form on the petals and hoist them to the surface. Clogging of the lines may or may not be a problem, but better to assume that clogging is a potentiality. However, having the hops float on the surface is not the optimal way to get the hop aroma infused into the beer. Commercial brewers use a bag, and that's what we recommend. If you weight the bag so it sinks, that's a lot better than just tossing it in. I have also tied the bag to the dip tube, but this is difficult. We sell a hop bag/hop weight "system" that consists of a drawstring cotton bag and a solid teflon weight. The weight attaches to the free end of the drawstring and that accomplishes two things: 1) The weight doesn't take up any room in the bag, and 2) This allows the bag to float up and be suspended in the middle of the beer to get optimal extraction.

The reason for the teflon weight is it's inert properties, you can safely boil it to sterilize, but most important is that it is gentle on glass carboys and won't scratch them or plastic buckets or stainless tanks. We considered using a stainless weight (would have been much cheaper than teflon) but were concerned that it might break a carboy in the process of putting it in or getting it out. The other nice thing about our design is that to get the hop bag out of the carboy, you invert the carboy to get the weight to drop through the neck, grab the weight and pull the bag through.

One more tip: It helps to wet the bag of hops before putting it in the beer. This displaces a lot of the air and helps make sure the beer gets into/out of the bag quicker. Fritz Maytag also recommends wringing the bag out into the beer when you remove it. (If you remove it, I just leave mine in the serving keg)

Sheesh! This was a long post and I didn't mean it to be. Anyway, John, the bottom line is, IMHO, keep the bag.

Subject: MI brewpubs and headaches.

My reason for making the distinction about brewpubs comes from when I toured Alpine Village Brewery here in Torrance CA. It is built adjacent to the Alpine Village Inn which has a huge bar with windows looking into the brewery. However, there is no door connecting the two. The Village Inn must buy the beer from the brewery and it is brought over by leaving the shipping dock of the brewery and entering the receiving dock of the Village Inn (basically the back door). Because of this however, the manager of the brewery was pretty clear about stating that is why it is not a brewpub. A minor difference I guess but a pretty big one when it comes to the law. It struck me as kind of odd at the time which is probably why I remember it.

WRT headaches and commercial beer. I have read a lot of different things about hangovers and the causes/cures and what seemed to be most common amongst the majority is two things.

1. the headache is usually caused by dehydration. Your brain has dried up and hurts because of it. My guess is that commercial beer tends to dehydrate more. My sinuses give me a lot of trouble and commercial beer will clog up my head in no time. The majority of a hangover headache for me is sinus related so a lot of water and some decongestants are the first thing I go for in the morning. Why homebrew would dehydrate less, I don't know.
2. Drinking alcohol does deplete your body of vitamin B. Homebrew has a lot of vitamin B contained in the yeast. However, I have read that vitamin B is used by your body to process food and/or alcohol and probably has very little to do with your headache. The lack of vitamin B I think has much to do with why after a night of drinking you eat some breakfast (or lunch) and 6 hours later you spew it back up literally unchanged. I find that with homebrew, I never have an upset stomach the next morning. I feel a bit groggy and that is about it.

These are nothing more than two theories that I have come up with after talking to many 'less-than-qualified' people in the medical field and various documents on the subject. Any comments, questions, and/or additions are more than welcome.

Subject: Phil's Mill Report

In HBD #1160, Mike Gildner asks about the Phil's mill. I have seen and used prototypes of Phil's Mill from Listermann Mfg., and submit this post not as an advertisement but as a consumer report.

This is a single roll mill, which has the grain pass between the knurled roll and a plate which curves partially around it. The gap between these two is adjustable by means of a machine screw and locknut.

The early prototype version I used seemed to work well, i.e. gave a good crush, and Dan (Listermann) has tested this observation by sifting the grist through a set of brewery screens, and comparing the (weight) percentages left on each to published data for 6-roll mills. The results showed that the Listermann mill could be adjusted to come close to the desired weight percentages, but this may or may not be the right thing to do, because the mechanics of the one roll mill crush are obviously much different than a 6-roll. Only more experience with the mill and brewing with it will tell. A Corona mill, adjusted to a nominal (compromise) setting gave far more large particles than desired, and a visual inspection of the particles revealed that the corona, to no one's surprise, damaged the husks much more. This could be observed both in the largest remaining husk particles and in the color of the fines at the bottom of the stack. In the case of the Corona, these were darker in color, perhaps indicating that some of the husks were ground into flour.

The early Listermann mill was faulted by those who tried it for being too slow.

The fancy-looking, nickel plated, pre-production prototype that I later saw was enlarged significantly, having a larger diameter and wider roll. I have not tried this version out first hand, but it looks like it will do the trick, with through-put and torque requirements (according to Listermann) similar to a Corona. Shipment of the first production models is imminent.

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
Subject: Siphon starters, headaches

To start a siphon, I have used with success a small clear plastic pump from an aquarium shop. Once the beer starts to flow, you unplug it from the tubing. They sell them for starting the siphon when you're cleaning out your fishtank but you don't want to put your fingers in there with Fang, your pet piranha. They're simple enough that you can sterilize them with your normal bleach solution procedure.

HEADACHES: Many theories have been espoused:

WORSE HEADACHES-----LESS HEADACHES

|                          |                                |
|--------------------------|--------------------------------|
| Heavier, Darker Beers    | Lighter, Clearer Beers         |
| Factory Made Beers       | Naturally Brewed Beers         |
| Adjuncts                 | All-Malt                       |
| Fire Brewed              | Steam-Heated Brew Kettles      |
| Fermentation By-products | Blow-off tube used             |
| Had a headache already   | Didn't have a headache already |

Yeah sure. Some of these may have a secondary effect. However, we are kidding ourselves if we ignore the primary cause of beer headaches:

|                    |                    |
|--------------------|--------------------|
| More total alcohol | Less total alcohol |
| in a session       | in a session       |

Remembering that the amount of alcohol in beer, especially homebrew, can vary widely, moderation will reliably reduce headaches better than any other method. Quit kidding.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: dry hopping/malt extract/siphoning

John Cotterill asked about hops floating during dry hopping. I have dry hopped successfully with pellets, although once I got what looked like a jump-strated fermentation, although I was advised by HBDers that it was really something else, having to do with CO2 bubbling out of solution (Sorry for the inept description - I'm a musician, not a chemist). One post in response to a question I had asked about dry hopping way back claimed that dry hopping with pellets can actually provide a sort of "fining" effect as the hop particles dissolve and sink through the beer. Don't know if that's true, but it's an interesting theory. Another response I got when I asked about dry hopping was to try leaf hops in a bag weighted down with sanitized marbles. I really like this idea but haven't tried it yet. However, it seems to me that one might be likely to get the best hop flavor this way, and zero problems with racking too.

Bart Thielges asks about inexpensive malt extracts. Since there is no homebrew supply shop in my neck o' the woods, I mail order all the time. William's Brewing in California and the Home Brewery (several outlets, I use the one in Missouri) both sell good quality brands of extract in 6 lb. pouches for \$12-14. Beats the hell out of the price we pay for those 3. 3 lb cans!

Also, about Bart's siphoning question: I personally use the turkey baster method. It fits right in the end of standard transfer tubing - I suck a couple of times, and away we go! I use this turkey baster ONLY for beer racking, and I sanitize before & after use. A friend of mine used to use the mouth method - and made kick-ass beer, by the way - and he used to rinse his mouth first with grain alcohol. Sounds like fun, but it's not for me. (The thought has ocured to me, though, that I ought to be quaffing a nice single-malt scotch while brewing, to cut down on the organisms from my mouth that I might be breathing into my beer, nudge, nudge, wink.)

Same here. I read somewhere, I think Charlie P.'s book, that the  
vitamin B in yeast helps replace what is lost during a bout of  
drinking. I'm pretty sure this is a valid statment. As an  
experiment, I took a vitamin B complex before a night of drinking  
megabrews a few times. I did not have a hangover one single time.  
Amazing! So, you might give this a try, if you're feeling  
particularly spunky. Likewise, I never have any hangovers after  
homebrew or craftbrew.

>was suprisingly low. It showed the mill clamped to a table  
>with a 2 liter bottle for a hopper. Has anyone seen or used  
>one of these mills?

Yes, I've seen and used the very first prototype. It seemed simply, but sturdily built and my only concern was with the way it was clamped to the edge of the table. In a recent conversation with Mr. Listerman himself, I've learned that the clamping portion of the mill has since been improved. The throughput is a bit lower than it's formidable competition. It has a single roller which crushes the malt against an adjustable, flat plate. The crush has been tested using standard screens and has been reported to be "textbook quality" and "comparable to commercial 4-roller mills."

The retail price should be between \$75 and \$85.

If you can't find it locally, email me and I think I can help you find a mailorder source ;^).

I meant to comment on this in the original posting. There is no way a refrigerator will keep all the CO2 in a tank liquid. Furthermore, unless you have a siphon type tank or turn it upside down, there is no way you will get liquid out of it. There is always some space above the liquid level and this will always be gas.

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: strawberries

Just for one data point, I recently made a mead with 12 lb strawberries in a 5 gallon batch. The strawberry character is reasonably strong, but could be stronger--if I do it again, I'll use 15 lb (i.e., 3 lb/gallon).

To put this in context, I was aiming to have strawberry be the dominant flavor. On the other hand, the mead was made with a relatively light honey, so there isn't a lot of other flavor fighting with the strawberry. But it does take more strawberries than other berries for comparable amounts of flavor.

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: Microwaves

The problem with sterilizing in the microwave is this: Microwaves do not heat a given volume of liquid evenly. The temperature can be at boiling in one part of your liquid, and well below it at another. This means that unless you boil for long enough that the liquid is thoroughly mixed by convection and by the bubbles rising through it, you can have living bugs still in there. This long boil takes just about as long as doing it on the stove, but when the stovetop boil is rolling, the WHOLE volume of the liquid is boiling.

However, I can confirm that the mini-mash in the microwave (M-MitM?TM?) works really well for preparing samples. I just need a mini-lauter tun and I can brew on the 1-bottle scale in no time flat! ;- ) P.

Subject: Re: How Long do Hops Float?

JC writes:

>I currently dry hop during secondary fermentation in a soda keg. My hops are placed into a hop bag that is dropped into the keg. I want to get away from using the bag. However, since I do not have a filter in the bottom of the keg, and don't want to add one, I am concerned that the hops will clog the dip tube in the keg. This assumes, however, that they sink to the bottom of the keg during the 7-10 days they spend in the secondary. So how long do Hops float?

I've found that pelletized hops don't even float a week and thus have avoided them for dryhopping. I've had whole hops float for three weeks although I recommend dryhopping for only 7-10 days. If you're concerned about clogging, you could put a stainless steel scrubbing pad at the bottom of the keg, in the little dimple, and then position the liquid dip tube so that it pins the scrubbie in the dimple. It would sanitize along with the rest of the keg.

Subject: sanitizers, the middle section

## 2. Reactivity with 304 stainless

Chlorine by itself is really not the issue with respect to reaction with 304 stainless. If it were, then iodine would also be a problem because the chemistry of the two is so similar. It is the alkalinity (high pH) of bleach that poses the problem. Alkaline solutions are caustic, i.e., corrosive. For example, lye or soda ash (sodium hydroxide) in water are caustic.

In an indirect way, it actually is soda ash that gives bleach it's caustic effect. Sodium hypochlorite is made by bubbling chlorine gas through water to which soda ash has been added. (If it's neutral or acidic water it's called chlorine water and hypochlorous acid is formed which is a stronger oxidizer than hypochlorite ion.) In other words, sodium hypochlorite is made in a very caustic solution.

The caustic effect is due to the concentration of hydroxide ions which is directly related with pH. The higher the hydroxide concentration, the higher the pH. If the solution is diluted, the hydroxide concentration drops concomitantly with the pH and the solution becomes less and less caustic, eventually to the point where it poses no problem. For example, lye will burn your skin but if you dilute it sufficiently it will not. In the case of aqueous sodium hypochlorite with 304 stainless, it's simply a matter of dilution.

So what dilution is needed. Laboratory tests done with brewing in mind showed 250 ppm of chlorine at "normal pH" is safe. "Normal" is nonsensical with regard to pH. normal for water? whose water? normal for bleach solution? what concentration in what water? all pH values are 'normal'. If the test was done by simply diluting the bleach with distilled water then the pH would fall as the concentration of chlorine (as hypochlorite) fell. In fact, if you know the pH, you know the chlorine concentration and vice versa.

250 ppm is 70 times greater than what is needed for sanitizing. Therefore we can conclude that even the most careless homebrewer can confidently use household bleach for a single use without worry about damaging his 304 stainless keg.

How about repeated use? The arithmetic would seem to be pretty simple. Since laboratory tests show no effect with a single use, let's put an appropriate number on it: ZERO. Let's do the test 1 billion times (lots of beer). The total effect is then ZERO times 1 Billion equals ??? I'll leave this as a homework assignment:-) In addition we have the testimonial of John Isenhauer of having used bleach at 50 ppm for 15 years on the same kegs without effect. Therefore, reasonable people can

only conclude that dilute bleach can be used with 304 stainless repeatedly without worry.

Now what about the corrosive effect of iodophor on 304 stainless? Some who condemn bleach use an iodophor which contains phosphoric acid. Phosphoric acid will react with 304 stainless. (My laboratory tests have confirmed this.) This is due to the acidity (pH again). Ironically, the individual using this iodophor is faced with the same problem for which he condemns bleach. Fortunately, the solution for phosphoric acid sanitizer is the same as that for bleach: dilution.

The type of iodophor containing phosphoric acid was designed to be used for the dairy industry, not the beer industry. Furthermore, it's my understanding that it is used commercially in 140-160 F water. I suspect it works pretty well, but the other iodophors such as BEST and BTF were specifically designed for the beverage industry and are more suitable for our purposes. These iodophors pose no corrosive threat at any concentration.

(the last part of this post appeared last friday.)

i hope this clears up some of the confusion and lays to rest some of the needless worry.

take care, don

From: John Pedlow <TKSJJOHN@UBVM.CC.BUFFALO.EDU>  
Subject: headaches

NOT about post-overindulgence happenings.  
NOT scientific, either.

During the past 10 years, at 2 social functions, Michelob was the only beer available. On both occasions about 45 minutes after beginning the first Mic I developed a "pounding" headache.

Met a Budweiser rep. Mentioned foregoing to him and also explained regular Bud did not promote headaches. Bud-man said only difference between Bud & Mic is the hops: Mic uses imported hops and Bud uses domestic.

I am an allergy sufferer (became ill on beer during desensitization treatments 20 years ago and MD suggested switching to ale --- which treated me just fine). Maybe some headaches are related to allergy to something in the brew... but, maybe not... none of the preceding passes any scientific test.

| Diastatic Activity |                 |            |       |       |         |
| (^oL) min          | 45              | 6060       | 50    | 70    |         |

Does anyone know the conversion for extract from L^o/Kg to units most of us will relate to? What precisely is S.N.R? And what is this significance of the figures under Diastatic Activity?

If in the UK you buy a 'generic' lager malt and it is from Baird's, you will be getting the Standard Pilsen.

#### SPECIAL MALTS

"Our Roast House is one of the largest and most up-to-date in the world."  
...

Modern roasting cylinders are used ...."

CARAMALT (Carastan) [ Note that Carapils is a trade mark in the UK and cannot

be used commercially, but colloquially is used to  
to define product a) ]

Colour:

- a) 20 - 30 )
- b) 35 - 45 ) ^oEBC by IOB method
- c) 50 - 70 )

"These materials are manufactured from germinating malt. ... transferred  
to a

roasting cylinder and heated to 65^oC for one hour. ... then raised to  
150^oC

for varying periods. .. This produces a material which, after cooling,  
has a

glazed internal appearance, pale brown colour and caramel/toffe-like  
flavour."

CRYSTAL MALT, also kown as Caramel Malt

Colour: ^oEBC by IOB method

- a) 100 - 120
- b) 140 - 160
- c) 180 - 210
- d) 230 - 260
- e) 375 - 425

"The method of manufacture is basically the same as for Caramalt, using  
the

same starting material with longer and higher temperature roasting."

AMBER MALT, also known as Brown Malt

Colour 100 - 140 ^oEBC by IOB method

"This material is produced by roasting kilned malt....,"

CHOLATE MALT

Colour 900 - 1100 ^oEBC by IOB method

"This is produced by roasting kilned malt. ..."

ROASTED MALT, also know as Black Malt, Farbmalz.

Colour 1100 - 1300 ^oEBC by IOB method

"This is manufactured from kilned malt by roasting at temperatures up to  
250^oC

..."

ROAST BARLEY (When exported is described as Roast Material)

Colour 1100 - 1300 ^oEBC by IOB method

"This is manufactured from barley by roasting at temperatures up to 250^  
oC. .."

You will see that this also answers the question about what Baird's mean  
when they package a product labelled "Roast Material".

I hope that is of help to some, and I expect explanatory notes from those  
who can interpret that lot in homebrew terms better than I can.

Happy brewing

Geoff

Date: Fri, 11 Jun 93 09:20:10 CDT  
From: jay marshall <marshall@pat.mdc.com>  
Subject: Fuller ESB maize (was Miller Lite...)

George,

In HBD 1158 you made mention of Fullers adding flaked maize to their ESB.

I like the ESB I get on tap very much, and was taken aback when I tasted the bottled version - it was much stronger and really tasted quite different.

My question is, since you've evidently been to the source, which is closer to the product served at the brewery, the U.S. tap or the U.S. bottled?

Also, I got a recipe for a Fuller ESB clone from Rick Melkor (thanks Rick)

that goes as follows:

10# 2-row  
1/2# crystal, 60L - 90L  
1/2# carapils  
1# brown sugar, 60 minutes  
2 oz Fuggles, 60 minutes  
  .5 oz Kent Golding, 30 minutes  
  .5 oz Kent Golding, 5 minutes  
1.5 oz Kent Golding, dry hopped in secondary  
Yeast London Ale (1028) yeast

OG: 1048

FG: 1012

The resulting beer was very good, but not quite there (compared to the tap version, which I prefer). The flaked maize would obviously change the taste a bit - can you recommend the quantity to use? Any other comments on the grain or hop bill would also be appreciated.

thanks very much,

- - -

From: jpgareri@acs.bu.edu (Joseph Gareri)  
Subject: Dogbolter(R)

I was recently given a Dogbolter(R) kit as a present. I'm not a fan of kits, but I'm not inclined to throw something out either.

Has anyone had any experience with either this kit or the commercial product? The kit says it originated in 1979 when David Bruce first opened the GOOSE AND FIRKIN in Southwark UK. It is supposed to be brewed to an OG of 1060.

I am hesitant to use the yeast packet that came with the kit, but I'm not sure what I should replace it with. Also, the instructions say to add 2 1/2 lb. white sugar along with the extract. This seems like a lot of cane sugar for the amount of malt. I'm guessing the can is 3.3lb.

Any help? They classify Dogbolter(R) as a "strong ale".

Subject: Hop Utilization

In the previous digest Mark paraphrased me as follows...

>Bob Jones writes that he doesn't believe that yeast affects  
>hop utilization, and would rather see the calculation split  
>into two..

I did not say "I don't believe you", I will repeat my suggestion that the calculations and measurements be seperated and give an example of why. If we assume this yeast flocculation vs hop IBU effect exists and we combine the two in a table or calculation, and later realize the phase of the moon effects the yeast side of the equation, then all the hop work is out the window. By keeping the effects seperate it allows each to be used, verified, updated, investigated, and argued independently. That's just plain old good scientific reasearch.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: re twist-offs

twist-off caps are said to be put on by something more complicated than a simple crown capper; the argument (which I find plausible from comparing the bottles) is that an affordable capper can't be sure of making a reliable seal around the threads of a twist-top bottle. It's possible this is a momily---but good bottles aren't that hard to find (bar bottles of any of the major brands, Sam Adams bottles, ...).

I suspect that it's more important to have a bottle with a tall collar (the secondary line of glass around the neck, below the lip that the cap wraps around), so the capper can get a solid grip; the cap certainly /looks/ more secure in these cases.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)  
Subject: home/commercial brew and hangovers

johng@adx.la.ca.us suggests that homebrew may be less dehydrating than commercial beers; I don't think this is likely. My understanding (from long-ago physiology) is that alcohol is a diuretic; i.e. it causes the kidneys to increase their net extraction of water from the bloodstream (so Bob Shaw was qualitatively right when he observed that you piss five pints for every four you drink).

My very rough guess is that the average homebrew is, if anything, / more/ alcoholic than the average commercial beer in this country. My vague recollection is that standard commercial beers are ~4% w/w (~5%v/v) alcohol; homebrewers do light fruit beers, milds, and ordinary bitters which are ~4%v/v, but they also do lots of ESB's, IPA's, [,doppel,trippel]bocks, imperial stouts, bieres de garde, Belgians, ... all of which run over 5%v/v, sometimes much higher.

Certainly dehydration plays a part in hangovers; if you've binged one of the better protections is aspirin and lots of water /before/ you crash. But

I don't think it connects to lack of hangover in homebrews. Yeast may be part of the effect, since B vitamins are commonly claimed to be effective against hangovers; I don't know whether any sound research has been done on this. But how much yeast is still in suspension in homebrew, especially in kegged beers? And has anyone noticed a difference in hangovers between factory beers (aka American light, aka American swill) and commercial beers with yeast in them (Belgians, Sierra Nevada, ...)? More important, is anyone on this list willing to drink enough factory beer to test?

Date: 11 Jun 93 07:42:00 PST  
From: John Fitzgerald <johnf@ccgate.SanDiegoCA.NCR.COM>  
Subject:

Let me start off by thanking the HBD'ers that responded to me about the beer fest in Temecula, CA, and all of the SS keg info. This digest sure is a great source of information!

With the recent talk about fruit beers, especially peaches, I thought I'd mention a 1 gallon experiment batch from last season. I added about 1.75 lbs. to the primary of a generic light lager, with fairly good results.

The result is a decent beer with a nice peachy aroma, and somewhat of a fruity taste, but my palate has trouble distinguishing it as a peach flavor.

What I did learn from this experiment was:

1. it is worth doing again (and I will as soon as I can harvest my mother-in-law's tree!) - 5 gallons if I get enough peaches
2. I won't put the peaches in the blender this year (what a mess trying to strain/siphon). I've heard that slicing the fruit thin enough should be sufficient for the yeast to get to the good stuff.
3. I will probably add more peaches this time (2 lbs/gal minimum?), and probably rack the beer onto them after primary fermentation subsides.
4. I have a lot more learning/experimenting to do.

On another note, I have a sufficient supply of 5 gallon cornelius tanks, but am having trouble finding a good source for used 3 gallons kegs. Local shops sell new ones for an outrageous amount, and I am told used ones are scarce. I have heard on this digest that BCI (Bev Con International?) is a good source, but I've given my name & address at least 3 times now to the nice person on the phone, but have never gotten a catalog from them. Is there anybody out there that might be in the reverse situation, that wouldn't mind trading a 3 gallon keg for a 5 gallon keg, for the cost of shipping?

oogy wa-wa,  
(for those of you who do not speak Zulu, you'll have to go the 'Brick' in the D.C. area for some good beer & a translation (great place, a beer drinker's candy store))

Date: Fri, 11 Jun 93 11:35:09 EDT  
From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Re: Iodophor & Belgium headaches

I'm back from beer hunting and wanted to comment on a few items in the last digest.

In the last digest:

Date: Wed, 9 Jun 1993 22:56:11 -0500  
From: donald oconnor <oconnor@ccwf.cc.utexas.edu>  
Subject: sanitizers part 2

<5. Cost and availability

Household bleach costs about \$1/gallon. Iodophor is typically about \$10 per liter. Bleach has 5 times as much sanitizing strength ounce for ounce.

Therefore, bleach is about 200 times cheaper than iodophor.

Brewery cost is closer to \$25 per large jug (1-2 gallons?) or about 25 times

as expensive (I cant remember how big the jug is). This is not to dispute the

retail price, but it does differ by a degree of magnitude.

<6. Personal safety

Both oxidizers will kill cells including yours and mine. Both should be handled carefully. But bleach is a stronger oxidant so a little more dangerous on this point. More importantly though is the caustic nature of

full strength bleach. This poses a more serious risk, particularly to eyes.

Iodophor is a safer product than household bleach.

I think this has been covered before:

My container of Diversity Iodophor indicates irreversable eye damage.

With respect to the corrosive nature of Chlorine on SS I would like to point

out that many homebrewers are not fortunate enough to be using 304 (or better)

SS. When I began brewing years ago, I bought several 16 qt SS pots from a

local catalog store. These are the cheap korean products with riveted handles.

The rivets are aluminum. At one point I used one of these pots as a blowoff

recepticle with a splash of chlorine in the water. As the blowoff tube deposited trub and beer into the solution, the pH dropped and the bubble

layer actually corroded straight through the SS in several pin holes. Now this may not be an issue with 304 SS but it certainly occurred in a very short period with cheaper SS.

On another topic:

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>

Subject: Siphon starters, headaches

<WORSE HEADACHES-----LESS HEADACHES

<Heavier, Darker Beers Lighter, Clearer Beers

<Factory Made Beers Naturally Brewed Beers

<Adjuncts All-Malt

<Fire Brewed Steam-Heated Brew Kettles

<Fermentation By-products Blow-off tube used

<Had a headache already Didn't have a headache already

<Yeah sure. Some of these may have a secondary effect. However, we are <kidding ourselves if we ignore the primary cause of beer headaches:

<More total alcohol Less total alcohol

in a session in a session

In general you are correct. I can personally note that some brewers like Rochefort do not conform to this rule. Just last Friday I had the pleasure of consuming too many Rochefort 10's at 11.3% ABV, as well as other high alcohol Belgium beers. Much to my delight there was not headache in the AM, just a well deserved cobweb effect. Just a data point that the Belgians do something different.

Good brewing,  
Jim Busch

Date: Fri, 11 Jun 93 11:54:06 EDT  
From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Re:CO2, Cherries & B vitamins

More comments on the last digest:

Re: B vitamin benefits of bottle conditioned beers. While it is true that one consumes vitamin B in these beers, I was under the impression that the alcohol also strips the body of these same nutrients, negating the positive effects. Does anyone know if this is true?

Re: CO2 tanks in fridge. What I have found is a problem with the tank in the fridge is the corrosive nature of the moisture in the fridge rusting and damaging the tank and regulator. For this reason all of my beer fridges have the CO2 line running through the side of the fridge. It is quite easy to buy CO2 tubing to fit the drill bit size and just push the tube through the drill hole. Its also well worth investing in the regulator cage to protect the regulator when the dog decides to chew through the Co2 line.

With respect to fruit additions to beer: Phil Seitz and I toured Liefmans brewery on June 2nd. We are compiling a detailed record of the trip and observations that will be forthcoming but FYI: the Liefmans Kriek contains 13 kilos of cherries into 100 Litres of beer. For the metric impaired, this is the equivalent of 28.6 Lbs per 26.4 gallons. Now this may or may not be applicable to the homebrewer mortals since I also believe it sits on the cherries for several years (Phil ,correct me if I am wrong here).

Good brewing & I'll post a review of the Stoudts Festival on Monday,

Jim Busch

Date: Fri, 11 Jun 1993 9:30:02 -0700 (MST)  
From: JLIDDIL@AZCC.Arizona.EDU (Jim Liddil)  
Subject: Iodophors Again?

% George Writes  
% Date: Thu, 10 Jun 93 10:08:52 -0500  
% From: gjfix@utamata.uta.edu (George J Fix)  
% Accord II was designed for breweries. The version in most homebrew  
% shops (the one containing the detergent instead of phosphoric acid)  
% was designed for dairies.

It is true Accord II is used in brweries but according to the technical  
rep for  
Diversity (George you know who he is) says that Accord II is made with a  
surfactant (detergent to the non-scientist) just like all iodophors. It  
also  
contains an excess of surfactant (detergent) to make sure all the iodine  
is  
bound up prperly and that there is not an excess of free iodine. It also  
contains phosphoric acid, but this is not for complexing the iodine.  
The technical rep went on to tell me that Accord II  
has the possibility to cause problems with head retention just as any  
product  
containing surfactants (detergent) does. The question is how much  
detergent  
can you tolerate before decreases in head retention become a problem.  
And Don writes

% The type of iodophor containing phosphoric acid was designed to be used  
% for the dairy industry, not the beer industry.

I have to disagree. I think a more correct statement is that the acid  
containing iodophors are designed for commercial industrial use and not  
home  
use. But the formulations usually contain 20% acid so by the time they  
are  
diluted out the amount of acid is small.

% Furthermore, it's my  
% understanding that it is used commercially in 140-160 F water.  
The ability of iodine to kill microorganisms is enhanced at higher  
temperatures  
and you can do this at home for steel but not plastics if you don not  
want them  
stained.

% These iodophors pose no corrosive threat at any  
% concentration.

But iodine can cause skin irritation in some individuals. And if  
absorbed  
through an open wound can lead to decreased thyroid function.

Jim Liddil

Date: Fri, 11 Jun 93 13:34:50 EDT  
From: Tom.Barstow@East.Sun.COM (Tom Barstow - Sun BOS Software)  
Subject: Starting a siphon

Bart Thielges asks:

>> 4) I realize that sterility is very important. All of the procedures  
>>that I've read mention that during racking, a siphon should  
>>be used to transfer the fermented wort. However, I have  
>>yet to figure out how to start a siphon without getting my  
>>mouth on the end of the hose. One procedure even specified  
>>"suck on the open end of the hose until you get a mouthfull  
>>of beer." Even though I brush twice a day, I still worry that  
>>I might contaminate through this contact. Is there any way to  
>>start a siphon without risking the contamination? Or am I  
>>just being too paranoid? Will my batch be ruined? And how  
>>do you know that the light in the fridge goes out when you close  
>>the door?

I bought a plastic stopcock that I use as my mouthpiece when starting  
a siphon. Sanitize both it and the siphon hose, stick the stopcock  
into the hose, open the valve, elevate the end of the hose, and  
suck. When the beer is within a few inches of the end of the tube,  
close the valve. Kink the hose near the end, remove the contaminated  
stopcock from the still-sanitized hose, and plunge the end of the hose  
in the target container. Works very well.

Subject: Hops Strawberrys and extracts

I have some questions I would like to put to your learned readership. I am currently residing in Central Florida. I am interested in trying to grow some of my own hops. Has anyone out there had any experience growing hops this far south? Where can I get hop rhizomes? Are there some heat resistant varieties that may have a better chance of surviving? Is there some recommended reading material available on the cultivation of hops?

I've read the last couple of issues of HBD(I've only just become aware of it's existence) and the articles on strawberry brews stuck out as I have just bottled a batch of strawberry ale. I added my mashed strawberries during the last ten minutes of the boil. If you add the strawberry to the cooled wort I agree you will enhance the strawberry flavoring but aren't you also taking a chance on adding any wild strains of yeast into the wort as well?

As to Bart Thielges inquiry about inexpensive malt extracts, I buy pure malt unhopped extract in 3 lb. cans for \$6.25 ea(you must buy by the case, 12 cans for \$75 shipping incl). I get it from a company called Specialty Products Inc. located in Chapel Hill, S Carolina. If he wants more specific information he can e-mail me.

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Re: sanitizers and SS

The only thing worse than a lack of information is a plethora of misinformation. A recent posting contained some misinformation regarding sanitizers and corrosion. Although I am not an expert in these subjects, I would like to clear up some of the more obvious errors:

In HBD #1161, donald oconnor <oconnor@ccwf.cc.utexas.edu> says:

>Chlorine by itself is really not the issue with respect to reaction  
>with 304 stainless.

Chlorine (and its dissociation products) ARE the problem. The relative concentrations of these species are determined in part by pH.

>If it were, then iodine would also be a problem  
>because the chemistry of the two is so similar.

Similar, but by no means identical.

>It is the alkalinity (high pH) of bleach that poses the problem.

It is NOT the alkalinity that is the problem. SS is relatively inert in caustic solutions (I believe many breweries and other food processing plants use concentrated NaOH to clean/sterilize their SS equipment.)

> Alkaline solutions are caustic, i.e., corrosive. For example, lye or soda ash (sodium hydroxide) in water are caustic.

Caustic is not a synonym for corrosive.

>(stuff deleted, pretty much accurate)

>If the solution is diluted, the  
>hydroxide concentration drops concomitantly with the pH and the  
>solution becomes less and less caustic, eventually to the point  
>where it poses no problem. For example, lye will burn your skin but  
>if you dilute it sufficiently it will not. In the case of aqueous  
>sodium hypochlorite with 304 stainless, it's simply a matter of  
>dilution.

One must be careful when gauging the effects of dilution on pH. Many complex solutions (including bleach, and wort) are "buffered", thus dilution will not necessarily change the pH significantly.

>(more stuff deleted)

>How about repeated use? The arithmetic would seem to be pretty  
>simple. Since laboratory tests show no effect with a single use,  
>let's put an appropriate number on it: ZERO. Let's do the test 1  
>billion times (lots of beer). The total effect is then  
> ZERO times 1 Billion equals ??? I'll leave this as a  
>homework assignment:-)

This type of math, however simple, is very dangerous. No material has a corrosion rate of ZERO in any solution. It may be so small as to be unmeasurable, but it is not zero. Thus, the correct math would be:

(something very small) times (something very big (1 Billion?)) equals (something which is NOT zero, and may in fact be quite appreciable)

>Some who condemn bleach use an iodophor which contains phosphoric acid. Phosphoric acid will react with 304 stainless. (My laboratory tests have confirmed this.)

I have seen several references that indicate that phosphoric acid is corrosive to SS only at high (>40%?) concentrations. I am guessing that the concentration of phosphoric acid in Iodophors is much lower than this (I may be wrong.)

>This is due to the acidity (pH again).

It is NOT due to the pH, but the chemical species involved!!

>i hope this clears up some of the confusion and lays to rest some of the needless worry.

Please note that I agree with (what I believe is) don's bottom line: household bleach, when used at low concentrations, will not harm SS. Contrary to what don states, I have heard (sorry, I can't remember where) that hypochlorite in a HIGH ph (alkaline) solution is SAFER for SS. Most municipal water supplies are alkaline, this may explain why bleach in muni water solutions are OK on stainless. I have used 1 tsp in 5 gallons water with a 10 minute contact time to sterilize my Cornelius kegs for several years now, and have observed no pitting or other form of corrosion.

Perhaps it would be a good idea for posters to this forum to include  
(1) Their relevant education, training, experience, etc., and/or  
(2) References for their assertions.

In this spirit, I will state that my formal education includes a B.S. in Chemical Engineering, 1985

Information on Chlorine chemistry may be found in:  
Chlorine, its manufacture, properties, and uses, JS Sconce, Ed. 1962  
Information on corrosion of stainless steel:  
Corrosion of Stainless Steels, AJ Sedriks, 1979  
Corrosion Engineering, Fontana & Greene, 1967

(Geez... sorry I wrote so much!)

From: bmv@plaza.ds.adp.com (Brian M. Vandewettering)  
Subject: All Grain Systems

I'm trying to gather as much info as I can on all grain brewing systems before putting my own system together. I've read several books on the subject but haven't come to a decision on the following items:

- + Boiling Kettle - what are the disadvantages of cutting up an old keg? Is a false bottom necessary? For a 15 gallon capacity (10 gallon beer batch) what should I look for in material thickness and other features.
- + Propane burner - Is 35K BTU's big enough? How long to heat 12 gallons of wort?
- + Wort Chillers - Right now I'm using a homemade immersion type. What are the advantages of the other style?
- + Thermometers - Where do you find thermometers that are accurate to +/- 2 degrees?
- + Refrigeration/Fermenting - Ideally one would build a walk-in or two. How do persons of ordinary means accomodate large numbers of fermenters and kegs?

Thanks,

-Brian

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Hop Utilization (again???)

Sorry to beat a cheesy hop into the compost, but here are my two cents on the subject. Bob Jones is right in questioning Mark Garetz's publishing of utilization vs boil time data that differs with respect to the flocculant characteristics of the yeast. Yeast effects on overall alpha acid utilization have absolutely nothing to do with boil time.

My preliminary data show that although many things affect the overall util % (eg wort gravity, wort pH, kettle geometry, boil temp, divalent cation conc, yeast strain, whether or not the beer is fined, filtered, or lagered, and more), none of these things affect the shape of the utilization curve. The literature and my early data indicate that the isomerization of alpha acids in the boil is a first order reaction. Those of you familiar with kinetics know that this means that Rager's (Eckhardt's?) and Garetz's numbers are just not right as far as the shape of the curve goes. Maybe someone who is \*much\* better than I at ASCII graphics could post the shape of a first order curve for A -> B. Things like I mentioned above affect the final number (util%-max) and \*maybe\* the rate constant, but certainly not the order of the reaction.

As I mentioned in a previous posting, I hope to have something comprehensive re: hop utilization by the fall and at Bob Jones' urging will publish here first (at least a thumbnail version).

Now for an embarrassing moment. Due to my lack of UNIX expertise, several catalog requests were lost in the ether. If you sent me mail in the last week please resend it to tinsethg@ucs.orst.edu. I will be on vacation until the 22nd so please be patient. Roy Styan: sorry for the big delay but I will make it worth your while when I return!

Please hit me with further util questions (Edwards and Liddil, I got your mail and am working at responses to your questions) and I'll try to help.

From: Mark A Fryling <mfryling@magnus.acs.ohio-state.edu>  
Subject: excellent mead yeast

Howdy,

With all the recent posts on the network regarding summer brewing and specifically the use of summer fruits in brewing, I felt compelled to share some info about the excellent results we've had on our last few batches of mead. In particular I've found that Lalvin 71B-1122 (s. cerevisiae) is a very good yeast for meads and melomels (mead with fruit). The reason I like this stuff so much is that the samples seem to be quite fresh (high apparent percentage of viable cells), the fermentation is active and very quick, and the strain is not overly attenuative so that a slight residual sweetness remains in the finished product (sorry but I dont have numbers on SG and FG). We've now made two batches of a spiced mead (no fruit) and both were completely clear and ready to bottle after spending 1 wk in the primary and only about 3 wks. in the secondary. Other yeasts I have tried (including Red Star Pasteur Champagne, and Eppernay 2) have taken much longer to clear out and have finished a bit dry for my taste. We also experienced very quick (about 5 wks.) clearing on our the one melomel we made using this strain (a Kiwi mead with 8lbs honey and 12lbs crushed kiwi fruit). A strawberry melomel (8-10lbs light honey and 15lbs frozen strawberries picked last weekend) is on the list for tomorrow. Here is the basic spiced mead recipie:

"Spicy Lemon-Ginger Mead"

10-15lbs light (clover, orange blossom etc) honey  
Bring to a boil with 2gal good brewing water

1/4 oz good flavor hops (I like cascade or hollertau)  
boil 15 min

4 oz grated fresh ginger  
1/4 oz good aroma hops (like hollertau, tettnang, or saaz)  
a strong tea made from 1 oz dried lemongrass, and several (5 or so) bags  
of your favorite blend (we have used chamomile and constant comment)  
Add these at the end of the boil and steep for 15 min

Cool to ca. 75F and dilute to 5gal

Add 1.25 tsp yeast energizer, and 2 pkgs (10g total) of Lalvin  
S. Cerevisiae rehydrated according to instructions.

When completely cleared in secondary, bottle with 3/4c glucose if a  
sparkling mead is desired

Believe it or not, this stuff tastes great after only a month or two in  
the

bottle. It has a mouthfeel that's not unlike a medium sweet champagne, but of course, the flavor is mead all the way.

For melomel, I generally cut back to about 8lbs of honey and replace the sugar with 8-15 lbs of crushed fruit. My best results, though done with different yeast, have been with black raspberries (fresh picked then frozen before use), and a combination of peaches and strawberries (yummy). I've heard of different techniques, but we've had good luck and no unwanted inoculations just adding the thawed and crushed fruit to the hot honey wort just at the end of the boil and steeping (read pasturizing) the fruit for 15min. Oh, BTW the spices should also be cut back or deleted all together to let the fruit character come through.

If anyone else has experience with this *Lalvin S. Cerevisiae* I'd like to know about it.

Mead is a wonderful drink for all seasons and is easy and inexpensive to make.

Cheers,

Subject: Texas Micros & Brewpubs

In HBD1160 J.Hutchison<jhutchin@us.oracle.com> writes the following about Texas micros and brewpubs:

"...good micro beer is not available..."  
This is quite simply UNTRUE!! I live in Houston, and frequently visit several excellent beer bars with literally SCORES of micro draft taps, including Anchor, Sierra Nevada, August Schell, and Boston Beer Company products. The Gingerman in Houston was called "One of the best beer bars in America" by none other than the famed British beer-hunter, Michael Jackson, in his influential Pocket Guide to Beer.

Texas micros available include Celis products (the White won a GOLD MEDAL at the last GABF!), Texas Brewing Co, and (debatably) Shiner Bock. Several new micros are now in their final planning stages. The number of Texas micros is likely to double within the next year. Check the Southwest Brewing News for the latest news on micros.

"...and pub brews are not legal in Texas."  
This will become UNTRUE as of Sept. 1, 1993, thanks to the combined lobbying efforts of The Houston Public News, The Southwest Brewing News, my Home Brew University BBS system, and concerned homebrewers and beer lovers all over the state. Several brewpubs are quite far along in their planning. I expect to see at least 5 operating brewpubs in the Lone Star State by Jan. 1, 1994. Again, check the Southwest Brewing News for the latest brewpub news.

"I buy (when my homebrew is gone) Celis bock and Westend Aussie lager but Texans need ALE!!"  
Look around - we already HAVE ale!!

"Is there a 'grassroots' organization logging Texas legislature to change the awful anti PUB BREW laws? Sign me up."  
The law has already been changed. Next time, try looking around and finding out what's going on before you start complaining.

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Source needed for fritted glass disks

I have been developing a set of rubber stamps for marking beer caps (neat idea huh?) and I'm up against a sourcing problem. The optimum inks for marking metal are solvent-based and require special stamp pads. The pad is a small jar about 1" i.d. with a pad of heavy felt that serves as a reservoir covered by a fritted glass disk that evenly distributes the ink onto the stamp.

My problem is that these special pads are too expensive to be a good deal for people that want to use the stamps with the best inks, \$5 @ in quantity. I want folks to have the best for the least cost, and this is too much...

So: Can anybody out there in ScienceLand give me a lead for a source of fritted glass disks? They are used by glass-blowers for coarse filters and bubblers (like in gas washing bottles). All I need is an address or phone # of a supplier (like Corning) for lab glassware parts. If I can get these cheap enough, I'd like to just toss them in with stamps.

BTW, fritting is a process like sintering metal, but applied to glass. Powdered glass is heated and then pressed to loosely bond the granules. The result is a porous piece of glass, like an aquarium bubbler. There is a more exotic process by which soft soda-glass and quartz powder is sintered with more pressure and then the soft glass is etched away with hydrofloric acid yeilding a much finer porosity. The resulting part can then be slowly heated to fuse the quartz solid. The piece shirinks without distortion during the fusing and can yeild extremely high mechanical tolerances. I thought it was the neatest trick in the world.... There, know you may know something new. I need the crude fritted stuff in 1" disks.

Thanks for any help
