

Welcome to The Homebrew Digest Text Search and Retrieval System

To begin, click on the Search button above.

Notes about this helpfile:

The articles in this help file were gathered from the Internet and placed into hypertext format using a program we wrote. Since we let the computer do it, there was no editing of the message content whatsoever. This has been shown to be both good and bad since some of the articles are decidedly uninteresting. Fortunately, these are in the minority.

In general, you should maximize the help window when viewing this help so as to keep the lines from wrapping around.

In addition, certain punctuation characters were lost due to incompatibilities between the conversion program and the Rich Text Format. In particular, the curly braces { and } were changed to ordinary parentheses and the backslash (\) was changed to a forward slash (/) in all cases. We hope that this doesn't cause many problems.

Nearly all of the people who contributed to The Homebrew Digest are still reachable via their e-mail addresses. Feel free to write them and/or to subscribe to the HBD (see below). The Homebrew Digest is an open, and usually unmoderated forum where anything can, and often does appear. Some of the language used in these articles may not be suitable for children, but then neither is beer in general.

Homebrew Digest E-Mail Subscription Information

Send articles for publication only to homebrew@hpfcmi.fc.hp.com
(Articles are published in the order they are received.) Send
UNSUBSCRIBE and all other requests, i.e., address change, etc., to:

homebrew-request@hpfcmi.fc.hp.com

PLEASE NOTE that if you subscribed via the BITNET listserver (BEER-L@UA1VM.UA.EDU), then you MUST unsubscribe the same way! If your account is being deleted, please be courteous and unsubscribe first.

Archives are available via anonymous ftp from sierra.stanford.edu. (Those folks without ftp access may retrieve files via e-mail from listserv@sierra.stanford.edu. Send HELP as the body of a message to that address to receive listserver instructions.) Please don't send me requests for back issues - you will be silently ignored. For "Cat's Meow" information, send mail to lutzen@novell.physics.umn.edu

Subject: a question

I am new to the net, and I need a answer to a question quickly because I am going on vacation and want to do some brewing while I am off.

It seems that most people are brewing large quantities at a time- 5 gallons or so. My question is- can a beginner brew only 1 or 2 gallons at a time and still get good results?

Any help on this is needed by New Years day at about 7 am, thats when my well deserved vacation begins. Thanks for the help. Bob

Subject: My extract rate woes, your responses.

I recently posted a note re: my poor extract rate and recvd a number of helpful responses. Thought I'd share them here.....

- I used only 3.5 gals of sparge water for 10 lbs of grain. Respondees unanimously suggested I up that to 4.5 or more gals. Thanx, I'll do that.

I ended up boiling the wort down to about 4 gals, and needed to add some to get back to 5 gals. I didn't test the gravity prior to the dilution.

- It was suggested that I do some analysis on my water. I should strive to get my sparge water to about 5.5 pH. Here's what I did...

I went to an aquarium store and picked up a pH test kit, (one of these where you drop x drops of this stuff into a measured amount of water, than note the color).

Results

Source pH

Water fresh (cold) from tap. 7.0 (Water district said it'd be 8.3)
Same boiled with cover off(20mins) 8.0
Same boiled with cover on(20mins) 8.0
Same raised to 180F 7.0
Same raised to 200F 7.3 (approx)

I noted absolutely no mineral precipitation in my boiler after a 1/2 hour boil. I had also expected the pH to drop as a result of the boil, but the opposite occured. Adding 1t of Gypsum to about 2 gals of boiled water did not lower the pH a measurable amount (still looked the same color).

I suppose it's near enough to neutral so as to expect little help from the gypsum.

What seemed odd was that the pH started to raise between 180 and 200F.

In any event, it seems I need to acidify. I'll see what's available at the local Homebrew supplier. I wonder, though, would a small quantity of Orange juice accomplish the acidification w/o making the resultant beer tastes like a morning breakfast drink. If so, how much?

Subject: Chicago Beer Society FAQ

Rob Bradley asked, so let's just make this general...

The Chicago Beer Society's monthly homebrewer meetings are held on the first Thursday of every month, at 7:30PM, at Goose Island Brewery, 1800 N Clyborn Ave. There are also monthly single-topic homebrewer meetings, where the making of a specific style is covered in depth, two major public blind tastings each year, an annual AHA-sanctioned homebrew contest, an annual Beer Judge Certification Exam, the Blues n Brews Cruise on Lake Michigan, a picnic, periodic pub crawls by chartered bus, and the annual Membership Meeting in January.

In general you should come to the Goose Island meeting on the first Thursday to find out about these.

Dues-paying members receive the (roughly) quarterly newsletter "Hoppenings", get major discounts on admission to all CBS tastings and other events, and get the year's "beer item", such as an apron (to keep wort splashes off your clothing), or some kind of glassware.

For more information, call or write
CHICAGO BEER SOCIETY, BOX 1057, LA GRANGE IL 60525, 708-692-BEER
or just show up at Goose Island on the first Thursday - complete membership materials will be available.

(No disclaimer. Yes, I am connected with the Chicago Beer Society.)

Subject: Refrig. temp control; effect of exposing fermenter to light

I have a question concerning the effects of exposing a fermenter to a constant light source. But first, I'll explain the reason for my question. Here's the scenario: I have been brewing my first lager in the refrigerator in my garage. I use a Hunter Air-Stat to control the temperature in the frig to within a degree or two. As the weather has gotten colder, however, so has the refrigerator, and there's nothing the Hunter monitor can do to correct for too low a temperature. A friend of mine suggested a simple solution to this problem: mount a light bulb inside the refrigerator, and always leave it on. This provides a slow but steady warming of the frig, regardless of the outside air temperature. I tried it, and it works quite well: a 15-watt bulb provides enough heat that the frig runs for a total of an hour or so in a 24-hour period (5 or 6 minutes at a time).

However, I'm concerned about the effects of light on the beer and yeast. I am aware that exposure to ultraviolet light is undesirable. I've been told that incandescent bulbs (as opposed to fluorescent) should not produce much UV light, and certainly 15 watts is not very powerful, but the bulb is only a foot or so from the fermenter. I've also read that plastic is a strong absorber of ultraviolet light. I normally use a plastic fermenter for the primary, and a glass carboy for the secondary, but in this case I used a plastic secondary as well.

Now for my question: does anyone know which wavelengths of light are most harmful to the beer/yeast? I'd like to use the glass secondary as I usually do. I could use a colored light bulb to eliminate various regions of the light, for example, a yellow bulb should filter out blue light, etc. Is there an easier (and inexpensive) solution? Maybe a very low-power heating element? Or am I just worrying unnecessarily about the exposure to light?

Thanks for your thoughts.

I've been told that incandescent bulbs (as opposed to fluorescent) should not produce much UV light, and certainly 15 watts is not very powerful, but the bulb is only a foot or so from the fermenter. I've also read that plastic is a strong absorber of ultraviolet light. I normally use a plastic fermenter for the primary, and a glass carboy for the secondary, but in this case I used a plastic secondary as well.

Now for my question: does anyone know which wavelengths of light are most harmful to the beer/yeast? I'd like to use the glass secondary as I usually do. I could use a colored light bulb to eliminate various regions of the light, for example, a yellow bulb should filter out blue light, etc. Is there an easier (and inexpensive) solution? Maybe a very low-power heating element? Or am I just worrying unnecessarily about the exposure to light?

Thanks for your thoughts.

Subject: a question

I am new to the net, and I need a answer to a question quickly because I am going on vacation and want to do some brewing while I am off.

It seems that most people are brewing large quantities at a time- 5 gallons or so. My question is- can a beginner brew only 1 or 2 gallons at

a time and still get good results?

Any help on this is needed by New Years day at about 7 am, thats when my well deserved vacation begins. Thanks for the help. Bob

Subject: My extract rate woes, your responses.

I recently posted a note re: my poor extract rate and recvd a number of helpful responses. Thought I'd share them here.....

- I used only 3.5 gals of sparge water for 10 lbs of grain. Respondees unanimously suggested I up that to 4.5 or more gals. Thanx, I'll do that.

I ended up boiling the wort down to about 4 gals, and needed to add some to get back to 5 gals. I didn't test the gravity prior to the dilution.

- It was suggested that I do some analysis on my water. I should strive to get my sparge water to about 5.5 pH. Here's what I did...

I went to an aquarium store and picked up a pH test kit, (one of these where you drop x drops of this stuff into a measured amount of water, than note the color).

Results

Source pH

Water fresh (cold) from tap. 7.0 (Water district said it'd be 8.3)
Same boiled with cover off(20mins) 8.0
Same boiled with cover on(20mins) 8.0
Same raised to 180F 7.0
Same raised to 200F 7.3 (approx)

I noted absolutely no mineral precipitation in my boiler after a 1/2 hour boil. I had also expected the pH to drop as a result of the boil, but the opposite occured. Adding 1t of Gypsum to about 2 gals of boiled water did not lower the pH a measurable amount (still looked the same color).

I suppose it's near enough to neutral so as to expect little help from the gypsum.

What seemed odd was that the pH started to raise between 180 and 200F.

In any event, it seems I need to acidify. I'll see what's available at the local Homebrew supplier. I wonder, though, would a small quantity of Orange juice accomplish the acidification w/o making the resultant beer tastes like a morning breakfast drink. If so, how much?

Subject: Chicago Beer Society FAQ

Rob Bradley asked, so let's just make this general...

The Chicago Beer Society's monthly homebrewer meetings are held on the first Thursday of every month, at 7:30PM, at Goose Island Brewery, 1800 N Clyborn Ave. There are also monthly single-topic homebrewer meetings, where the making of a specific style is covered in depth, two major public blind tastings each year, an annual AHA-sanctioned homebrew contest, an annual Beer Judge Certification Exam, the Blues n Brews Cruise on Lake Michigan, a picnic, periodic pub crawls by chartered bus, and the annual Membership Meeting in January.

In general you should come to the Goose Island meeting on the first Thursday to find out about these.

Dues-paying members receive the (roughly) quarterly newsletter "Hoppenings", get major discounts on admission to all CBS tastings and other events, and get the year's "beer item", such as an apron (to keep wort splashes off your clothing), or some kind of glassware.

For more information, call or write
CHICAGO BEER SOCIETY, BOX 1057, LA GRANGE IL 60525, 708-692-BEER
or just show up at Goose Island on the first Thursday - complete membership materials will be available.

(No disclaimer. Yes, I am connected with the Chicago Beer Society.)

Subject: Refrig. temp control; effect of exposing fermenter to light

I have a question concerning the effects of exposing a fermenter to a constant light source. But first, I'll explain the reason for my question. Here's the scenario: I have been brewing my first lager in the refrigerator in my garage. I use a Hunter Air-Stat to control the temperature in the frig to within a degree or two. As the weather has gotten colder, however, so has the refrigerator, and there's nothing the Hunter monitor can do to correct for too low a temperature. A friend of mine suggested a simple solution to this problem: mount a light bulb inside the refrigerator, and always leave it on. This provides a slow but steady warming of the frig, regardless of the outside air temperature. I tried it, and it works quite well: a 15-watt bulb provides enough heat that the frig runs for a total of an hour or so in a 24-hour period (5 or 6 minutes at a time).

However, I'm concerned about the effects of light on the beer and yeast. I am aware that exposure to ultraviolet light is undesirable. I've been told that incandescent bulbs (as opposed to fluorescent) should not produce much UV light, and certainly 15 watts is not very powerful, but the bulb is only a foot or so from the fermenter. I've also read that plastic is a strong absorber of ultraviolet light. I tried it, and it works quite well: a 15-watt bulb provides enough heat that the frig runs for a total of an hour or so in a 24-hour period (5 or 6 minutes at a time).

However, I'm concerned about the effects of light on the beer and yeast. I am aware that exposure to ultraviolet light is undesirable. I've been told that incandescent bulbs (as opposed to fluorescent) should not produce much UV light, and certainly 15 watts is not very powerful, but the bulb is only a foot or so from the fermenter. I've also read that plastic is a strong absorber of ultraviolet light. I normally use a plastic fermenter for the primary, and a glass carboy for the secondary, but in this case I used a plastic secondary as well.

Now for my question: does anyone know which wavelengths of light are most harmful to the beer/yeast? I'd like to use the glass secondary as I usually do. I could use a colored light bulb to eliminate various regions of the light, for example, a yellow bulb should filter out blue light, etc. Is there an easier (and inexpensive) solution? Maybe a very low-power heating element? Or am I just worrying unnecessarily about the exposure to light?

Thanks for your thoughts.

Subject: a question

I am new to the net, and I need a answer to a question quickly because I am going on vacation and want to do some brewing while I am off.

It seems that most people are brewing large quantities at a time- 5 gallons or so. My question is- can a beginner brew only 1 or 2 gallons at a time and still get good results?

Any help on this is needed by New Years day at about 7 am, thats when my well deserved vacation begins. Thanks for the help. Bob

Subject: My extract rate woes, your responses.

I recently posted a note re: my poor extract rate and recvd a number of helpful responses. Thought I'd share them here.....

- I used only 3.5 gals of sparge water for 10 lbs of grain. Respondees unanimously suggested I up that to 4.5 or more gals. Thanx, I'll do that.

I ended up boiling the wort down to about 4 gals, and needed to add some to get back to 5 gals. I didn't test the gravity prior to the dilution.

- It was suggested that I do some analysis on my water. I should strive to get my sparge water to about 5.5 pH. Here's what I did...

I went to an aquarium store and picked up a pH test kit, (one of these where you drop x drops of this stuff into a measured amount of water, than note the color).

Results

Source pH

Water fresh (cold) from tap. 7.0 (Water district said it'd be 8.3)
Same boiled with cover off(20mins) 8.0
Same boiled with cover on(20mins) 8.0
Same raised to 180F 7.0
Same raised to 200F 7.3 (approx)

I noted absolutely no mineral precipitation in my boiler after a 1/2 hour boil. I had also expected the pH to drop as a result of the boil, but the opposite occured. Adding 1t of Gypsum to about 2 gals of boiled water did not lower the pH a measurable amount (still looked the same color).

I suppose it's near enough to neutral so as to expect little help from the gypsum.

What seemed odd was that the pH started to raise between 180 and 200F.

In any event, it seems I need to acidify. I'll see what's available at the local Homebrew supplier. I wonder, though, would a small quantity of Orange juice accomplish the acidification w/o making the resultant beer tastes like a morning breakfast drink. If so, how much?

Subject: Chicago Beer Society FAQ

Rob Bradley asked, so let's just make this general...

The Chicago Beer Society's monthly homebrewer meetings are held on the first Thursday of every month, at 7:30PM, at Goose Island Brewery, 1800 N Clyborn Ave. There are also monthly single-topic homebrewer meetings, where the making of a specific style is covered in depth, two major public blind tastings each year, an annual AHA-sanctioned homebrew contest, an annual Beer Judge Certification Exam, the Blues n Brews Cruise on Lake Michigan, a picnic, periodic pub crawls by chartered bus, and the annual Membership Meeting in January.

In general you should come to the Goose Island meeting on the first Thursday to find out about these.

Dues-paying members receive the (roughly) quarterly newsletter "Hoppenings", get major discounts on admission to all CBS tastings and other events, and get the year's "beer item", such as an apron (to keep wort splashes off your clothing), or some kind of glassware.

For more information, call or write
CHICAGO BEER SOCIETY, BOX 1057, LA GRANGE IL 60525, 708-692-BEER
or just show up at Goose Island on the first Thursday - complete membership materials will be available.

(No disclaimer. Yes, I am connected with the Chicago Beer Society.)

Subject: Refrig. temp control; effect of exposing fermenter to light

I have a question concerning the effects of exposing a fermenter to a constant light source. But first, I'll explain the reason for my question. Here's the scenario: I have been brewing my first lager in the refrigerator in my garage. I use a Hunter Air-Stat to control the temperature in the frig to within a degree or two. As the weather has gotten colder, however, so has the refrigerator, and there's nothing the Hunter monitor can do to correct for too low a temperature. A friend of mine suggested a simple solution to this problem: mount a light bulb inside the refrigerator, and always leave it on. This provides a slow but steady warming of the frig, regardless of the outside air temperature. I tried it, and it works quite well: a 15-watt bulb provides enough heat that the frig runs for a total of an hour or so in a 24-hour period (5 or 6 minutes at a time).

However, I'm concerned about the effects of light on the beer and yeast. I am aware that exposure to ultraviolet light is undesirable. From: Jack Thompson <jct@reed.edu>

Subject: UV/fermenter

I am not competent to answer Tom Kaltenbach's question about the effect of

UV on fermenting beer, but I can suggest a couple of things about light and UV in general (there's a reason that most beers are bottled in brown (or green for a few brews) bottles. Increased shelf life (Miller's and Henry Weinhard's must sell very fast!).

Incandescent bulbs put out upwards of 75 microwatts/lumen of UV. That is not very much energy, but UV is a mutagen, and plastic, unless it has a UV

absorber incorporated with it, does not slow UV down to any appreciable extent. A couple of things which you might do are to put black paper around the fermenter and paint the inside of the refrigerator with a titanium white paint. Titanium absorbs UV better than any other white pigment.

Looking forward to reading any other postings to your question.

Jack Thompson

From: Phillip Seitz <0004531571@mcimail.com>
Subject: Alcohol and health

Now that the holidays are safely over, HBD readers may be interested in a recent review article on alcohol consumption and health published in the November 1992 issue of NUTRITION ACTION HEALTH LETTER (Vo. 19 #9). This is a publication of Center for Science in the Public Interest, a non-profit organization that focuses on nutritional issues. Their article is footnoted for those who wish to peruse the original publications in the NEW ENGLAND JOURNAL OF MEDICINE, LANCET, JAMA, etc.

First the good news: moderate consumption of alcohol lowers your risk of heart disease. For instance, a study of 44,000 men by the Harvard School of Public Health found that those reporting consumption of one half to two drinks a day had a 26% lower risk of developing heart disease. These findings have been reinforced in studies by the American Cancer Society and other organizations. (A "drink" is defined as 1/2 ounce of pure alcohol, or in homebrew terms about one can of Budmilloors). The director of the French National Institute of Health and Medical Research is quoted as saying that "there is no other drug that is so efficient [at preventing heart attacks] as the moderate intake of alcohol."

Why is this? It appears that alcohol has a significant ability to raise HDL cholesterol levels (this is the "good" cholesterol); drinkers have been found to have 10-15% more HDL than non-drinkers. "As alcohol intake goes up, HDL goes up," according to the director of the Framingham Heart Study (although it should be noted that after 2-4 drinks a day there is no increased benefit in further consumption). However, the article also notes that there is no direct link between alcohol and reduced risk of heart disease--the above studies show correlation, not necessarily cause--and there is a possibility that differences in lifestyle between drinkers and non-drinkers may account for some of the effect.

Now the bad news. Actually, this comes in two parts. The first part is that while alcohol consumption lowers risk of heart disease, when it passes from moderate to heavy it increases risk of cancer, stroke, and death from other causes. There is therefore a balance between risk and benefit, and it cannot be stated that more you drink the better off you are.

The second part has to do with the definition of "moderate". This differs for men and women. "Moderate" alcohol consumption for men lies somewhere between one and two "drinks" a day (note that this means quantity of alcohol consumed, not the bottles of doppelbock!). Basically, once you pass 2 drinks a day the scale tips toward the unfavorable. As the article says, "At four drinks a day, while a man is 25 percent less likely than a non-drinker to die of heart disease, he is 30 to 35 percent more likely to die of cancer or stroke. He's also more likely to become addicted to alcohol." (p. 6) A handy reference chart with the relative risks is printed on this page for those who like to gamble.

Women have it tougher: the break point appears to be between 3-7 drinks a week, with increased risk of breast cancer being the major problem. One study showed that women drinking 3-9 drinks a week cut risk of heart disease by 40 percent, but increased risk of breast cancer by 30 percent. Doctors therefore urge women to

take their own medical history into account when regulating alcohol consumption, but can't offer any firm guidelines. The reason is that while the cancer risk goes up for women, many more women die of heart disease than of cancer--by a factor of about 3.5 to 1--so reducing heart risk at the cost of increased cancer risk may have net advantages. In the opinion of one of the co-investigators on the above-mentioned (3-9 drink) study, "A drink a day for a woman is not too much. There's little health reason to stop." (p. 6)

Just in case any of your are thinking about it, the article also notes that binge drinking does not provide the health benefits of smaller portions regularly spaced out. Drinking your week's allowance of booze in one sitting doesn't have the same effect.

In spite of all this, the pundits are reluctant to encourage people to start drinking, or to drink more. In my own opinion this is at least partially due to a cultural bias against drinking, but it is also true that a substantial minority of drinkers cannot control their consumption. Also barred are pregnant women, people taking certain medications, and people driving or operating other machinery.

In other words, if you're in the moderate range (up to 2/day for men, 1/day for women), don't worry. If you're drinking more, well, you might consider worrying a little.

Anybody who's interested in further information should contact CSPI at 1875 Connecticut Ave., NW, Suite 300, Washington, D.C. 20009. Telephone: 202-332-9110.

Subject: Calculate First, TV and TJHB!

Always Compute First.

Just a reminder for those of us who are still in our 20th or so brewing...I just finished a double brewing session, making a stout (the last batch at 7 weeks was great, but I made a couple modifications for this batch), and a Pilsner on its back. The Pilsner was from a recipe in ZYMURGY. After I ground the grains and mashed, I thought the grain looked a little thin, but what was I to know, I've been running around brewing bunches of 1.055-60 beers the past few months. When the O.G. came out at 1.036 I nearly died...THEN I went to my handy dandy Darryl Richmond shareware converted to EXCELL and mucked with spreadsheet and found that no extraction rate possible would have been able to hit the O.G. of the published brew with the bill of grain listed....normally I ALWAYS run things through the spreadsheet or at least calculate them out on a piece of paper by hand... The first time you're brewing anything, don't trust what you read. Compute it yourself factoring in experience with your own equipment. Live and Learn.

Strange Things On TV.

My wife was sitting in the living room writing on our portable with some nameless noise on TV when she suddenly called me into the room. Apparently it was some cop show (on Saturday evening) and they were going to arrest some guy for having a 'still'. When the cameras followed into the guys house it was obvious from the Cajun-type cooker and setup that he was home-brewing. In the back of the squad car as they were loading everything in was a copy of Papazian's JOY OF HOMEBREWING! The cop gave this grand speech about how normally this stuff would come out ok but all he has to do is deviate from the recepie and it could kill someone...They were still convinced they had a hard-liquor still. This probably wouldn't have made it to the

Subject: Some Questions about Lambic

The temptation to join a conversation which on the one hand involves hot-side

aeration (HSA), and on the other Martin Lodahl & Lambic, is too great to pass up. Martin's reply in HBD#1045 to Steve Anastasi's interesting post in HBD#1044 reminded me of a number of questions I always wanted to ask him. Since these topics are current, I thought now was as good a time as any to do so.

I have always assumed that in a beer style like Lambic, where flavor complexity is taken to the outer limits possible in a grain based beverage, that the usual rules do not always apply. I suspect that this may be the case for Lambics as far as HSA is concerned. This, however, like everything else in this post, is more of a question for Martin than a statement of fact by me.

Negative effects due to HSA are usually reflected in a flavor the Germans call "Herbststoffe." Roughly translated this means "grain bitter" or "grain astringency." Although, I do not have Martin's vast tasting experience with Lambics, the ones I have tasted in Europe have never shown any indication of Herbststoffe. Sometimes I pick up astringent tones in bottled Lambics which have been imported to the U.S. I believe, however, these flavor tones are artifacts, i.e., resulted from the beer's long journey across the Atlantic, and are not intrinsic to this beer style.

There are some theoretical considerations which suggest HSA should be a nonissue. Ironically, the same issues arise in a project I am currently working on which involve beers very far removed in character from Lambics. Herbststoffe arises from the presence of what could be called HSA aldehydes. These in turn arise from the interaction of ethanol in beer (as well as some other things) and products which were oxidized on the hot side of wort production. The HSA aldehydes have been isolated, and definitely display "grain astringent" flavors. Moreover, it has also been shown that most *Saccharomyces* will ignore them. Thus, in most beers, if present, they will spill over into the finished beer and display Herbststoffe. With Lambics, on the other hand, there is a good deal more to the story. As Professor Verachtert and his students at the University of Leuven in Belgium have shown, there are a large number of microbes which get onto the playing field. It is conceivable, although definite proof is lacking, that some of these might find the HSA aldehydes inviting targets, and reduce them to alcohols. Given the large fatty acid composition of Lambics, the alcohols would probably be converted to esters, and form a small part of the very large ester pool in Lambics. If true, this would mean that all of the splashing of hot wort that takes place in Lambic brewing does no harm.

What bothers me (slightly) are the implications of this for North American Lambic brewers. At the present time they will not be dealing with a "full deck" with respect to the relevant microbes, and this conceivably could be an important issue. To cite a specific example, we have in the Southwest a number of really dedicated Lambic brewers. A couple of these have gone to great lengths to simulate the actual Lambic brewing environment, including both splashing hot wort as well as having cob webs in their brewing area. While I really enjoy tasting their beers, they consistently have a flavor tone which I will oversimplify and call "metallic."

I do not remember ever tasting anything like this in Europe, although I have tasted something like it in selected bottles which were imported to the U.S. I, of course, defer to Martin for a final judgement on "metallic" flavors in Lambic. But, assuming for the moment that they are artifacts and not intrinsic to Lambics, this raises the issue of the possible need for brewers in North America to modify the traditional process. If I were given a vote, I would place as No. 1 on the list the removal of the cob webs; removal of splashing comes further down on the list! However, in general which of the rules we use for normal beer (whatever that might be!), should be followed, and which should be rejected in favor of traditional Lambic practice?

Martin, I realize this is the first working week of 1993, and everyone has a lot to do. Thus, I hate to put a number like the above in a good friend's lap at this time. Nevertheless, when you have the opportunity, I would really enjoy your insights into these matters, even if they are only preliminary and tentative opinions.

Subject: Enzyme for brewing "dry" beers

Last Thanksgiving I was in the Chicago area and I picked up a "dry beer" kit made by Glenbrew of Scotland. I usually don't buy kits or hopped malt extract, but I was intrigued by this kit because I've never really understood how the mega-breweries go about making a "dry" beer. This kit apparently is imitating Michelob Dry, as there was a big picture of a Michelob bottle on the label, minus the Michelob name, of course. The reason I am posting this message is that the kit included a packet that was stamped "DRY PILSNER ENZYME, ADD WITH YEAST". Presumably this contains an enzyme that helps break down the higher, unfermentable sugars in the wort into simple sugars that can be metabolized by the yeast. Use of such an enzyme might be an interesting new variable to try in different recipes. Does anybody know what this enzyme might be? Is there a commercial source for it?

>Strange Things On TV.

The show is Cops on Fox. I saw it too. As they sorted through the incriminating evidence, I realized I have every piece of the same equipment (chillers, mash tun, burner, large boiling vessel). If you watched the whole story, though, the cops, in their planning of the raid were careful to note that brewing was legal and that they would have to be careful about this (although I don't think they really knew what was involved in homebrewing).

As I understood it, they did not find a functioning still, but did catch this guy homegrowing something else as well. They took him away, but his face was blurred, which may indicate that he was not found guilty.

The bad press given to TCJHB was strictly due to the show, like it was some kind of manual of sorcery or something. The reference to a bad batch causing health problems was to a bad batch of distilled liquor...this is true. Looking at the guys house, it's not unbelievable that he wasn't also distilling liquor...it could be done with homebrew equipment & slight modifications.

Subject: homebrew cop tv

Homebrew COP TV:

I saw the episode mentioned in HB 1047. Actually, the guy was arrested for distilling alcohol and growing marijuana. In the pre-raid meeting of police, it was stated that brewing beer was legal, that they were looking for a still.

I assumed that the police grabbed all the evidence that they thought could be used, thus the carboy and brew book. Better safe than sorry, eh?

The interviewed cop DID repeatedly refer to the distilled spirits as being 'brewed'. (e.g. "When you brew that stuff, the result could blind someone, or in a worse case kill them")

Subject: Competition Announcement

***** Competition Announcement - Bay Area Brewoff *****
**

This is your last notice for the Bay Area Brewoff hosted by The Draught Board homebrew club. This is a medium size competition, last year we had 150+ entries. We always have good, experienced judges at this competition.

The competition will be held at Lyons Brewery in Dublin, Ca. The competition will be held on Jan 23, 1993. Last year we had a Holiday beer category as an experiment. The response was so good, we are going to do it again.

The entries are to be shipped to arrive the week of Jan 2-9. An entry consists of two 12 oz bottles. Entry deadline is Jan 9, 1993. The entry fee is \$5.00 per entry. Label each entry with the category, your name, address, phone number and club affiliation, if any. For entries in the Holiday Beer category, specify any spices/herbs/special ingredients used. For entries in the Mead category, specify melomel, cyser, or metheglin as necessary. If you have any questions, you can call John Pyles (competition coordinator) at (510) 791-0589.

Entries should be shipped to -

Lyons Brewery Depot
7294 San Ramon Road
Dublin, Ca. 94568

The categories are as follows -

India Pale Ale
Pale Ale - American & English
Dry Stout
Porter
Barley Wine
Amber Lager (Steam style)
Mead (all types)
Holiday beer

Interesting. I know that many people, including George, have complained about the quality of domestic kilned malt. I have made several beers with 100% domestic "Munich" or "Vienna" and invariably the result is dry, a little bit tart, has a weird cherry-grape flavor component, and has a noticeable metallic component. These were all ales

I used to attribute this to oxidation, HSA, or what have you. That may well be, but other beers handled similarly are clean and have no oxidation-like defects. I wonder if perhaps this grain is at fault. Is oxidation/HSA a real problem with high proportions of these malts? Any comments?

Subject: water treatments

Hi All,

In HBD #1046, Jim White writes:

>I noted absolutely no mineral precipitation in my boiler after a 1/2
hour
>boil.

Water "hardness" is a measure of carbonate content. Since no carbonate precipitated out, I'd venture to say that this water is already fairly soft.

>In any event, it seems I need to acidify.

It may not be necessary to acidify for mashing. When water is added to grist, it will acidify naturally to some extent.

My water source is a private well, the water is quite hard. After pre-boiling my mash water, I get a lot of precipitate, but the pH is still close to 7. Once the water and grist is mixed however, the pH drops to roughly 5.4-6.0, depending on the type of malt. If I use English pale malt, the pH drops to 5.4-5.5, and I leave it at that. If I use less modified pilsner malt, the pH gets to ~6.0, and I use a teaspoon of gypsum to drop it to 5.4-5.5. My theory is that the degree of kilning accounts for this difference, as the acidification effect is more pronounced if dark malts are added to the mash.

Anyway, I'd recommend not acidifying any mash water until after mashing in the grain, as it may not be necessary.

>...I wonder, though, would a small quantity of
>Orange juice accomplish the acidification w/o making the resultant beer

If your water has a pH of 8 after boiling, you probably should acidify for sparging. Use a "food grade" acid like citric, lactic, or acidblend, and be very careful not to overdo it. I use 1/4 *teaspoon* of acidblend to acidify 4 gallons from ~7 to ~5.5. A little goes a long way, and you don't want to let the pH of the runoff drop below 5.0.

There was a discussion of sparge water acidification in HBD about two weeks ago, issues #1033 and 1034 if memory serves. Check the archives.

Cheers,
Jim

From: cush@msc.edu (R. Cushing Hamlen)
Subject: brewing Munich Dunkels

This last weekend I tried my hand at brewing a true Munich Dunkel. After reading Miller, I decided to do so using all Munich malt. My source for Munich malt states that the malt is enzymatic, with sufficient enzymes to convert starch without using pale malt.

Well, to make a long story short, I ended up with about three gallons of starchy barley malt porridge....it did not even begin to convert! The process was a protein rest at 130F, conversion at 150F for two hours, another hour at 158F (out of desperation). PH was 5.2. Mash was 9.1 pounds of grain with one quart of water per pound of grain.

So, the question is this: has anyone out there make a Munich Dunkel using all Munich malt, and had success doing so? I am wondering if the 'Munich' malt we can buy here is simply not a good malt to use to make a dunkel, or if I happened to get some malt whose enzymes had been inactivated.

This is likely a good topic for open discussion on the HBD, so go ahead and post any responses.

Subject: COPS & TCJOHB

The Saturday 2/1/92 episode of COPS on the FOX network had an interesting case that related to homebrewing.

The West Precinct of the Pierce County Sheriff office (Washington State) obtained a search warrant to look for a still in a guys house. Deputy Andy Estes was explained in the briefing that they want search the mans house and find the still. It wasn't clear if a still was all they were after but a man from the Liquor Board was also present at the briefing. They had some info on where the still was kept in the house from an informant. Deputy Estes stated that the man had brewing equipment (Homebrewing is legal) and he had a still (Illegal). He presented the procedure that they would follow to serve the warrant.

The sheriffs served the warrant and searched the house. They found the burner (A high BTU burner like we use to boil a large wort) and stated that it was used for the still. They also found several soda kegs. They called the company that owned the soda kegs and stated that they were stolen and asked if they would like them back. Also found was a wort chiller and other homebrew equipment. The guy had a keg setup for mashing the grains and the Liquor board guy said thats what was needed to make the whiskey or grain alcohol.

In the search of the house they found a greenhouse in the closet that he was using to grow you-know-what, not hops but its second cousin.

They packed the brewing equipment into a van and took him off to jail.

Deputy Estes stated that all this guy needed to do was to make one bad batch and everyone who drank it would go blind.

Comments:

I don't know if the man involved was selling his product(s), the beer, the alcohol or the green stuff.

The camera focused on a book in the man's house: Guess what it was titled. YUP! Papazians "The Complete Joy of Homebrewing."

The Liquor Board guy stated that if copper tubing was found it was part of a still. I think the guy was brewing beer from grains and the copper tubing was part of the chiller.

The man in question also had a cooler that had tubing running through it.

All the equipment that I saw related to homebrewing and it seemed to be an advanced set-up.

It seemed as if all the legal authorities involved had no clue on the chemistry or engineering involved with homebrewing beer.

I don't have the name of the Liquor board guy or the man in question.

I can get these names off the video tape if anyone wants to pursue this further (someone in Pierce County Washington?).

I really have a life, I was waiting for Ren&Stimpy to come on :^) !

Questions:

If you obtained soda kegs via a deposit are you stealing from the beverage company? His kegs had warning labels on them. What if you buy refurbished kegs, do these have the names of beverage companies stamped on them? Mine do. I meant to say that the kegs in the first sentence were obtained from a redemption center.

What is law on distilling alcohol for personal consumption?

Did anyone else see this show? Comments? Let's write some letters and set the authorities straight on this. I think that punishment is in order for his "plant" growing, even though Clinton didn't inhale.

I am willing to send the tape to anyone who wishes to view it as long as it gets passed around. Note: My VCR is screwed up such that the tape may be of good quality when viewed on your VCR (Head Problem).

Subject: Glo:gg Brew

Dear Brewers,

Well, the holidays are over and I thought I'd send a little note about the reactions I received from my Glo:gg Ale brewed for the season. First of all, I want to thank all who offered their advise and know-how, all were very helpful. Unfortunately, I'm afraid that I chose the wrong method... Not that the brew was a failure - in fact I got a great deal of responses that it was quite good... but...

The overall opinion was that it was "interesting" in that it tasted alot like a cinnamon and rasin roll, moreso than a beer (even a holiday brew!). Let me recap what I did:

Following Papezian's recipe for 'Elbro Nerkte Brown Ale' I thought I'd simply add the glogg spices (in essence form - soaked in alcohol) at bottling. Instead, however, I decided to add them to the secondary after steeping them in 1 gal of water, much the same way as if I were steeping specialty grains at the start of a boil. In effect, I added a 'tea' of glogg to the secondary (spices and all) and let ferment for 10 days. Then bottled.

My personal reaction to the brew is that it is certainly drinkable, but perhaps best left for a desert-type beverage. It is heavily spiced (I presume due to the steeping, rather than simply adding them as is - dry - to the secondary... or even added to the boil when I added the finishing hops...). Further, I misread the original recipe and added 1/2# rather than 1/4# black pattent malt, and that oversight added a rather dry bitterness to the finish. The carbonation was almost too good (best yet!).

I think that if I try this one again, I'll go even easier on the black pattent malt (maybe 1/8#?) and add the spices (sans rasins this time) with the finishing hops. In all, I'm glad I got the experience, but next time I'll go for something less extravigant that won't act some-like prune juice!

Cheers,
John

Subject: CO2 Utilization

I am getting tired of waiting till my tank runs dry to report back on a discussion of about a year ago.

Here is what I have gotten thus far out of the last one, filled in Dec 1991:

49 kegs force carbonated and dispensed

Hundreds of bottles counter-pressure filled

There are still a few pounds in the tank and I think it is safe to say that the CO2 is in the noise, as an expense in the force vs natural carbonating argument.

I should point out that I always turn off the tank when not dispensing and thereby eliminate losses from leaks.

Subject: Sources of Supplies

YEE HAA !!

Santa came through this year and brought me a Microbrewery kit (by Billingtons of Kirklands, WA). Included in the kit is everything a newcomer needs for the first brew. I'm not sure of exactly what the syrup was I added (my guess is that is a blended extract of barley, hops and malt) to the water along with the sugar and yeast, but want to make more when this batch is bottled. Enclosed is an order form for resupplies. The supplier is Coopers Brewery, (Australian) handled through Billingtons catalog sales (of Portland, OR).

Being as novice as one can be to the brewers art, I don't want to get into messing with the actual grains yet, and am content to experiment with the syrupy extract (exactly what is in the stuff anyway), but I would like to see what else is available out there through other suppliers. I live in the Jackson, MS metro area, and there are no HB Supply stores, or other (known) establishments that stock associated items.

Would someone please be so kind as to send me an address or list of reputable supply company addresses so I can get catalogs and/or additional info. I found and quickly perused Miller's book, but as far as suppliers, he merely suggests joining some association, subscribe to Zymurgy, and obtain addresses from the advertisers.

Thanks in advance. Any and all help appreciated.

Subject: Homebrewers as fodder for TV cop shows

Did anyone happen to catch the TV show COPS? I walked in on the middle of a segment from Washington state, where they had taken someone into custody for running a home still -- where it looked to me that what he was doing was making home brew.

The numbskulls put up a photo of the cover of THE COMPLETE JOY OF HOME BREWING just to show what a really dangerous criminal they were dealing with. There was also a "detective" making comments about people going blind and so on and so forth.

I bring this up because it will be that much more difficult to get my friends to try my (quite drinkable) home brew. I am also not thrilled by the spectre of having to explain that it's not illegal to make home brew -- no matter what you see on TV.

Date: Mon, 4 Jan 93 15:57:59 CST
From: Jacob Galley <gal2@midway.uchicago.edu>
Subject: Low OG

Last night we whipped up an Ad Hoc Weiz-Steam-Bock from some old extract and grain that was lying around, and the OG is surprisingly low. Here's the details:

For 5 gallons, mash at ~165°F:
~3 lbs English 2-row
3 lbs American wheat
.5 lb Barley flakes

Add to:
~10 lbs Munton & Fison LMX
~3/4 oz N. Brewer hop pellets (90+ minute boil)
~1/2 oz Fuggles hop pellets (30 minutes)
~1/2 oz Tettnang hop pellets (2 minutes)

Pitch:
California Lager Wyeast slurry

We had to boil all this for at least 2 hours because we started with much more water than we should have. I'm talking 10 gal down to 5 gal. This is also the first time I've used my chiller, which is just 25 feet of copper tubing that lies in my bathtub submerged in cold water. It works great!

Anyway, this brew produced some amazing cold break. After it settled overnight, there was about 4-5 inches of trub. While I racked this off, I measured a gravity of 1037 or so, which seems very low considering how much extract we put in. Can anyone explain why? Would the amount of trub be related in any way? Might this have been a poor reading because it was taken from the top of the carboy (even if this was a full boil, ie not water on top of wort), ie would the heavier sugars & stuff settle to the bottom of the carboy overnight?

Another question: We siphoned the wort into the chiller with a J-cane and generic plastic tubing. We couldn't help but notice that our J-cane became very limp in the boiling hot wort and is now sort of an S-cane (or maybe a xi-cane). How nasty/toxic will this make my beer?

Thanks,
Jake.

Subject: Light and the fermentor

In HBD #1046, reference was made to UV light in the 'frig with a 15W bulb to keep the temperature up a bit in very cold weather. Well, to really cut the UV down, why not use a higher wattage bulb and dimmer? You know that 15W of mostly heat is what you need; by shifting the bulb's output from the visible towards the IR, UV will drop dramatically. If you run a bulb which only glows a dull red, UV will be virtually nonexistent. In fact, why not use the built-in (presumably) light socket in the 'frig? I suppose a screw-in dimmer might be a bit tough to come by.

>Munich malt states that the malt is enzymatic, with sufficient enzymes
>to convert starch without using pale malt.

This differs from my understanding. Munich malt is kilned to a degree sufficient to produce about 10L/lb/gal. I've always believed that moderate to high levels of kilning inhibit or destroy subsequent enzyme activity during mashing. I use Munich malt frequently for Euro-lagers, but always mash it along with several pounds of pilsner malt. Most of the literature I've read recommends handling Munich malt in this manner, i.e., mash it along with high enzyme malt such as pale or pilsner.

Lots of discussion regarding recent episode of "COPS". From Rick Hapanowicz:

>The guy had a keg setup
>for mashing the grains and the Liquor board guy said thats what was needed
>to make the whiskey or grain alcohol.

>The Liquor Board guy stated that if copper tubing was found it was part of a still.

It doesn't surprise me in the least that some pinheaded minion from a government beaurocracy would be so totally clueless, even given that the agency involved was the Liquor board and the agent should presumably be able to differentiate between legal brewing and illegal distillation.

>It seemed as if all the legal authorities involved had no clue on the chemistry or engineering involved with homebrewing beer.

Does anybody else find this a little scary? The marijuana cultivation not withstanding, when this man answers to the illegal distillation charge, he will find himself in the position of having to prove his innocence, rather than the prosecutor having to prove his guilt. In view of the "evidence", how many of us could find themselves in the same situation?

Sorry to turn this into soc.our.legal.system.sucks.bigtime, I'll come down off the soapbox now, and get back to discussions of brewing.

Also in HBD #1048, Jack Schmidling writes:

>Here is what I have gotten thus far out of the last one, filled in Dec 1991:

>49 kegs force carbonated and dispensed

>Hundreds of bottles counter-pressure filled

>There are still a few pounds in the tank and I think it is safe to say that

>the CO2 is in the noise, as an expense in the force vs natural carbonating

>argument.

I bought a filled 5 pound tank this spring, and so far I've carbonated and dispensed 25 kegs, counter-pressure filled several dozen bottles, and there is still some left in the tank. I've called around, it would cost me about \$7 to get it re-filled, so I consider the cost as trivial.

Cost aside, the degree of control over carbonation levels that force carbonation gives is just great! By keeping the beer re-fridgerated at a constant temperature, I can carbonate the beer to a level appropriate for any given style, just by adjusting the regulator.

>I should point out that I always turn off the tank when not dispensing and

>thereby eliminate losses from leaks.

Ditto, there's no such thing as a 'leakproof' system.

Cheers,
Jim

Subject: OVERNIGHT MASH

Just for drill, I tried something new with the last batch. I doughed it in before I went to bed and mashed it in the morning. My thoughts were along the lines of, the longer it sits in the water, the more likely to soften and saturate all the starch and hence, improve the extract yield. I used water below room temp instead of the usual 90F so as to discourage bacterial action.

I got my usual 30 pts/gal/lb so it didn't help a bit and I may have only proved that my mill does a good job but it would be interesting to know if it helps others who use Coronas or poorly crushed grain.

It is still in the primary but I can not detect any obvious difference in the taste at this point.

>> Same raised to 200F 7.3 (approx)

> I noted absolutely no mineral precipitation in my boiler after a 1/2 hour boil. I had also expected the pH to drop as a result of the boil, but the opposite occurred. Adding 1t of Gypsum to about 2 gals of boiled water did not lower the pH a measurable amount (still looked the same color).
> I suppose it's near enough to neutral so as to expect little help from the gypsum.

> What seemed odd was that the pH started to raise between 180 and 200F.

The temp of the water does effect the color drop PH test. I know this because of testing my spa - if I leave the test water in the tester overnight the results (colors) will be different then when I first tested at 100F. Why this is true - I don't have a clue.

Another thing that effects the color drop PH test is chlorine - this can be corrected with chlorine neutralizer drops. I don't remember off hand which way the chlorine effects the PH test.

The PH in my area is so high it is off the scale - the highest listing on the tester is 8.0 and is a medium dark red color and my water turns almost purple. Since I only do partial mash's, I have not worried about lowering the PH to an exact level (just throw some gypsum in), but when I start to I'll have to buy the acid stuff by the gallon!

Subject: hop questions

Having just read Continental Pilsener (xmas gift) I have a few questions/comments that may spark some discussion.

1. Miller indicates that pellet hops yield a greater utilization than whole hops , thus, less ounces of pellets are required than whole hops.

2. Miller indicates that pellets need only be boiled for 15 minutes.

3. Miller indicates that extract brews need not be boiled for more than 45 minutes and maybe as little as 15 minutes.

Did I misinterpret.... Does anyone have any comments on these Items as they seem to be somewhat contrary to what I have previously believed. But, far be it for me to contradict Miller.

Happy Brewing

Subject: Light Protection

Tom Kaltenbach asks about protecting his beer from light produced by a 15W bulb in the fridge. Here's my two cents.

Some plastics are good UV absorbers, and others are fairly transmissive. Untreated polycarbonate lenses (commonly used in spectacles) transmit less than 0.1% in the UVB region, and around 3% in the UVA. I've seen other plastics transmit up to 30% in UVB and 75% in UVA. While I'm only about two feet from a transmittance spectrophotometer, I don't have any plastic fermenters handy, so I can't say what their transmittance properties are.

On the other hand, the visible part of the spectrum may cause harm to your beer as well. I've seen references stating that 520nm light (green) is particularly effective at making beer go skunky, although this magic number of 520nm seems to be steeped in a certain amount of mystery. The point is, to be on the safe side, you want to protect your beer from visible light as well as UV. Here's the low tech solution:

Take a standard grocery bag and cut an airlock sized hole in the bottom center. Invert the bag and place it over your standard 5 gallon glass carboy, with airlock protruding thru the airlock sized hole. Your carboy will be neatly jacketed, and protected from light. This should be more than enough protection from a 15W bulb.

Subject: Belgian Ale Book - Comments wanted

hi all

just a short reminder to all those who noted problems, misunderstandings or any thing of positive or negative nature dealing with Pierre Rajotte and his Belgian Ale Book.
Several people have commented that the book was not hitting the mark...

I will be traveling to Montreal - probably in late Febuary/ early March, of which I will be spending a majority of the time with Pierre. I have talked to him about this and he agreed to clarify any points of confusion. These responses will either be mailed back via email, posted or snail-mail, depending on how many I receive (so far very few...).

I will send one more reminder out a couple of weeks before I leave..
So take your shots now or forever hold your books ;)

All comments can be sent to the address below, I will print them and deliver to Pierre.

Subject: Lambiks, HSA, Spiders

From: gjfix@utam.uta.edu (George J Fix)

>Negative effects due to HSA are usually reflected in a flavor the
>Germans call "Herbstoffe." Roughly translated this means "grain bitter"
>or "grain astringency." Although, I do not have Martin's vast tasting
>experience with Lambiks, the ones I have tasted in Europe have never
>shown any indication of Herbstoffe. Sometimes I pick up astringent
>tones in bottled Lambiks which have been imported to the U.S. I
>believe, however, these flavor tones are artifacts, i.e., resulted
>from the beer's long journey across the Atlantic, and are not intrinsic
>to this beer style.

Does this so called "grain bitterness" taste anything like the usual
flavor defects we associate with oxidation? (sherry==>cardboard) Or is
it a different beast? If I wanted to taste this flaw, where could I
find a clear example? Would an old bottle of Anchor suffice?

As far as lambiks go, traditional brewers go to great lengths to avoid
oxidizing their aging beers. It is considered very important to not
disturb the pellicle that forms on aging beer, because it provides some
protection from the air in the ullage. Furthermore, oxidized or metallic
tastes are definitely not the norm for a lambik. I suspect that they
don't suffer from the effects of HSA, but can't be certain until I've
found a clear example of Herbstoffe.

>we have in the Southwest a number of really
>dedicated Lambic brewers. A couple of these have gone to great
>lengths to simulate the actual Lambic brewing environment, including
>both splashing hot wort as well as having cob webs in their brewing
>area.

[snip]

>If I were given a vote, I would
>place as No. 1 on the list the removal of the cob webs; removal of
>splashing comes further down on the list!

In Belgium, there are different schools of thought regarding the presence
of cob webs in a lambik brewery. There are those who consider them a
valuable asset. The Cantillon brewery for example has quite a large
spider
population. The pro spider camp points out (as did Martin) that spiders
are useful in reducing the number of fruitflies, which harbor acetic acid
critters.

On the other hand, when I was visiting Timmerman's, they were in the
process of scrubbing down the walls. I questioned my host, Mr. Jack
VanAntwerpen, about the possibility of disturbing friendly biota. His
reply was something to the effect of "BUNK!" His feeling was that
although the image of a cob web laden brewery was poetic, there are
better ways of controlling fruitflies than with spiders!

There are certainly some very picturesque breweries in Belgium, and the
cob webs definitely add to the ambiance. But if you're interested in
making psuedo lambiks, there are many more important things to consider
than your spider population!

Cheers,
CR

Subject: Changes at the Archives

Over the holidays I spent some time reorganizing the Homebrew Archives at Sierra.Stanford.EDU. The first change that you will notice is that almost all files have been placed in subdirectories such as "docs", "programs", "digests", etc. The most significant change however is that the issues of the Hombrew Digest are now stored as individual files rather than shar files or tar files. The Digest index files now cover a whole year and the index for the current year is updated with each new issue. New issues will also be placed directly in the appropriate subdirectory (i.e. digests/1933) as they are received.

Storing the digests in individual files was done primarily for those who must access the archives via the listserver, as the monthly shar had gotten too big for most mailers, but it also seemed that most of the ftp access was for only one or two issues.

Those of you who don't follow the rec.crafts.brewing newsgroup might be interested in the contents of the "images" directory. It currently has about 70 files containing pictures of various beer labels and coasters in GIF and JPEG format.

Subject: Small Batches, Wort Starters

I don't know who remembers, but a few months ago I started trying to brew small, 1-gallon batches of experimental beer. I got a lot of advice from people through the HBD, so I thought I'd post a status report.

As a quick recap, I started playing around with small, all-grain batches so that I could try many different grain bills without the cost and alcoholism that lost of 5-gallon batches would require. I'd just bought a slew of Belgian malts and, as always, patience was the resource in short supply. What flavor would biscuit malt add? How Aromatic? Should I use 1 or 2 pounds? Despite several letters that implied disaster, I figured, what the hell.

The first two batches were basically 1/5 scaled versions:

Recipe 1	Recipe 2
Belgian Pale Malt	2.5 1.5
Belgian Caravienne	-1.0
Gypsum	1/4 tsp 1/4 tsp
Cascades (boil)	1/4 oz 1/4 oz
Cascades (aroma)	1/4 oz 1/4 oz
Irish Moss	~1/4 tsp ~1/4 tsp

Mash-in @ 122 degrees (30 min), heat to 155 til done, mash out at 170. I did the best on measuring the hops using a little postal scale.

I ended up using every pot that I owned, but brewing two small batches was less work than one 5-gallon batch. The only difference was that the boil was better for the small batches; I'll have to scale the boil back to duplicate my 5-gallon capabilities.

The people who said that I would have trouble with hop rates and measuring hops were correct. Maybe it was the active boil. The small batches had hops like I've never brewed before! One week after bottling, the hops flavor would have been classified as 'caustic' for both batches, although at this point the hops have relaxed a bit and the beer is damn good, with a pleasant lemon/citrus flavor that I expect came from the Cascades. My wife loved it too, puzzling me (as always) me no end. Unfortunately, the subtle differences in malts were completely lost.

People said that, with the small thermal inertia of 1 gallon, the old cooler/lauter-tun wouldn't work well and that infusion mashing was probably out of the question. Well, nyah nyah nyah-nyah nyah! I converted a 1-gallon cooler to a mash/lauter-tun and (to my chagrin) it worked better and more efficiently than my big 44-quart, slotted-copper-pipe rectangular one. It held temperature quite well for hours. I liked it enough that I got a two-gallon cooler for small high-gravity batches, but I haven't tried it yet.

Given the hops overload, I made batches 3, 4 and 5 this way:

Recipe 3	Recipe 4	Recipe 5
Belgian Pale Malt	2 #	1.5 # 1.5 #
Belgian Caravienne	1 #	

Belgian Aromatic 1 #
Cascades (boil) 1/8 oz 1/8 oz 1/8 oz
Cascades (aroma) ~1/16 oz ~1/16 oz ~1/16 oz
Irish Moss ~1/4 tsp ~1/4 tsp ~1/4 tsp

The aroma hops weights were more by eye than weight. I bottled them a week ago, but I haven't tried them yet. We'll see how these go, but I'm having fun so far.

On another note, yesterday I was brewing a medium-high gravity ale (14# of grain) and, as expected, after I got my 6+ gallons the runoff was still reading about 1.020. I let the lauter-tun empty into the spare pot and I got about a gallon of weak wort, all dressed up with nowhere to go. I had also just used up my last quart of starter. Some time ago I started canning yeast starter wort in mason jars, and it's a great time-saver. Just boil some wort, pour it into hot jars, put on new lids and boil in water a few minutes. The jars are sterile and ready whenever I need them. So after thinking about the added hassle of looking for my last pound of DME, I actually had a good idea and used the runnings to make 4 yeast starters.

I do have a question: does canning the wort (sometimes stored for months) introduce any problems that anyone can think of? I know cooling a wort slowly is supposed to allow DMS to build up, but I hope the concentrations in a quart will hurt much. The jars are clear, but they're in the dark with the rest of my preserves. Any other considerations I've missed? I hope not, since it's really handy.

Subject: Charcoal Water Filters

Back in HBD #1040 (24 Dec. - I just caught up from the holidays!) Darryl Richman says:

> There is no need to boil all your water before you brew. If your water
> comes with a lot of chlorine, an activated charcoal filter will remove
> it. You need only boil and decant your water if you have a lot of

This is true but I misread it at first and thought I would emphasize that if you use a charcoal filter you should boil all of your brewing water either before or while you are brewing. Many of us extract brewers boil only part of the wort and I must confess that when I lived in a town with better tap water, I made up the 5 gallons straight from the tap. I have since moved to a new town that has a lot of chlorine in the water (0.7 ppm) so I bought a chlorine water filter for the house thinking this means I don't need to boil the water from the tap. Well, according to Miller (I think it's his new book, "Brewing the World's Great Beers") and my backyard neighbor (who sells filters & such to industry) active charcoal filters are great breeding grounds for bacteria. In addition to collecting all sorts of organics for them to munch on, the media itself promotes growth.

>Ditto, there's no such thing as a 'leakproof' system.

Okay, dumb question. If you turn off the gas at the tank and let the system sit for a while, and you have (the inevitable) leaks, won't the beer go flat? Or do soda kegs have check valves built in? I have a tapper-fridge with a Sankey tap, which is hooked up to a half-barrel which sits there for up to 2 months before it gets finished; my 5-lb CO2 cylinder has lasted through 3 1/2 half-barrels but I think it's getting low....

Not so dumb question: anyone know of a cheap source for a gas check valve?

Subject: % alcohol by weight vs. by volume

>From: mfetzer@ucsd.edu@chem.UCSD.EDU (The Rider) (Michael Fetzer)

>How do I compute %alcohol by weigh in terms of %alcohol by volume.

OK, the simplistic answer is that alcohol weighs roughly 80% of what water does for the same volume, so you can translate 5% alcohol by volume into 4% by weight (or use the inverse of 1.25 to go from 4% by weight to 5% by volume).

For the particularly picky among you, this simplistic approach would mena that if the beer were 100% alcohol by weight, it would be 125% by volume, clearly ridiculous.

So, here is the complete approach, with percentage stated as 70%, not .7 (you can substitute 1 for the 100s if using 0-1 values):

$$\begin{aligned} & (\%AbV * .8) * 100 \\ \%AbW = & \frac{\hspace{1.5cm}}{(100 - \%AbV) + (\%AbV * .8)} \end{aligned}$$

Which has 5% AbW converted to 4.04% AbV.

$$\begin{aligned} & (\%AbW * 1.25) * 100 \\ \%AbV = & \frac{\hspace{1.5cm}}{(100 - \%AbW) + (\%AbW * 1.25)} \end{aligned}$$

Which translates 4% AbW into 4.95% AbV.

From: cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)
Subject: re PH vs color test kits

The variation of color (of pH tests) with temperature may be caused by the fact that acidity/alkalinity is temperature-sensitive. pH is the \log_{10} of the reciprocal of the concentration (moles/liter) of H^+ ions; thus pH 7 is a concentration of 10^{-7} .]In sufficiently pure water[the H^+ can come largely from the (very slight) tendency of H_2O itself to dissociate into H^+ and OH^- ; pH 7 is "neutral" (at room temp) simply because the concentration of OH^- is also 10^{-7} . Not surprisingly, H_2O dissociates more readily at higher temperatures; "neutral" at $\sim 100C$ is pH ~ 6 . Without knowing just what is in the test solutions I wouldn't begin to guess the effect of a higher concentration of both ions, except that I wouldn't expect it to be the same as at room temperature; the behavior of the active compound(s) in the solution itself could also change.

I don't know what the standard is in professional brewing, but based on the above I would /expect/ that they read pH only in samples cooled to room temperature, or possibly via probes and equipment that correct for the effect of high temperature.

Date: Wed, 6 Jan 93 11:08:00 EST
From: davehyde@tecnnet1.jcte.jcs.mil
Subject: Kegged!

Several people wrote and asked for forwards of the stuff I received on kegging. Rather than forward everything, I've summarized it here. Hope its helpful. BTW, credits follow. Sorry if I missed anyone, but I don't keep mail very long and I didn't expect the number of requests for info that I got.

Where to get equipment:

I can't be of much help here. I got my taps and CO2 bottle from our neighborhood association (?!) since we rarely use them anymore, and the keg came from a friend who is on excellent terms with a distributor. Several people have recommended scrap metal yards, though.

removing that dang ball tap!:

There's a leaf spring at the top of the tap between the tap and the keg neck. I worked the end of the spring back to one of the bayonette slots in the neck where I pried it out with a screwdriver. Once the spring is out lift then twist the tap up and out of the neck. This was the hardest part because it was stuck and there's not much to get a grip in. Re-installing is just the reverse.

carbonation, racking, pressurizing:

Some people recommended priming with 1/4-1/2 c corn sugar before pressurizing. Another recommendation was to pressurize and let the beer set a day or 2 in the fridge. I didn't want to wait, so I force carbonated and agitated the beer. I racked the beer straight from the carboy to the keg with no priming. I put the tap back in and pressurized it to ~25 psi. I didn't get any guidelines as to pressure vs. style, so this was a guess based on a recommendation of 20-40 psi. I removed the lines and rolled the keg around for 10 min or so on the basement floor and tapped it. Stand Back! The first few pints were well carbonated but slightly cloudy. This disappeared over the next day or so.

Comments:

Unfortunately I didn't bottle any of this batch to do a taste comparison. It is, IMHO, my best batch by far. The raspberries aside (see below) the beer has a wonderful color, is crystal clear, and the head is incredible. Same feel and consistency as Guinness Draft cans with that nitrogen thingy in them. Lasts forever too.

The only problem:

I can't bottle any to give away. I tried quietly filling a bottle for a friend, but when he opened it it was flat. So...keg party time, perhaps.

Many thanks to:

bobc@Eng.Sun.COM: removing that dang ball tap!
sag5004@yak.ca.boeing.com (Ford Prefect): carbonation
Jonathan Butt <jbutt@cs.mun.ca>: carbonation
dipalma@banshee.sw.stratus.com (James Dipalma): carbonation, racking,
pressurizing

and to davet@ncsa.uiuc.edu (Dave Thompson), who asked about my raspberry lager: I didn't want to mess with fruit, so I used a recipe from a supply place near Baltimore, MD that was basically an amber lager with 3/4 tbsp of raspberry soda extract added to boil for 15 min. At bottling (or kegging, as in my case), another 4 tbsp were added to the (now) finished beer. I wouldn't recommend this unless you really like raspberry beer. STRONG! But I like it.

From: tony@spss.com (Tony Babinec)
Subject: hops,extracts,pilsners

(1) Miller is not alone in talking about different utilization of whole (leaf) hops versus pelletized hops. However, it seems that there are a lot of variables involved, such as: how were whole and pellet hops handled? were they kept bagged and chilled as much as possible? does the pelletizing break the resin glands, thereby altering the bittering potential of the hops? what is the boil length? what is the vigor of the boil? what is the gravity of the boiling wort? In the end, aim at a style, try a recipe, taste the result, and modify your process accordingly!

(2) Whether the hops are whole or pellets, the same general rules apply: boil 45 to 90 minutes for bittering, 20 minutes or so for flavoring, and 10 minutes or less for aroma.

(3) In all-grain brewing, a 90-minute boil is probably a reasonable minimum. There are various chemical reactions occurring that require that length of boil, plus you are typically boiling your wort down from 7 or more gallons to 5 gallons at the finish. With extracts, in part the concern is that longer boils darken the wort, and other things equal, it's more difficult to make a very pale beer such as a pilsner with extract. You should probably aim for a 45-60 minute boil so that hop bittering occurs. Although it is bad practice, you hear stories about how some recipes recommend stirring malt extract syrup into water without a boil and then racking to primary.

A pilsner is a pale, bitter lager of conventional strength. An extract brewer could make a decent pilsner:

- use unhopped extra-light or light malt extract,
- hop with noble hops (Saaz, Hallertauer, etc.) and hop for appropriate bitterness,
- Boil for 45 to 60 minutes,
- Use a lager yeast (Wyeast has good ones) and ferment at an appropriate temperature (48 to 50 degrees F).

Miller has some other good pointers in his pilsner book in the text preceding the recipes, which summarizes points made earlier in the book.

of
> starchy barley malt porridge....it did not even begin to convert! ...
>
> So, the question is this: has anyone out there make a Munich Dunkel
using
> all Munich malt, and had success doing so?

Long ago I made a Maerzen based on Miller's recipe which calls for 9 or
10
pounds of Munich malt. I asked the same sort of question on the HBD (i.
e.
will it convert all by itself) and a few people stated they couldn't see
how
it could convert. I said "what the h*ll" and went for it. Well, it
converted
and fermented just fine. Then the problems began. Most of the batch
wouldn't
carbonate (I added the priming sugar, honest!). It was a lager so after
bottling I lagered as much of it as would fit in the fridge (as per
Miller's
recommended method of lagering). None of the beer ever had any kind of
head
whatsoever either. Now here's the weird part. The few bottles that did
carbonate were from the portion that was lagered in the fridge. None of
the
bottles that were stored at room temperature ever carbonated to any
significant degree. That was a real bummer because other than the lack of
carbonation the beer tasted pretty good. I used Wyeast #2308 on this
batch.

If I were to do this again I think I would at least add a pound of wheat
malt to improve the head potential. Since Munich malt is kilned at a high
temperature I believe much of the head producing proteins are gone.

Subject: Yeast question

- ----- REPLY ATTACHMENT -----
SENT 01-06-93 FROM KRUSE_NEIL

I have a yeast question...

My usuall recipe is 6# Alexanders amber syrup extract, willamette hops, boil around 45 mins. Put carboy with the five gals. of wort in bathtub to cool, pitch ale yeast. The next morning the carboy is bubbling like crazy and the beer always turns out great. BUT... Last night I helped a friend follow my award winning recipe with one difference, we used 6# of DRY malt extract. This morning he called me to tell me it was not bubbling at all...nada, nonthing. My question is why? Should he add more yest? Is the temperature off? I thought my recpie was idiot proof, I guess I was wrong ;)
Thanks

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: KETTLE MASHING

The following article was rejected by Zymurgy's editorial department for some obscure reason, so I will post it here in serial form.

KETTLE MASHING

By Jack Schmidling

Mashing and sparging in plastic buckets of one form or another has become so universal that the method I am going to discuss might seem like something new. However, it is more or less the way beer had been made since time immemorial. Until that is, a certain very popular book on home brewing appeared.

Kettle mashing, as I call it, has some advantages and some disadvantages over the now "traditional" plastic bucket method and until one understands both approaches, a commitment to one or the other can lead to a good deal of unnecessary frustration.

Kettle mashing is simply using a kettle with an appropriate screening device and spigot to "cook" the mash in and once the mashing is complete, the same kettle becomes the lauter tun. After sparging in the lauter tun, the kettle is used for boiling and if it has a close fitting cover, can be used as the primary fermenter.

The most fundamental advantage of the approach is the ease with which the transition from extract to all grain can be made. The only new requirement is a straining device in the kettle already used for boiling extract beer. The investment required to "give it a try", is quite minimal and if you decide you don't like the program, you end up with a great brew kettle that sports a spigot that won't get clogged up with hops and specialty grains.

The other advantages are a bit more technical and I will point them out when we get to them.

The key to the system is the screening device and the spigot for the kettle. The first one I made was to be used in conjunction with an overlaying false bottom. The false bottom was a stainless steel plate the size of the kettle bottom with a zillion holes laboriously punched into it. It created no end of problems on the very first batch. Mash got under it and scorching was just about impossible to control. So in disgust, I pulled it out, continued the mash and assumed a disaster was at hand.

Much to my incredulous delight, when I opened the spigot, the wort ran clear after less than a cup of turbid runoff. I have since made about 30 batches using only the screen

device and get very consistent and respectable extract yields.

We will begin the discussion, by describing the screening device and spigot that is installed in the brew kettle. The first one I made was made from galvanized pipe fittings and window screen, installed in a 32 qt enameled canning kettle.

The current version is all brass, copper and stainless installed on two stainless kettles, a ten gallon for mashing and fermenting and a sixteen gallon for boiling. Having two kettles allows one to be prepared for the next operation while the other is doing its thing.

Fig. 1 shows an exploded view of the spigot and strainer. The strainer is simply a 2 x 6 inch piece of screen, rolled into a six inch tube and clamped to the copper tube. The last half inch is bent over itself to seal it off. The copper tube has a slight bend in it to allow it to be rotated so that the end is right on the bottom leaving almost no wort behind. It is easily removed for cleaning.

The spigot passes through a clearance hole drilled in the kettle and is retained by the female connector and a washer to take up the treads and make a tight fit.

All the parts are available at a good hardware store. For those not inclined to hunt down the parts, a complete kit is available from the author.

Once the spigot/strainer device is installed in the brew kettle, you are ready for the plunge. If you are shopping for a kettle, my only advice is the bigger the better. I consider the 32 qt canner about the minimum for a 5 gal batch.

Subject: What to see, barley wine help needed.

Sorry about posting one of those "I'll be in your neighborhood where should I go" posts... but

I am getting married in the end of July. For a honeymoon the general plan is to start in Seattle, head to the coast take a left goto california take a left head through painted desert and goto colorado, take another left and head home. If I sell my 911 in time we may make the trip in a miata (with no luggage room). Or use my fianceses ford explorer (ie room to pick up a six pack here and there :-)

I am interested in interested places and brews to see along the way. (Note: places may or may not include some non beer related places like cannon beach OR). I am interested in two beer styles in particular: alt, and barleywine. A recent trip to Levenworth WA revealed a new brewpub and I want to see how their alt compares with others. Also I have been interested in finding commercial examples of real barley wine (not barleywine like style). I tried to make some myself, but the results are very sweet and not what I expected.

Any help/flames/etc would be helpful. As far as places to see "Check out the Whomper Inn a couple of little towns south of tillamok on 101" would be sufficient (I know how to use a phone book, If I could just get the paper ones to grep :-). Also I would be glad to meet some of you electronic people, maybe we could quaff one in your favorite spot.

Also, I would like some feed back on "my" barleywine recipe. I stole it from somewhere (sorry I don't remember where) so it isn't really mine, but I would be happy to hear how to improve it. Also how long is it supposed to age? When I made this recipe (twice) I was just starting to go all grain, I have been making slow incremental improvements as I go, but still have along way to go. BTW, the small beer made with the second runnings was quite tasty.

May 10, 1991 and May 25 1991

9 gal water
2 tsp gypsum
32 lbs Klages
2 lbs Crystal
1/4 lb Chocoalte malt

throw in grains at 170F stir...temp drops to 152F...wait 90 minutes sparg until 6.5 gallons collected (8 the second time).

2oz Cascade 60 minutes
2oz Centenial 60 minutes
1 tsp Irish moss 20 minutes
2oz Fuggles 5 minutes

boil 60 minutes, OG 1.106 (1.095 2nd batch)
used whitbred ale yeast + redstar champagne
after ~3 weeks I transfered to another carboy
and another 3 weeks later I kegged with a FG of 1.038 (1.028 2nd batch)

I have not tasted the second batch (yet), but the first one is very sweet and almost no hops. Again any advice would be appreciated. If

you are local, maybe we can arrange a tasting.

thanks

Subject: need help kegging

Hello everyone,

I have now made the jump to kegging my beer and now I have a question or 2.

I bought a generic regulator from a welding shop and it works great, one problem though, the second gauge is scaled for liters per minute and cubic feet per hour. It is the same as a pressure guage but the scale is set up for unrestricted flow, as in MIG welding.

Does anyone have a conversion table for this scale?
[ie when the pressure equalizes at 7 lpm, what would that equal in psi]

Thanks

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>
Subject: [Resend] HSA & Lambix

In HOMEBREW Digest #1047, George Fix made my day:

> The temptation to join a conversation which on the one hand
> involves hot-side aeration (HSA), and on the other Martin Lodahl &
> Lambic, is too great to pass up ...

Gosh, George <blush!> ... I wrote up a reply and submitted it that evening, but it was too huge for HBD by any conceivable standard, and was bounced, as it should have been. I'll make it more brief this time.

> Negative effects due to HSA are usually reflected in a flavor the
> Germans call "Herbststoffe." Roughly translated this means "grain
> bitter" or "grain astringency." Although, I do not have Martin's
> vast tasting experience with Lambics, the ones I have tasted in
> Europe have never shown any indication of Herbststoffe. Sometimes I
> pick up astringent tones in bottled Lambics which have been
> imported to the U.S. I believe, however, these flavor tones are
> artifacts, i.e., resulted from the beer's long journey across the
> Atlantic, and are not intrinsic to this beer style.

I've run across astringency in some of the best lambiks I've had, and most especially in some of the young (vos) lambiks served from casks in specialty cafes. I don't have your experience of German beers and wouldn't recognize true Herbststoffe, but the astringency I'm thinking of in this instance is of the husky, grainy sort we often associate with hot sparges, and as lambik brewers frequently sparge hot, I've been assuming that was the cause. "Nutty", "sherry-like" and even "cigar-like" oxidation products are frequently named in my tasting notes. These could well be HSA products, couldn't they? Oddly, these flavor notes seem altogether appropriate to the beers I've found them in -- not a defect, but part of their character, even their charm. Many lambiks, whether insipid (Belle Vue), regrettable (Lindeman's) or splendid (Frank Boon) don't have identifiable astringency, but many seem to.

> ... Herbststoffe arises from the presence of
> what could be called HSA aldehydes ...
> ... most Saccharomyces will ignore them. ... It is
> conceivable, although definite proof is lacking, that some of
> these [microbes] might find the HSA aldehydes inviting targets,
> and reduce them to alcohols. Given the large fatty acid
> composition of Lambics, the alcohols would probably be converted
> to esters, and form a small part of the very large ester pool in
> Lambics. If true, this would mean that all of the splashing of hot
> wort that takes place in Lambic brewing does no harm.

This is to say the least, intriguing! It's true that despite wild splashing of the hot wort into the cooling trays and subsequent storage in gas-permeable containers (barrels) for two or more years the results are nothing like what you'd get if you treated a pale ale the same way. The remaining identifiable oxidation products actually add to the character of the lambik. And I've never tasted the paperlike or cardboard notes in a lambik that we often associate with oxidation. Most lambiks have a very substantial ester component. One gueuze (St. Louis) was so fruity that I first thought I'd been served a fruit lambik by mistake!

> What bothers me (slightly) are the implications of this for North
> American Lambic brewers. At the present time they will not be
> dealing with a "full deck" with respect to the relevant microbes,
> and this conceivably could be an important issue.

I believe you're right. There are definite flavor differences between the synthetic products some of us have been experimenting with, and the "real thing" made the traditional way.

[...]

> they consistently have a flavor tone which I will oversimplify and
> call "metallic." I do not remember ever tasting anything like
> this in Europe, although I have tasted something like it in
> selected bottles which were imported to the U.S.

My experience has been just the same, though right offhand I can't pin down any Stateside encounters with that flavor in lambiks either, but if CR Saikley's reading this, perhaps he can jump in? Exactly that note is coming through like gangbusters in the pseudo-lambik I brewed 18 months ago that I'm sipping as I write this. The biological spectrum in it was limited (as far as I know) to *S. cerevisiae* (Wyeast 1007, in fact), *Pediococcus damnosus*, and a not particularly aggressive strain of *Brettanomyces bruxellensis*. Sparge temperature was allowed to rise to 190F, and I splashed the wort some, but hadn't yet concluded that it would be helpful to the development of the Brett. flavor profile.

> ... But, assuming for the moment that they are artifacts and
> not intrinsic to Lambics, this raises the issue of the possible
> need for brewers in North America to modify the traditional
> process. If I were given a vote, I would place as No. 1 on the

> further down on the list! However, in general which of the rules
> we use for normal beer (whatever that might be!), should be
> followed, and which should be rejected in favor of traditional
> Lambic practice?

I'm struggling with exactly that question, and lack both the background and data to reach a satisfactory answer. Conference attendees could hardly forget Mike Matucheski's remarkable paean to *Brettanomyces*. Mike is a strong believer in following the traditional processes in hopes that the local microflora will be suitable, and while his creations don't have a lot in common with most of the Belgian products they're certainly similar to the hardest available lambiks. "Hardness" in a lambik is a descriptor of the acetic acid contribution to the flavor, and while the Belgian spiders help to keep hardness under control by taking fruit flies to lunch, their American counterparts may not be so helpful. Some of the test batches of J-X Guinard, "father" of the "pure cultures" method of home lambik brewing, tasted more like the "real thing" than mine, and the biggest difference between his process and mine is that he fermented in plastic water carboys, while I stayed with the glass I usually use. Mike Sharp's experiments using an oak cask were even closer to optimal, and what Mike's and J-X's flavor profiles had that mine didn't was primarily a major improvement in the flavor contribution of the *Brettanomyces*. What does all of that have to do with HSA? Well, just that it raises the question of whether there is a relationship between *Brettanomyces*, which seems to contribute more to the final flavor when exposed to (some) air, and the lack of the degree of staling one would normally expect in beers that don't harbor *Pediococcus* and *Brettanomyces*.

I must be crowding the size limit by now. Thanks for asking,

George!

From: Sandy Cockerham <COCKERHAM_SANDRA_L@LILLY.COM>
Subject: lost in the wood

Not long ago I bottled my first attempt at an oat pale ale. I made a blunder though. I added 2 oz. of toasted oak chips to the secondary. Needless to say, the oak character is QUITE pronounced. I was really bummed. The carbonation is great, nice head retention, it is very clear (gee, I remember someone getting flamed for saying their beer was clear, oh well...), and it is a deep golden color (golden oak, I'd say.).
The moral of the story? Be aware of those evil oak chips!
I hope this mellows, it has only been in the bottle since Thanksgiving.

Subject: Re: Light Protection

To protect wort in a fermenter in a refrigerator from light from a small light bulb, I suggest simply wrapping the bulb with aluminum foil.

Date: 06 Jan 93 23:28:16 EST
From: Bill Crisafulli <73750.2427@compuserve.com>
Subject: Lights in the fridge

I have a little different scenario that ultimately leaves me in the same boat wrt light bulbs. I have a fridge used during the Chicago summer for temp control, but since fridge is in a detached, unheated garage, things get pretty nippy in the winter. Since I like to store beers in the fridge year round (both kegs and some bottles to savor), I did the following.

I salvaged a cheap, plastic mechanic's light (you know, the kind in a little cage that has a long cord coming out the end and a switch on the handle under the light). I cut the cord a few feet off the lamp, and attached a new plug. I then plugged that into a \$12 thermo switch dohickey (technical) that powers its outlet when temps drop to 35F, and powers off at 45F. This seems to be doing the trick and keeping the temp stable when outside temperatures are hitting 0F.

I'm not sure how long the light is on, or exactly what the relationship is wrt the outside temp. Also, I have a 70W bulb in there, facing a wooden inner fridge door to try to reduce direct light and reflection. The plastic lamp says don't exceed 75W, so I don't feel too comfortable enclosing the thing inside anything else for fear of a blazing fridge (and cars, etc) if it overheats. I certainly don't worry about the kegs (stainless), but the bottles of my Belgians and Hardy's and monthly Beer Across America specials (light as they have been) are making me wonder what the danger is?

Bill
I kinda like the idea of using a brown bottle to cover it. I could take a 750ml beer/wind bottle and do something with that, I think. But really, what is the danger? I protect from direct light via shelving, but what of indirect?

From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)
Subject: Stuck fermentation?

I am a new homebrewer working on my first batch. I used 3.25 lbs of Edme Bitter Hopped Malt Extract and 3 lbs of Laaglander Amber DME for 5 gallons.

I started the yeast (1 package Edme Ale Yeast) in one cup of water boiled with 2 Tablespoons DME, at 80 degrees. 1 oz of Fuggles pellets were boiled

for 30 minutes, 2/3 oz of Hollertau for 10 minutes, and 1/3 oz Hollertau for 5 minutes. The yeast was pitched at 90 degrees (is this too high? -- I

followed the online beginners guide from Rob Gardner, but have since read that pitching should occur closer to 75-80 degrees).

A fermentation lock was placed on the primary (bucket) and the fermentation

began in a 62 degree room. The OG was measured as 1.048. Bubbling began within 5 hours and was vigorous the following day. My concern is that on the second day the bubbling in the fermentation lock has completely stopped. This seems too soon. Bubbling fermentation only occurred for 36 hours. As the bubbling had stopped, I opened the primary and measured a SG

of 1.022. This seems too high. My question is: what should I do now? Should

I rack to the secondary and wait for fermentation to restart? Is this the fault of the Laaglander DME, which is apparently notorious for high TG's? Do I need to add yeast nutrient? Do I need to add more yeast? Should I rack

to secondary and then bottle after a week? How will this high TG affect the taste of the final product?

Thanks in advance for any advice.

Subject: RE: gas leaks

Hi All,

In HBD #1050, James Smith writes:

>Okay, dumb question. If you turn off the gas at the tank and let the
>system sit for a while, and you have (the inevitable) leaks, won't the
>beer go flat? Or do soda kegs have check valves built in?

Not such a dumb question, I think it's just that James has a much different setup than mine. I use soda kegs, not 1/2 barrels, and I don't have taps installed in the fridge as he does. I keep about 12-15 psi on the kegs as a "maintainence pressure". When not in use, I don't leave the hose barbs connected to the keg. Both the gas "IN" and liquid "OUT" fittings on soda kegs have a check valve in them, which is closed when the hose barbs are removed, keeping the keg sealed. If the hose barbs are left on, the check valve is open, and the only remaining seal is between the small rubber gasket on the fitting and the inside of the hose barb. IMHO, this is a primary candidate for both gas and (shudder) liquid leaks, not to mention the wear and tear on the valve spring from keeping it compressed continually.

Cheers,
Jim

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Cops are after you from Micah Millspaw

About this search for the still. This greatly concerns me, many times I have had people who know that I homebrew, ask if I have a still (with which I make the beer) I say no. When people come over and ask if they can see my brewing equipment, they look at it and say, so this is the still. This line of questioning bothers me a great deal and I often make efforts to explain. The problem is, that per BATF regs (a vestige from the Volstead Act) it is not legal to possess a still (in the USA) for any reason or use.(it is possible to obtain a permit from the BATF but this requires a bond and so on) In the USA the possession of a still can result in forfeiture of the property that the still was found on as well as other punishment. The Volstead Act was the enforcement aspect of Prohibition. The precedents set by this Act are the basis for the narcotics seizure and property forfeiture laws. Start looking at the BATF regulations and you will start to wonder if prohibition was actually repealed.

The rubb is that homebrewing equipment is basically the same as the larger part of the stuff need to distill. It will most likely be proven in court that the homebrewing equipment could be used for illegal distillation wither it was or not. Be concerned this could happen to you. Also discourage people from going around saying so and so has a still and he makes beer. Because some, over zealous cop will break down your door and arrest you and your will have to get a lawyer to prove (at your expense) that you are innocent, if possible. It could be proven, by an expert of course, that your homebrewing equipment is in fact potential distilling equipment and then what do you do, say yes it could be used for that, but I didn't do it. Remember if your innocent can't be convicted.

It seems that many people beleive that brewing and distillation are the same. All that it could take is for someone to say that so and so has a still (which you don't) and next thing you know the police are breaking down the door. Most are ignorant of the laws concerning the production of alcoholic beverages. I've encountered people who make their own wine and brandy (making brandy is illegal) but were shocked at my making beer because they were certain that homebrewing is illegal. These same individuals later told me that it was legal for ethnic Portuguese only to make their own brandy in California (and they actually beleive this).

I've even had the pleasure of being grilled by the FBI over my homebrewing. The FBI agent asked if I knew that I had admitted to committing an illegal act by naming homebrewing as one of my hobbies. There was also concern that if I was making beer that I was probably making other drugs as well. Make beer and your in bad company. They also annoyed my neighbors about this as well, which did little to improve my standing in the area. Also there is an article in the latest issue of American Brewer that tells of the state of Georgias efforts to stamp out homebrewing by busting home beer and wine making shops for selling illegal parphen-
alia, such as yeast.

I guess that the point that I am trying to get across is that this could happen to any homebrewer. And that educating the public, ie.. friends, neighbors,etc...,is the only way to prevent such an incident. Misinformation can be very hazardous to you.

From: Mark Cronenweth <CRONEN@vms.cis.pitt.edu>
Subject: Lab Grade >= Food Grade ?

My biology teacher buddy just acquired an unused 5-gallon container which we think might be useful somewhere in the brewing process. It's a heavy-duty opaque plastic "jug" with a screw-on lid about 6" diameter, with a spigot near the bottom. My friend believes that, since this vessel was intended for lab experiments, the plastic is inert and free from bad chemicals, since these might ruin the data. He says it's "Lab Grade". I have 2 questions:

Do any of you scientists out there know how a "lab grade" container compares with "food grade"? Would it be OK to consume beer that has come in contact with a lab grade container, assuming it was clean to begin with?

Also, since the spigot is about 1.5" from the bottom of the container, I thought it would make an ideal vessel for secondary fermentation, since we could tap the beer right off the trub into bottles. Also, if we left the screw-on cap in place, we might be able to use it to carbonate or maybe lager a batch in the fridge. Any ideas about this?

> I racked the beer
>straight from the carboy to the keg with no priming. I put the
>tap back in and pressurized it to ~25 psi. I didn't get any
>guidelines as to pressure vs. style, so this was a guess based
>on a recommendation of 20-40 psi. I removed the lines and rolled
>the keg around for 10 min or so on the basement floor and tapped it.

First of all, you need to get the beer cold before you agitate it,
and secondly, do not disconnect the pressure lines before agitation-
the beer will absorb the CO2 in the headspace and more is needed
from the tank after agitation begins. How much pressure you need
depends upon how cold the beer is-you need less when it is colder.

Subject: Herbstoffe and Spiders

Many thanks to Martin Lodahl for fielding the questions sent to him. Boy, did we get our money's worth with his responses. To wit:

>I've run across astringency in some of the best lambiks I've had, and
>most especially in some of the young (vos) lambiks served from casks
>in specialty cafes. I don't have your experience of German beers and
>wouldn't recognize true Herbstoffe, but the astringency I'm thinking
>of in this instance is of the husky, grainy sort we often associate
>with hot sparges, and as lambik brewers frequently sparge hot, I've
>been assuming that was the cause. "Nutty", "sherry-like" and even
>"cigar-like" oxidation products are frequently named in my tasting
>notes. These could well be HSA products, couldn't they? Oddly, these
>flavor notes seem altogether appropriate to the beers I've found them
>in -- not a defect, but part of their character, even their charm.
>Many lambiks, whether insipid (Belle Vue), regrettable (Lindeman's)
>or splendid (Frank Boon) don't have identifiable astringency, but
>many seem to.

Many people, and yours truly is as guilty as they come, detect astringency very easily, and then consciously or unconsciously consider it a flaw. It has been reported that overconcentration of one's brewing activities on Viennese style beers can do this to one's palate! Nevertheless, as Martin's comments suggest, with Lambik these issues are far more subtle. By the way, I did fly the term "Herbstoffe" by some language experts and they noted that the translation "grain astringent" was correct but incomplete. This term also conveys a "unpleasant" feature as well. Thus, if "common use" rules are used, then astringent tones like those cited above should not be cited as examples of "Herbstoffe". Great point Martin. C.R. Saikley's comments in HBD#1049 were, as always, dead on target as well.

I have also received some really witty e-mail from members of the Spider Appreciation Society. They correctly point out, as did C.R. and Martin, that spiders provide protection against fruit flies and other bugs. They also make the excellent point that this is natural protection and does not involve chemical cleaners, etc. Anyone with even the slightest social conscious will be sensitive to and applaud that point. Nevertheless and alas, I remain a hopelessly unreconstructed reactionary on this point, and if given a vote, it would go toward removal of the cob webs. Perhaps this is related to the severe emotional trama received upon walking into a room with an open fermenter in high kraeusen, and with everything (including the sides of the fermenter) being adorned with cob webs. Surely there is a better way to go. One that is natural, yet one that is less stressful to those who worry about what it is that spiders do after lunch.

Martin > Outstanding post.
Spider Society > You folks seem like a really fun group. When and where
do
 you meet?

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: KETTLE MASHING

KETTLE MASHING, Part 2

The following procedure is intended only as a starting point that I know works well enough to assure a successful, first, all-grain experience. I do not want to get into endless discussions about the pros and cons of the procedure at this time nor do I even claim that I brew beer this way. There are an infinite number of variations that could be fodder for future articles but the object of this one is to introduce the approach and brew a simple batch of all grain beer.

MASHING

The first step is to dump 8 lbs of crushed pale malt into the kettle. Don't forget the screen! Add 3 gallons of warm tap water and mix thoroughly.

Apply heat and raise temp to 155F. Stir frequently to avoid caramelizing and to distribute the heat. Hold this temp for 30 minutes by adding heat and stirring as necessary.

After 30 mins at 155F, crank up the heat and continue stirring until 178F is reached. This step is known as "mashout" and is difficult or impossible to do with the plastic bucket approach. It is my opinion that it eliminates one source of a common problem with first all grain batches known as a "set mash."

Hold this temp for 10 minutes, then turn off the heat and let it rest while heating water to a boil on another burner. Use a pan that holds at least two quarts of water.

SPARGING

The level of wort in the kettle should be about an inch above the grain when it settles. Lay a small bowl on top of the grain to distribute the sparging water and minimize the disturbance of the grain.

Open the spigot just a trickle and run the wort into a cup until it runs clear. Pour the turbid runoff back into the kettle. With this setup, it will run clear after a few ounces. Again, as comparison, it sometimes takes gallons with the other system and this must be recycled back into the mash till it does run clear.

The object of sparging is to extract as much sugar from the grain as possible. The longer it takes, the more efficient the extraction. Adjust the outflow so that it takes at least 10 mins to fill a gallon jug. Pour the boiling water into the bowl as available or necessary to keep about an inch of water over the grain. The availability of boiling water will probably be the limiting factor on sparge rate.

Most brewers will tell you that the sparge water should not exceed 170F but if you use boiling water in this system, the average temp will be far below 170F and you will be lucky to keep it above 150F. You can fiddle on your next batch. Trust my on the first.

The first runoff should be about 1.080 and you quit when it gets below 1.010. The total blend will produce 6 to 7 gallons at about 1.035 which, after boiling will yield 5 to 6 gals at 1.040. Collect the wort in gallon jugs or five gallon plastic buckets (can't get away from them).

Continued.....

From: Richard Childers <rchilder@us.oracle.com>
Subject: Re: COPS, homebrewing, and the WOD

Regarding the recent thread about the busted homebrewer, I see three possibilities ... in order of likelihood :

- (1) The cops were using the home brewing equipment in bad faith, since they knew he wasn't running a still but knew that the judge wouldn't know that and that the situation could be safely misrepresented, to get the warrant to bust him for marijuana cultivation - which, as others have noted, is far more a service to his community ... like homebrewing, it is being independent and productive and creative and nurturing - than a threat or anything that might damage the commonwealth that the COPS allege to represent.
- (2) The cops were as stupid as the judge, and misled by the informant, who had a grudge, or a bias against marijuana.
- (3) The guy was genuinely running a still ... which does not, prima facia, seem to be the case, although, off hand, I'm not sure it would be possible to prove this, since the equipment needed for both is essentially identical, and a wort cooler could probably be used as a distillation coil. This means this could happen to any of us, and anything you have that is illegal on the premises will be used to justify their action - anything. Unregistered gun, for example, they could and probably would parley it into a federal case if they could, before they'd admit that they had made a mistake and owed you compensation / apologies.

Personally, I don't see the difference between brewing beer, wine, and other alcohol so long as you are neither selling it nor creating a threat to the wellbeing of your neighbors.

What this sort of implies is that if they're going to break down your door when you're not distilling, and try to make it look like you are ... you may as well, anyway.

I think the circumstances suggest that marijuana was the target and home-brewing was used to justify it, no thought given to the thousands of well-meaning and generally law-abiding homebrewers. This is consistent with War On Some Drugs thinking. How do y'all like it when it returns to roost ?

Subject: Stand up to COPS!

I am writing in hopes of convincing a large number of you to voice your opinion in defense of homebrewed beer, a subject near and dear to most of our hearts. I figure that that many of us (including myself) do not watch shows such as COPS, however the rumblings heard here weren't as bad as my personal rumbling when I read the transcription of the segment sent to me by Rick Hapanowicz (after he reviewed the video he mentioned here on Tuesday). As discussed earlier the show COPS broadcast an episode where they allegedly arrested a man for distilling liquor, while in actuality all they showed was homebrewing kegs, immersion chillers, being confiscated and referred to these as illegal equipment. The show was so disturbing to me personally that I have written a letter to both the local Fox station and the producers of the COPS show, and would like to very strongly encourage you to get as many letters sent as possible from your own contacts. I have already sent out mail to club contacts throughout the country, which includes the transcript of the show segment detailing what I personally feel are misrepresentations in the show. I am willing to send this transcript to anyone who wishes it, to encourage you to voice your opinion to your local fox affiliates, and to the COPS producers at the address I have given below.

A small number of brewers here have been apathetic about the negative exposure, saying that the people who watch a show of this nature aren't worth trying to educate. I would like to point out that this may not seem so trivial as some ignorant neighbor results in your arrest and the confiscation of your brewing equipment.

So if each of you could take some time to voice support for homebrewing I feel it would be to the benefit of all involved. I feel this is one point most all of us should agree on, and hope we can make our voice well heard. If anyone would like a copy of the transcript, or the letters I sent to COPS, and the local affiliate, I would be happy to forward them in hopes that this would induce more response from homebrewers around the country. Thanks in advance for your efforts

This is an excellent point. Even though one may have had success in
the past relying on tap water, there is no guarantee that the tap
itself has not become contaminated by some food particle or other vector.

This is another good point. You can, however, buy charcoal filters
that are impregnated with silver, which acts as a bacteriostat. These
will eventually grow bacteria when they get near their usage limits.

Subject: Botulinum in canned malt extract?

I just got a 1.5 kg can of a malt extract "with hopps added". It must have been sitting for a couple of years in this guys store. I took it to a friend who has some experience in homebrewing. As we opened the can the malt started oozing out and some air/gas came out. We figured it might be the result of some bacterial growth, but the malt looked and smeled just normal. We autoclaved the malt for 20 minutes. We used it for making 25 lit. of what would hopefully become beer. Questions:
Has anyone seen bacterial growth in canned malt extract?
Can C. botulinum grow in the presence of hopps?
If there was any botulinum toxin in the malt extract do you know if we have inactivated it by the 20 min autoclaving.
In short, should we not take the risk, dump this batch and start all over with fresh malt extract (which will take me another month to get)???

With respect to the pressure--carbonation level--temperature discussion:
In
Miller's new book Brewing the World's Greatest Beers, he gives a set of
guidelines on carbonation level for various styles, and a table of
temperature
vs. pressure that yields a given level. And this past week, I borrowed
a
kegging system from my local homebrew supplier, IMO (Thanks, Roy), looked
up IPA
to get a carbonation level, and dialed-in 17 lbs on the pressure gauge
because
of the cold temperature. Voila, perfectly carbonated beer. Gallons of
it. So,
the table is really what you need. The book has other things to
reccommend it
too -- I'd say its worth the price. And I want a kegging system now. Of
course, I'll need a regerigerator too...

From: mtavis@gemini.hyperdesk.com (Mike Tavis)
Subject: Diminishing Yields

I have just bottled my third attempt at all-grain brewing. I've been very happy with the results so far, but I have noticed a disturbing trend -- my extract rates are plummeting with each batch. My first batch yielded 29 pts/lb/gal (a number I never expected to get the first time). My second batch dropped to 22 pts/lb/gal and my third batch was a miserable 18 pts/lb/gal.

All three of these batches had different grains bills, but the technique was pretty consistent. In fact, I tried to do everything the same as the first batch in order to recreate the results. Everything seemed close to that first batch -- the crush was the same, the pH was the same, the temperatures and times were the same -- but my yields are still going in the wrong direction.

After many different discussions, one of my brewing buddies asked, "Has the temperature of the wort coming out of the lauter tun been the same?"

I said, "I never take that temperature. I just make sure that the sparge water is about 168-170."

He said, "Well depending on the size of the grain bed, the sparge water will be lowered and if it gets too low it won't be effective at rinsing the sugars from the grain."

I said. "That makes some sense because in each successive batch I have used more grain -- specifically, the first batch used 8 lbs, the second batch 10 lbs, and the third batch 12.5 lbs."

So what do you guys think? Should my sparge water temperature depend on the size of my grain bed or do I need to go back to the drawing board? Thanks.

Subject: COPS and the still

At the risk of supporting gung-ho policemen...

For those of you unfamiliar with marijuana culture, yes; dope and a still go hand in hand. If you take high percentage grain alcohol and soak marijuana in it; the oils from the plant dissolve into the liquid. If you then evaporate the alcohol you are left with a very sellable product- pot oil. (I have a friend who does this). I do not defend the cops in their actions on that particular bust (they did seem pretty ignorant of what they stumbled onto), but if this guy was growing large quantities of grass and had brewing equipment around, the odds are pretty good he was distilling for oil producing purposes.

Subject: growing hops

jfunk@MAIL.CASI.NASA.GOV asks about growing hops:

Jim,

It's not too early to start thinking about starting hops in the Mid-Atlantic region. Last year was my first hop harvest, so naturally I feel free to consider myself an authority on hop growing. I'm in SE Pennsylvania, not so different from N Maryland. I got my hop rhizomes in March from Freshops in Philo, Oregon. I planted them immediately in 1-gallon plastic pots and set them in a sunny window until after the last heavy frost. This was late April, and the hop shoots were about 1-2' high. I gave them a dowel-string contraption to climb. Hops like rich, well drained soil, so if you have brick-like clay like I do, you're best off making mounds of soil-compost mixture to plant the shoots in. Choose a sunny spot if possible. Once they start growing, hops are like a weed, and don't really need much fertilizer. The real work is to give them something to climb. I made 7' trellises from a frame made of furring strips and a random network of string. This was OK for the first season, but will clearly not be adequate for established hops.

Harvest is in August and September, varying with hop variety. Figuring out when to pick the hops is the trickiest part, but once you have the knack, it's easy. They turn from hard to springy, get a "papery" look to them, and display orange globules at the base of the petals. If the petals turn brown, you waited too long, but you have a fair amount of leeway, so don't worry. The hops do not all ripen at once, so the harvest is spread out over several weeks. After the frosts kill the vine in the fall, I covered the mounds with copious amounts of compost.

Limited probing under the mounds has shown an amazing network of rhizomes. I'm offering cuttings to interested parties within driving distance of Allentown (Varieties: Mt. Hood, Chinook, Cascade, Willamette and Nugget).

Here's a harvest summary that I sent to another Digest member by email:

First year Freshops rhizomes, planted in April in eastern Pennsylvania

Variety	Dried weight (oz)	Comments
===== Cascadel2	===== Yow!	=====
Mt. Hood	5/8	Meager
Nugget	3/8	Maybe next year
Willamette	3/8	Ditto
Chinook	1/2	Mutant giant cones

All the vines were vigorous, but the Mt. Hood didn't grow very high despite the fact that it took a dramatic early lead over the other varieties. I suspect that I should have taken seriously the advice to thin the shoots to 2 or 3.

Picking Cascades and Chinooks is a sensory experience to say the least.

I had no pests to speak of. A few leaves with holes, and a (very) few cones that something bored through, and a couple of Japanese Beetles that were really much more interested in other things in my yard. My theory is that hop-loving pests may give a 1-year grace period before they gather in number to devastate your hop yard.

For any hop flavor profile experts who have read this far: how would you describe Chinook flavor/aroma? What other hop varieties are similar? I find it a bit odd (though not unpleasant).

Subject: Proper Sparging Technique

Hello to all,

The college where my wife works is currently between semesters and is offering a class on homebrewing during their "interim" schedule. It is being taught by a team of two instructors, one a philosophy professor/20 year homebrewer and the other a chemistry/microbiology professor. In general the class is pretty good with nightly tastings of the various beer styles, and three MANDATORY brewery tours, (like I wouldn't go!) Anyway, a question came up in class last night that I volunteered to pose to the net for "the real answer".

The chemistry professor asked why the homebrew professor didn't totally drain the mash tun before adding any sparge water. She said that we would get the best possible extraction rate if we followed this "two-part" sparge. There was no definitive answer presented so I made my offer to post to this group.

Thanks for your help in advance,
Tom

Subject: Leaky Kegs

>From: SMITH@EPVAX.MSFC.NASA.GOV (The Ice-9-man Cometh)
>Subject: Gas leaks in keg systems

> If you turn off the gas at the tank and let the system sit for a while, and you have (the inevitable) leaks, won't the beer go flat? Or do soda kegs have check valves built in?

The disconnect is a check valve but only if disconnected from the line and they too can leak. One of the most common leaks is around the large gasket of the opening and the check valve doesn't help any.

In the unlikely event that one would leave a keg sit around so long that it goes flat, one only has to repressurize the keg to drink it. On the other hand, an empty CO2 tank is real depressing, especially if it is on the first keg.

From: casagran@gdstech.grumman.com (Lou Casagrande)
Subject: Lab Grade plastics

Regarding the question of whether lab grade plastics are of equal or better quality than food grade: when I was a grad student (I'm a chemist), we used a jug that sounds just like the one described to hold our supply of deionized water. As Mark surmised, we had to keep our water free of impurities. However, we were careful not to keep it around for too long. One of the reasons has to do with acidification by absorbing carbon dioxide, obviously not a concern here. We may have been concerned about leaching of "plasticizers" into the water, too. Although I'm not a plastics chemist, my understanding is that all plastics are made with them, although some might contain less than others. My point is that your food grade fermenter was made similarly, so it's probably worth trying the lab grade jug for one batch. Just don't keep the wort in it for too long (i.e. no lagering). Also, be sure to attach a tube to the spigot in order to drain it so as not to aerate your brew.

On your second question, DO NOT use the jug for a keg or for anything that becomes pressurized. I'm sure you would come home some day to find five gallons of your latest all over your floor, besides which you would have to store the brew in it for too long, giving what plasticizers there are a chance to leech into it.

Hope this helps.

From: connell@vax.cord.edu
Subject: Alsan sterilizer

I recently received a bottle of Alsan sterilizer from the James Page Brewery (which also sells homebrewing supplies). Their catalog identified Alsan as the sanitizer they use in the brewery so I thought I'd give it a try. But when it came, I was a bit intimidated by the label. It warns of permanent eye damage etc and recommends gloves and goggles. I called the brewery, but the guy I spoke with couldn't tell me what sort of stuff this is. It doesn't smell like a chlorine and it suds a bit. Can anyone out there tell me what this stuff is and whether it is a good thing for homebrewers to use?

A second information request: I recently acquired a keggung setup (5 gal soda keg) but I'm having trouble with carbonation. I've seen several thank yous for good info on kegs appear on HBD recently so I ask for help too. I put 3 gals of hefewiezen under 20psi at 45F. What I get is tons of foam but absolutely no carbonation. When I tried aggitation at these pressures, I just got more foam but still no carbonation. Any advice will be received gratefully.

From: arf@ddswl.mcs.com (Jack Schmidling)
Subject: KETTLE MASHING

KETTLE MASHING, Part 3

BOILING THE WORT

When the wort is collected, dump the spent grain on the compost pile and rinse out the kettle. I always save a few pounds in freezer containers for beer bread. The seven gallons of wort will barely fit into the kettle for the boil so it is best to bring a smaller portion to a boil initially to avoid boilover. After evaporating some and getting the boil under contro, the rest can be added. A minimal one hour boil will evaporate about a gallon so you can play with the volumes in various ways. You can increase the gravity by more boiling or boil less and have more beer.

Add half of your hops as soon as boiling begins. Save one forth for the end and the remainder at regular intervals during the boil. If you need a suggestion, try 1.5 oz of Chinook for your first batch.

CHILLING AND FERMENTING

After the boil, the wort is cooled, either overnight or with a wort chiller if you have one. I draw it off, after chilling, a gallon at a time so that I can shake it vigorously and "glug" it into the primary to oxygenate it prior to pitching yeast.

If you hold the chilled wort in a carboy or gallon jugs, you can clean out the kettle and use it again as the primary fermenter if the lid fits well. Just boil a cup of water in it with the lid on for about 5 minutes to sterilize it.

The kettle seems to be universally available for about \$35 and the rest of the stuff can be had for under \$20, making it a pretty inexpensive system.

So, that's what kettle mashing is all about. Try it, you may like it.

js

Addenda.....

Here is the list of parts required:

1. Brass "air cock", 1/8" male pipe thread at one end, bibb spout at the other and lever on top.
2. Brass "female connector", 1/8" female pipe thread at one end, 3/8" copper tubing compression fitting at other end.

3. 6" length of 3/8" copper tubing flared at one end and bent so the end rests on bottom.

4. 4 X 6 inch screen (window, brass, copper or ss) rolled into tube and clamped to flared end of copper tube. (flare prevents it from falling off at inconvenient times)

All it takes is a 3/8" hole in your kettle, near the bottom. If you run a 1/8" pipe tap into the hole, you can screw on the air cock and it will not leak. However, as most kettles are too thin to provide enough threads for a safe and permanent fit, I modify the fittings by rethreading the aircock and connector with STRAIGHT pipe threads. This allows the connector to be screwed on to the aircock in such a way that you achieve a snug fit by compression instead of relying on the tapered pipe threads.

Aside from the brass screen, you can find this stuff at a good hardware store. I used window screen for months and see nothing wrong with it.

>dear to most of our hearts.

Below is a letter I am sending to the COPS people. Does anyone have the address for FOX?

COPS
c/o STF Productions
P.O. Box 900
Beverly Hills, CA 90213

Hello.

I am writing regarding your recent program which concerned a man getting arrested for growing marijuana. In that program, several pieces of homebrewing equipment were depicted as distilling equipment.

As I'm sure you are aware, home beer brewing is very much legal, and is a quickly growing hobby (just as microbrewed beers are the quickest growing segment of the beverage industry). Distillation, on the other hand, is a Federal crime.

I'm sure you are also aware of the current civil forfeiture laws. Under these laws, anyone possessing any equipment similar to distillation equipment can have all of their property seized, without being charged for a crime: the police simply need to show "just cause" (i.e., an "informant"). By blurring the line between perfectly legal home beer making and home distillation, you have done a *great* disservice to home brewers. You have greatly increased the possibility of "midnight raids" and civil forfeiture against law-abiding people.

As you may guess, I am a homebrewer. In my experience (I communicate with hundreds of other homebrewers), homebrewers are beer connoisseurs and professional people. They are not beer-guzzling yokels. By connecting homebrewers with bootleggers, you have insulted and endangered a large number of your viewers and others. I belong to a computer mailing list on the worldwide Internet computer network. This mailing list consists of hundreds of professional people (mostly computer engineers). There has been a lot of fear expressed on the list since your show aired. People worry about a disgruntled neighbor telling the police that they are distilling, and then having their house raided by armed men at night. This is not a pleasant prospect, to say the least. Many have expressed the opinion that they should now keep their brewing secret, to avoid this possibility.

I strongly urge you to air a segment on an upcoming show to clear up this issue. You should make it clear that home beer making is perfectly legal. You should also make it clear that the equipment that was shown being seized on your program was not, in fact, distillation equipment, but homebrewing equipment, and that while much homebrewing equipment can be used for distilling, that it is the *use*

of distilling equipment that is illegal, and not the possession of something that *looks* like distilling equipment.

If you do not air such a segment, you are further endangering a large and growing population of law-abiding people.

Subject: Sediment in Carboy

First, thanks to all of you who responded to my inquiry of mail order sources of brewing supplies. I've got ten names on the list in just a few days.

Every supplier that I have contacted so far has said they would send a catalog.

You home brewers seem to be an OK crew. If anyone is interested in getting the compiled list, drop me a line. Not having purchased any reference books yet,

I have a couple of questions which are probably easily answered . . .

I eagerly await my first batch to stop fermenting so I can bottle and try it. Lately in the HBD there has been talk of culturing one's own yeast.

Not

that I as a rank amateur want to attempt anything as exotic as that, but the

subject brought a couple of questions to mind regarding the sediment in my carboy.

First question: Is this sediment (trube, correct?) the source of the yeast culture base, or is the sediment which will settle in the bottles after secondary fermentation the source? Why use one and not the other?

As I anticipate being able to bottle the batch somewhere between Monday and Thursday, should I save this precipitate for anything? I recall when one of my

older sisters returned from school in Britain many years ago, she introduced the

rest of the family to a product called VEGEMITE. The container stated that it

was a by-product of the brewing process, but I forget if it was a grain or a yeast based product.

At any rate, it was like a pate or paste which you spread on toast or crackers. Malty & salty, and you couldn't eat too much in a single sitting/snack. A few years ago I was stationed in Huntsville, Al, and there was

a real-life Australian restaurant in town called The Down Under. As well as

Australian brews and wines, kangaroo steaks and other exotics, they sold at the

cash register a similar product called MARMITE. Again the container stated it

was a by-product of the brewing process (grain ? yeast ? I can't remember).

My sister (now working at Univ. GA) has always told me to keep an "eye out"

for it, and my wife likes the stuff too, but we never see it in any stores.

Just as a matter of curiosity, does anyone out there know exactly what these

products are made from and how? Would it be possible/viable to make
one's own
"HOMEBREWMITT" ? How?

Subject: Re: cold plate question

Mike McNally writes:

>Many HBD's ago, Jack S. described a wonderful-sounding contraption called a "cold plate", I think. I have the impression that the thing is some sort of in-line rapid-chilling device that chills beer from a room-temperature pressurized keg on the way to the glass. Is that correct? If so, can these things be bought for not much money (i.e., less than the cost of a spare fridge to keep the kegs in)?

Superior Products at (800)328 9800 carries the cold plates. A single product plate costs \$37. I can not yet comment on how they work since mine hasn't arrived yet, but I'll be able to do so in a week or two.

I've already got the spare fridge, but I can't ferment ales and keep kegs at drinking temp at the same time so I decided to go ahead and get the plate for use when the fridge is being used for fermenting.

Incidentally, it was Jack who turned me on to Superior Products.

Subject: Germany suggestions?

Hello all,

I've found out I'll be travelling to Germany shortly, and was wondering if you might be willing to offer suggestions on places to go & beers to try?

I'll be over there from 1/18 until 1/25, and will be flying into Munich, then going north, staying about 1/2 way between Bamberg and Regensburg. (A little town named Vilseck (sp?).) We'll be staying with a friend, and will have a rental car, so I'm interested in suggestions around Bamberg, Nuremberg, Regensburg and Munich. I'd read in M.J.'s book about a monestary near Munich (Andechs monastery?); is it as alluring as he makes it sound? We'll also be (hopefully) taking a day trip to Pilzen & Prague, so suggestions for there are also helpful.

I'd posted about a year ago for my friend who was in Germany then; some of the suggestions I got then were:

Rauchbier - This is availble in the spring
Any beer ending in -ator. Kulminator, Pirminator are two
If you're into the ales, try an Alt beir.
Eisbock. Kick-butt thick like molasses heavy duty beer. Mondo alcohol,
Pilsners, especially Czech BudVar
Hefe-weizen dunkeles & helles

I'm not terribly thrilled with wheat beers, especially in the winter. I lean more towards ales generally. I've had one alt beer (Schlosser Alt) and loved it; should I have any problem finding it, or am I in the wrong area?

Lastly, I see the literature mentions limit of 2 l. per person. Is that a hard limit, or do I just have to declare it if I bring more than that back? I've gotten conflicting answers from people on this one.

Any/all suggestions welcome. PLEASE email them to me (also) if you decide to post back here, I don't want to miss a scrap of info! :-)

Thanks in advance,
David Arnold

Subject: re: COPS

Things are actually a little bit worse than Micah puts them. <shudder>

Property siezures place the burden of proof on the owner to PROVE that the seized items were not used in the commission of a crime. Since possession of some things is itself a criminal offense, a vehicle can be contributing to the possession of anything found inside of it.

As a former distiller, I would point out that the essential element of a still is the vaportight still-head, not the condensor. A copper tubing coil is not sufficient evidence of a still, without some other supporting parts, such as a head, slobber-box etc. So if all that poor guy in Tacoma had was a wort chiller, he should get that charge dropped.

What's the AHA doing about this travesty? I would think that Charlie P. has an interest in defending his good name, never mind helping out all of us dues-paying members.

Paul.

Subject: Our image as brewers

Folks, I am concerned about the image that we project to new readers of r.c.b and the Digest.

As devotees of this noble passion, we naturally want to inspire those who are new to brewing, and to imbue them with our enthusiasm for this most salutary of crafts. Unfortunately, I am afraid we may fall short of this aim.

Yes, I'm talking about the fact that two of the regular posters to these forums have the usernames "gak" and "arf". Are these the words that we want others to associate with homebrewing and homebrewed beer? I am sure you will agree that they aren't very appealing. "Hey, would you like to try some of my homebrew?..." "Gak!! Arf!"

Who knows how many times a reader might be exposed to these words in just a single issue of the HBD? All the worse if they don't actually read the 'From:' header fields, because then these unwholesome sounds are transmitted *subliminally*. And who knows how many other crude and obnoxious usernames have escaped my notice?

Just something to think about.

Happy brewing!

Unfortunately, when the liquid is drained entirely from the grains,
gravity compacts the grain bed, leading to stuck sparges. Keeping the
water leve above the grain bed helps keep the grain bed loose, and
facilitates the circulation of sparge water while preserving the
filtering properties of an undisturbed grain bed.

Indeed, Some brewers sparge this way (Pierre Roujette (sp?) for one, if
you've read his book.) Now that my Zapap lauter is on its final leg, I
just may adopt the method if it works well with the picinic cooler/
slotted
copper pipe manifold style lauter which will replace it (apparently,
such a sparge system is less prone to "sticking" than a Zapap lauter)

Subject: re:kettle mashing pt 3

In the last digest:
<From: arf@ddsw1.mcs.com (Jack Schmidling)
<Subject: KETTLE MASHING
<Add half of your hops as soon as boiling begins. Save one
<forth for the end and the remainder at regular intervals
<during the boil.

This is not recommended for infusion mashing. The wort should be boiled a minimum of 30 minutes prior to the first hopping. This is due to the need to break down and make floc large proteins that carry over into the kettle. After the 20-30 minutes of boiling, there will be large amounts of flocs that can be skimmed off the top. Then add the first hops for a minimum boil of 60 minutes, adding finishing hop as desired. If you hop immediately upon boiling you will quickly coat the hops surface with the proteins thereby considerably reducing the hop efficiency. If you don't care about efficiency, I guess it doesn't matter as long as you account for the reduced efficiency. 1.5 oz of chinook is a lot of hops so I guess this works for Jack. Also, if you are adding hops at 30 min. to end of boil, these will contribute significantly to the overall IBUs, so this should be taken into account.

From: Jon Binkley <binkley@beagle.Colorado.EDU>
Subject: Lab Grade vs. Food Grade

I agree with Lou Casagrande that the Lab Grade plasticware will probably be okay to use for brewing. However, this does not apply for chemicals or additives. Use Food Grade or USP (pharmaceutical) Grade chemicals ONLY!! Other grades of chemicals, e.g. reagent grade, contain significant (read above EPA and FDA limits) of various nasties such as lead and arsenic. So stick to food grade, at least for additives.

Subject: RE: sparge water temp, precrushed grain

Hi All,

In HBD #1052, Mike Tavis writes:

>I said, "I never take that temperature. I just make sure that the
>sparge water is about 168-170."

>So what do you guys think? Should my sparge water temperature depend
>on the size of my grain bed or do I need to go back to the drawing
>board?

IMHO, maintaining the temperature of the sparge water at 165F-170F
is less important than maintaining the temperature at the surface of
the grain bed at that level.

Many brewers use some means of diffusing sparge water as it's added
to the lauter tun. I use a Zapap system with a collander sitting on
top to diffuse the sparge water I add, which then falls 2-3 inches
before striking the surface of the liquid covering the grain bed. It
has been well reported in this forum that water that is diffused then
passed through air in this manner cools rapidly. I sparge with
water at ~190F, the temperature at the surface of the grain bed is
~165F, the temperature of the runoff ~150F, and these numbers are
consistent with grain bills that vary between 9-13 pounds of grain.
Your mileage may vary Mike, but try heating your sparge water enough to
get the grain bed to 165F-170F.

Also in HBD #1052, John Rogers writes:

>I would like to start mashing. I also would like to save
>some money and buy the grain in bulk (55 pound sack). Since I do
>not own a grinder I would be interested in information on storing
>crushed grain.

>What is the shelf life of crushed malt? (i.e what age /
>storage conditions will affect mash results, flavor or any other
>important characteristics?

I wouldn't recommend this at all. Once malt has been crushed, it
deteriorates quickly. There was a post on r.c.b a while back, wherein
someone related a conversation with the headbrewer from a well known
microbrewery. This headbrewer stated that if it was necessary to grind
the malt at night before adding it to the mash tun the next morning, he
increased the amount of the base malt in the grain bill by 10%. This was
done to compensate for the extraction lost by the grain sitting around
pre-crushed *overnight*.

>Does the benefit of crushing your own grain outweigh the
>possible negative affect of pulverizing (rather than grinding)
>the grain by using a "non-optimized" home crusher?

Yes! It's very important to get the crush right! Grinding it too
coarse
results in low extraction, grinding it too fine (and thus pulverizing the
husks, which sounds like what you're planning to do) results in poor

filtering and a hazy finished product.

Consider buying a mill. Whatever money you spend, you'll eventually recover it in the savings from bulk grain purchases. I buy 55 pound sacks, and the cost per pound is less than half of the cost of a pound of pre-crushed grain. By the second sack, I'd already saved more than what my mill cost.

Cheers,
Jim

>Yes, I'm talking about the fact that two of the regular posters to
>these forums have the usernames "gak" and "arf". Are these the words
>that we want others to associate with homebrewing and homebrewed beer?

Mark certainly is right, this isn't good. But there are so many other
homebrewing words with *good* connotations, like "sparge" and
"counterflow
wort chiller". In fact, I've had this idea for a while to write a sort
of "call to homebrewing":

Be a homebrewer!

Learn the secrets of good head.

Rack off as often as you like without being embarrassed.

Be able to say words like "sparge" and "fuggles" with a straight face.

Amaze your friends and inebriate your enemies (or the other way around)

...

If that appeal doesn't attract new brewers, I don't know what will.

Subject: flame off, OK?

Yesterday I posted an article about the unappealing sounds of the names "arf" and "gak".

If you have read that article and are getting ready to send me some flamage over it, please stop right now and read this carefully:

IT...WAS...A...JOKE !!!

I've gotten a couple of flames already -- incidentally none from gak or js (a.k.a "arf", I know what it stands for, thank you kindly). I take full responsibility, I should have included at least one ":-)" for those who forgot to take their humor pill. Clearly, the humor wasn't as obvious as I intended, and some people actually thought I was serious, and took me to the woodshed for being uptight about other people's usernames. I just thought we could use a little injection of humor, that's all.

From: Bruce Mueller <mueller@sdd.hp.com>
Subject: Plasticizers

Lou Casagrande was concerned about lab grade plastics for brewing. Three issues he was concerned with were:

>by absorbing carbon dioxide ...
>leaching of "plasticizers"
>DO NOT use the jug for a keg or for anything that becomes pressurized.

I am a chemist and agree 100% with the first, especially in regards to HDPE. This plastic is notorious for its permeability to CO2. However, I do not agree with the second or third.

In the second case, Lou went on to say that all plastics contain plasticizers. Not true. And in the case of lab grade plastics, plasticizer migration is unacceptable. From a safety standpoint, a few years ago Nalgene (a big manufacturer of lab plastics) had a problem with bottles cracking after long-term exposure to certain chemicals. I believe that the plasticizer they had used migrated out (either into the solution or the surrounding air), stiffening the bottle. They recalled these bottles. Well, reformulation must have occurred to alleviate this. If a plasticizer is still used, it must be much less likely to migrate. Thus, unless used for long-term storage, virtually none will be leached out. In fact, I would go so far as to say that if washed well in hot, detergent-laden water before use (a good practice anyways to remove any mold release from the outside, easing labeling), even long-term (e.g. 3 months) storage should not be a problem. In this case, I would wash between each long-term period to remove any plasticizer which can migrate from the inside surface of the bottle.

Third, these bottles tend to hold pressure reasonably well. I have used them numerous times to ship stuff which will go in an aircraft's hold, which is not well pressurized. They don't leak! Now, at higher pressures (20 psi?) the worst which would happen would likely be a slow leak at the cap (and some through the walls--remember the CO2 permeability), not the catastrophic case Lou predicts. Yes, I would definitely place the pressurized container where catastrophic failure would not be disastrous in other ways just to be safe. I'll step down from the soap box now.

Subject: Carbonation, Yield, Fillers

>From: mcnally@wsl.dec.com

>Many HBD's ago, Jack S. described a wonderful-sounding contraption called a "cold plate", I think. I have the impression that the thing is some sort of in-line rapid-chilling device that chills beer from a room-temperature pressurized keg on the way to the glass. Is that correct?

Right on!

>If so, can these things be bought for not much money (i.e., less than the cost of a spare fridge to keep the kegs in)?

They start at \$37 for a single product unit and are available with up to four pathways for dispensing 4 different products simultaneously.

They are available from Superior Products. Call (800) 328 9800 for catalog or to place an order. They really are the Cat's Meow.

>From: bliss@csrd.uiuc.edu (Brian Bliss)

>First of all, you need to get the beer cold before you agitate it,

That is good advice in general but I would not want to have those without fridges to think that it is absolutely necessary. Because I use the above cold plate for dispensing and counter-pressure bottling, I do not ever refrigerate my kegs. I force carbonate at room temperature which ranges from near 80F in Summer to as low as 55F in Winter. I use the same procedure regardless of the temperature.

I start at 50 lbs and gradually reduce the pressure to around 25 lbs after the initial rush while shaking. I lower the pressure each time the drop in pressure slows down while shaking. With the cold plate, the pressure can be left at 25 lbs for normal foam free dispensing. The very narrow SS tubing in the cold plate simulates a very long feed line so there is a substantial pressure differential from keg to tap.

You can dispense at just about any pressure as long as the keg is given enough time to equilibrate. Unlike most systems, foam is usually cured by INCREASING the pressure and the post chilling is death on foam.

>From: mtavis@gemini.hyperdesk.com (Mike Tavis)

> I've been very happy with the results so far, but I have noticed a disturbing trend -- my extract rates are plummeting with each batch... After many different discussions, one of my brewing buddies asked, "Has the

temperature of the wort coming out of the lauter tun been the same?"

>I said, "I never take that temperature. I just make sure that the sparge water is about 168-170."

I think your friend may have a clue and most brewers seem to be contented if the temp of the sparge water on target. I have written many times on the importance of knowing what the mash temperature actually is and not relying on the temp of the sparge water. I find that even with boiling water going in at the top, the average temperature of the mash is around 150F. This assumes that you maintain an inch or so of water over the top of the grain bed. Take a thermometer and poke it around. I guarantee you will become a believer.

Assuming that you had complete conversion according to an iodine test before you started sparging, the fact that the yield was a function of grain quantity would indicate inefficient sparging and temp is one place to look. The other would be in the method of sparging. Make sure to maintain at least an inch of water over the grain and stir or "cut" the mash several times during the process. Use a long knife to cut through it radially and circumferentially while trying not to disturb the area near the false bottom or screen. I stir the mash thoroughly after all the sparge water is in and let it settle again for a last run. The gravity of this last run is 10 to 20 points above what was coming out before stirring.

>From: lager!wtm@hellgate.utah.edu (Tom McCollough)

> I am in the market for a counter-pressure bottle filler. Before constructing my own, as it seems many HBDers have done, I would like to find out about commercially available fillers.

In my experience, it seems that all the producers use a single probe for CO2 and beer. I am not sure how this can work but I guess it does. The one I made has a two hole stopper with separate gas and beer lines. One goes to the bottom and the other ends at the stopper. Nothing goes out the gas line till the bottle is completely full. Perhaps someone can explain how the single probe filler works and why people insist on making them that way.

>From: mark@verdix.com

>Yes, I'm talking about the fact that two of the regular posters to these forums have the usernames "gak" and "arf". Are these the words that we want others to associate with homebrewing and homebrewed beer? I am sure you will agree that they aren't very appealing. "Hey, would you like to try some of my homebrew?..." "Gak!! Arf!"

Surely, you jest? Probably not. Well, be comforted by the fact that things

could be worse. ARF stands for the Amateur Radio Forum and was at one point in my life, more important than home brewing. Your comfort should come from the fact that there is also a Better Amateur Radio Forum out there and the host of BARF is not interested in homebrewing.

Subject: Belgian Malts

Chris writes (in his description of his 1-gallon test batches):

```
> Recipe 3      Recipe 4      Recipe 5
> -----      -----      -----
>Belgian Pale Malt      2 #      1.5 #      1.5 #
>Belgian Caravienne      1 #
>Belgian Aromatic      1 #
>Cascades (boil)1/8 oz 1/8 oz 1/8 oz
>Cascades (aroma) ~1/16 oz ~1/16 oz ~1/16 oz
>Irish Moss ~1/4 tsp ~1/4 tsp ~1/4 tsp
```

I'd just like to point out that Recipe 4 equates to a 5-gallon batch with 5 lbs of crystal malt in it. The DeWolf-Cosyns Belgian malts that begin with "Cara" are caramel or crystal malts. In general the DeWolf-Cosyns malts fall into four categories (I'm not sure, however, who created these categories). The comments are based upon comments provided by DeWolf-Cosyns and the degrees Lovibond are the actual results of the first test of the malts (also provided by DW-C). Although I don't think that they said anything about it, I assume that if Aromatic (at 25.7L) will convert itself (i.e. can be mashed alone), then surely their Munich should also. Note that Roasted Malt is basically Black Patent.

BASE MALTS deg L comment
Pilsner 1.83
Pale Malt 3.21
Wheat 1.75

COLOR MALTS
Munich 7.83
Aromatic 25.7 will convert itself

CRYSTAL MALTS
Cara-Pils 7.87
Cara-Munich 21.65
Cara-Vienne 77.5
Special B 221

ROASTED MALTS
Biscuit 22.5 probably not-enzymatic, i.e. won't convert itself
Chocolate 497.5
Roasted Barley 557.5
Roasted Malt 601

Subject: hose couplers

I have an idea. Have you seen these quick-disconnect gadgets for hose connectors? I think you can find them in the garden department. Anyway, you can install them on your sprinklers, spray nozzle, hose bib, &c. Each coupler has a threaded male and female half which fit together with an O-ring seal. From then on you just snap on, snap off.

When I get a few extra bucks, I'm going to pick a few up and install them on my faucet adaptor, bottle/carboy washer and wort chiller. Then I can just snap and unsnap things instead of screwing and unscrewing. It seems like I'm always screwing my bottle washer on for something and then realizing I need water, or something else like that.

You could also get one of those Y-connector things with a valve on either arm -- then you could always draw water even if something is hooked up to the faucet. Another possibility would be to get one of those kitchen spray nozzles on the end of a length of vinyl hose. That might come in handy.

Subject: Pilsener head

In HBD #1053 chuckm asks:

>My question is..... Has anyone out there been able to brew a pilsener
>with such a dense head. I have read Miller's book on pilsener,
>but I don't
>remember it discussing this point very much.
>Any feedback will be welcome.

Just a method that seems to work ok for me:

(Using a 2-step decoction mash)

Add 5 to 10 % of unmalted barley at the beginning of the
alpha-amylase rest (around 70C).

The reason for this is that unmalted barley contains a lot of
proteines, while the protelase enzyme is no longer effective at this
temperature, so lot of large proteines will end up in your wort.

Note that this is standard practice in many German breweries

(only, since they are not allowed to use unmalted grains, they use
'legally malted' barley or cheat-:)malt)

You will need to cold-condition your beer as you are likely to get
some initial chill-haze using this method, but that's what I do for
almost every beer anyway.

Hope this may contribute to solving your head troubles.

Subject: Lab grade vs. Food grade

From: Jon Binkley <binkley@beagle.Colorado.EDU>
writes-

>probably be okay to use for brewing. However, this does not
>apply for chemicals or additives. Use Food Grade or USP (pharmaceutical)
>Grade chemicals ONLY!! Other grades of chemicals, e.g. reagent grade,
>contain significant (read above EPA and FDA limits) of various
>nasties such as lead and arsenic. So stick to food grade, at
>least for additives.

I am not sure if ignorance is the cause of the sentiments here, but the poster seems to have a rather deluded notion about the usefulness of the FDA and EPA, apart from their own self preservation, and defintiely a very poor idea of toxicology. I use regular lab grade phosphoric acid for pH control, and need very little of it. The 0.1 ppm arsenic and .001% heavy metals as lead really have me shaking in my boots!!! The amount I add probably has negligible influence on the level of these elements naturally occuring in my water anyway. Actually, the limits for these contaminants in food grade phosphoric acid (from Food Chemicals Codex. 3rd ed.) are not more than 3 ppm arsenic, not more than 10 ppm HM as lead and not more than 10 ppm flouride. Flouride wasn't even listed, but when chloride was 1ppm, it is safe to assume flouride is negligibile.

Lab chemicals are very pure. I suspect that the 'sacred' USP grade phosphoric acid used in tons by Coca-Cola has similar heavy metals profile as this, but it is hardly worth Fisher's while paying the FDA megabucks to have their chemicals approved for food use, so they display not for food use on their containers to cover their legal behind.

As homebrewers we produce huge quantities of poison, but we don't consume it all at once. Fearing minor quantities of heavy metals is irrational. If I broke a mercury thermometer in a batch, I'd fish out the bead and brew on. The quantitie of mercury that could dissolve would be negligible and unless you consume mercury everyday you have nothing to fear. If a child eats mercury from a thermometer, you have little to fear. The bulk of mercury will pass straight through the child. However if the child eats a bead of mercury every day, then you would have a problem. I suggest anyone with an irrational fear of very small quantities of toxins read the article on it in the Oct/Nov 92 issue of Garbage magazine.

From: casagran@gdstech.grumman.com (Lou Casagrande)
Subject: Lab grade vs. Food grade again

Bruce Mueller's reply to my posting seems to have more authority behind it than my posting did--as I said, I'm not a plastic chemist, and he seems to have more experience than I. I also had never tried pressurizing these jugs, but other plastics I've used have buckled under pressure. Since Bruce has pressurized them, it sounds reasonable to use them as kegs. To set the record straight, though, I was *not* concerned about CO2 leaching *into* the brew--we produce copious amounts of that gas during fermentation. I don't know about it leaching *out* however--probably not a big concern.

Lou Casagrande

From: grumpy!cr@uunet.UU.NET (C.R. Saikley)
Subject: Diminishing Yields

In a recent Digest, Mike Tavis says:

>>my extract rates are plummeting with each batch. My first
>>batch yielded 29 pts/lb/gal (a number I never expected to get the
>>first time). My second batch dropped to 22 pts/lb/gal and my third
>>batch was a miserable 18 pts/lb/gal.

[snip]

>>All three of these batches had different grains bills,

[snip, snip]

>>He said, "Well depending on the size of the grain bed, the sparge
>>water will be lowered and if it gets too low it won't be effective at
>>rinsing the sugars from the grain."

>>I said. "That makes some sense because in each successive batch I have
>>used more grain -- specifically, the first batch used 8 lbs, the
>>second batch 10 lbs, and the third batch 12.5 lbs."

To which Jack responds:

>I think your friend may have a clue and most brewers seem to be
contented if
>the temp of the sparge water on target. I have written many times on
the
>importance of knowing what the mash temperature actually is an not
relying on
>the temp of the sparge water. I find that even with boiling water going
in
>at the top, the average temperature of the mash is around 150F.

Some years back, I began measuring temperature profiles thru the mash
while
sparging. Like Jack, I found that my water had to be much hotter than 168
to
get the mash up to that temp. This makes sense for at least two reasons :

1) Losses in the system, especially if your sparge water is sprayed over
the
grain bed.

2) Reaching equilibrium temp. The grain bed is below the optimum temp,
thus
the water must be higher than optimum temp for the grain/water mixture to
equilibrate at optimum temp.

The effects of point #2 can be minimized by mashing out.
Note also that the temperature difference between grain bed and sparge
water
will be reduced as the sparge proceeds (ie the mash heats up). With my
system,
I found that sparging with boiling water was fine at first, but
eventually the
temp at the top of the bed got up to 185! OUCH!

Getting back to Mike's problem, increasing the amount of grains used increases the thermal mass of the mash. Thus the temp of the sparge water would have to be raised to achieve the same equilibrium temp, assuming the same amount of water is added. This is one factor in Mike's diminishing yields.

Jack also says,

>Assuming that you had complete conversion according to an iodine test before
>you started sparging, the fact that the yield was a function of grain
>quantity would indicate inefficient sparging and temp is one place to look.

Here I disagree. Yield is necessarily a function of grain quantity. Higher gravity beers suffer from reduced yields for fairly straightforward reasons. The extreme example being a barley wine that is not sparged at all. There's so much sugar left in the grains that some even make a second beer out of the second runnings.

Assuming you're consistent, one pound of grain will yield x amount of sugar when sparged with y amount of water. If sparged with y/2 per pound or 2y per pound, you will get reduced or increased yields respectively (to a point). If you use 12 pounds of grain instead of 8 for a 5 gallon batch, the ratio of sparge water to grain is reduced, and the yield is reduced accordingly. This is a second factor in Mike's results.

As Jack pointed out, getting around the first factor is pretty simple : raise the temp of your sparge water. Getting around the second problem is more of a hassle. You would sparge with more water, and collect more (weaker) wort. Then boil the *%\$# out of it to reduce the volume. Some commercial breweries do this. In Belgium there are brewers who boil for up to 6 hours! Personally, I'd rather accept lower yields than boil the day away.

Sorry for the length.

Happy Brewing,
CR

William Seliger asked about breweries in Jamaica. I don't know the details on the brewery, but I can say there is some very fine island-brewed beer. I believe the brewer is Desnoes and Geddes in Kingston. The products are Red Stripe Lager and Dragon Stout. Red Stripe is O.K. (it has a full, if not refined, taste - it's fun to watch the frat boys' sour faces when they first taste it!), but the real treat is Dragon. It's a very enjoyable, extra malty, super potent brew that I couldn't (and still can't) get enough of. I strongly encourage you to seek it out (it won't be hard to find.) Oh, and according to local lore, Dragon has one other important quality. When a local saw me with a bottle in hand, he said while pointing to my girlfriend: "Dragon! Good for you, mon. Makes you do your homework!" ;-) ;-) nudge, nudge.

Randy

P.S. Are there any HBDers out there in the southwestern Virginia (i. e. Virginia Tech) area? I just moved here a few months ago and am feeling isolated from the good beer experience.

You can get couplers like this, but made to screw onto a kitchen
faucet. They are often used to connect portable dishwashers.

I have my (low-flow, on-off lever) aerator, Jet bottle washer, and
hose all connected to these fittings. When I got the fittings, they
tended to pop off if asked to withstand full water pressure (i.e.,
faucet turned full on, aerator valve turned off). Since they are
solid brass, and put together with spring steel C clips, I took them
apart and added shims to move the locking balls outward to facilitate
tighter locking. I've had no problems since.

Highly recommended.

Subject: Re: COLD PLATES leave me cold.....

Cold plates are the most amazing things I've ever seen for serving ice cold beer from warm kegs in the middle of a Chicago August. That's what they're designed for.

BEWARE: They are not a great alternative to proper longterm/everyday serving and refrigeration of precious homebrew. At recent 'all draft' beer tasting/competitions here in The Windy City, we've had the darned things freeze up on us and it seems that the only temperature the beer comes out at is 'ICE COLD'.

Consider your uses! Think about your long term needs. Shop around at used appliance places, ask them to call when the good ones come in. Refrigerators are our friends, and a good one with a tap or three on the outside IS a great way to serve your homebrew. It's always right where you put it, and it keeps your beer from spoiling!

#1 reason not to use cold plates:
Much too difficult to decorate with refrigerator magnets.

I accept the recommendation but what does it have to do with the method of mashing?

>The wort should be boiled a minimum of 30 minutes prior to the first hopping. This is due to the need to break down and make floc large proteins that carry over into the kettle.

Don't understand this as it is already in the kettle if one is boiling.

> After the 20-30 minutes of boiling, there will be large amounts of flocs that can be skimmed off the top. Then add the first hops for a minimum boil of 60 minutes, adding finishing hop as desired. If you hop immediately upon boiling you will quickly coat the hops surface with the proteins thereby considerably reducing the hop efficiency.

This makes sense and as I do not usually skim because most of the hops is in the foam, it sounds like a good idea just on general principles. However, as my wort is entering the kettle continuously from the lauter tun, it is not obvious when to start the clock.

> 1.5 oz of chinook is a lot of hops so I guess this works for Jack.

It is a bit much even for my 7 gallon batches and I have reduced it to 1.0. I thought I changed that in the article. Thanks for the pointer.

>From: mark@verdix.com (Mark Lundquist)

>Have you seen these quick-disconnect gadgets for hose connectors? I think you can find them in the garden department. Anyway, you can install them on your sprinklers, spray nozzle, hose bib, &c. Each coupler has a threaded male and female half which fit together with an O-ring seal. From then on you just snap on, snap off.

Great idea and it just proves that you are almost as smart as me because I did all that about a month ago. However, aside from a connection to the sink, the garden size is not convenient for homebrew size hoses.

You can however, get similar type fittings that are made for plastic and copper tubing of all sizes. I have them on my wort chiller, bottle filler, lauter to kettle line and everywhere else I could think of. McMaster-Carr carries a complete line of them. (800) 833 0300

Subject: re: boiling,skimming and hopping

In the last digest Jack asked for some clarifications of my comments:

from: Jim Busch <busch@daacdev1.stx.com>
<From: arf@ddsw1.mcs.com (Jack Schmidling)
<Add half of your hops as soon as boiling begins. Save one
<forth for the end and the remainder at regular intervals
<during the boil.

>This is not recommended for infusion mashing.

<I accept the recommendation but what does it have to do with the method of
<mashing?

A decoction mash will break down the larger proteins and gums into easier to handle products. These substances will be less detrimental to the brewing process, and will be less capable of coating the hops.

>The wort should be boiled a minimum of 30 minutes prior to the first hopping. This is due to the need to break down and make floc large proteins that carry over into the kettle.

<Don't understand this as it is already in the kettle if one is boiling.

You are doing the right thing to begin boiling the wort as soon as possible. In my process, the sweet wort will begin to boil just as I am ready to add more runoff. This will of course, cool the wort to below boiling. This procedure repeats until the kettle is full. Each time the wort comes to a boil, more of the proteins will floc and coalesce. You can skim these off with a standard strainer. Once the kettle is full and brought to a boil, it is still a good idea to boil 30 minutes prior to the first hopping. You can reduce this time if you have been boiling and straining during the kettle filling process. If you employ a decoction mash, all of this is less important. The breakdown of the large molecular weight proteins that occur during a decoction mash is also why this technique is important for trouble free lautering of wheat beers.

From: orgasm!davevi@uunet.UU.NET (David Van Iderstine)
Subject: Cold Plates

I've had some experience with these things, which was not good. I made the mistake of adding ice over the cold plate before I had beer running through it. It seems that ice crystals formed *inside* the plate's tubes, with the result being incredibly foamy beer at the tap that did not go away for days (it was a looong party! :-). The advise I was given (I'm afraid much too late!) was to get the beer running first, then chill the plate down.

From: ryan%phmms0.mms.smithkline.com@smithkline.com (Dominic Ryan)

Subject: Sparging with initial drain off.

I would like to again compare sparging with chromatography where there is a tradeoff between speed and efficiency. If one uses a very tightly packed support for the column (i.e. the grain bed) then one will use less 'sparge water' and get better efficiency. However the tradeoff is that it can take a *lot* longer unless forced under pressure.

Another factor that lowers efficiency and ends up requiring significantly more liquid is letting the bed drain, even partially. The problem is that

air channels develop in the bed and these can take a lot of 'sparging' to close up. This will sometimes more than double the amount of liquid required to get all the desired material out of the bed. I would therefore not expect draining the wort off of the bed initially to be a good thing. Getting as tight a bed as you can afford to spend time sparging will get you the best sparging efficiency with the least amount of sparge water used and therefore the minimum in husk astringency.

As others have pointed out keeping the grain bed hot is essential, this will really improve flow through the bed and solubility of the sugars in the water. Getting the grain bed heated up properly should be happening with mashout at 75-80oC and then dumping it all into the sparge bucket. I find that I must keep the initial runoff at least that hot if it is to be recirculated, after all that is the sparge 'water' initially. I also do not sprinkle water on top of the bed. I pour the water onto the inside of

a big spoon as I move the spoon around the top of the bed. I do this with

almost no liquid on top of the bed until there is really no extractable sugar left at the top of the bed. After that I fill up the top of the sparge bucket to the lip with water only a little hotter than ideal, say 80oC. Others have pointed out correctly that sprinkled water will cool significantly. Rather than heating to boiling and guessing at the temperature of the resulting sprinkle just pour carefully and you will have no trouble. Finally, I keep the bottom of the sparge bucket in a hot

water bath. That seems to have the greatest effect on sparge speed, presumably because the bottom would otherwise be cooling fastest.

There can be too much of a good thing with a tight grain bed, my recent 5 hr sparge was just a little too tight for liking by about 2:30AM...:-) That one was my own fault though.

From: ml4051@mwvm.mitre.org (John DeCarlo)  
Subject: Misc. Stuff

1. Temperature of water as it goes into the grain.

Basically speaking, the temperature of the water on the stove doesn't make a bit of difference--it is the temperature it is when it goes into the grain. So if you carefully pour or siphon water in, it won't change temperature too much. If you splash it through the air, into a bowl, where it then splashes through the air *\*again\**, before hitting the grain, it wouldn't surprise me too much to find that the temperature of the water entering the grain has gone from 212F on the stove to 180F or less.

The point being that different methods *\*can\** produce different apparent results.

2. Someone recommended I start skimming as soon as appreciably thick foam started forming on the boiling wort, *\*then\** add the hops. I have switched to this method and it seems to result in better hop utilization and much reduced opportunity for boil over (I no longer have to *\*stop\** a boil-over in progress). Caveat-I haven't measured anything here, especially not hop utilization.

Subject: lab grade again

Ulick Spaford apparently knows exactly how much heavy metals you can consume safely (knows more about it than the Evil Government Agents who are out to subvert and control our lives, anyway). This is fine for him, and for anyone else willing to put in the years of research necessary to find out such information.

For myself, I'm still going to stick to the food grade stuff, and stick to my recommendation that homebrewers not motivated enough to be as much an expert on the subject as Ulick obviously is to also avoid reagent and lesser grade chemicals as food additives.

Ciao,  
Jon Binkley

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: Diminishing yields

In HBD #1052, Mike Travis was disappointed that his extract rates were steadily dropping for his first three all-grain batches. He himself brought up the issue of sparge temp, so all the discussion has been about that.

However, I usually make batches using anywhere from 8-10 lbs of grain, and I don't see any difference in extract rate even though I sparge with the same temp water. I don't think that 2 lbs of grain will create enough difference in the sparge efficiency (all other variables being the same) to cause a 7 pts/lb/gal decrease.

I think James Dipalma got closer when he addressed Mike's extract rate problem and someone else's question about storing pre-crushed grain in the same post (HBD #1053). He mentioned the anecdote that some brewer would increase the grain bill 10% if the crushed malt had to sit even overnight.

That 10% seems a little extreme. However, if Mike bought a large quantity of pre-crushed malt and used it to make his three batches several weeks apart, it might degrade enough to account for the loss in extract.

Also, make sure your later grain bills didn't include disproportionately high percentages of specialty malts like Munich or crystal. If you don't have enough pale malt, you won't get enough enzymatic activity to get a full conversion. (Try the iodine test next time if you're not sure -- a drop of iodine in a bit of mash liquid will turn purple/black if there are still unconverted starches.)

Just a couple more thoughts on the problem.

Subject: ZYMURGY IMPROVEMENTS

Howdy 'all,

I thought I'd drop in to express some encouragement to some of you who have seemed pretty dissatisfied with zymurgy as of late. I haven't caught the whole thread, in fact I only came across one comment from A. Dietz from Morristown, NJ, but I'm assuming (maybe I'm assuming a bit too much, if so let me know) that there was considerable discussion about dissatisfaction regarding the contents of the magazine.

I was thinking about this and we have really benefitted in the past from people like yourselves when you have directed your dissatisfaction to us directly, so we can consider doing something about it. But perhaps much more importantly, we know there are a lot of people like A Dietz who know far more than the average homebrewer and could really offer the membership some good information by perhaps contributing some technical articles themselves. A. Dietz and others are just the kind of guys (or gals) we're looking for as your knowledge goes way beyond the content of what zymurgy is able to presently offer. Why not help us help you and others like you and give us some outlines and ideas on some technical subjects that, perhaps, we have not covered in the past 2 or 3 years. We'd really appreciate that.

As a matter of fact all of the growth and improvements that we've been able to offer over the years have come from people more knowledgeable than the average homebrewer.

I understand that there has been some concern that we have rejected several good technical articles. If you folks could be more specific that would help us solve this problem, if indeed it is a problem. Elizabeth Gold (Editor) and I review all the manuscripts and ideas that are submitted. Neither of us are recalling any incidences where we rejected quality, accurate technical articles. But if we have done so inadvertently or otherwise, please drop us a note and we will look into things.

Thanks for listening and keep up the [constructive] griping.

Fermently,

Charlie P.

p.s. I can be reached at my CIS address, though after january 20 you should direct any messages to James Spence at the AHA at 70740,1107, as I will be on vacation for a couple of weeks and won't be checking my e-mail.

Date: Wed, 13 Jan 93 12:57:53 -0800  
From: mark@verdix.com (Mark Lundquist)  
Subject: Can I use this keg?

My brother inherited an empty beer keg from some college roommates, who moved out without returning their keg. It just didn't seem right to throw the thing away, so he's had this beer keg in a shed in our folks' back yard for a couple of years now, probably with a bunch of other stuff that it just didn't seem right to throw away.

Anyhow, the other day he thought of me, thought of that beer keg, and gave me a call. So we visited Mom and Dad.

Much to my disappointment, the keg (a quarter barrel) was a "one-holer". From what I have heard, these aren't suitable for homebrewers, because you have to have a special machine to wash 'em out.

Is there any way that I can adapt this thing for home use, or am I stuck with a worthless piece of junk?

It seems like the filling and cleaning issues could be taken care of by cutting a bung hole, \*except\*...except I'd still need a way to clean out the internal plumbing of the keg. Any ideas?

Also, the keg is aluminum so any fittings that I might need would have to be TIG welded.

Thanks for any help!  
- --Mark

PS This keg was actually not empty, it was "almost empty", in that special way that only an almost-empty keg can be after a couple of years! Phew!!

From: CCASTELL.UNIX11@mailsrv2.eldec.com (CCASTELL)  
Subject: Sparge-O-Matic

I was wondering if anyone has tried Sparge-Magic from Scientific Brewing Systems. It's your typical two-bucket-with-grain-bag system EXCEPT that the hose coming out the bottom of the bucket goes to a carboy stopper. The stopper also has a hose running to a gizmo (pardon my use of technical jargon) that connects to a faucet which creates a vacuum in in the carboy. The wort is essentially "sucked" out of the grain rather than allowing it to slowly flow using gravity. Allegedly, this method allows one to use sparge water with no concern about temperature.

I've used it five times with varying degrees of success. Does anyone have any comments on such a system (based on experience, common sense, gut feel, conventional wisdom, or folk lore)? Should such a system produce better extraction rates (as claimed)? Would it tend to suck things out of the grain that would be best left where they were?

Thanks.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: desperately seeking help

Dear brewing experts,

I'm desperately searching for what I'm doing wrong in my extract brewing. The trouble is beer which (I think) develops a strong flavor after being in the bottle for a short while. I never had this problem while brewing using kits, where I never boiled anything, just dumping the kit directly into the fermenter.

My latest problem is a batch which I bottled 11/30 last year and tried last night, to be very disappointed in the strong flavor. It's hard to describe but is similar to one which I dislike in another brew in which I used amber extract, crystal and chocolate malts. I thought I'd used too much chocolate malt that time. The peculiar thing is that this flavor was not apparent at bottling time. I think my sanitation is good, by soaking all the bottles in bleach overnight, and the caps also. The flavor is kind-of burnt, but there were no black marks on the inside of the boiler.

This latest batch was originally brewed in a 3-gallon batch using M&F light extract, although the final product is far from light. I used 3.3 lbs and boiled this in 1.5 gallons of water for 60 minutes with 1/2 oz of Pride of Ringwood hops. The yeast was Nottingham Ale.

Can anyone give me pointers to any possible problems? Can beer oxidize in a month to produce a strong flavor? What other things can result in beer apparently changing so much. Is it maybe subjective that it's changed and the original tasting when it was flat and with cloudy yeast in suspension sort of disguised the flavor? If the wort was caramelized during the boil would this show up as a strong flavor?

Is 60 minutes too long for a "concentrated" extract boil? Should I try reducing it to 30 minutes and use more hops? The one thing this beer and the other dark one have in common is a 60 minute boil. Is an electric element and a stainless steel stock pot a risky combination?

Any advice would be much appreciated. I've had so little luck with migrating from kits that I'm almost ready to return to them, but somehow that smacks of a retrograde step and a defeatist attitude.

Yours desperately,

Peter

From: greg@bandit.Berkeley.EDU (Greg Jesus Wolodkin)  
Subject: Physics, surface tension, and bubbles ;-)

In reading Papazian's book (I paid for my copy ;-) I came across a statement in Appendix 9 (p.375) that made me curious. To quote,

"A big explosive bubble feeling in the mouth is due to the use of fermentable ingredients other than barley malt. A beer made with all barley malt will tend to have a smaller (almost a creamy sensation) bubble feeling in the mouth. This phenomenon can be explained in terms of physics, surface tension, and bubbles, but need not be gone into here."

This reads as if it should have a few smileys at the end of it.. is there any truth to this statement? Any comments/explanations? While I have a strong physics background, I don't see how one can separate malted barley from malted wheat, corn sugar, honey, or in general from the myriad of other fermentables in terms of the bubble size which will be produced in the finished beer.

As I read it, this statement has nothing to do with priming (i.e. the common corn sugar vs. malt extract vs. gyle controversy) as far as I can tell, but seems to refer to the entire grain/adjunct bill. So Charlie, if you're reading this, explain away ;-)

Best wishes,  
Greg Wolodkin greg@bandit.berkeley.edu

>Cold plates are the most amazing things I've ever seen for serving ice cold beer from warm kegs in the middle of a Chicago August.

> BEWARE: They are not a great alternative to proper longterm/everyday serving and refrigeration of precious homebrew.

I see no reason why they are not a great alternative to everyday serving but  
I do agree that a caveat is in order regarding long term storage. Ageing and  
storing beer in a refrigerator is not the same as aging and storing at room  
temperature. I have no personal experience with what difference it makes but  
I am sure the experts have many. My only concern is that the beer not spoil  
in Summer and thus far I have had no problem but I never seem to be able to  
keep a keg for more than a month or so and it has never spoiled in that time.

I think the issue would only be the characters of a true lager. I have been  
bottling a sixer of each batch and storing them in the fridge so that in a  
few months I will have some properly aged to compare with my keg stuff.

>At recent 'all draft' beer tasting/competitions here in The Windy City, we've had the darned things freeze up on us and it seems that the only temperature the beer comes out at is 'ICE COLD'.

Not to doubt your anecdotal experience but there is nothing in my physics  
books that would explain how that could happen unless someone thought you  
were making ice cream and put salt in the ice.

It does however, make very cold beer but there is no law that says you have to  
put a ton of ice on it. For a two glass serving, I use about two cups of  
cubes and about half are still there after drawing the beer in winter. In  
Summer they are just about gone.

> #1 reason not to use cold plates:  
> Much too difficult to decorate with refrigerator magnets.

Don't want to be flamed for a commercial but I have a special this week on  
aluminum magnets and they are designed to work best on horizontal surfaces.

#10 reason TO use cold plates:

You never have to lift a full keg off the ground.

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: Re: Diminishing Yields

CR says (Jack says):

) I find that even with boiling water going in  
) >at the top, the average temperature of the mash is around 150F.  
)  
) Some years back, I began measuring temperature profiles thru the mash  
while  
) sparging. Like Jack, I found that my water had to be much hotter than  
168 to  
) get the mash up to that temp. This makes sense for at least two reasons  
:  
) [etc.]

I doubt that it makes much difference what the temperature of the  
mash during sparging is so long as it is relatively hot and <165-170F.  
If it's <168F, sparge slower. The sugar \*will\* diffuse out, no matter  
what the temperature is.

) [etc.]  
) 1) Losses in the system, especially if your sparge water is sprayed  
over the  
) grain bed.

This is easily avoided if you have a cover over the bed. I have a  
Zapap-type setup and have a perforated lid on my inner bucket.

Usually the stuff coming out of my sparging setup is pitifully cold  
(140-155F) but I get yields in the 30-33 points/lb range for barley  
malts,  
so it can't be hurting me. Not much, anyway!

) As Jack pointed out, getting around the first factor is pretty simple :  
raise  
) the temp of your sparge water. Getting around the second problem is  
more of a  
) hassle. You would sparge with more water, and collect more (weaker)  
wort.  
) Then boil the \*%\$# out of it to reduce the volume. [...]

Old British Beers suggests collecting wort until the gravity has fallen  
to 15 points below the target gravity (i.e., 1.085 for a beer that  
is to be pitched at 1.100), then, if you want, boiling whatever you  
collect afterward separately until it reaches 15 points below. I  
have no evidence to support my belief, but I think this should  
reduce carmelization and color changing effects.

<get a full conversion. (Try the iodine test next time if you're not  
<sure -- a drop of iodine in a bit of mash liquid will turn purple/black  
<if there are still unconverted starches.

In general, this is not true. Domestic malts will contain more enzyme potential than you could ever use. Even modern continental malts will have enough enzymes for just about any all malt beer. The use of Munich and crystal malts in just about any reasonable percentage will work fine. I believe low yields are primarily related to methods of mashing and lautering. All other variables being the same, if your extract goes down when your grain bill goes up, check the lauter tun. When I was using the Zapap method, there was a breakeven point where more malt yielded the same extract. I blame this on the compaction and loss of efficient lautering due to higher grain mass.

I have a friend who uses the (IMHO) poorly designed Phils lauter tun and he has the exact same problem with compaction yielding lower extract efficiency. My complaint with the Phils system is that the tube from the false botom has to rise up out of the false bottom to then exit the bucket. This can lead to a problem with an air bubble forming inside the tube. I have seen extremely slow runoffs that I think are due to this design. Of course, anyone can correct this (and see if Im right!) by simply drilling a hole in the bottom and plugging up the normal tube outlet.

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: lab vs food grade, Krausening, and The Brews Paper

Jon Binkley responded to my article with a number of inaccuracies and an arrogant attitude. I thought that the idea of this forum was to pass brewing information of use to brewers, rather than passing old myths, like that lab grade (ACS grade) chemicals will kill you quicker than 5 ml of sodium pentathol (or whatever).

Myth 1. Food grade chemicals (Codex) are purer than lab chemicals -NOT.

ACS grade is the highest grade that can be obtained reasonably, unless it's not good enough and ACS will set a higher standard for manufacturers to aim at. ACS standards are improved as technical feasibility of production improves. Food grade is that which satisfies certain health standards for toxins. For instance, I listed certain parameters for lab and food phosphoric acid. Both have the same heavy metals as lead requirement, but for the other parameters the lab grade was much, much, better than the food grade.

Myth 2. Lab grade is cheaper than food grade -NOT

500 g of phosphoric acid costs around \$25 from Fisher or \$12 from Sigma. I am sure Coca-Cola pays much less. But the problem is that food grade phosphoric acid does not seem to be available in small quantities.

CAVEAT: While I am very happy that lab grade phosphoric acid is better than food grade, this may not be the case for all chemical you may use. However, be aware and educated. Question all statements that are not backed up by solid evidence, especially those where the reason is no better than you're not supposed to because the government say so. And beware of supposed experts wearing underpants on their arms!!

Other things. I noticed in r.c.b that many people have been defining krausening as priming with sterile wort, rather than the correct definition - priming with a small quantity of beer in the krausen stage. The source of this misinformation seems to be Charlie P.'s book. Perhaps he should write an erratum pamphlet (a sheet wouldn't be big enough).

Anyone seen a paper calle The Brews Paper?

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: HDPE and Lab Chemicals

Wayde writes in HBD#1054,

>If these HDPE plastics are permeable to CO2 then wouldn't O2  
>(oxygen), being a smaller molecule, be as or more capable of passing  
through  
>the plastic? Maybe Bruce Mueller can comment?

Well, you might think so. Chemistry isn't that simple :( . I had to get  
the  
numbers this time (I knew the other answer, but not quantitatively) so  
here  
they are:

Permeabilities in cm<sup>3</sup>xmm/s/cm<sup>2</sup>/cmHg (yes, pressure in cmHg) at 30C:

O2: 10.6 CO2: 35 H2O (vapor, 90% rel. hum., 25C): 130

For comparison purposes, the numbers for PET (soft drink bottles):

O2: 0.22 Wow! CO2: 1.53 H2O (same cond'ns): 1300

My reference is "Polymer Permeability" edited by J. Comyn. It's a  
British  
book I believe. Isn't that PET amazing at keeping O2 in or out?

Lou in the same issue "accused" :) me of pressurizing my HDPE jugs.  
Actually, this isn't true. I counted on the airline to do the reverse--  
the hold  
is at low pressure, the bottle filled at about sea level. But based on  
this,  
about 1/2 atm vacuum not causing any liquid leakage AND HDPE's strength,  
I extrapolated to the pressurized case. Extrapolating is sometimes  
dangerous,  
but I certainly wouldn't worry in this case, because HDPE is not brittle.  
Please DO NOT pressurize ANY water bottle style carboy, glass or plastic.  
Come to think of it, one of the British contributions to homebrewing is  
the  
polypin (see Dave Line's "The Big Book of Brewing"). These are  
polyethylene  
and used as "kegs". Probably not the best idea, in light of its oxygen  
permeability (Wayde referred to this).

On another note, Ulick had a great point about non food grade chemicals.  
I  
trust the assays on these (e.g. ACS grade) as much as or more than the  
USP  
variety--they are generally purer. In HBD#1055 Jon recommend again  
against  
these, unless one is aware of toxicology. This is a good point. Would  
some-  
one knowledgeable about toxicology enlighten us about the "real" limits  
for  
long-term consumption of e.g. lead? I think most homebrewers who would  
go to  
the trouble of obtaining lab-grade chemicals also would have sufficient  
ability to calculate their "dosage" of such nasties (simple dilution). I  
hope

so.

I hope this time more than the header gets through!

Yours in brewing,  
Bruce Mueller  
Analytical Chemist by training

From: rstya@mda.ca (Roy Styan)

**Subject: decoction mashing**

I have been experimenting with decoction mashes for the last 5 or 6 brews, and have been experiencing a common problem with each. The final gravities have all been very high, typically 1025. This seems to be independant of yeast strain (I've used several different ones, both lager and ale) and only somewhat dependent of mash temperature. With very low temps (64C - 65C) I have brought the gravity down to 1018, but this is not always the case.

So what gives? Does docoction destroy more of the alpha enzymes than beta, yielding full conversion, but with lots of dextrans? Is it possible to get a low final gravity with decoction?

- Roy

Date: Thu, 14 Jan 93 11:28 CST  
From: korz@iepubj.att.com  
Subject: The Dangers of a High Temp Sparge

Recently, there's been some discussion of sparge water temperatures. At least two brewer's have suggested using very hot boiling or almost boiling water for sparging. The usual argument against using sparge water over 170F is that additional tannins are extracted from the grain above this temperature. I agree that a too-hot sparge will make your beer a bit astringent (due to the increased tannins), but there's another reason for keeping the sparge water below 170F, and that is STARCH EXTRACTION. Once you're done with the saccharification rest, you should make very sure you're not extracting any more unconverted starch from your grains. One very cloudy beer I've tried in the past was, upon further investigation, sparged with boiling water.

Finally, I've brought this up once in the past, but no one commented and I just forgot about it, but I'd like to bring it up again for the sake of discussion:

Could it be that we don't want the grain bed during the sparge to be \*AT\* 170F, rather we want the \*sparge water\* to be at 170F and we should let the grain bed (in an insulated tun) settle at whatever temperature it wants? Can someone who has "Brewing and Malting Science" please look this up? Darryl, what sparge temp is used for Pilsner Urquell?

Comments?

Al.

From: arthur@chiba.esd.sgi.com (Arthur Evans)  
Subject: Cold plates, Mash tuns

-> Cold plates and other serving devices

Since there's been some discussion of cold plates for serving beer here, it might be worthwhile to mention that there's an article in one of the Zymurgy special issues (I think it's the "gadgets" issue) has instructions for building a "mini-jockey-box."

Basically, this consists of a water cooler with a beer line running through it. On one side you have a serving tap, on the other side you have a line running to your keg, and inside the cooler you have a coil of copper tubing ("look, officer! it's a condenser!" sorry--wrong show) connecting the two. Beer flows through the line and gets cooled by the ice that you cleverly placed in the cooler for this purpose.

Anyway, it sounded like it would work and not cost too much, and best of all, it's yet another excuse to play around in the garage with power tools. (And isn't that half the fun of new equipment?)

Anyway, I've seen some version of these jockey boxes at a number of events (beer festivals, outdoor concerts, etc.), and they seem to work all right, but I'd be interested to hear if anyone has tried making one at home. I'm thinking of making one for my illustrious brother's wedding (to serve beer, not as a wedding present--so don't get your hopes up, Stew).

-> Mash tuns

On a completely unrelated topic, I'm contemplating the leap into all-grain brewing after many a year of extract brewing. I'm thinking about constructing a picnic-cooler type mash tun, and I'm wondering what size I need. The local Sears sells 5-gallon coolers, but I suspect that's too small for making 5-gallon batches. Can anyone who has this kind of mash tun tell me 1) what size they have, 2) what size batches they make (how much grain, how many gallons), and 3) where they scored the damn thing?

Many thanks to anyone who can help me on this,

-arthur

From: woessner@psych.purdue.edu (Leo Woessner)  
Subject: Pete's Wicked Ale

I would like to try to clone Pete's Wicked Ale. I would appreciate anyone who has made such a ale, to post the recipe, and/or mail me a copy. A friend of mine mine has just started to brew and very much enjoys Pete's Wicked Ale. Being a beginner I would like a extract recipe. Any sugestions on O.G., Hops, and malt will be very helpful.

Over Christmas I visited my parents in Colorado and had the fortune to visit the Walnut Street brew-pub in boulder. The served a tremendous stout called Devils Thoubm Stout. It was a mild stout (closser to a Porter) with a coffee aroma and taste. I was taken by the way in which the maltyness of the beer went with this coffe-like flavor. I asked the man who gave us a tour about the beer. He tpld me that there was no coffe in the beer but they used generous amounts of amounts of chocolate-malt to achieve the flavor. He was not teriably informativ , so I am not totally convinced that there is no coffe in the beer. Last week-end I made a porter with 3/4 pound of chocolate malt to try to get the coffee-like flavor. Recipe:

3.3# John Bull dark malt extract  
3.3# Munto and Fision light extract  
1/2# amber DME  
3/4# chocolate malt  
1oz cascade hops(60 min)(4HBU  
2oz fuggles hops(60 min(10 hbu)  
1oz cascade hops (steep 20 min while cooling)  
1/8 oz Hallertau hops(steep)(Just because I had them ;-)  
Whitebread Ale yeast

If anyone out there has made a stout or a porter similiar to Devils Thomb stout

I would appreciate a recipe. I also would apreciate any recipies, tips, hints, or magic spells that would help me make such a stuot or porter.

Thanks in advance

Estes of Manang

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Cold Plates

I feel like Don Quixote on this issue but when I find something that really works, I tend to be a real crusader.....

>From: orgasm!davevi@uunet.UU.NET (David Van Iderstine)

>I've had some experience with these things, which was not good. I made the mistake of adding ice over the cold plate before I had beer running through it. It seems that ice crystals formed \*inside\* the plate's tubes, with the result being incredibly foamy beer at the tap that did not go away for days (it was a looong party! :-).

I am not sure how or why ice crystals would form inside but they would quickly go away when the warm beer hit them and they certainly are not the reason for the foaming.

>The advise I was given (I'm afraid much too late!) was to get the beer running first, then chill the plate down.

In my case, it is always hooked up so there is always beer in the line. You do have a different situation but not likely to have anything to do with foaming.

In the likely event that THAT advise didn't work either, try mine.

Turn off your brain and crank up the pressure. Don't think about it, it causes migrains. Just DO it! Try 25 or 30 lbs.

I guarantee you, there is some pressure somewhere that will pour properly and with a cold plate it is about twice what you are used to.

somewhat  
<dependent of mash temperature. With very low temps (64C - 65C) I have  
brought  
<the gravity down to 1018, but this is not always the case.

I would suspect an inadequate rest time at around 64C for the  
saacharification  
rest of the decoction prior to boiling the decoction. Maybe you are  
resting  
at this temperature, it is hard to tell without more details. Possibly,  
you need to rest for a longer period prior to the actual boiling of the  
decoction. 1.018 would seem a bit high depending on style, but not out  
of range. Certainly 1.025 is quite high. My weizen decoctions have been  
ending around 1.013-1.017 but I am certain of the quality and quantity of  
viable yeast at pitching time. I assume you are pitching a large healthy  
starter? FGs of 1.012 are possible with decoctions but the rest temps  
can  
be tricky to hit and maintain.

on another subject:

they make (how much grain, how many gallons), and  
3) where they scored the damn thing?

I used to brew in a 5 gal Gott Water cooler (K-Mart, about 25\$). This  
was  
capable of mashing 13 lb of malt in a single infusion (1 qt H2O/lb)-  
plenty for  
a 5 gal all grain batch and even enough for the occasional 10 gal of low  
gravity beer (milds). It works great-loosing less than 1C over a 60 min  
mash.  
By draining the thin mash, heating and adding back you can hit a mash out  
temp  
prior to sparging.

I now make 10-15 gal at a time and use a 10 gal Gott of the type that  
football  
players like to dump on their coaches (sez Gatoraid on the side, but who  
cares). This big boy can do step mashes, decoctions and single  
infusions. 25  
lbs is as far as I have gone, but that's plenty for my taste.

Subject: Bottle filler info wanted

hi all,

this is not yur average request for info - what i am looking for is 2 items:

- 1) anyone know of a company in New York under the name of Prospero Equipment Company???????
- 2) that failing any one know of where i could aquire a multi spout siphon bottle filler, similar to the one offered by the Compleat Winemaker?

the specs i need to meet are:

good polished tank welds, sanitary  
1.5" triclover inlet  
floor standing  
easily cleaned  
some type of float valve or mechanism to set the liquid level in the tank  
able to fill 12 oz, 16 oz, 22 oz, 750ml bottles  
multi spouts 6 or more (up to 12) - capacity of 12+ bottle/min  
not going to cost more than a few grand

these type of contraptions are not counter pressure devices, are mainly used in the wine/champagne industry....

any help???

Whoops, sorry if I mislead anybody. When I said "disproportionately  
high percentages" I was thinking of ridiculous percentages, like  
\*replacing\* your pale malt with Munich. I'm sure someone out there has  
tried it (no, not me :-).

> My complaint  
> with the Phils system is that the tube from the false bottom has to  
> rise up out of the false bottom to then exit the bucket. This can lead  
> to a problem with an air bubble forming inside the tube. I have seen  
> extremely slow runoffs that I think are due to this design.

So back to lautering tuns. I lauter with a slotted copper manifold  
system that drains via a ~24 inch standpipe connected to a siphon. I  
don't know exactly how the Phils system works, but I imagine my setup  
could have a similar problem. However, I almost always get >30  
pts/lb/gal yield. Perhaps the siphoning pressure removes any air  
bubbles that might get in the way.

On another note, Arthur Evans asks about picnic-cooler mash tuns. I  
believe Gott manufactures 10-gallon (40 qt) liquid coolers, the kind you  
see on the back of construction-company pickups. You can also use  
rectangular food coolers, which I've seen in sizes up to 54 qts, though  
you probably don't need anything larger than 28 qts. I mash in a 40 qt  
stainless kettle, and my mashes usually amount to no more than 20 qts or  
so for an eventual 5 to 6 gallon batch of beer.

Which brings us back to lautering. If you're moving to all-grain you  
need a way to lauter. I've used both the Zapap double-bucket setup  
and the slotted copper manifold setup, and the manifold wins hands  
down both in speed, ease of use, and efficiency. Stuck sparges due  
to grain bed compaction were common with my Zapap; I've had nary a one  
with my manifold (even when making beers with >50% wheat).

Both lautering setups have been discussed many times in the digest, so  
check back issues or email me if you want more info.

From: Martin Wilde <martin@gamma.intel.com>  
Subject: HSA not a problem if chilled?

As a bunch of us were recently talking at a brewing club meeting the other night, the topic swung to HSA (hot side aeration). I had mentioned the talk which has been going on in HBD about this and how most people thought it was a nasty thing. I then recalled pictures I had seen of Sierra Nevada and English breweries using a hop back and watched some local brew pubs using them also. Someone came up with a reason why these breweries products do not have the nasty tastes associated with HSA.

Could it be after you dump the wort over the hops and then immediately chill it to ~70 degrees the nasty phenols do not have time to develop?

thanks

From: frank@Solbourne.COM (Frank Jones)  
Subject: Simple (low-cost) Kegging system

Greetings,

This is a long one, but useful I think...

I recently found a low-cost kegging system which I wanted to share with the Digest. It is very new to the market; I found out about it at our local brew club (The Unfermentables, Denver) when the manufacturer came and gave us a short talk on their product. (The manufacturer, QUOIN, is based in Golden, CO.) I was looking to go to a kegging system, and this caught my attention. I purchased one keg as a trial and filled it with Christmas Ale, which was consumed (decimated?) at a party the weekend before Christmas. This past weekend I filled it again, and if anything it was easier. All went as advertised, and I am very pleased with its performance. Well enough of that, but I wanted to establish that I \*had\* used this system, not just heard about it.

I've delayed announcing this for two reasons: 1) I just changed jobs, and now have a real Internet connection, and 2) I was about to use the keg a second time, and wanted to wait until that was behind me to see if anything else cropped up.

The Keg system is produced by Quoin (pronounced "coin") Systems Inc., (address below). The bottle was developed by Coors Inc. originally as a take home cheap returnable keg for their distributors (e.g. like a party ball), but the system was abandoned by them, I believe, because of the difficulty with the charging system. Quoin Systems (consisting of former Coors employees) bought the kegging system, and came up with their own charging system, which is unique (and patented). The charging system is a pouch which contains a (food grade) mild acid & sodium salts in a multi-compartmented pouch. The acid is kept separate from the salts by a pressure sensitive barrier, which is triggered once the keg is pressurized (with a small hand pump). Once the pouch is activated the chemicals mix, producing CO2, which makes the pouch expand, filling the head space in the keg. The contents of the pouch are totally isolated from the brew. The beer is primed as normal with sugar/wort. The pouch is only to keep the brew under pressure, about 15psi, and the head space filled. When the keg is empty, you simply puncture the pouch, remove it and throw it away.

The Keg is made of brown PET plastic, with removable aluminum clamp rings for the plastic valve system. These things were designed for public use, so are of very stout construction. The keg holds 10 liters total, but only about 8 liters (about half a 5 gal batch) of brew with the required head space.

Quoin is marketing the keg to home brewers and micro-breweries. They are a very small operation, but they tell me they are selling quite a few, and are staying up with the demand. I understand that the Breckenridge Brewery (a local Colorado Micro-brewery) has purchased some for take-home/returnable customer use.

I'll try and head off some of the obvious questions:

how much does it cost?

\$29.50 .. 8 liter Keg, valve assembly, horizontal stand with carrying strap (neat design) & 2 pouches

\$ 4.00 .. 2 plastic sleeves for standing the keg upright for filling

\$ 5.00 .. activation pump

\$ 3.00 .. 1 pouch (\$33.00 for 12 of them)

(normal startup requires the keg, pump, and stand \$38.95, additional kegs don't require the pump or stand)

\$ 5.00 .. shipping per keg.

Colorado residents add 4.3% tax.

They accept Master Card & Visa or checks payable to QUOIN.

\_what about contamination?\_

The pouches are pre-sterilized, and are sealed in a second pouch. The air that is introduced to activate the pouch, once the pouch is in the keg, is just outside air; however it is bled off immediately after activation, so shouldn't be much of a factor. The keg itself is easily disassembled, with the mouth opening being about 2 1/2" in diam, and is very easily cleaned. Since it is PET plastic, care should be taken not to scour/scratch it. but it cleans up quickly and easily.

\_What is it called?\_

The best part: "The Party Pig"(tm) :) When the keg is assembled with valve, and is in the horizontal stand, it does indeed look like a pig. the only things missing are ears, eyes & tail (aftermarket options???)

Where to order?

Quoin Systems Inc.

401 Violet St.

Golden, CO 80401

phone (303) 279-8731

\_Disclaimer?\_

Yeah, I guess I should. I do not have \*any\* monetary affiliation with Quoin Systems (damn it), other than being a customer.

Problems: A brew buddy of mine purchased one at the same time I did, and had a problem assembling the valve/restrictor assembly which ended up damaging the valve. After looking at it the problem appeared to be that, when the two parts are pushed together the valve was depressed (opened) in the process which pinched it between the two parts. She replaced the entire assembly for \$5 but I think that the valve itself might have fixed it. If care is taken when assembling the restrictor, e.g. pushing on the valve body itself, this shouldn't re-occur.

If you have any questions that I can answer please feel free to post either directly to me, or to the Digest, and I will answer all that I can. Also since Quoin is a local call for me I would be happy to forward any questions/queries to them that I don't feel qualified to answer.

fj..

Subject: Computer error

During the week of 1/11-1/15, utamat, our local workstation, frequently down so the operating system could be upgraded and additional memory installed.  
To make a long story short, selected mail to gjfix@utammat.uta.edu was trashed due to a failure to properly backup the system during these changes. I was told that some of the lost mail was to me, and at least a couple had the term "HSA" in the subject title. I would be grateful if anyone who sent e-mail to this node and has not received a response could resend their message. More generally, I would be grateful to anyone who requested but has not received the original HSA article could do the same.

I believe it was either Steve Stroud or his wife who gave the following sage advice. "One can never be too rich, too thin, or have too many backups". I believe the same applies to CO2 tanks, but that is a another matter!

I hope everyone caught CP's post in HBD#1055 about Zymurgy. I believe these folks are quite sincere about these matters. This would mean that the ball is now in our court, and those interested should definitely respond.

Subject: Cleaning agents, Papazian

Sorry this is a bit late, but my mail was down for a day.

C. Papazians article struck me as somewhat odd in HBD #1055. I agree with his general point that people who have problems with Zymurgy should contact Zymurgy, of course that is NOT to say that they that they shouldn't use this forum as well.... the point that struck me as odd was that it sounded like nobody on the Zymurgy staff was a regular reader of the HBD. If that's the case, they certainly are missing many great ideas for articles...

Secondly, Scott the BadAssAstronomer was looking for a new cleanser. I've been told by a local brewer that DRANO contains something that is very similar to what is used to clean hop residue out the industrial aging tanks. I've never tried it, but he suggested a teaspoon in 5 gallons really cleans up nicely. I suggest a lot of rinsing...

good luck  
doug@bitstream.com

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: HBD 1056

Hi All,

In HBD #1056, Roy Styan asks:

I have been experimenting with decoction mashes for the last 5 or 6 brews, and have been experiencing a common problem with each. The final gravities have all been very high, typically 1025. This seems to be independent of yeast strain (I've used several different ones, both lager and ale) and only somewhat dependent of mash temperature. With very low temps (64C - 65C) I have brought the gravity down to 1018, but this is not always the case.

So what gives? Does decoction destroy more of the alpha enzymes than beta, yielding full conversion, but with lots of dextrans? Is it possible to get a low final gravity with decoction?

I've used decoction mashing extensively, generally for Bohemian pilsners and German festbiers. I've also experimented with styles that do not traditionally call for decoction mashing, such as pale ales. Both the pilsners and the pale ales typically finish around 1.015. I'm also aware that wheat beers are commonly brewed using decoction mashing, and can finish as low as 1.010, though I've never done this. A few suggestions come to mind, some of which you've already covered.

Yeast attenuation: Roy mentions trying several different yeast strains, I assume they had different attenuation ratings. If so, then yeast performance may be eliminated as a factor, and the discussion focused on mashing procedures.

Water/grist ratio: a higher water to grist ratio will produce a thinner mash, which favors the beta amylase enzyme. I use 1.3 - 1.5 qts/lb (I can hear the gasps from the infusion mashing crowd), which also helps reduce the darkening effect of decoction. This is very important in preserving the pale, delicate color in a pilsner.

Conversion temperature: the lower end of the sugar rest temperature range also favors the amylase enzyme. 65C is ~149F, still sounds a little too high if you're after a thinner bodied beer. Quoting from Noonan's "Brewing Lager Beer":

"temperatures below 149F(65C), on the other hand, seriously limit dextrin formation while favoring the formation of maltose by Beta amylase. Because starch granules are not gelatinized or dispersed below 149F, Beta amylase activity at lower temperatures serves only to eliminate the dextrans formed in the decoction, without further significant starch reduction."

Try a brief rest at 140F-145F, should result in a less dextrinous wort.

\*\*\*\*\*  
\*

Also in HBD #1056, Al. Korz on sparge temperatures:

> The usual argument against  
>using sparge water over 170F is that additional tannins are extracted  
>from the grain above this temperature. I agree that a too-hot  
>sparge will make your beer a bit astringent (due to the increased  
>tannins), but there's another reason for keeping the sparge water  
>below 170F, and that is STARCH EXTRACTION.

Point well taken, I'd agree that water that is actually in contact with the grain should never exceed 170F. My use of sparge water at ~190 is a result of the characteristics of my own brewing equipment. As stated in a previous post, I mount a collander atop the lauter tun as a means of diffusing sparge water, minimizing disturbance of the grain bed. This setup cools the water rapidly, as the temperature at the top of the grain bed is 160-165. I believe this is the hottest point in the system, and still maintain that this is the key data point. What difference does the temperature of the sparge water make when it's not in contact with the grain? Extraction of tannins and unconverted starch is not likely to occur when the sparge water is sitting in a pot on the stove.

Cheers,  
Jim

Date: Fri, 15 Jan 93 11:05:04 PST  
From: hartman@varian.varian.com (John Hartman)  
Subject: Bottle Filler

Allow me to suggest yet another counter pressure bottle filler. It's simple, inexpensive, and effective. Call it John's Cheaper Filler.

To make this filler you will need the following:

Standard 3-piece plastic airlock \$.95  
No. 2 rubber stopper w/hole (beer bottle size) \$.30  
3/8" ID vinyl tubing, 9" in length \$.30.  
3/8" ID vinyl tubing, 2" in length \$.05.

The total capital outlay for this little project is \$1.60, leaving extra fun money for the rest of the brewery. Use a saw of some sort (I used a hack saw) to turn the 3-piece airlock into a 4-piece airlock. Cut the stem of the airlock off at the top, where it meets the bleach water reservoir. Keep the stem and discard the rest of the airlock. Slid the stopper over the stem so that the stem protrudes from both the top and bottom of the stopper. Attach the 9" length of tubing to the stem below the stopper. Attach the 2" length of tubing to the stem above the stopper. You've done it. You now have your very own bottle filler and you're ready to bottle.

To bottle a beer from your keg attach the 3/8" tube on the top of the stopper to a plastic cobra/picnic tap coming from your keg. Insert the assembly into the bottle. Place 20 PSI of pressure on the keg. You may need a different keg pressure for your system, but I bet it'll be close to 20 PSI. Hold the stopper down and open the tap. Beer will fill the bottle to about 1/4 full and then the flow will stop as the pressure in the bottle reaches the keg pressure. You should see some foam. Wait about 10 seconds and the foam will subside. Now carefully loosen your grip on the stopper so that a little air escapes from the bottle. The tap should still be open and as the air escapes beer will gently fill the bottle with no additional foaming. As the beer approaches the neck slow down. There will be about 1" of foam. Loosen your grip again to allow the foam to be displaced by beer. Be careful or you'll be wearing that foam. If you do get foamed remember you're a homebrewer and you like this kind of stuff. Once the foam is displaced you can close the tap and then slowly remove the filler. If you pull it out too quickly the beer will foam and you'll loose carbonanation. You can now cap the bottle.

One obvious draw back to this filler is that the beer will potentially be oxidized by the air in the bottle when you start. For those concerned with oxidation, a second filler could be attached to a second keg filled with CO2.

Just before a bottle is filled you could blast the bottle free of O2 and then proceed as above. I haven't found this to be necessary, but I thought I'd mention it as we never seem to stop talking about the evils of oxidation.

It works for me. Try it!

Cheers,  
John

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re: Rikard's Red

A few people have asked about Rikard's Red which is widely available in Ontario. It is brewed by MOLSON'S, and IMHO is an attempt to prevent the micro's grabbing too big a segment of the market. They try to downplay who makes it in an attempt to cash in on the microbrewery mystique. All this wouldn't be so bad except that the beer tastes more or less like generic Molson's (Canadian, Export, etc.) with a touch more flavour and body. It can't hold a candle to any of the good micro-beers like Wellington, Connors, or Hart. This is a matter of taste however, and some who like a more mainstream beer may appreciate Rikard's. Labatt's attempted to do the same thing a while back. The beer was called something like 'Duffys' and was particularly vile. Haven't seen it in quite a while. I must confess to a certain bias against such imitation micro-beers in that the big breweries have a lot of leverage (who's kidding who, they have a government sanctioned monopoly on beer sales and distribution and MAKE the rules) that they already use to make life hard for the micro's. Also, the whole thing smacks of dishonesty. Is it any wonder that many beer lovers view Molson and Labatts as the 'great satans'?

Cheers,  
Rick C.

Subject: Under Pressure...

Bruce writes:

>Lou in the same issue "accused" :) me of pressurizing my HDPE jugs.

Okay, okay, so the airline does the actual work, but the result is the same. ;^) He says he has extrapolated from this ~1/2 atm vacuum to determine if the jugs would withstand priming pressure. But how much pressure is generated by priming? My assumption before reading his posting was that there would not be too much. However, it seems that this might not be correct: Assume 1 lb priming sugar, glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>), or 454.5 g at 180 g/mol gives us 2.53 mol. Now assume that every glucose molecule gives us 2 ethanol and 2 CO<sub>2</sub> (I'm not sure about this): C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> --> 2C<sub>2</sub>H<sub>5</sub>OH + 2CO<sub>2</sub>. Now we have 5.05 mol CO<sub>2</sub>. Using the perfect gas law (imperfect, yes, but sufficient for our purposes), pV=nRT, rearranging gives p=nRT/V.

n=5.05 mol

R=0.0821 l atm/mol-K

T=298 K

V=4 l (I'm assuming you're using 5 gal of a 6 gal jug)

p=30.9 atm! Am I going bonkers, or is this a lot? Even if I'm off by a factor of 2 somewhere, there is still 15 atm of pressure generated. Is Bruce's extrapolation still good? Maybe. Is there anyone out there who knows for sure? Bruce or Ulick? Your turn.

Hopping Along,  
Lou Casagrande

Date: Wed, 15 Jan 92 16:28:25 -0600  
From: gjfix@utammat (George J Fix)  
Subject: Sparge Temperatures

It is possible that the time honored temperature range 168-172F for sparging seen in many books on home brewing are a carry over from older commercial practice. I know from direct experience at some regionals using older brewing practices (e.g., Straubs in St. Marys, Pa. and Pittsburgh Brewing to cite two examples), considerable effort was extended to achieve this temperature range throughout the grain bed. The rational behind the procedure was to terminate all enzyme activity in a predictable way. Both breweries were sensitive to even small changes in the wort % fermentability as well as to yield.

I use to do the same until a few years ago Mark Carpenter of Anchor suggested an alternative. At Anchor, after conversion they raise the mash to only 160F, and sparge with water at 168F. (Russ, please help if my numbers are not current). I tried this and found that for most beer styles the change was positive in terms of finished beer flavors. In my system there was a drop in yield, but also less husk based material was extracted. (Russ, does Anchor have any other reasons for using this procedure?)

A very radical procedure that was discussed in the commercial literature, was to lower the mash temperature to 32F-34F, hold for a definite period, and then sparge with water at that temperature. After that the mash was heated back up and boiled as usual. The authors claimed only small reductions in yield, and at the same time a ten fold reduction in anthocyanogen levels. This article appeared in a peer reviewed journal, which means their results were likely checked with care. I have personally tried the procedure for a 5 liter batch, and the results were consistent with their findings. Having said that, let also say that I have zero interest in trying it with a 50 liter batch for obvious reasons.

I now believe that the traditional numbers should not be seen as engraved in stone. If a particular brewer finds a particular combination of temperatures which consistently gives beers to their liking, then to quote a well known personality from my neck of the woods, "end of story". ( Well, at least I didn't use the phrase "you people" in this post.)

Subject: Dangers of a High-temp Sparge

I wrote:

- > Darryl, what sparge temp is used for
- > Pilsner Urquell?

Two brewers wrote to me suggesting that knowing the sparge temperature used to make Pilsner Urquell would probably not be as useful as I had initially theorized. For example, Spencer wrote:

>Is this a relevant question? PU is heavily decoction mashed, so it  
>seems to me that the sparge conditions wouldn't yield the same result  
>as when applied to our typical infusion mash.

My initial response to both was something like this:

- > Well, yes -- I feel we can learn and adapt from every source.
- > After you dump your mash into the lauter tun, does it really
- > matter which method of mashing was used to convert the grains?

And then I thought (in my reply to Spencer):

- > Hmmm... then again, decoction mashed grains will have much less
- > unconverted and trapped starch than infusion mashed, so they
- > could probably get away with a hotter sparge than us infusion
- > mashers. Perhaps you're right. Perhaps my earlier argument
- > is the key to the demise of my PU comparison. In any event,
- > maybe it will start some new discussions.

In Noonan's "Brewing Lager Beer," he says that the primary advantage of decoction mashing (and the reason that it yields slightly higher extract efficiencies) is because as the during the decoctions, the heat causes the starch grains burst and become available to be converted. This was the basis for my contention that too-high a sparge temperature could cause unconverted starch to be sparged out of the grains. Miller advises against high-temp sparges also (for the same reason, I believe) in his "Continental Pilsener" book from the AHA Classic Style Series.

That I asked Darryl if he knew the sparge temp for PU was a mistake, since as Spencer (and the other person (sorry)) noted, the fact that PU is decoction mashed means that its mash's grains have much less unconverted (and unavailable) starch than our typical single- or step-infusion mashes. Therefore, knowing their sparge temperature would not be as useful as I had initially anticipated (not that I'm not still interested).

Bottom line, the point I was trying to make was, that I feel that the best way to lauter is to:

1. take the mash that you have raised to 170F during mashout,
2. put it in an insulated lauter tun,
3. sparge with 170F water (acidified if necessary), and
4. if your runoff is too cold (heck, I don't know, say, below 140F), then insulate your tun better, rather than raising your sparge water temperature.

Subject: Please help me convert mg/L to ppm

I recently requested and received a report from my water supplier listing all the junk in my tap water. Now I could use a little help interpreting what they sent me. What I expected was a breakdown of how much junk in parts-per-million is in the water; what I got was how much junk in MG/L is in there. Assuming MG/L means milligrams-per-Liter (bad assumption?), can I read that as being pretty close to parts-per-million? Since a liter of tap water has a mass really close to 1kg, can I say that 1 mg/L is 1mg/kg here? mg/kg looks a lot like parts-per-million, if the ratio is a mass-of-junk to mass-of-water ratio. Does "ppm" normally mean "mass-of-one-part-junk to mass-of-one-million-parts-water?"

The person that sent me the report couldn't help me convert MG/L to ppm.

Any help is appreciated.

Subject: questions

I am looking for three receipes for brews.  
One is for "Taddy porter"  
The second is for a "New castle brown ale" and third is  
for a "corona" (not for me).  
All are for extract brews.  
Also is there any problems with the way that I cool my wort?  
Here it goes..  
I put 3.5 gollons water into a plastic fermanter and put it in my  
large  
chast freezer, Yes I cover and seal it tight.  
I boil the wort then strain it into the 33 degree water.  
It brings the temp down to around 65 degrees. then pitch the yeast

Also is there any problems with using those 5 gal. slightly tinted  
water  
bottles that spring water comes in as a secondary?

Thanks Gary Cote gcote@leotech.mv.com

Subject: party ball revisited

Seeing the post today about the party ball system was somewhat ironic. I just purchased one yesterday at Great Fermentations, Indianapolis. The one I got is in the traditional Coors party ball configuration, that is, once the seal is punctured, the beer should be consumed within 24 hours. Hey, its only a 2.5 gal keg... shouldn't be a problem. My questions are: how much priming sugar do I add? and what is the time frame for the beer to be ready? Once primed & carbonated (and still sealed) can this keg be stored in my fridge for a month or two? Since the initial beer is pushed out of the keg by CO2, could the basic rubber stopper counter pressure bottle filler also mentioned in today's post be used to fill a couple of bottles (just in case you wanted to) ?

From: casagran@gdstech.grumman.com (Lou Casagrande)  
Subject: CO2 Pressure Correction

Fellow Brewers,

Okay, I blew it big time. In the last issue I submitted what turned out to be some very premature calculations of the priming pressure for a five gallon brew. First of all, when I got home Friday night, I checked a conversion table for confectioner's sugar (the closest thing I could find to brewer's sugar) and found that there are only 4 1/2 oz in one cup, meaning that in the standard 3/4 cup priming sugar, there are only 0.21 lb, or 0.53 mol of glucose. So now my calculations were off by a factor of 5, at best.

I admit, I also forgot about that standard high school chemistry property of solubility. I checked the CRC Handbook of Chemistry and Physics, and CO<sub>2</sub> is soluble in H<sub>2</sub>O at 1.45 g/l at 25 C. Upon reflection, the brew is probably saturated from the primary fermentation, since 1.45 g/l is only 27.4 g in 18.9 l (5 gal), or 0.62 mol, less than even the 1.07 mol from priming. Even forgetting for a moment that pressure will drive this solubility higher, the 1.07 mol CO<sub>2</sub> will produce an overpressure of 6.5 atm in 4 l, or ~1/5 my original estimate. As I said, solubility will be driven higher by the pressure, and the pressure correspondingly lowered. Anyway, I'll think before I leap next time.

I still do not know, though, what the exact proportions of CO<sub>2</sub> produced by fermentation are. My gut instinct says they must be less than a simple chemical equation, otherwise where does the material to make new little yeasties come from?

Yeast-headidly,  
Lou Casagrande

Subject: Coffee stouts and porters

In regards to Leo Woessner's questions about coffee beer. Late last year I made a clean out all our ingredients brew with a friend. I think we started with some kind of bitter kit, added some spraymalt, didn't have enough fermentables so we added 1-2 lbs corn sugar (boohiss), and a pot of very strong french roast coffee (along with bittering and aroma hops). I forget if we used any adjunct grains. The result was surprisingly drinkable. We brought a bottle to the local homebrew supply store and the proprietor thought it tasted like an imperial stout (we didn't tell him what it was until AFTER he tasted it). We named it BOOTPOLISH, and anybody who has tasted it and likes strong stouts has liked it. So, Leo, experiment!

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: Keg priming

Lou, this isn't a flame, just trying to keep the facts straight.  
You made the following statement regarding priming the now notorious  
HDPE jug.

>meaning that in the standard 3/4 cup priming sugar, there are only 0.21  
lb, or  
>0.53 mol of glucose. So now my calculations were off by a factor of 5,  
at best.

Using 3/4 cup priming sugar sounded scary to one who kegs. I force  
carbon-  
ate, so I had to check back issues of the digest for a reference from a  
natural carbonator. In HBD#1003, Robert Haddad said 1/2 cup of corn  
sugar  
gave him about 25 psi at serving time. Unless he kegs much differently  
than  
I do, there would be very little headspace in the keg.

Lou, you correctly mentioned that CO2 is soluble in water. Using Henry's  
Law  
(ooh nooo, Chemistry!), you can calculate just how much does dissolve and  
thus  
the remaining pressure. I will leave that as an exercise for whoever  
wishes  
to, because I'm very satisfied with Robert's empirical evidence. For you  
thrillseekers, CO2's constant is  $1.64 \times 10^3$  atm at 25C. The formula you  
want  
is

$$p(\text{CO}_2) = H(\text{CO}_2) \times x(\text{CO}_2)$$

where  $p(\text{CO}_2)$  is the equilibrium pressure  
 $H(\text{CO}_2)$  is the constant above  
 $x(\text{CO}_2)$  is CO2's mole fraction; you can safely assume that water  
contains  
55.6 moles/ l (CO2 is negligible where Henry's law applies)  
thus,

$$x(\text{CO}_2) = \text{moles}(\text{CO}_2) \text{ dissolved} / 1 / 55.5$$

Have fun, don't worry!

From: Bruce Mueller <mueller@sdd.hp.com>  
Subject: The Answers, Natural Carbonation in Kegs

Hi all,

Well, I just couldn't resist the chance to do a simple theoretical chemical calculation. In a 5 gal. container, assuming all the CO2 dissolves, 1/2 cup yields 16 psi and 3/4 cup only 24 psi. Well, my fear was unfounded regarding this higher priming level. However, I bet the beer would initially gush pretty good with the latter pressure behind it.

Robert Haddad overestimated his pressure by about 55% way back in HBD#1003.

That's all folks!

> $n=5.05$  mol  
> $R=0.0821$  l atm/mol-K  
> $T=298$  K  
> $V=4$  l (I'm assuming you're using 5 gal of a 6 gal jug)  
> $p=30.9$  atm! Am I going bonkers, or is this a lot? Even if I'm off by a  
>factor of 2 somewhere, there is still 15 atm of pressure generated.

you're forgetting how much CO2 is dissolved in solution (over 90% of  
the CO2 in a typical bottle is in solution). It doesn't all go in the  
headspace. Also, most homebrewers don't give their beer time enough for  
all the priming sugar to ferment - if you did, you would only need about  
2-3 oz per 5 gal beer to obtain average carbonation. Anybody with a  
kegging  
setup can tell you that there is around 1-1.5 atm (14-21 psi) in (on?)  
carbonated beer at serving temps.

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Decoction mashing

James, quoting from Noonan's "Brewing Lager Beer", writes:

"temperatures below 149F(65C), on the other hand, seriously limit dextrin formation while favoring the formation of maltose by Beta amylase. Because starch granules are not gelatinized or dispersed below 149F, Beta amylase activity at lower temperatures serves only to eliminate the dextrans formed in the decoction, without further significant starch reduction."

My practical experience causes me to question this. I haven't read Noonan, but I have found that starch conversion often tastes as if it is 50% complete by the end of a half hour protein rest at 50C. (By the way, why does the mash effervesce? I have never seen this phenomenon even mentioned). Regarding the problem of extracting unconverted starch during sparging, I am wondering how significant this is in practice. When one considers that the brew will ferment for 1-2 weeks, then condition for at least another 3 weeks, it is worth considering how much starch will actually remain in suspension by the time of serving. My gut feel is that protein and glucan hazes are much more enduring.

From: "John L. Isenhour" <isenhour@lambic.fnal.gov>  
Subject: Corona Grain Mill adjustments

I'm trying to adjust my Corona Grain Mill to minimize the uncracked grains that pass through. I ground the tip of the stem (which presses against the ball bearing in the clamp-on arm) flat, this stopped the adjustable grinding plate from changing depth during turning.

The outer grinding plate is held on by a cotter pin, and it is free-floating (i.e. it wobbles around). This would seem to allow some grain to escape. I'm wondering if I should try to affix the adjustable plate to the stem in such a way that it could not wobble and yet maintained a parallel position in respect to the other plate. Anyone tried this?

I'd also like to motorize this operation. Anyone done anything with a pully or something?

tnx!

From: STROUD%GAIA@leia.polaroid.com  
Subject: Phil's Phalse Bottom

In HBD # 1056, Jim Busch commented on the commercially available "Phils Phalse Bottom.":

>My complaint with the Phils system is that the tube  
>from the false bottom has to rise up out of the false  
>bottom to then exit the bucket. This can lead to a  
>problem with an air bubble forming inside the tube.  
>I have seen extremely slow runoffs that I think are  
> due to this design.

For those people who are not familiar with this piece of equipment, it consists of a circular piece of plastic shaped like an inverted dome. This sits on the bottom of an Igloo/Gott-type cooler. It is perforated with small holes, effectively operating as a false bottom by holding back the grains/husks, but permitting sweet wort to pass through unimpeded. The amount of "dead space" under the dome is reasonably small, certainly much less than with a Zapap-type of lauter tun. There is a 90 degree plastic elbow that rises up out of the center of the false bottom, and a connection can be made between this elbow and the outlet hole at the bottom of the cooler with plastic tubing or a rigid tube.

A friend of mine bought one of these this past fall and I have used his a couple of times. The first time I simply ran a piece of plastic tubing from the elbow through a rubber stopper which was wedged into the outlet hole. I then attached an adjustable tubing clamp to control flow and directed the effluent from the lauter tun directly into the bottom of the boiling kettle.

Unfortunately I ran into the exact problem described by Jim. Try as I might, I could never get a very quick flow of sparge from this setup. Like Jim, I first assumed that I had an air bubble stuck in the line that would not permit flow of liquid. However, upon examining the situation more closely (and reading the directions that came with the Phalse Bottom!), I concluded that the problem actually was due to the collapse of the plastic tubing in the lauter tun, caused by the relatively hot temperatures of the mash/sparge water.

When I used the Phalse bottom a second time, I butted a rigid plastic tube right up to the plastic elbow and connected them with a VERY short piece of plastic

tubing. The rigid tube was then run through a stopper wedged into the outlet hole in the cooler, and a piece of tubing was attached to direct the sparge into the boiling kettle.

This arrangement worked quite well, and I had no trouble with a slow runoff.

When used this way this false bottom works reasonably well and is a cheap way to quickly convert an Igloo-type cooler to an insulated lauter-tun (though there are other even cheaper ways of doing this that aren't much more work). I think that it certainly superior to the grain bag/vegetable steamer combo commonly used by many homebrewers.

I think that the holes in the false bottom are a bit large and would like to see this unit manufactured with smaller holes and more of them. It would also be easy to replace the plastic elbow with a threaded copper one, so that one could attach a piece of copper tubing to this via a compression fitting, by-passing the use of plastic tubing entirely.

From: "John L. Isenhour" <isenhour@lambic.fnal.gov>  
Subject: BEST iodine (idophor?)

I just got some BEST iodine type sterilant, and was wondering about the dilution of it. Handwritten on the bottle was "1 1/4 teaspoons per gallon". I cannot locate any tables that convert teaspoons to milliliters, and when I tried measuring 1.25 teaspoons with various kitchen measures, I was getting different results when I measured it in milliliters (on a 2 ml pipette). I was trying to make up a quart of solution, and I ended up adding 1.5 ml of BEST. In a mason jar, this looked like american pilsner, and I used it on my glass racking canes and carboys. When I drained it, it had left suds behind and I was concerned about not rinsing it (so I did).

Could someone with experience give some advice? How many ml's in a teaspoon?

tnx!,

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Under Pressure

In hbd1057 Lou Casagrande did some calculation that achieved a pressure of 30 atm priming 5 gallons in 6 gallons with 1 lb sugar. The main error was a failure to allow for the amount of CO2 dissolved in the beer, which at 0C would be around 171 ml/100ml. Adjusting the calculations thus gives a pressure of around 3 atmospheres - still high, but then 1lb is a lot of priming sugar.

From: "Kevin (K.W.) Golka" <golka@bnr.ca>  
Subject: Grain, Volume vs Weight

On the weekend we brewed an all grain lager. The recipe was similar to a Pilsner we had made before but our intention was to increase the volume of water and end up with more beer with a lower OG.

Specifically our original Pilsner has a starting OG of 1053 for 23 L. By scaling up the grains and adding more water we were hoping to obtain an OG of 1047 for 29 L.

After the protein rest was finished and we added the mash water, my friend commented on the amount of head space we had left in the tun. We use a cylindrical drink cooler. With similar volumes of grain in the past (13 lbs) we expected to have only a 2" to 3" of head space. We ended up with about 7".

Since we were concerned about head space we ran the protein rest a bit stiffer than usual. We had overall 2 L less water in the tun. This would account for 1" to 2" of head space. We suspected that we somehow measured the grain incorrectly and had left out about 2 lbs. We decided to proceed as is and live with this since we had reached the desired strike temperature.

When we finished the collected volume of 20 L gave an SG of 1074. This was pretty close to our original target SG assuming 13 lbs of grain and an efficiency of 28 pts/lb/gal (US). So we actually did have the correct amount of grain in the tun all along!

So how did we end up with all of this head space? The grain we used came from the same 45 kg bag we have been using all along so it should have had the same volume per weight.

Is there a rule of thumb for grain volume vs weight? I suppose this depends on the moisture content but what are the extremes, 0 % moisture (if possible?) and 100 % moisture.

Any thoughts would be appreciated.

Kevin Golka, 613-763-3474

These opinions are my own and not necessarily those of NT or BNR.

> Whoops, sorry if I mislead anybody. When I said "disporportionately  
> high percentages" I was thinking of ridiculous percentages, like  
> \*replacing\* your pale male with Munich. I'm sure someone out there has  
> tried it (no, not me :-).

Let's clear up a misconception here. Real Munich malt, whether  
domestic or imported, has enzymes. It has sufficient enzymes to  
convert itself, and perhaps just a bit more. If you want to make a  
real dark Munich lager, then use Munich malt. I've made several bocks  
with high percentages of Munich (60-80%) and it works just fine.

In particular, the imported 2 row Munich malt is far superior to the  
domestic 6 row "Munich" malt because it is prepared differently. The  
domestic is regualr pale malt that is given a final kilning at a higher  
temperature to increase the color. It does do this, but not a lot, and  
it doesn't prepare the malt to produce the malty aromas that are really  
appropriate for most of the dark lager beer styles. Read Fix's "Vienna  
\* Maerzen \* Oktoberfest" for more discussion about this. The imported  
2 row Munich malt is prepared by heating it briefly while still moist  
and then drying it. This produces the most color and malt aroma for  
the temperatures.

Crystal malts are prepared in the same general way, but rather than a  
brief heating while moist, the malt undergoes as complete a  
saccarification as possible, and then is subjected to higher heating  
temperatures for longer periods to really enhance the color formation.  
They have no enzymes left because of the higher, longer heating. They  
also have much darker color ratings than Munich malt.

In HBD#1057 ogilvie@ficc.ferranti.com (jim ogilvie) asks....

>Subject: Please help me convert mg/L to ppm

>I recently requested and received a report from my water supplier listing all the junk in my tap water.

>SNIP<

>can I read that as being pretty close to parts-per-million?

>SNIPSNIP<

YUP...

mg/l and ppm are exactly the same.

Also... 1 ppm = 0.058 grains/US gallon or 1 grain/US gallon = 17.1 ppm

>Jim(ogilvie@ferranti.com)

While we are back to nasties in water, I looked up some MCL (Maximum Contaminant Level) for some of the goobers found in tap water that may apply to us. These numbers are per the 1986 version of the EPA's Safe Drinking Water Act...so they must be "safe"...right ;)

They are listed in ppm or mg/l...take your pick.

```
Pollutant MCL
- - - - -
Arsenic 0.05
Chloride 250.0
Copper 1.0
Cyanide 0.01
Fluoride 1.4 to 2.4
Iron 0.3 (>0.3 makes water red)
Lead 0.05
Manganese 0.05 (>0.1 forms brown-black stain)
Mercury 0.002
Nitrate 45.0
Sulfate (SO4) 250.0 (>500 has a laxative effect)
```

The list gets pretty extensive..these were the ones that looked usefull. If you want others, post or send me email...

Most people cannot tolerate drinking water that exceeds 300 ppm carbonate, or 1500 ppm chloride, or 2000 ppm sulphate.

NOTE: According to my reference "Exposures over safe limits can result in a variety of serious health problems ranging from liver and kidney damage, high cancer risk, nervous system disorders, skin discoloration, hypertension, an a variety of others."

Not to scare anyone away from brewing...i just get dangerous with a reference book sometimes...sorry

From: steve\_T@fleurie.compass.fr (Steven Tollefsrud)  
Subject: 1) right yeast for Barleywine? 2) Priming with malt extract?

I plan to make a Barleywine soon. I have two recipes. One calls for champagne yeast because it will survive above the levels of alcohol which would normally kill off regular lager or ale yeasts. The second recipe calls for lager yeast?! I am afraid of compromising the taste of the "beer" by using champagne yeast (is this a valid concern?). On the other hand, I don't want to have a sickly sweet, half fermented Barleywine because the alcohol level killed the lager yeast.

Has anybody out there got any experience with this? Is the recipe calling for lager yeast incorrect? What about fermenting it with the lager yeast and then adding the champagne yeast when the lager yeast dies? (a sort of compromise intending to benefit from the qualities of both)

I recently experimented with adding refined table sugar to a lager batch (approximately 70% malt extract to 30% sugar) to see how it would affect the taste. The result was lighter bodied, well carbonated, with an unpleasant cidery aftertaste. Now I want to avoid using sugar at all, even for priming. In order to make a completely sugar free, all malt lager, I would like to try priming with dried malt extract. Should I use the same quantites of malt extract as I would with sugar? One homebrew guide I have says to prime until the specific gravity increases by .005. Won't it be necessary to use more dried malt extract because of the unfermentables?

Subject: stuck fermentation?

Dear Brewers,

I have a quick question. I had such success with Papezian's recipe for Propensity Lager last year that I decided last week to give it another go. It is delicious stuff!! However, I think I might be experiencing my first stuck fermentation. I'm storing the brew in my pantry at about 47F constant (I leave the window cracked open and the door shut to help cool the room). I'm using a blow-off method (again), but this time I'm using liquid yeast. I've used liquid ale yeasts before and have had good beers, but this is my first try with liquid lagers.

I used Wyeast liquid lager (pilsen), and all was going gang-busters within 12 hrs of bursting the inside package of the yeast packet. It had swelled almost to the point of bursting itself. I made a batch of starter that night, and watched as that too grew vigorously - the smell was (for brewers anyway) heavenly! Then, after brewing the wort according to the recipe, I cooled the brew and pitched the yeast.

That was almost two days ago, and as yet, there seems to be no action through the blow off tube...Not even a kreusen yet. However, the beer does seem to be clearing (is it settling too soon?).

So my question(s) is/are: is it too soon to tell if the brew is stuck? And, if it is stuck, how can I nudge it along? Could the temperature be responsible for the (apparently) slow start? If so, should I try closing the window, opening the door, and warming the pantry/lagering closet up a bit??

Thanx, and Cheers!

John  
(ps to Jcusick@luccpua - lost yer number, but saved you a Christmas Ale!! 'Twas the season - 'tiz the last (brew, anyway). Call me or "E" me. Will try you @ Micro soon. - jn

Subject: Hop question?

Some time back I saw a similar question, but never read a reply.

When adding boiling hops, does the selection of the type of hop (Kent Goldings, Northern Brewer, Cascade, etc.) make any difference on the final taste profile? I am wondering if I only need to be concerned about getting the number of IBUs correct, or if it is significant to get the correct number of IBUs from a particular hop when

attempting to duplicate recipes/styles. I understand that hops added for flavor and aroma do give the beer distinct characteristics, but I am curious if anyone believes that the boiling hops do?

> Robert Haddad overestimated his pressure by about 55% way back in  
> HBD#1003.

Well, Bruce, I must say that quoting me in such a scientific exchange did lots for my ego, even to show that I may have goofed, and, I hope, this will be taken into consideration when my tenure review takes place... :)

However, I stand by my original reading of about 25lbs of CO2 because something was omitted in the midst of all these numbers, namely that I pumped some 10lbs of CO2 in the keg at priming time to ensure an adequate seal (which, according to your numbers would make sense, 16lbs with 1/2 cup of glucose, plus some 10lbs for good seal)

Anyway, on another note, perhaps you or someone else on the line can explain to me why my "Pilsner Urquell" (Cats Meow2, Don McDaniel), which has been at 50 deg for 70 days, still registers a gravity of about 1.020 (down from 1.050). Does this qualify as stuck fermentation? Should I keg as is, with no priming, and hope that fermentation will continue during lagering? What if I want to bottle some (I have 20 gals of the stuff!).

Thanks,

Robert Haddad

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: priming sugar and head retention

I've been having difficulty in getting a good head on my beers. I can generate a reasonable one by pouring "forcefully" but this tends to make the rest of the glass somewhat flat. Is the standard 3/4 cup supposed to be able to generate a good head and also preserve good carbonation in what remains?

One 3 gallon batch I made I inadvertently put in 3/4 cup which translates to 1.25 cups for 5 gallons. That batch has PLENTY of head- too much, but it gave me the idea of increasing priming. What are thoughts about increasing priming to around 1 cup? This should generate plenty of CO2 for head forming, but is this heresy?

Something like dandelion wine?

No. Genifer. She's a great little bottle washer

>From: korz@iepubj.att.com

>At least two brewer's have suggested using very hot boiling or almost boiling water for sparging.

Just for the record, and to clarify MY current view, I suggest using whatever temperature it takes to get the proper (see below) temp in the grain bed.

> Could it be that we don't want the grain bed during the sparge to be \*AT\* 170F, rather we want the \*sparge water\* to be at 170F and we should let the grain bed (in an insulated tun) settle at whatever temperature it wants? Can someone who has "Brewing and Malting Science" please look this up? Darryl, what sparge temp is used for Pilsner Urquell?

>Comments?

Excellent food for thought. My guess is that the number is a "momily" based on some particular system that has since been chipped in stone and followed blindly.

What is "proper" for a commercial sized batch is not likely to be the same for a ten gallon kettle and certainly not the same for an insulated vessel.

We need a number for the actual mash, based on chemestry and how we get there is our own responsiblity. Perhpas we can even put an end to the flame fests everytime someone uses boil and sparge in the same sentence.

Just as an aside, I make my sparge water as I use it in a small boiler, fed directly from the tap. It runs out of the boiler, and falls into the lauter

tun. The temperature loss in my system is a hidden blessing because it allows me to boil off the chlorine at a higher temp.

>From: arthur@chiba.esd.sgi.com (Arthur Evans)

> in one of the Zymurgy special issues (I think it's the "gadgets" issue)  
has instructions for building a "mini-jockey-box."

Just a point of caution on "jockey boxes". First of all, they probably are more efficient than a cold plate for continuous use because of the amount of beer in the tubing. However, for the occasional glass, all that beer in the copper tubing, is beer you probably do not want to drink if it has sat there for a day or more. You will have to dump a glass or two to flush the system and that simply would not do.

The cold plate has very thin and much less tubing along with a good aluminum heat sink to increase the efficiency. The one I have only holds an ounce or so of beer and the tubing is stainless. It is much better suited for casual and occasional use.

js

If I posted this already, file it under too much aluminum....

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: decoction mashing

Hi All,

In HBD #1058, C.V.Copas writes:

...Regarding the problem of extracting unconverted starch during sparging, I am wondering how significant this is in practice. When one considers that the brew will ferment for 1-2 weeks, then condition for at least another 3 weeks, it is worth considering how much starch will actually remain in suspension by the time of serving. My gut feel is that protein and glucan hazes are much more enduring.

IMHO, anytime starch makes it into the wort, either through incomplete conversion or extraction during sparging, it's a significant problem. It's not so much the aesthetics of the haze itself, but that beers with a starch haze taste slightly infected. I confess to brewing a couple of beers that had this problem while transitioning to all grain brewing, and the off-flavor got worse over time, not better. I've since tasted other brewer's beers that had this problem, same slightly infected taste. It seems to be a common problem among beginning grain brewers who are trying to learn to mash and sparge properly.

In a typical scenario, a brewer will pitch a large quantity of yeast, which multiplies and quickly metabolizes sugars in the wort, preventing any bacteria that is present from getting established and causing flavor problems. Is it possible that the presence of starch in the wort provides a growth medium for bacteria that would otherwise have none? I have no background in microbiology, so I'm not qualified to answer that question definitively. Perhaps others who are would care to comment?

Cheers,  
Jim

From: "Daniel F McConnell" <Daniel.F.McConnell@med.umich.edu>  
Subject: 100% munich malt

Subject: Time:4:32 PM  
OFFICE MEMO100% munich malt Date:1/19/93  
Regarding the 100% munich malt question:

A friend of mine (Jeff Renner-used with permission) recently made a 100% munich malt brew for a male-bonding-TV-football-saturday. Ohio State vs Michigan. It was made intentionally low in gravity (but not in flavor) so they could drink it all afternoon. The target beer was a Munich style dark beer. There were no problems in the mashing or conversion, perhaps because this was only 10L malt and plenty of enzymes were available.

For 7.5 gal:  
10 lb Ireks Munich malt (10L)  
mash in with 8 qts H2O at 65C to rest at 55C--30 min  
raise with 3 qts boiling H2O and heating to 67C--85 min  
remove thinnest third, boil and add back to rest at 75C--10 min  
sparge to collect 8 gal  
boil 90 min  
1st Hop addition-42 gr (3.8%) Hallertauer pellets-90 min  
2nd hop addition-10 gr (3.8%) Hallertauer pellets-20 min  
3rd hop addition-10 gr (3.8%) Hallertauer pellets-0 min  
Ferment with Bavarian Lager yeast at 60F--14 days  
2ndary at 33F-- 22 days  
OG=1.040 TG=1.012

This turned out to be very good, with nice, light malty sweetness, but certainly NOT the \*Munich\* style as was expected. I'm sorry I missed the party, but at least some was left over in the keg.

From: Brian.Smithey@Central.Sun.COM (Brian Smithey)  
Subject: using steel cut oats in stout

Hi,

I'm getting ready to do an oatmeal stout, and I'm planning on using steel cut oats rather than rolled ("Quaker") oats. I was planning on cooking the oats before adding them to the mash, figuring that the cut oats would require gelatinization prior to mashing.

However, when looking through "Cat's Meow" for inspiration (and to take another look at Jay Hersh's great steel cut oat experiments), I didn't find any mention of cut oats being cooked, but rather recipes that implied adding the raw cut oats directly to the mash.

I'd like to hear any experiences with using steel cut oats in an all-grain brew -- whether you cooked or not, how much you used, how the beer turned out, etc.

Thanks,  
Brian

From: cook@uars.DNET.NASA.GOV (Chris Cook, NMOS Quality Engineer - (301) 386-7807)  
Subject: Questions about mashing, sweet finishes, clean burners, etc.

All right, I have a few quick questions. Or maybe not so quick...

1) In Greg Noonan's book "Brewing Lager Beer," he describes decoction mashes using phrases like "...draw off the thickest third of the mash..." Look, after all the stirring he describes, isn't the mash pretty uniform? Could someone who does this describe what the "thickest" or thinnest part is, and how you draw it off?

2) After tasting Thomas Hardy's Ale, Royal Oak Pale Ale, Samuel Smith's Oatmeal Stout and others, I've fallen in love with these beer's sweet finishes. How do they do it? Is this simply a result of mashing temperatures, or are we talking artifice here? Thinking minds want to know.

3) I have one of those Mount Saint Helens jet propane burners. It roars, jets, flames up high and almost completely contaminates every pot and pot resting place I own every time I brew. Does anyone have any tricks for making the thing burn cleaner so that it makes less soot? I remember the thread a few months ago about containing the flame around the pot, but I'm talking about avoiding the soot factor. I know the signs of an inefficient burn when I see them.

4) Oh, and finally, is everyone being honest with their grain extraction rates? I realize the pressure to talk up your extraction points and all, but are we talking reality here?

That's enough for now. I'll add more information as I learn.

From: Carlo Fusco <G1400023@NICKEL.LAURENTIAN.CA>  
Subject: compiling new list

Ok, I'm getting tired of hearing the question about where to find a good brew in city X. I have decided to be the coordinator of a list that will finally tell people where to go in which city. I am hoping to produce this list so that it is accessible as a FAQ. [who can tell me where to send the final list for achiving to.I would also like to update my list about brewing online but I don't know where to send this list to, or how to archive it....any ideas?]

The way I see it, this list will be a update to the "publist" found in HBD. If you wish to submit entries into this list please send them to me. I would like the entries to be in the following format:

Country, City  
Name of establishment, what is it? [eg. restraurant, brewpub, bar, etc]  
street address and phone number, if possible.  
why should I go there?--eg. it has 1 million beers on tap  
[keep this to 4 lines or less]

I think this should take several weeks to compile but I a willing to do the work.[In other words, don't look for the list for at least a month] Remeber, tell your friends...afterall we all have a different idea of how good a place is.

Send submissions to G1400023@nickel.laurentian.ca

And a special request to all those Canadians out there, send your entries in so I know where to go when I visit your hometown...Heck, I may even call you to join me.

\*\*\*\*\*

-----

Date: Wed, 20 Jan 1993 21:47:16 +1030  
From: Murray Robinson <robinm@mrd.dsto.gov.au>  
Subject: Kegging.

I've finally gone and bought my self all the bits and pieces  
(mostly second hand) I need for a draught beer system. ie:

Cornellius Keg with screw top.  
Disconnect fittings  
Tubing  
Tap suitable for through fridge wall mounting  
Regulator  
Chest freezer.

COST: \$135 Australian.

The Gas bottle I rent at \$4 per month.

What I now need to know is the correct procedure for using it. This is  
what I had in mind so please let me know any problems, improvements, etc  
you can think of.

- 1) Sterilise Keg, fittings, lines, tap etc.
- 2) Purge keg of all air by sealing the lid, turning gas cylinder on,  
connecting  
the gas line from the gas cylinder and pressurising to 15 psi. Purge CO2/  
O2 mixture  
via the safety valve. Repeat.
- 3) Turn gas cylinder off and release all pressure in the keg via the  
safety valve.  
Open the lid of the keg, and gently fill the keg with beer to within 2-3  
inches of  
the top of the keg.
- 4) Reseal keg, turn gas cylinder on and pressurise to 15 psi. Purge any  
remaining O2  
in the keg using the method described in (2).
- 5) Pressurise the keg to 25 psi and place in a cold fridge for a day or  
so.
- 6) Remove keg from fridge and roll it vigorously to dissolve the CO2 into  
the beer.  
Replace keg in the fridge.
- 7) When ready to serve beer, bleed excess pressure from keg and connect  
gas line set a  
about 7 psi to push beer from the keg.

Any comments?

P.S. I have allready replaced the rubber O Rings and seals on the keg.

Cheers and Beers,

Murray.

Subject: sweetness of products in wine/cider/beer

Hello all of you,

I am looking for information on what the perceived sweetness (compared to sucrose) is for some products which are present in wine/cider (and perhaps also in beers). I am thinking of products like:

- alcohol (in the range of 4 to 15 % vol.)
- glycerol (in the range of 0 - 20 gr/litre)

I have some ideas about the sweetness of other products (like glucose, lactose and maltose). Perhaps other people have even more information on other products (not mentioned).

Because sweetness is not a linear scale, I have putten some info of the concentrations of the products. So if there is some info about this non-linear process, I am also very interested.

Hope somebody can help or point me to some articles/papers.

All the best,

Victor

From: mlobo@sentry.foxboro.com (Michael T. Lobo)  
Subject: kudos & gripes

First I want to thank Stephen Hansen for the new structure of the HBD archive structure..very practical & quite easy to use..

On that note, I want to ask that we all get in the habit of being more specific in our \_Subject\_ comments. In the archive indexes, this is all we see, and when the topic is \_re:HBD \*\*\*\_, it makes for a useless entry. I have been guilty of this in the past, but since using the archives, I see the reason others have complained in the past.

later,

IN HBD # 1058 I said, in regard to Phil's Phalse Bottom:

>>it certainly is superior to the grain bag/vegetable steamer combo  
~~~~~

and Jay Hersh replied:

>My grain bag and copper coil works wonderfully.
~~~~~

Jay,  
Note that I never mentioned a copper coil. I was specifically referring to the vegetable steamer commonly used by many brewers. This setup requires the use of a grain bag because the steamer doesn't fit tightly in the bottom of the cooler. There is also quite a bit of dead space associated with the steamer.

I have looked at your copper coil setup and am sure that it works as well or better than PPB. However, PPB is an off the shelf item that takes about 2 seconds to install :-), an advantage for some people. I still doubt that you need to use the grain bag with your setup, though it probably does make cleanup easier.

The only one that leaps to mind is "Rock and Roll Music" with the  
line  
"drinking homebrew from a wooden cup" (a song snippet I occasionally use  
in my  
.sig file) but that is actually a Beatles cover of a \*Chuck Berry\* song.

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Goodies for the TechnoBrewer

The January catalog from American Science & Surplus (601 Linden Place, Evanston, IL 60202) has a couple of goodies which might be useful to you technically inclined brewers out there. On page 27, they have a small Bunsen Burner that is jetted for use with propane for \$4.75. Just the thing for flaming those loops, etc. Second, on page 20 they have 0-15 PSI pressure guages for \$3.00 each. These should be just the ticket for use on CO2 lines, counter-pressure bottlers, etc. I have no connection with AS&S other than as a satisfied customer etc. blah blah blah. Their catalog is a hoot, and useful stuff can be found in most copies.

From: pyle@intellistor.com (Norm Pyle)  
Subject: Brews Paper / Grain mill rollers

Ulick and Jack commented on the Brews Paper. I think this thing is a piece of junk. I'm not sure why I received their first issue, but I guess it has something to do with my subscription to Zymurgy. Anyway, there are soooooo many typos in the thing, I started to believe they were there on purpose. On the front cover they have a quote something like: "We ain't too serious". When I saw it at first I thought it was a good thing. After reading the BP cover to cover, I decided they need to be a bit more serious. The writing was at a junior high school conversational level, to boot. If any BP folks are reading this digest, I suggest you work on issue #2 a little longer before it goes to press. Sorry for the long tirade but bad "journalism" bugs me... (On a lighter note, I did enjoy the jokes, etc.)

Roller mill rollers: anyone have any good sources? I have a wonderful little homemade roller mill, but the rollers are a weak point. One good suggestion I received was conveyor belt rollers from a junk yard, but I thought I'd solicit more suggestions here.

Cheers,  
Norm

translates to  
> 1.25 cups for 5 gallons. That batch has PLENTY of head- too much, but  
it gave  
> me the idea of increasing priming. What are thoughts about increasing  
priming  
> to around 1 cup? This should generate plenty of CO2 for head forming,  
but is  
> this heresy?

I too was unhappy with the level of carbonation when using 3/4 cup  
of corn sugar for priming. I have experimented with priming and  
find that I am most happy when using 1 cup of priming sugar for a  
5 gallon batch. I believe this is a matter of taste, I  
personally enjoy the carbonation I get from 1 cup, and find 3/4  
too little and 1.25 too much.

I have also experimented with the addition of sweet-n'-low during  
bottling. I use dry yeasts, and decided to try David Line's  
suggestion (p. 21, Brewing Beers Like Those You Buy, "However if  
you can only get home brew beer yeasts instead of the recommended  
commercial 'Brewer's Yeast' the flavour balance can be acceptably  
restored by adding five saccharin tablets"). I have found that 10  
packages of sweet-n'definitely adds too much sweetness (more is  
not better, in this case). I have also experimented with five  
packages of sweet-n'-low and believe this to be my best batch  
yet. Many people have enjoyed this ale, and I found that this  
batch disappeared quickly (leaving me with three earlier  
batches). Even with 5 packages of sweet-n'-low the sweetness  
could be lowered slightly. Next I will try 4 packages. Has  
anyone else using dry yeasts expermented with artificial  
sweetners? If so, I'd be interested in hearing your comments.

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Answers

In hbd1059 Chris Cooke asks a number of questions.  
re: decoctions, there are several ways to remove thick or thin decoctions.

I personally, use a sieve to remove a thick decoction, and a small pot as a large ladle to remove thin decoction. I have one comment in general about decoctions. I have found that I need much larger decoctions than Noonan recommends for reaching strike temperatures. This is probably because I mash in a 7gallon Gott that has a large heat capacity, itself. I typically in a 2 decoction mash remove a 50% thick decoction to raise from protein rest to saccharification, and if the strike temperature is particularly high will usually need to add more boiling water. I may use 60% for the lauter decoction.

re, burner - if there is soot, the mixture is obviously too rich. Tweak down your gas flow if you can.

re extraction rates. My last batch was 3lb Munich, 6lb 2-row lager, and 1lb 6row CaraPils. I got 12B in 6+gallons. That is about 29 sg points. Just a data point.

js praises The Brews Paper. I personally think it is not that great (well OK for nothing - but personally I think the \$15 annual subscription could be better spent on Imported hops or something). It should be noted that js is not an unbiased observer as the publication carries advertisements for his products. Incidentally, does anyone know who is responsible for the ads in Zymurgy selling Coronas with the statement that it is better than the js rollermill (someone in St. Louis)?

re: slow yeast, I have a similar problem (I can't remember who posted the note). I pitched a batch of Vienna lager with a yeast (Wyeast Bavarian) that I had used several times before and washed in acidified Ammonium persulphate. I then fermented the sludge out twice with a rather stodgy 1020 wort prepared from low quality DME, but the second ferment seemed

reasonable. I then pitched it into 6 gallons of wort chilled to 40F and left it for 6 hours at 40F to settle. I then racked off the trub.

However,

I am sure I left most of the yeast behind as I doubt if much managed to get into the wort well at 40F for 6 hours. It is now been 60 hours+ at around 48-50F, without any real visible fermentation. I am not worried yet, considering my problem to be mainly due to a low cell count, and it will eventually hit krausen, but should I be??? Comments.

From: Chris McDermott <mcdermott@draper.com>  
Subject: bottle sediment, "partial d

bottle sediment, "partial decoction"

Since going all-grain, I've developed a problem with sedimentation in my bottled beers. The beers are crystal clear, but have a layer of loosely associated sediment at the bottom that's about 1cm thick. I don't think that this is yeast, but I'm not sure what it is. Has anyone experienced the same problem, and if so what causes it?

I've really enjoyed the recent thread on decoction. Noonan's book is a great resource, but its self-contradiction disturbs me a little. So, this additional discussion helps to sooth my nerves a bit.

Anyway, my mashing method, which I dub "partial decoction", is infusion in a 40 qt. Gott-Mash/Lauter-Tun. Hot water is added to reach the protein rest temperature. Boiling water is added to reach the saccharification temperature. And then the thinnest 3rd of the mash is removed, boiled, and returned to reach the mash out temperature. Is this method standard among a subset of us mashers, or am I and a few others (see Daniel F McConnell's post in HbD#1059) all alone out there? If there are others, I'd like to hear about your experiences with this M.O.

Subject: Re: yeast, Windsor Ale; Wyeast lager

In the last exciting episode of Homebrew Digest (#1059), Bill Crick mentions Windsor Ale Yeast. Recently, I brewed a Christmas ale using this yeast with satisfactory results:

INFAMOUS CHRISTMAS GLO:GG BEER

5# LIGHT AMERICAN MALT EXTRACT SYRUP  
2# LIGHT CLOVER HONEY  
1/2 OZ SAAZ HOPS (BOIL)  
1/2 OZ SAAZ HOPS (LAST 2 MIN. THEN STEEPED 10 MIN.)  
1 25 ML ALCOHOL BASED GLO:GG SPICE  
1 package WINDSOR ALE YEAST - REHYDRATED (no starter)  
(Glo:gg spice is made up of ginger, cinnamon, cardamom and clove.)

Boiled for 30 minutes. Cooled to 70 deg. F. pitched yeast.  
Fermentation began within 8 hours. Finished within 3 days.

OG=1.053  
FG=1.008 (after 2 weeks)

This was a very quick and easy recipe; a real plus around the holidays. The beer was rather tasty, although the spices were rather pronounced (covering up any defects if present). The yeast was very fast and attenuative. I have some more of it, so I'll post the results of that brew.

Also, in the same episode, Steve Tollesfrud had some trouble with Wyeast lager yeast. I brewed a batch using the same yeast and had the same problem. After pitching I put the fermentor in a refridgerator at about 45 degrees F. I had no action for 4 days and nothing happened until I warmed the wort to 65 degrees. I kept it at that temperature until primary fermentation stopped, and then slowly eased the temperature back down to 45. Racked to secondary and kept at 45 deg for 1 month. Racked to bottling bucket, and I am now aging in the bottles at same temperature.

I tasted the beer before bottling and it is quite good.  
After bottle conditioning it should be delicious.

Has anyone else had this problem with Wyeast lager?  
Marinated minds want to know.

From: Kieran O'Connor <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>  
Subject: Andre Pruitt 8000

FWIW here's the Andre Pruitt 8000, mashtun and lauter tun set up.

I have finally made an all grain batch and I was trying to make a set up with a combo lauter and mash tun.

Here's the set up--thanks for the tips from you folks:

Igloo 10 gallon cooler.  
Plastic Fermenter  
Bottling Spigot

OK--her'es the deal. Origianlly I was oging to hook up a Phil's False bottom to my cooler and replace the spigot with a 1 inch bottling bucket valve. My friend, Andre Pruitt, said, forget the false bottom--use a bottling bucket.

So I drilled a bazillion holes into the bottom of my original plastic fermenter. I also cut off the first "ring," the first inch or so of the fermenter.

The I drilled a bazillion holes in the lid also.

Andre drilled the spigot hole to 1 inch--but be careful--dont just use a wood bit--use the kind which drills a pilot hole first, and put osomething inside the cooler so the drill wont shake while you drill.

Now--to the brewing:

Put the fermenter into the cooler, and put the grain inside. Mash in. Then let it mash for the time specified. To sparge, we put the lid on top of the fermenter and sparged through the holes. I'm going to cut the lid so that it will sit right on top of the grain.

You can alter the speed of the sparge with the bottling bucket valve--so it was quite nice.

Over the mash--it lost 2 degrees in 50 minutes.

At the end, pull out the bucket, put it into another, and then you dump the grain!

Volia, the Andre Pruitt 8000 Mash/Lauter Tun.

Comments welcome--suggestions too!

Kieran O'Connor

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: HBD 1059

Hi All,

In HBD #1059, Chris Cook asks:

>All right, I have a few quick questions. Or maybe not so quick...

> 1) In Greg Noonan's book "Brewing Lager Beer," he describes decoction  
> mashes using phrases like "...draw off the thickest third of the  
> mash..." Look, after all the stirring he describes, isn't the mash  
> pretty uniform? Could someone who does this describe what the  
> "thickest" or thinnest part is, and how you draw it off?

Decoctions are generally done after some sort of rest, i.e., acid,  
protein, or saccharification, so the mash at these points is not uniform.  
The thickest part of the mash is the grist, which tends to settle on the  
bottom during rests, the thinnest part is the liquid that's atop the  
grain.

I use an Igloo cooler to hold saccharification rest temperatures. For  
thick decoctions, I tip the cooler so the liquid runs to one side, and use a  
small saucepan to withdraw the grain from the other side. To achieve mash-  
out, I use a thin decoction, scooping the liquid from the top with the same pan.  
Not very "high-tech", but effective.

\*\*\*\*\*

Also in HBD #1059, Steven Tollefsrud asks:

>I recently experimented with adding refined table sugar to a lager batch  
>(approximately 70% malt extract to 30% sugar) to see how it would affect  
>the taste. The result was lighter bodied, well carbonated, with an  
>unpleasant cidery aftertaste. Now I want to avoid using sugar at all,  
>even for priming. In order to make a completely sugar free, all malt  
>lager, I would like to try priming with dried malt extract. Should I  
>use the same quantities of malt extract as I would with sugar? One  
homebrew  
>guide I have says to prime until the specific gravity increases by .  
005.  
>Won't it be necessary to use more dried malt extract because of the  
>unfermentables?

Yes, I've used 1 to 1 1/4 cups of dried malt extract to prime a 5  
gallon batch versus 3/4 cup of corn sugar. It will also take a week or  
so longer to achieve good carbonation.

\*\*\*\*\*

Also in HBD #1059, John of the odd looking Bitnet address asks:

>I used Wyeast liquid lager (pilsen), and all was going gang-  
>busters within 12 hrs of bursting the inside package of the yeast packet  
>It had swelled almost to the point of bursting itself. I made a  
>batch of starter that night, and watched as that too grew vigorously -  
>the smell was (for brewers anyway) heavenly! Then, after brewing the

>wort according to the recipe, I cooled the brew and pitched the yeast.

>That was almost two days ago, and as yet, there seems to be no action  
>through the blow off tube...Not even a kreusen yet. However, the beer  
>does seem to be clearing (is it settling too soon?).

>So my question(s) is/are: is it too soon to tell if the brew is stuck?  
>And, if it is stuck, how can I nudge it along? Could the temperature  
>be responsible for the (apparently) slow start? If so, should I try  
>closing the window, opening the door, and warming the pantry/  
>lagering closet up a bit??

I've experienced fairly long lag times, on the order of 24-30 hours, when using liquid lager yeast, and pitching when the wort had cooled to ~50F. I've managed to cut this down to 12-18 hours by pitching when the wort is slightly warmer, ~60F, pitching a somewhat larger volume of starter than for ales, and leaving the primary fermenter in a warmer place until signs of fermentation are evident.

I'd say that 47F is a bit too cool for the yeast to get started. Try moving the fermenter to a warmer room, or closing the window. When fermentation starts, re-open the window, but try to avoid sudden, drastic temperature swings. Also, if you decide to pitch your next batch at a higher temperature, be aware that you'll get a bit more diacetyl in exchange for the faster start. Not a major problem, I've managed to deal with it by utilizing a diacetyl rest.

Cheers,  
Jim

From: hoodj@gov.on.ca (Jim Hood)  
Subject: Did tin do me in? (and ruin my beer?)

My first attempt at all-grain (10th batch overall) produced my first throw-away batch. There are no visible signs of infection, though no doubt there are bacteria which are more subtle about their presence. The beer looks and smells fine. It has a terribly bitter, almost metallic (though not all tasters agree with this description) aftertaste. One person commented "It's like you overhopped by an order of magnitude." I didn't.

The recipe was Tony B.'s version of SNPA, which he posted late last summer. Procedure pretty much ala Miller. Good sanitation observed (no problems that way from previous extract and partial mash brews).

My nomination for the culprit is my boiler. I obtained one of those old copper boilers, some folk refer to them as "jam boilers". A lot of these, I am told, were tin plated on the inside (beats me why). I'm wondering if the acidic wort reacted with the tin to produce the bad taste that this batch has. The only reference to tin I found in Miller who said keep it out.

Of course I'm open to other suggestions, if these kind of boilers haven't been a problem for other brewers. Also I'm willing to UPS a bottle to anyone who cares to run a personal diagnostic, as long as you're not too far from Mich. upper peninsula.

From: HOWED@bcvax1.bc.edu  
Subject: The Cinnamon Stopper, resolved

A while back, I posted a problem with a batch of cinnamon beer. Since then I have fiddled around with it a bit, and I seem to have figured out the problem and how to carbonate the beer.

I reprimed each bottle by hand and recapped them. This has been effective in carbonating. The best guess that has been made about why it didn't take the first time was that by adding the cinnamon to the priming sugar when bulk priming, the cinnamon turned into a syrup which collected the sugar into a few bottles, thereby turning them into gushers.

Since then, my partner and I have ventured out yet again into new combinations [for us anyway] and we have made a chocolate wheat beer. A tasty idea that has definitely panned out well for us.

Subject: Trivia/Barleywine Yeast

Gak writes:

>Which Beatles song refers to homebrewing?

Well, it's a bit of a trick question. It's actually a Chuck Berry song, redone by the Beatles: Rock & Roll Music.

Just so this post is not just trivia...

Steven writes:

>I plan to make a Barleywine soon. I have two recipes. One calls for  
>champagne yeast because it will survive above the levels of alcohol  
>which would normally kill off regular lager or ale yeasts. The second  
>recipe calls for lager yeast?! I am afraid of compromising the taste  
>of the "beer" by using champagne yeast (is this a valid concern?).  
>On the other hand, I don't want to have a sickly sweet, half fermented  
>Barleywine because the alcohol level killed the lager yeast.

If you can get a hold of some relatively fresh Sierra Nevada Pale Ale or SN Porter or Stout (I'm assuming you can't get Wyeast 1056 in France)

, you could culture it and use that exclusively. Chico Brewing Co. uses this yeast for their Bigfoot Barleywine, so you can too.

Using a beer yeast at first and then a Champagne yeast to finish off (as Steven later suggests) is a good idea if you can't get the gravity down with just the beer yeast. Make sure you pitch A LOT of yeast and AERATE THE WORT VERY WELL, so the yeast has a fighting chance. I've read that some brewers rouse the yeast on very high gravity beers, but if you do, you're probably better off doing this in the secondary so you don't stir up the trub. Also make sure to not aerate the wort during the rousing -- I just agitate the fermenter, being careful to not spill the airlock into the fermenter (note this is with glass -- you can forget about trying to not suck air on a plastic fermenter -- it's impossible).

From: mark@verdix.com (Mark Lundquist)  
Subject: Keg questions

Thanks to those who responded to my question about how I might make use of a keg that I "inherited". The keg was one of the new-style "one-holer" (Sanke?) brewery kegs. The most sensible-sounding suggestion was that I find a distributor who would be willing to trade me a Golden Gate keg for my keg.

So...now I have some questions:

- 1) Should I naturally condition my kegged beer, or should I artificially carbonate? Will there be any difference in the quality of the finished beer?
- 2) How do I keg-condition beer? (For bottled beer, I prime with 1 cup DME per 5 gal.)
- 3) How do I artificially carbonate beer?
- 4) How long can kegged beer be stored if a CO2 tapper system is used?
- 5) How can I bottle from a keg?
- 6) How do I clean my keg? What sanitizing agents can/should I use?

Is there anything else I need to know about filling, storing, serving, etc. with my keg?

Thanks!

Subject: Corona Adjustments, Nitrosamines

>From: "John L. Isenhour" <isenhour@lambic.fnal.gov>

>The outer grinding plate is held on by a cotter pin, and it is free-floating (i.e. it wobbles around). This would seem to allow some grain to escape. I'm wondering if I should try to affix the adjustable plate to the stem in such a way that it could not wobble and yet maintained a parallel position in respect to the other plate. Anyone tried this?

Even if you were willing to sacrifice adjustability and welded the assembly together, you could not avoid the problem you point out. It is the nature of the beast. You have a four point system with only two "bearings". It relies on the two faces rubbing against each other for alignment. When used as we use it, it relies on the grain to keep them properly spaced. If you keep it full, it will more or less do this.

What I find helpful is to set the spacing using a .055" gage on each side of the plate. Dimes are about the right thickness but a bit hard to work with. Adjust the pressure so they can just be pulled up and down. This will give you the nominal spacing used on most rollers mills as a starting point. Note that this is only true when the mill is full and cranking.

>I'd also like to motorize this operation. Anyone done anything with a pulley or something?

I defer to those who have done this but point out that the "bearings" are iron against iron and not intended for high speed or rigorous use.

>From: Darryl Richman <darrylri@microsoft.com>

>The imported 2 row Munich malt is prepared by heating it briefly while still moist and then drying it. This produces the most color and malt aroma for the temperatures.

>Crystal malts are prepared in the same general way, but rather than a brief heating while moist, the malt undergoes as complete a saccharification as possible....

I am glad you cleared that one up. It is amazing what threads can follow

from the seemingly innocent use of two words in the same sentence. In this case Munich and crystal.

I would like to use this opportunity to re-address the nitrosamine issue as these two malts are produced in exactly the way that produces the maximum precursors for this potent carcinogen.

Crystal malt is probably the worse of the two because of the time spent in the hot, moist state but as it is used in only small quantities, it may be less of a hazzard than Munich which could make up the entire batch.

My advice is, know your maltster and his process. Indirect kilning, eleviates the nitrosamine problem and I would advise against using malt, especially crystal and Munich, produced in direct fired kilns.

It can be inferred from their literature that the Munich malt produced by De Wolf - Cosyns is indirectly kilned. Inferring things from literature can be dangerous so I ask that Tim Norris or any of the other dealers reading this make the effort to find out for sure and report back.

From: gjfix@utammat (George J Fix)  
Subject: Refractometers

Apparently many people have started using refractometers to measure gravities because they are simple and very accurate. Isn't it nice to be able to do these measurements at any temperature and with only a few drops of wort instead of the contents of an entire hydrometer jar!

One should be aware that the presence of alcohol in fermenting (or fermented) wort will skew the refractometer reading. Actually the same is true for hydrometer readings, but this is often overlooked. To get accurate results from either instrument, one needs to first boil off the alcohol from a sample and then replace the volume lost with distilled water. The reading one gets at this point is the real extract (RE), and in degree Balling (or Plato) is % sugar that is actually there (by wt.). It is different from the rather artificial number measured by a hydrometer without alcohol removal. The latter is called the apparent extract (AE), and the relation between AE and RE has been discussed in this forum. Unfortunately, the relation between refractometer measurements with and without alcohol removal is not known to me, and possibly does not exist.

This post does not mean to imply that refractometers are a "must have" item for homebrewers. There are many leading long and happy lives, and brewing sensational beer to boot, who are very content with their hydrometers. My private e-mail, on the other hand, indicates that there is a nontrivial interest in refractometers. I am often asked about where one can purchase such an instrument. I am a few years removed from this. My model comes from Cole-Palmer, but I understand their prices have soared in recent years. One of course can always count on Fisher Scientific to lead the league in high prices. If anyone has done a recent search, then a post on HBD might be helpful. It could be that there is a wide variation in prices for instruments of comparable quality.

From: "Jim Ellingson" <jimme@pi28.arc.umn.edu>  
Subject: Priming, CO2, psi, Temp, Kegs. (long)

Fellow Brewthren,

I've been watching this psi vs pounds of sugar debate for a couple of days, hoping it would de-pressurize itself. Clearly it will not. My apologies for the length of this post. I normally give wonderful advice ]:~) such as this via private e-mail.

In the archives, there is a chart of volumes of CO2 in beer, versus temperature and pressure. CO2 pressure is given along the top of the chart. Temperature is given down the left side. It makes little sense to discuss pressure without also giving the temperature.

All other things being equal higher (lower) temperatures will lead to higher (lower) pressures since the CO2 gas is more soluble at lower temps. Equally, the vapor pressure of CO2 is a function of temperature.

In a corner of the chart are the following guidelines for volumes of CO2 for different styles of beer at whatever temperature and corresponding pressure (I'm guessing these are volumes of CO2 at atmospheric pressure.):

Volumes of CO2:  
British style beers = 2.0 - 2.4  
Most other beers = 2.4 - 2.85  
High-carbonation beers = 2.85 - 2.95

That is, if I'm force carbonating, I need to push between 10 and 15 gallons of CO2 gas into my 5 gallons of beer. The pressure required to do this is a function of temperature.

If I'm using natural carbonation, I need to provide enough fermentables to generate just over 10 to 15 gallons of CO2 gas in my 5 gallons of (bottle conditioning) beer. The amount depends on the style. The amount extra depends on the head space, but we always want much more beer than headspace.

While the rate at which the yeast will consume the priming fermentables and carbonate our beer is a function of temp, the volume in the finished product is not. (Yes, yes, I know, provided the temp is high enough for the yeast to work and low enough not to kill the yeast and . . . provided we wait long enough).

Let's look at a couple of examples. If our beer is kept at 50°F, then we have the following set of pressures and volumes:

|         |      |      |      |      |      |      |      |      |      |      |      |      |      |
|---------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| psi CO2 | 11   | 12   | 13   | 14   | 15   | 16   | 17   | 18   | 19   | 20   | 21   | 22   | 23   |
| 24      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| volumes | 1.98 | 2.06 | 2.14 | 2.21 | 2.30 | 2.38 | 2.45 | 2.54 | 2.62 | 2.70 | 2.78 | 2.86 | 2.94 |
| 3.02    |      |      |      |      |      |      |      |      |      |      |      |      |      |

If I want 2.7 volumes of CO2 in my pilsner,

I set the regulator to 20 psi. If I want 2.3 volumes of CO2 in my porter, the regulator should be set to 15 psi. While this chart does give equilibrium values, it says nothing about how long it would take for 2+ volumes of CO2 to find its way into the beer. (This is where higher pressures and/or shaking the keg come into play.)

If we are priming, things get more complicated. Being very simple about it, a given volume of priming sugar/extract/gyle should yield a known amount of fermentables. For a given amount of fermentables, we can expect the creation of a known volume of CO2. (Let's keep the yeast attenuation, time to full condition, alcohol toxicity and any other favorite nits hidden for the time being)

Going back to the chart, and keeping our beer at 50°F. If priming with 1/3 cup of dextrose yields 11 psi (1.98 volumes), then priming with 1/2 cup of dextrose should yield 23-24 psi (2.94-3.02 volumes) in our keg.

I hope this helps. Sorry about the length.  
Cheers,

Subject: Re: using steel cut oats in stout

>I'd like to hear any experiences with using steel cut oats in an  
>all-grain brew -- whether you cooked or not, how much you used,  
>how the beer turned out, etc.

Hi Brian,

I've made at least 2 batches of Oatmeal Stout using steel cut oats. I believe that I used on the order of 2 pounds for a 13 gallon batch, but I don't have my recipes here at work and so am not sure what percent of the grain bill the oats were, but it was less than 10%.

I gelatinized the oats prior to adding them to the mash. The steel-cut oats that I got at a health food store were quite coarse and very hard. I believe that just adding them to the mash dry would have required a MUCH longer mash time to achieve starch conversion... even boiling took quite a while to soften the oats.

I found that I had to add a LOT of water to the oats during gelatinization. They just seem to keep soaking it up. I had to reduce the amount and temperature of the rest of my mash water since I was basically adding a substantial quantity of boiling oatmeal to the mash.

The stouts made using the oats have turned out very well. They have always finished with a fairly high terminal gravity ~1.020, but I'm not sure how much of that is the result of the oats and how much is due to the other ingredients. The oatmeal stouts that I have made this way have had a very nice creamy mouth-feel to them with a bit of residual sweetness.

Let us know how your's turns out!

From: mmlai!lucy!gildner@uunet.UU.NET (Michael Gildner)  
Subject: solder

Recently, I've seen some mention of lead-free solder being a bad thing for homebrewing. Evidently the tin in lead-free solder can react with beer. I didn't realize this several months ago when I made my wort chiller. I constructed the chiller with soft copper tubing. The coils didn't stay together very well so I put a spot of solder between each coil of the chiller to help keep it rigid. Now with all this recent talk of the incompatibility of solder in brewing I've starting worrying.

How does the solder react negatively with beer/wort?  
Is there some attribute I might recognize in my beers that point to solder contamination?  
Does anyone have any suggestions on how to cleanly remove the solder from the copper coils?  
What would be an efficient way to keep a soft copper coils together so they form a nice cylinder?

Thanks for any responses.

Subject: Munich Malts

Darryl Richman writes:

>Lets clear up a misconception here. Real Munich malt, whether  
>domestic or imported, has enzymes. It has sufficient enzymes to  
>convert itself, and perhaps just a bit more. If you want to make a  
>real dark Munich lager, then use Munich malt. I've made several bocks  
>with high percentages of Munich (60-80%) and it works just fine.

Anyone who has had the good fortune of tasting Darryl's bocks know they are more than "just fine". They are sensational! His version which took 1st place in the AHA nationals a few years ago was one of the finest bocks I have ever tasted, amateur or commercial. The following is data which support his observations. D-C stands for DeWolf-Cosyns, while G-W stands for Great Western. Their 2-row malt is a Klages-Harrington blend. DP stands for diastatic power, it is a measure of the strength of the malt's enzyme system. The symbol "\_" means too low to measure.

```
DP  Yield(%)Protein(%)
-----
BASE MALTS  D-C Pale Ale60  7610.0
  D-C Pils  105  7510.0
  G-W 2-row 135  7612.5

COLOR MALTS  D-C Munich  50  77 9.9

ROASTED MALTS D-C Caravienne  _  72 8.9
  D-C Caramunich  _  7210.6
  D-C Special B  _  6610.0
```

NOTES:

1. The strength of the enzyme system of the Munich is not dissimilar to that of the pale ale. Practical experience has shown that if DP > 40, then the grains will have sufficient enzymes to convert their own starch. The roasted malts do not have much in the way of an enzyme system, but Darryl noted this in his post.

2. For those who missed the yield discussions on HBD, the following are points on the yield-gravity point line:

```
yield(%) pts./lbs./gals.
-----
60 28
65 30
70 32
75 34.5
80 37
```

3. The yields quoted were obtained under laboratory conditions. It is generally not possible, nor desirable in most circumstances, to achieve these in a practical brewing situation.

4. I have found that both the color and roasted malts have starch with a large number of 1-6 links. These will not be broken in a normal mash. Thus

these malts will always make nontrivial contributions to the dextrin pool, even if they are included at the start of the mash.

5. Many highly respected maltsters in the US claim it is impossible to make color and roasted malts from two row barley. The low protein levels of the D-C malts indicate that they indeed come from 2-row barley, and very high quality to boot. Sonja, noted as Europe's best 6-row barley, never has protein levels below 13%. Hector, a mid-western feed barley (which I sometimes fear finds other applications as well!), never falls below 14%.

In HBD #1060 Norm Pyle writes about the Brews Paper being poorly edited and needing a bit more polish. Well, I'm glad somebody other than myself felt this way toward it! With all the material that is available I just can't see sending money to these people for a poorly published paper.

Mr. Charlie P. if your listening: If these people did get there mailing list from the Zymurgy subscription list I would like to indicate that I don't appreciate Zymurgy selling/giving my name to them.

OK... I'm done bitching now... On to grain mill rollers.

I've settled on using some 6" pipe that I got from some local pipe fitters. I figured the bigger teh diameter the better the grind. I'll be welding sides to the pipe and then welding a bar through the centers. The bar will get mounted in pillow blocks and the pipes spun by a motor with a belt. This is pretty much a nock off from the one in Zymurgy. On additional feature that I plan to add is to put a scroll on the pipe to pull the grains toward the center.

Cost.... grrr... I got the stuff from a guy that loves to swill my brew but he charged me full price for that stuff rather than simply pulling some scrap for me. Ended up being just under \$20 for 2 18" sections.

> line set a about 7 psi to push beer from the keg.  
>  
>  
>Any comments?

In my opinion, skip step 6 and just leave the beer in the fridge at 25  
psi for  
1 or 2 more days, depending on the carbonation level desired.

Shaking the keg simply increases the rate at which CO2 dissolves into the  
beer.  
By not shaking, carbonation takes a bit longer, but you don't disturb the  
yeast  
and protein sediment that precipitates when the beer is put into the  
fridge.

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Keg pressures

Jim Ellingson's notes on kegging in the last digest were right on, I would like to point out one additional thing that most keggers overlook. Your regulator gauge may not read your real keg pressure. This is due to the pressure drop across check valves that may (should) be in your CO2 lines. I have experienced about a 2 psi drop across each check valve. I have one at the regulator output and one at each output from my gas manifold. This means I must set my regulator to 16 psi to get 12 psi at my kegs (16psi - 4psi=12psi). Your systems may vary.

Subject: Stuck Pilsner Urquell

Robert Haddard asked about a highish final gravity of 20 on his attempt at my Czech Pilsner recipe:

I don't recall what my final gravity was, but I know it didn't ferment out really dry. I wouldn't call 20 stuck. Depending on the yeast, that's in the normal range. However if you're kegging, there's no reason you can't forgo priming and see what develops. If it is too flat after lagering, you can always force-carbonate it then.

What about a yeast culture from Thomas Hardy? Will that work or  
has the high alcohol content mutated the yeast. In December, Micah had  
mentioned making Barleywines when their kids were born. Anyone  
have a copy of Micah's Barleywine recipe?

On a similiar note, Miller mentions that it is difficult making  
an all-grain Barleywine and his recipes call for adding extract.  
He never fully explains what the problem is. Is the problem the  
quantity of grain needed to get the og high enough without  
adding extract? Or is there some other problem?

Neil

From: tony@spss.com (Tony Babinec)  
Subject: steel cut versus rolled oats

It's been said before on the net, but can't be said enough.

Steel cut oats are not gelatinized. You might first soak them overnight. You must boil them (say, 45 min) to gelatinize them. In my experience, echoed by someone on a recent HBD, they soak up a lot of water and can be quite gummy and starchy. Once gelatinized, they must be mashed.

An easier alternative exists in rolled oats, such as are commercially available from Quaker Oats. You'll find these in 3 forms: original, quick, and instant. The original and quick differ in that they take 5 and 1 minutes, respectively, to cook into oatmeal. For homebrewers, the Original are the hulled whole oats run through rollers, and are therefore gelatinized. The quick and instant are thinner cuts. You can add rolled oats straight into the mash.

Another easier alternative is flaked oats, sold through homebrew supply shops.

Does anyone have a source for malted oats?

> but I am curious if anyone believes that the boiling hops do?

This is a topic that doesn't get much attention. I believe that the reason is that once we engineering types (well, most of us do seem to fit that description, don't we?) have a way to hang a number on something, we feel it must be solved and move on to the next problem. If only there were a way to describe hop aroma with a number...

Anyway, it is my personal opinion that more than just bitterness is extracted from hops, even during a long boil. I feel that the low alpha hops tend to provide a cleaner, crisper flavor with a more pleasant, less cloying aftertaste in the finished beer than many of the high alpha varieties. (These were developed, after all, in order to satisfy bean counters and not brewers.) I also find that using a minority contribution from some of the high alpha hops -- sometimes exactly those varieties I don't like the most as the only bittering contributors -- can add "complexity" and interest to a beer. If this doesn't make sense, well, then I guess I'll have to renounce my membership in the ACM.

If you let the mash rest for 10 or 20 minutes, the "thickest" or heaviest part will settle to the bottom of the tun. I've seen folks use the restaurant 1 quart steel ladles to pick it up, but I use a half gallon Tupperware measuring cup. Since I use an 80 quart (yes, that's right) picnic cooler for 15 gallon batches, the grain bed is not too deep, and I can get a bottom sample pretty easily.

> 4) Oh, and finally, is everyone being honest with their grain  
extraction  
> rates? I realize the pressure to talk up your extraction points and  
> all, but are we talking reality here?

I would claim that I am getting about 30-31 pts/lb/gal, but it's also the case that my measurement may not be very accurate. Since I make 15 gallons batches -> 25-35 lbs. of malt, and since I have to weigh it out about 2 lbs. at a time, there is a great possibility for error to creep in. However, I don't believe it to be systemic in one direction, so it might be self cancelling. Or this might be the purest rationalization.

Question: Where can I get information on the strains of Witbread  
The only one I can find has no number, and is simply called  
Witbread Ale Yeast.

Has anyone ever seen a German Ale yeast that comes in green 5 gram  
packets? I opened it up, and it looked and smelled like sawdust.  
I rehydrated it, but it still smelled and looked like sawdust. I  
threw it out and used something else.

I'd rather eat \$1 on yeast than \$30 on a whole batch. Was I wrong?

>hours at 68-70. This is slightly inconvenient as I'd been planning  
>to brew Sunday. Has anybody had the same experience with 1008? With  
>other strains?

At the end of the summer, my local homebrew supplier was tossing out Wyeast packages that were more than 5 months old, and replacing them with fresh stock. I obtained some of the old packages gratis, including a 1098 culture that was 9 months old. I intended to burst the inner package, and if it swelled, to try culturing it.

I popped the package on a Wednesday night, by Friday morning, ~36 hours later, it was ready to burst. I pitched it into a starter, when I returned from work Friday night, the starter was vigorously fermenting. I ended up using it to brew that weekend, got a lag time of about 4 hours, and primary fermentation completed in 2 days. This particular culture turned out to be one of the most vigorous I'd ever used. Both of the other "outdated" packages(1084, 1338)swelled within 2 days of popping the package, I got viable yeast out of both of them.

IMHO, there is no correlation between the date code and the time required for the package to swell, as I've also had 1 month old packages take 6 days to swell. As Rob mentioned, this is inconvenient, as timing is fairly important. This inconsistency is one factor that lead me to start culturing yeast in the first place. I can reliably grow a pitchable starter from a slant in 3 days.

Cheers,  
Jim

>other strains?

Well, I have often wondered about this, as all my packages are ready in about 24 hours, no matter how old they were.

So let's take a step back and wonder about these instructions. If yeast double their population in about 3 hours, then in 24 hours they could increase their population by a factor of  $2^8$ , or 256. So in 4 days, they could increase their population by a factor of  $256^4$  (4,294,967,296), roughly 4 billion (US).

OK, so some of this time is spent producing CO2 and not reproducing, say 6 hours, so divide everything by 4 and get 1 billion. Does this mean that Wyeast expects only 1 yeast cell in 1 billion to be alive after 4 months? Sounds pretty unlikely to me.

Anyway, if more than 999 in 1000, say, of the yeast cells have died, you probably are going to have some problems, maybe? In which case you shouldn't ever need more than a factor of  $2^{10}$  or so, requiring 30 hours or so, plus some time for CO2, say a day and a half.

Now there are lots of unspoken assumptions, such as doubling rates being applicable at 70F or somesuch. Still, as someone who knows nothing of yeast growth, I would appreciate some feedback on this to see if I am seriously off anywhere (which I expect I am).

Christopher -- I doubt you will get much support from this digest's  
subscribers for your use of Artificial Sweetener. People have commented  
on Dave Line's use of saccharin on the HBD a few years ago, and most  
posters  
said something like, "well, you do what you want, but \*I'M\* not putting  
saccharin in \*MY\* beer." The note about Brewer's Yeast that you quoted  
from Line is key to this whole issue. If you like beers with  
considerable  
residual sweetness, I suggest you try Wyeast #1338, European Ale. It  
leaves the most residual sweetness of any of the Wyeasts or dry yeasts.

To me it seems a shame to use the finest ingredients (better than most  
industrial brewers) and put in a lot of your time and then use an  
artificial sweetener. Try the #1338 -- I wouldn't be surprised if you  
stuck with the liquid yeasts and quit with the saccharin.

>  
>Has anyone else had this problem with Wyeast lager?

I made a batch of bock that has done quite well in several competitions using Wyeast #2308. The way that I did it was, incubated the popped package at 68F, chilled the completed wort down to exactly (as close as I could) 68F, aerated very well, pitched the yeast, and put the carboy in the crawlspace which was at 57F for 12 hours. After the 12 hours, a small bead of kraeusen was forming, so I put it in the beer fridge at 50F. After two days, I lowered the temp in the beer fridge to 45F and that's where it stayed for the six weeks of primary and secondary fermentation. After bottling, I lagered the beer in the bottles at 40F for 4 months (till the perm nose went away ;^).

The recipe has been posted here before, it's called Bo^bs B. Birthday Bock.

Look, after all the stirring he describes, isn't the mash pretty uniform? Could someone who does this describe what the "thickest" or thinnest part is, and how you draw it off?

Nice to know there are other critical readers out there. I simply ignore this bit of advice. Even if you let it settle, you could hardly "draw" off the thickest part.

I routinely do a partial dicoction, if for no other reason than just to have something to do while waiting.

After STIRRING, I remove 3 quarts to a separate kettle and bring to a boil. I add this back to the mash and stir till the temp is again uniform and then do it again. I can get three or four of these in during the one hour mash and it is about what is required to maintain the sacc temp and the last one starts it on the way toward mashout temp.

I make no claims about the usefulness of this but as I said, it keeps my humble brain active.  
.....

CONGRATUALTIONS to Dave Wiley for taking First Place in the First Annual Net Brew-Off. Dave scored 44 out of a possible 50 points. Yours truly was honored with 38.

We all thought the organizer, Mark Nightingale absconded with the goods as he has never responded to email since soliciting the entries. He now says they decided to wait six months to "age" the beer properly and announced the results by mail.

Don't know if excuses are necessary but considering that my entry was my 5th all grain batch, I could have done much worse. The negative comments were, over carbonated and needs more malt. Considering that I only used 8 lbs of malt in the 7 gal batch, it is not surprising and I am now using 12 lbs. I now force carbonate and CP bottle so I am ready for the next Net Brew-Off.

Subject: Tennents Milk Stout

Gary writes:

>Has anyone out there had a brew called "Tennents Milk Stout"?  
>I had one when I was in St. Maartin in november but I  
>have never seen it here in the states.  
>It was stronger than a Guinness Stout in taste and in  
>alcohol.

I had one somewhere between Martinique and Barbados (it helps to make friends with bartenders on cruise ships -- it was from his private stock) and saw some in a grocery store near the dock in Bridgetown, Barbados. I too, have never seen it outside of the Caribbean, but this does not mean it is not available -- just a data point.

I don't recall it being strong in alcohol, but indeed it was stronger in flavor than Guinness. It's not really fair to compare it with Guinness, however, as Guinness is a dry stout and as you can tell from the name, Tennents \*Milk\* Stout is a sweet stout. A bit drier than Dragon Stout (made by D&G in Kingston, Jamaica and \*available\* in the US), but the sweetness is up there.

An interesting note about Guinness in the Caribbean. The Guinness I had in Jamaica, was also made, under contract, by D&G. The Guinness I had in Barbados was made by Banks (again, under contract) in Barbados. I don't recall 100% percent if this was on the label, but on the cap these two beers said "GUINNESS -- FOREIGN-STYLE STOUT," I believe. The Guinness that we get in the Chicago area, is made in \*DUBLIN\* and the label and caps say "GUINNESS EXTRA STOUT." According to the AHA style descriptions, "Foreign-style Stout" is a dry stout with a higher OG and associated alcohol level. The bottled Guinness that we get in the US is definately stronger in alcohol than the Guinness in Ireland -- that's a documented fact. I seem to recall that the Guinness I had in the Caribbean was a bit sweeter than the stuff we get from Dublin, but I could not say for sure without a side-by-side comparison. I think I may have brought back one full -- we'll see.

Subject: The Brews Paper

I received my copy of this already infamous newspaper yesterday, and in spite of the bad language and grammar, I managed to get through most of it. I was not impressed. In addition to the lack of content or humor in most of the articles, I found many of the comments to be blatantly sexist. But before someone quickly points out that several members of the Brews Paper staff are indeed women, just let me say that the same goes for many of the mens' magazines that are found at your local news stand.

The most depressing thing about it is that our names were almost certainly given to the newspaper by the AHA. I had thought the AHA was making an effort to treat homebrewers of either sex equally, and not delegate the women to the chore of bottle washing, but the support of the Brews Paper definitely convinces me that they are still mired in the 80's. I think that in the future, the AHA should do more research before handing out their mailing list to such a low-budget, low-quality publication such as this. I'm sorry to waste your time.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: re:Barleywine yeast & high alpha hops

In the last digest, Neil Mager asks about brewing barleywines with Thomas Hardys yeast. I have done this, using a culture from a bottle of 1991 hardys. The strain was isolated on a plate, so I would assume that I was fermenting with the bottling strain, which could certainly be different from what the initial ferment strain is in the Eldrige Pope Brewery. Anyway, I grew a one liter starter, brewed a 26 degree P BW, and pitched the culture. It took off quite well, producing a large amount of blowoff. After a week or so of primary fermentation, the gravity was down to around 11 P (~1.044) and the ferment appeared to be dead. At this point I racked quietly and pitched a ton of american ale yeast slurry (~150 grams of Old Dominion Ale yeast, off a uni). This yeast happily began chewing up the remaining fermentables and the resulting finish was about 6 P (~1.024). The beer was a great BW, but I would caution anyone who intends to use this method to be prepared for a high FG or be prepared to repitch.

Neil also inquires about adding extract to produce a BW. I feel this is a fine method, depending on your equipment. When I was brewing in my older setup, getting a good volume of high gravity beer was not possible. I would max out my system to yield about 5 gallons of 20-22 P wort, and add 3 lbs of DME. Worked fine. Now that I have a larger mash tun, I just reduce my yield by 30%, increase my grain bill by 50% and make a small beer in my older kettle. Last BW made with this method yielded a BW of 23P and a small beer of 8P. The small beer was astringent from the spraging, but enough Kent Goldings took care of most of that flavor.

Darryl Richman notes his experience with high alpha west coast hops. I agree 100%, beers made exclusively with a low to medium alpha hop tend to much more pleasing on the palate. Beers made with Chinook tend to much harsher, in my experience. I do like the notes that Centennial hops can contribute, but I still try to keep the quantities added to the initial boil low. This hop does lend itself nicely to dryhopping, though.

Anyone out there tried Liberty hops?? I have used the Mt Hood hops with fine results and intend to try Liberty soon.

From: Cisco <FRANCISCO@lan.ccit.arizona.edu>  
Subject: PH Adjustments

Last weekend I was brewing an all grain stout and following Miller's suggestion of a ph of 5 to 5.6 for the mash - no problem with the hard water I have. But I couldn't lower my sparge water to 6.5 from 8.1 using gypsum. After dumping in a teaspoon at a time and taking reading with a digital ph meter, I could only get the ph down to 7.6 after I used up the entire one ounce package of gypsum. The ph seemed to drop down to 7.6 after the addition of 1/2 ounce of gypsum but any further addition didn't seem to lower it any further. Does anyone have any suggestions about what I can use to lower my sparge water ph to 6.5?????

I should mention that I've been an all grain brewer for ten years. The stout that I'm brewing has the addition of one of those small bottles of coffee extract used for making Kahlua(spelling?) that I added at the end of my boil with my final addition of finishing hops. I'll let you all know well it turns out in a couple weeks.

Subject: mareseatoatsanddoeseatoatsand...

Greetings all,

In HBD #1061, Tony Babinec suggests using rolled oats rather than steel cut, for the sake of convenience. Good advice, IMHO, until, after discussing the different types of Quaker oats, he got to the statement

"Another easier alternative is flaked oats, sold through homebrew supply shops."

Seems to me that the price will likely be the only difference between flaked oats sold in a homebrew supply shop and rolled oats from a grocery store. The best prices on many types of non-malt grains (whole, rolled, and otherwise) can usually be found at food cooperatives (real coops, not the yuppie natural food stores). For example, my local coop carries organic flaked barley for \$.69/lb, or I can go to the local homebrew shop and pick up a prepackaged pound of flaked barley for \$1.59. Sure, this is only one observation. But the next time you are in the market for adjuncts you might consider a stop at your local food coop. If they don't stock what you are looking for, they can probably order it.

Tony ends with

"Does anyone have a source for malted oats?"

I didn't see any last time I stopped by the coop, but I'm sure I've seen an ad for them lately, though I can't remember where. I thought it was The Malt Shop (1-800-235-0026), but the most out-of-the-ordinary thing they carry (at least according to my somewhat outdated catalog) is malted rye.

Ooogy wawa,  
John

From: tony@spss.com (Tony Babinec)  
Subject: wyeast package swell/lag times

Here's another data point on Wyeasts...

In my experience, if I pop a very fresh Wyeast packet, it will swell in a day, but otherwise it can take several days. The 1 month lapsed equals 1 day "rule" is only a rule of thumb. If the freshness date is months ago, then the yeast in the packet are somewhat stressed, and upon breaking the seal, the yeast will use the sugar to replenish their glycogen reserves and other such things to get them ready for the job awaiting them in the wort.

I find it easiest to start the process several days to one week ahead of anticipated brewing. American Science Center, for example, has 250, 500, and 1000 ml flasks that can be fitted with a stopper and fermentation lock.

If your packet swells, pitch it into a flask and toss in some sterile wort and build up the yeast.

To those who pop the packet and find that it swells before they're ready to brew, you should pitch it into some starter wort and build up the yeast mass. If you don't have flasks, use a 12 oz beer bottle!

If you let the package swell up and pitch directly into your 5+ gallons of wort, you're underpitching. This is especially true for lagers. I don't have the numbers in front of me, but this has been talked about at past AHA conferences, for one. Biochemistry works more slowly at 50 degrees F than at 65 degrees F, and therefore one must pitch with proportionately more lager yeast. The compromise method of setting the wort in a somewhat cool spot until signs of fermentation begin is a way to shorten the length of the lag period. If you pitch lager yeast into your cool wort, even after one pitch into a starter, the lag can last 4 days or more. If you build up the yeast first, you'll have a much shorter lag time.

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Micah's Barley Wine Recipe

Micah's Barley Wine recipe can be found in one of the recent Zymurgy issues.  
I beleive it was about 1 year ago. It took a second or third at AHA comp. He named it "Trespassers Will Be Violated".

The best Barley wine I have EVER tasted was when I judged at the recent Calif. State Homebrew Competition. The BW made by Jack Dawson took best of class and had also won best of class previously at the Calif State Fair and won the AHA Barley wine is fine. One of the things that amazes me is the how that many judges could agree! One of the judges at the All State Comp who I judged with was Steve Harrison, a long time friend and sale manager for Sierra Nevada. He made the comment about a couple of the BW's that "I hope these guys don't go into business!" Tom Altenbach's BW was just edged out, and took a second place. The first place BW was just a little more complex than Tom's. MaybeTom could post his recipe for interested parties.  
My question is "could Jack Dawson do it again"? Didn't Jack's recipe get posted here in the HBD last month?

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: What I did on my Christmas vacation

I spent 3 weeks in Chicago over the holidays. In the days since I left it's gotten to be a better home for homebrewers.

The most fun I had with my clothes on was at the CBS first Thursday meeting at Goose Island. This is an informal meeting held by the Chicago Beer Society every month. Chicago area homebrewers who don't attend should have their heads examined. Homebrewers bring their beer and share it around, and non-brewers are welcome too. I met a lot of great people and drank a lot of great beer. I brought some of my own, which held up well despite travelling from NY via Montreal and Ottawa. Everywhere there was good talk, good beer and goodwill to all.

Interestingly, the world's greatest brewer (tm?) didn't attend, although he threatened to do so publicly, right here in the HBD.

Another fun outing was the Chicago Brewing Company. They hold brewery tours every Saturday at 2:00. They proudly claim to be the only brewery bottling beer in Chicago. This is technically true; however, there is an excellent lager called Baderbrau bottled in the 'burbs, and good draft beer is brewed within the city limits, notably at Goose Island.

The CBC brews three fine beers. Their Legacy Lager won a gold at the GABF and their Heartland Weiss took a bronze. My favorite is a good bitter ale with lots of body called Legacy Red Ale. Before I tasted it, I thought "Irish Red Ale" was a scam perpetrated by Coors et al. I've never seen any of these beers on Long Island. >big surprise< I don't know how far afield they're distributed.

Co-owner Steve Dinehart gives good tour and he's quite knowledgeable on the subject of Chicago brewing history. The set-up is a 100 bbl system bought from the Manhattan Brewing Company when they closed shop a few years back (soon to re-open, I understand). The kettles are new: a two-kettle system with 50 bbl capacity. Kettle #1 doubles as mash tun and boiler while #2 is the lauter tun. Nice looking hunks o' copper.

Some interesting notes: the wheat beer is 2/3 malted wheat and 1/3 6-row. All beers are bittered with Chinook. Finishing: Mt. Hood for the lager, Willamette for the Ale (or was that Fuggle?), none for the wheat. The wheat beer has great clove phenols, the ale exhibited a little of the same. It was more pronounced in some of the December beer I had at the brewery than in some older bottles (Sept?) purchased in a store. They were planning to go back to a fresh slant in January.

There are plans in the works for both a porter and a cream ale. I got some bottles from an experimental batch of cream ale and was most impressed. Look for it when it comes out: smooth and quite bitter with a color similar to the red ale.

When I lived in Chicago (89-91) there were no good brewstores. This, too, has changed for the better, but perhaps I'll leave that for another time. Suffice it to say that I shared the drive back to the right coast with grains and hops.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
Subject: Re: solder (holding wort chiller together)

Somehow this is a problem it had not occurred to me to have. My immersion chiller holds together fairly well on its own. It is made of standard 3/8" tubing. And having it as loose coils makes it easier to clean, too, since stray hop petals that get caught in it come right out while cleaning it by simply separating the coils slightly. But anyway, if you really must hold your coil together, this idea might work for you:

Just take bare solid copper electrical wire, size #14 or #12 (cheap, readily available, and pure copper) and weave it amongst the coils, at two places 180 degrees apart. If you are clever and even the slightest bit artistic, you can leave enough wire leftover at the top to fashion handles and put two of those thick fibre tubes that department stores provide for carrying string-wrapped packages home with. Then you can lift the thing out of your wort easily.

For removing the solder, go to Radio Shack, and you can get a thing called a Desoldering Wick, which comes with instructions. Heat the copper tubing with your torch, and the wick should soak up nearly all of the solder once you get it hot enough.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Old Wyeast 1008 with short lag

Thanks to all of you who replied to my posting concerning the Wyeast 1008 which exhibited no noticable lag in getting started despite being 4 months old. A significant piece of data which I had omitted was the fact that I bought the yeast the day it arrived in the brewshop -- it was 3 days old -- and brought it straight home. I kept it at a constant temperature in a bag at the back of my fridge. So it had been well cared for. It was pointed out that Wyeast probably plays it safe, assuming that the older the package is, the more often it has been mishandled.

Yeast that starts faster than expected is a whole lot better than yeast whcih starts slower than expected. Obviously! It gives you the opportunity to make a starter. If you'd been planning on making one anyway (I had) you can work it up in 2 or 3 steps, perhaps beginning as small as a cup, perhaps ending up as large as half a gallon, instead of the wimpy pint- or quart-sized starters most of us seem to use for 5 gallons.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Which dregs to culture?

I'm thinking of using recultured Chico yeast for my next brew.

Plan 1: Buy some SN Pale Ale. Open 3 bottles and pour the dregs into a starter, treating them as I would a Wyeast culture.

Plan 2: Same, but with three bottles of my own pale ale, brewed from a fresh pack of Wyeast 1056.

I suppose SN's cleanliness/quality control is superior to RB's, but at least I know that my beer has been well cared for since bottling. My beer is almost 4 months old, but here on Long Island I can't be sure that SNPA will be any fresher.

Any suggestions? Musings?

Cheers,

Rob

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Barleywine Yeast Method

On the subject of proper yeasts for barleywines, I'd like to offer my own suggestion, having brewed a couple successfully. I make a BIG yeast starter, i.e., a whole batch of ale and get that up and running, then use the yeast from that to ferment the barleywine. The first time I did this was because the champagne yeast \_pooped out\_ after two days! Fortunately, I brewed some ale shortly after and pitched fermenting beer into the barleywine. It took off and fermented out completely.

More recently, I deliberately made of a batch of pale ale, intending to follow the same procedure. As it turned out, however, I delayed brewing for a week, racked the ale off the yeast pack (WYeast 1056), and ran the cooled barleywine wort on top of the pack. Kablooie! Those yeasts were hungry and fell on the barleywine like reporters on a free lunch.

The notion of using champagne yeast is pretty bizarre, when you thithink of it. Can you imagine any self-respecting British brewery using some Frog yeast? Part of the problem may have arisen from the homebrewer's notion that everything should be quick and easy. The British barleywines I've tasted have all required \_years\_ to reach a drinkable stage--but they \_will\_ get there.

Subject: chiller construction (was solder)

I don't know how you're going to get rid of the solder you've got on there now, but, when you do:

Strip enough 16 or 14ga solid copper wire to do the job.  
Cut the wire into three or four pieces.  
Bend the pieces in half.  
'Weave' the wire into your coils.

```

$
0 (0)
 X
0 (0)
 X0 = copper tubing
0 (0)
 X ()X// = copper wire
0 /0)
 / / X
/0/ (0)
 X X
(0) (0)
```

a b

- a - wrap the wire around the bottom coil, cross over, cross again over the next coil, etcetera ad finem.
- b - when done twist the ends together well and turn the ends under so they won't snag on your sleeve.

Subject: Barleywine problems

Neil writes:

What about a yeast culture from Thomas Hardy? Will that work or has the high alcohol content mutated the yeast.

I'm not a ubiologist, but I know that Chico Brewing crops (harvests) yeast from all their beers except the Bigfoot Barleywine, the Celebration Ale and (I think) the Pale Bock (which is a lager yeast anyway). I believe the reason for not reusing yeast from the strong-alcohol beers was, just as Neil suggested, mutations.

On a similiar note, Miller mentions that it is difficult making an all-grain Barleywine and his recipes call for adding extract. He never fully explains what the problem is. Is the problem the quantity of grain needed to get the og high enough without adding extract? Or is there some other problem?

The problems are that if you only use first runnings, you have to use bushels of grain to get enough (1080+) runnings for a 5-gallon batch, or, if you do sparge, then you have to boil 20 gallons down to 5 somehow!

I seem to remember reading somewhere lately that the ratio of  
alpha- to beta-acids also plays a part in the hop bitter profile  
of the finished beer, not just the total iso-alpha acid "count",  
and that high alpha hops usually don't have correspondingly high  
beta acid levels. I wish I could remember where I read/heard this,  
perhaps this will jog the memory of somebody who can provide more  
detail (maybe it was Warner's "German Wheat" book, I was reading  
that recently). Maybe the crisp/clean vs. cloying flavors that  
Darryl describes are a result of low vs. high alpha to beta ratios?

> He never fully explains what the problem is. Is the problem the  
> quantity of grain needed to get the og high enough without  
> adding extract? Or is there some other problem?

My problem usually is that I can't sparge enough grain for a 5 gal batch in a Zapap lauter. Let me go out on a tangent here. Has anyone noticed a correlation between the length of the mash and the speed of the runoff? 3 weeks ago I did a sour-mash stout (15 hour mash), and the runoff was quite slow. A week later I made a partial-mash barleywine (10 lbs of grain) with a 45 minute mash (usual is 2 hours for me), and it had the fastest runoff ever. Perhaps the husks decompose some in a long mash, making for a bad filter bed.

Back to barleywines...

Miller claims that it requires an extended boil go concentrate all the wort, but I do not find this to be the case. A 2 hr boil (standard for me) easily condenses 10 gallons down to 5 with my setup. I usually wind up adding boiling water to the wort to keep it from concentrating too much.

Since I switched to hops plugs (the freshest), I find that the 5 oz + necessary in a barleywine absorbs over a gallon of the precious wort. In the last batch I squeezed 2 gallons out of the hops left in the boiler, stuck the wort in the fridge overnight and let it separate from the trub, then siphoned off the good stuff, re-boiled it, and added it to the fermenter.

I would recommend adding some sugar to a barleywine, though, even if you want a super-rich taste like Hardy's. Barleywine can be notorious for stuck fermentations, but batches where I have added brown sugar (turbinado sugar is yummiier) seem to just keep glugging away.

I always use dry Whitbread Ale yeast with barleywines. I wrap the fermenter in a towel and let the vigorous fermentation take the temperatures into the 80-90F range for 1 day, and then try to get it back down to 60-70F. I find this makes for just the right amount of esters with said yeast.

None of this is carved in stone, of course. Barleywines are kosher for experimentation - they always turn out great!

Born and bred a techno-weenie myself (BSEE/MSEE), I have the same kind  
of tendency, although I'm missing some of the information needed to  
interpret the attached hop data. Perhaps someone can post the meaning  
of all these hop fractions? Perhaps someone can massage the data  
enough to assign an AROMA FACTOR to each variety? Alas, I've drifted  
from my heritage, let my membership to the ACM and IEEE lapse, taken  
to believe that brewing is more of an art and less science than we would  
like it to be and traded my slide-rule for a penlight. The bottom line,  
I feel is still that the human senses are our most useful tools as  
brewers  
and a beer that tastes good on paper doesn't necessarily have to taste  
good in your glass. That said:

Subject: All-grain barleywine

neilm@juliet.ll.mit.edu ( Neil Mager ) says:

On a similiar note, Miller mentions that it is difficult making an all-grain Barleywine and his recipes call for adding extract. He never fully explains what the problem is. Is the problem the quantity of grain needed to get the og high enough without adding extract? Or is there some other problem?

So far as I can tell, he's either 1) in too much of a hurry, or 2) reluctant to make beer in a way that doesn't give 33+ pts/lb of extract.

If you sparge to near completion, you will have a 3-6 hour boil if you want to get your wort to 1.100 or higher. The long boil means that your wort will have an orange-ruby color, which may or may not be what you want. It IS a lovely color, though!

If you begin with a fairly stiff mash and use grain to the tune of 4-10 lbs per gallon of wort desired (!), then sparge very slowly, you can collect wort at 1.085+, which will need only an hour or so of boiling--essential for making that most difficult and tedious of (non-lambic) beers, the very pale barleywine.

While it may seem ghastly to some (including me) to get only 15 or less points of extract per pound of grain, a few 8-10 hour barley wine brewing sessions involving very long boils can bring about a softening in this attitude. Anyway, when you think about it, if making 5 gallons of barleywine requires a \$35-\$50 bag of grain and you have the facilities to do it all at once ... what's the big deal? Costwise it's still competitive with extract.

Second runnings can make very good beer. I do not recommend boiling them for over a hour, though, since the result (in my experience) seems to be a bit astringent, even when my sparging water is acidified and reasonable in temperature. Don't worry--make a "light" beer. The slightly unbalanced grainy character is a positive contribution to flavor in that case, especially if you dry-hop out the wazoo.

A good reference for making very strong beers is the wonderfully succinct and matter-of-fact "An Introduction to Old British Beers and How to Make Them," by Dr. John Harrison and the Durden Park Beer Club. You can order this from Great Fermentations of Santa Rosa. For example:

(per Imperial gallon):

28 Usher's 68/~ Mild Ale (1885)  
OG 80

A high gravity mild ale virtually unique to Scotland.

2 lb Pale Malt    1 1/3 lb Carapils  
0.9 oz Goldings Hops

Mature for 4 months.

| Miller High Life     | 5.0  | 2.6  | -13.8 |
| Natural Light        | 4.8  | 2.0  | 9.1   |

Overall, sales of beer in the US grew just 0.3% in 1992, this following a 2% decline in 1991. The increase in sales is mostly attributed to a very slight increase in domestic sales and a 4% increase in imports.

The #1 beer, Budweiser, saw its sales slip 0.5 million barrels to "only" 24.1 million barrels, its lowest production since 1985. Overall, however, Anheuser-Busch continued its march towards 50% of the market because sales of several of its other brands were up significantly. A-B's overall production increased from 86.1 to 87 million barrels and its overall market share went from 45.5% to 45.7%.

The other major players all saw their sales decrease in 1992. Miller went from 42.8 to 41.9, Coors from 19.5 to 19.3, Stroh from 14.7 to 13.5, and Heileman from 10.3 to 9.5 million barrels. Pabst's sales increased from 6.7 to 7.1 million barrels, largely on increased sales of Olde English 800 (yum!).

Underscoring the importance of growing small regional brands like Rolling Rock and Sam Adams, brewers in the "other" category doubled their overall sales to 5 million barrels and a 4.5 % market share.

Imports sales were up sharply. Heineken continued by far the biggest seller, and Corona's sales were up for the first time since 1987.

The top 10 imports in 1992 were:  
(name, estimated millions of GALLONS, % of import market)

|               |      |      |
|---------------|------|------|
| Heineken      | 60.5 | 23.8 |
| Corona Extra  | 29.5 | 11.6 |
| Becks         | 23.2 | 9.1  |
| Molson Golden | 19.0 | 7.5  |
| Labatt's Blue | 13.4 | 5.3  |
| Amstel Light  | 11.0 | 4.3  |
| Tecate        | 8.6  | 3.4  |
| Foster        | 7.9  | 3.1  |
| Moosehead     | 7.0  | 2.8  |
| Bass          | 5.5  | 2.2  |
| Guinness      | 5.5  | 2.2  |

Cheers,  
Steve

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: diminishing desperation

I received a lot of suggestions about my wierd tasting beer and many thanks to all who responded. Although the problem hasn't been completely isolated I'm happy to announce that my latest batch is excellent. Since I used exactly the same procedures and equipment this tends to rule these out as a problem. What I did change is the malt, yeast and hops. The remaining common items between the two batches with this flavor are:

Nottingham Ale yeast  
Munton & Fison malt (although one used light and the other amber)

I'm wondering if anyone else has had strange flavors from using either of the above.

Peter

Subject: brewspaper

Producing a newspaper is an enourmous task, with the overriding concern being: get it out on time. Producing the first edition is even harder, with the overriding concern beging: just get it done. As they said in their "letters" section: This is the first edition - "we don't have any letters - we're adlibbing." You guys should wait till you see the next couple of editions before you convict them of editorial negligence.

As for Zymurgy giving them a list of subscribers (if this is indeed what happened), I think you have a legitimate bitch here, but in the chance that receive something useful from their distributing my address I am grateful. As long as I don't start recieving a bunch of "BREWCARD" credit card\* (which may be used at any of my favotive mail-order shops) offers with a 21% interest rate, I will be happy.

Give 'em a break!

Subject: Brewspaper, Super Corona

>From: pyle@intellistor.com (Norm Pyle)

>Ulick and Jack commented on the Brews Paper. I think this thing is a piece of junk. I'm not sure why I received their first issue, but I guess it has something to do with my subscription to Zymurgy. Anyway, there are soooooo many typos in the thing....

How bout the way they consistantly spelled "lauder tun"?

>Roller mill rollers: anyone have any good sources? I have a wonderful little homemade roller mill, but the rollers are a weak point.

Please be so kind to share what you find with the rest of us. I gave up looking long ago and use custom made rollers.

>From: Ulick Stafford <ulick@bernini.helios.nd.edu>

>js praises The Brews Paper.

I believe I only referred to the humor.

> I personally think it is not that great (well OK for nothing - but personally I think the \$15 annual subscription could be better spent on Imported hops or something).

It was sent out to everyone on the Zymurgy mailing list at no cost to anyone.

I think we can all gain from having another national publication promoting our hobby/business. Remember all the griping about Zymurgy rejecting articles? Well, here is another place to send them.

In addition to airing our criticism here, we should also take the time to write the editor and let him know what we want in an alternative journal.

Personally, I have no problem with humor but I do not think it should be the dominant feature and I have expressed my views to the editor.

>It should be noted that js is not an unbiased observer as the publication carries advertisements for his products.

I think my views are pretty straightforward. If nobody likes it, nobody sees my ads no matter what I say about it.

> Incidentally, does anyone know who is responsible for the ads in Zymurgy selling Coronas with the statement that it is better than the js rollermill (someone in St. Louis)?

Sure. He is the one and only person to return a MALTMILL for a refund.

However, as he is a regular contributor to this forum and r.c.b, I will give him the opportunity to identify himself and enter into the discussion so he can make his case publicly.

>From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
>Subject: nitrosamines

>Jack, I've asked this before, and since you brought it up, I'll ask again: What is the level of nitrosamines in fire-kilned malts,

I have answered this before. It is required to be less than 5 PPM.

>especially as compared to what one might get in a grilled entry at the local pub? It doesn't make sense to me to avoid ordering a stout when your hamburger on a toasted roll has orders of magnitude more n. amines in it anyway.

As I do not eat hamburgers on toasted rolls, you will have to do your own homework. You are also confusing the toxins in toast with those in malted barley and they ain't necessarily the same. The nitrosamines in malt are a result of precursors formed during the germination of the grain combined with the combustion by-products of the flame. It happens long before they come even close to being toasted.

From: roy.rudebusch@travel.com (Roy Rudebusch)  
Subject: diacetyl

From: roy.rudebusch@travel.com

Dear Fellow Brewers;

I would like to share with you the benefits of single infusion mashing in a picnic cooler mash/lauter tun. Mostly the time savings and not having to handle the mash. You too can "brew beer like the micros"! Typical yield is 28<sup>^</sup>/#. Good enough.

9:00 AM begin to run water for a 12.5 gal batch, 6 gal for mash and 14 for sparge.

9:05 started to crush 22# of grain, with a motorized Corona Mill. OBTW, blind side-by-side comparisons between grists crushed with a corona mill and a "you know who" rollermill have shown the corona crushed grist to be superior. The Corona Mill produced less flour and smaller starch granules and the husk was left more intact. Analysis was done by several professional brewers and scores of accomplished homebrewers.

9:10 Began to heat mash water to 180F

9:40 Added the 6 gal of 180F mash water to picnic cooler mash/lauter tun. Plastic tubing manifold system. Igloo 36 Qt.

9:45 Doughed in grist when temp of strike water is ~175F.

10:00 Mash temp is 156F. Just right!

11:00 Mash temp now 150F. Began to runoff.

1/2 bbl brewpot is on the burner closest to the tun. 1/2 bbl brewpot (hot liqour tank) with the sparge water is on middle burner. Cloudy wort is diverted to a 5 gal pot on the far burner.

11:20 Recirculated about 4 gal of cloudy wort. Wort running clear.

11:21 Started to collect clear runoff in brewpot.

12:00 Sparged to the 8 gal mark in brewpot, wort now beginning to boil. Added first hop addition.

12:51 Stopped collecting.  
Collected over ~15 gal of wort ~2 of which has boiled off.

1:05 Added finishing hops, immersion wort chiller.

1:15 Started to chill.

2:45 Finished chilling, ran chilled bitter wort into fermenters through a spigot in the bottom of the brewpot, whole hops seem to filter back the hot and cold break. The hopback is a 1" copper tee with a 12 x 8" piece of copper screen rolled up and inserted through it and then wadded scrap copper screen placed into both ends.

Prosit!

From: Jim Grady <jimg@hpwarga.wal.hp.com>  
Subject: HBU -> IBU question

I realize that this has been discussed before but could someone please e-mail or post the calculation for IBUs as a function of alpha acids, s.g., boiling time and anything else I might need to know? I am trying to compare two recipes for a Pilsener. The first is in the Traditional Beer styles issue of Zymurgy and the second is in Dave Miller's "Brewing the World's Great Beers."

The first recipe calls for:  
5.75 HBU Chinook @ 60 min.  
+ 3.5 HBU Saaz @ 15 min  
+ finishing hops and dry hopping

The second recipe calls for  
10 HBU (pellets) or 12 HBU (whole) Hallertau or Tettnanger @ 30 min.  
+ finishing hops

Both recipes are extract based. My question is, are these hopping rates roughly equivalent given the different boiling times?

Thanks!

From: Eugene Zimmerman <ezimmerm@hp.uwsuper.edu>  
Subject: Homebrew Shareware suggestions anyone?

Salutations!

I'm a comp sci major and am learning the fine art of C programming. Not that you really care about my education, but I am embarking on a new adventure. I'm going to be programming and then releasing in the form of Shareware a homebrew program. I would like suggestions from anyone who has any suggestions on it's content.

So far, I'm thinking of including a database of previous brews, a DB of beer styles, DB of hops (which will be user alterable for specific tastes)

and a brewing calculator/recipehelper. This recipe thing will be able to import data from the other databases so you could work off of the classic style of say a Bock and then 'tweek' it a tad if you wish. Once declaring what kind of style you wish to emulate, the program would import

the recipe for you to alter. You could also import previous brews. I'm thinking it would calculate out the specific grav, HBUs as well as IBU's and other things. What I need from the brewing community is suggestions as

I am but one brewer and together we are many, with many needs and wishes when it comes to brewing aids. So, if you would please reply to me at :

ezimmerm@hp.uwsuper.edu

it would be greatly appreciated.

I plan on finishing the first version by spring (living in Duluth, this means late May ).

Gene in Duluth

From: des@pandora.swindon.ingr.com (Desmond Mottram)  
Subject: All grain barley wines - second runnings

Joseph Hall (amongst others) makes some good points about making barley wines. First the waste of grain if you only use the first runnings, secondly that you can make very good beer with the second runnings:

> While it may seem ghastly to some (including me) to get only 15 or  
> less points of extract per pound of grain  
...  
> Second runnings can make very good beer.  
...  
> uunet!joebloe!joseph (609) 273-8200 day joseph%joebloe@uunet.uu.  
net

I agree totally and have successfully done it. I mashed 10# (possibly more?) pale malt in 3+ gallons of water and ran off 2 gallons without sparging at 1085 to make the barley wine. I then sparged the rest with about 4 gallons of water. This gave 5 gallons of 1040 wort and made a very good beer.

The only problems I encountered were (a) the difficulty of getting the hop rate right for only two gallons of 1085 wort, and (b) racking the wort off the trub after boiling, as it threw a huge quantity. More exact details can be supplied on request.

The barley wine was utterly revolting and undrinkable for at least six months, but carries a punch like a heavyweight boxer. I've had it now for a year and it has improved only slowly. I suspect it won't be at its best for years. Maybe I wasn't so successful after all?

From: mlobo@sentry.foxboro.com (Michael T. Lobo)  
Subject: keg foam fix/weast 3056

A few months ago I brewed my first batch of weizen beer using Wyeast 3056..here are my results...  
The Wyeast was 3 months old, but swelled almost to the bursting pt. w/in 24 hrs.  
I used a starter and pitched the next day. After the usual primary wait, I kegged this and let it sit in 60 deg. for 1 month. I tapped the keg Saturday, and after tasting it was VERY happy - nice flavor ( just like a "real Weizen.. who would have guessed ;^)

Up until now, I have had some foaming problems with my kegs. I force carbonate and the problem was that it took about 1/3 of the keg for the foam to subside enough so I could get a properly carbonated beer( that 1/3 keg usually ended up in the keg cooler..major bummer!). I always allow the excess pressure to bleed off via the CO2 connector on the keg before trying to draw the first few beers, because of the high pressure. Well, the first glass of Weizen looked like airport runway foam, and I was not about to go through the 1/3 keg ritual with this one. I could see the beer leaving the keg ok, but about 5" into the hose, the foam was starting and by the cobra tap - foam-a-rama. The hose was ~ 24" long. I cut my hose with the cobra tap so it was only 2 inches long, and viola! no more foam! Needless to say, this really made my weekend...so much, that we tapped a second keg ( an IPA ) on Sunday to see if it was a fluke, and it also poured great from the start...

IMHO, the keg should be allowed to settle for at least 24 hrs before tapping. This has helped my keg pressures considerably. Also, the colder the keg when you force carbonate, the easier it is to do (for the weizen I needed alot!).

enjoy,

From: smanastasi@mmm.com  
Subject: Solder and beer - whats the deal?

I've been following the thread on solder and beer. I recently made a lauter/mash tun using the slotted copper coil design (and had fun doing it). I used lead-free solder for all my joints.

Is there a valid concern with exposing lead-free solder to a liquid (wort) with PH down to 5.1 or so? Since there is some solder on the exposed surfaces of joints, my wort will come in contact with the solder (as well as smaller amounts of solder on the interior of each joint).

I realize that there is tin in the solder but I did not think that that a mild acid such as wort would cause any problem, especially since the exposure time is only a couple hours or so - albeit at elevated temperatures.

Maybe in another article, I will post my advice on making the slotted copper coil. I learned a few things.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hops, nitrosamines

For all my recent batches, I've pulled apart the finishing hops to expose more of the good stuff at the core. Yesterday I used a coffee grinder, and the results were spectacular! Loosely load whole hops into the grinder, give it a few spins, and out comes chopped hops, with an incredible aroma. A bonus is a sort of hops-hash (for lack of a better term) that collects on the edge of the grinder. Scrape that into a vial with vodka...hops oil! Another bonus for those using immersion chillers is that the chopped hops don't cling to the copper as much as whole hops do; cleaning is easier.

Ok, so malt must be < 5ppm nitrosamines. Any nutritionists out there, or cancer specialists, with the number on grilled meat? If not, I'll find the time to look it up myself; my gut (ha!) feeling is that the quantity in malt is minute compared to that in grilled beef.

And, for the record, it *is* possible to get a stuck sparge with a 10-gallon cooler/strainer lauter tun...too fine a crush, too long a settling stage (2+ hours vs. the usual 30 minutes). It was nice to have a Zapap tun to fall back to.

Russ

\*\*\* Resending note of 12/30/92 09:24

I've recently read comments by Bob Jones (thank again...) for this barleywine recipe named "blind squirrel barleywine" which took a first place at the California State comps at Stern grove, SF this fall, and just recently won the AHA's Barleywine is Fine (I think) comp. I call it blind squirrel because, it's the first brew I've ever done which has won anything.... which proves only that even a blind squirrel sometimes finds the acorn :)

Cheers.Jackjdsaws1@pb1.pacbell.com

OK - as far as I can recall from the extensive records I've kept:)

Batch size: 5 gal.

Extract:6 lbs. Williams light Australian syrup

5 lbs. Williams light Australian dry

Grain: 1 lb. 10-L crystal steeped

1 lb. 40-L crystal steeped

Hops: 3 oz Chinook pellets aa%13 (60 min)

1/2 oz CFJ-90 pellets aa%9 (5 min)

1/2 oz CFJ-90 " " (dry-hopped in 2ndary)

Water 1 tsp gypsum at start of boil

1 tsp irish moss (30 min)

Yeast: 14 g. Whitbread dry

Primary fermentation - glass for 5 days at 65'

2ndary fermentation - glass for 16 days at 65'

Bottled: June 15, 1991

Note: Wort was boiled in 4 gal. pot (3 1/2 volume) with 2 gal. water added

to primary fermenter.

>seemed to drop down to 7.6 after the addition of 1/2 ounce of gypsum  
>but any further addition didn't seem to lower it any further.  
>Does anyone have any suggestions about what I can use to lower my  
>sparge water ph to 6.5?????

Acidification of sparge water was discussed at some length in this forum about a month ago. The consensus (huh? on HBD?? :-)) was that not every brewer needs to acidify the sparge water, and that even those who do so should be careful not to overacidify.

I have very hard water as well, and had the same difficulty lowering the pH of the sparge water adequately. The symptom was a very distinct taste

of tannin in the runoff when the gravity was still over 1.020. A pale lager

I brewed was noticeably astringent. I started using acidblend, which I understand to be a mixture of citric, malic, and tartaric acid, to acidify

4 gallons of sparge water from ~7 to ~5.5. This required only 1/4 teaspoon

of acidblend, as a little goes a long way. Several others pointed out the danger of making the wort *\*too\** acidic, i.e., lack of a good hot break.

So the moral is, *\*if\** you have this problem with your brewing water, use a "food grade" acid like citric or tartaric, and be very careful. You want to deliver wort of about 5.5 - 5.7 pH to the boiler.

Cheers,

Jim

> but any further addition didn't seem to lower it any further.  
> Does anyone have any suggestions about what I can use to lower my  
> sparge water ph to 6.5?????

Clearly, this bears repeating. You *\*can't\** lower your *\*sparge water\** pH appreciably by adding gypsum. The goal of water treatment is to allow your *\*mash\**, not your *\*water\**, to reach optimum pH. The reason for treating sparge water is that as you remove the wort from your mash, you are removing most of the acidifying material. If you have water with carbonates in it, it will drive the remaining material into an alkaline state. You should only be concerned with the pH of your mash, not your water.

The reason that gypsum tends to lower pH is that it dissolves and dissociates into Ca and SO<sub>4</sub>. The calcium will then combine with malt components to form a weak organic acid. If nothing else intervenes, this settles the pH of the mash at a good point. However, carbonate is somewhat basic and can overcome the acidity of this weak acid. Especially when much of the acid is removed, as it is during sparging.

From: bickham@msc2.msc.cornell.edu (Scott Bickham)  
Subject: Enzymes in malted wheat

Yesterday, I wrote:

"Munich malt not only converted itself, but also the 5 lbs. of malted wheat." Before I get flamed too badly, let me admit my mistake - I confused the malted wheat in the Weizen with the unmalted barley in my last batch - a Belgian White. Maybe someday I'll learn my lesson about posting without reviewing the facts ;-)

John Francisco wrote:

"Does anyone have any suggestions about what I can use to lower my sparge water ph to 6.5?????" I recommend investing in some food grade lactic acid, which you should be able to order from a pharmacy in your area. I found a pint bottle for \$23, and it should last many years since it only takes 1/4 tsp. to lower the pH of a gallon of sparge water from 8 to 5.5.

Rob Bradley asked about culturing Sierra Nevada dregs. Isn't there three different strains involved in the fermentation, as well as three initially in the Wyeast 1056 pouch? The first strain starts rapidly, but isn't tolerant to ethanol and settles out rapidly, and then a second strain takes over. The third strain starts very slowly, but is responsible for the bottle conditioning. I have heard of very slooow fermentations from yeast cultured from SNPA dregs, so maybe only the third strain is viable at that time. Any comments?

Scott

From: bszymcz@ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: All-Grain Barleywine

In the last two issues there have been a lot of comments on the feasibility of all-grain barleywines. I recently bottled an all-grain batch of barleywine which had an initial gravity of 1.100 using my rather primitive (Zap-Pap lauter tun) equipment. To get a higher initial gravity I split the mashing of 22 lbs of pale ale malt and 2 lbs of crystal malt using 2 kettles. (Actually I needed 3 pots since my two 4 gallon pots were filled to the brim with mash). The mash was relatively stiff at 1 quart per pound of grain. Two separate sparges were done where I collected the first runnings plus enough wort to make 3 1/2 gallons from each sparge for a total of 7 gallons. I didn't have the time nor the equipment to use the rest of the runnings so I simply dumped the partially sparged mash into my compost pile.

I use a ten gallon stainless steel pot for boiling, and boiled the wort down to 6 1/2 gallons in the first half hour and down to about 5 3/4 gallons the next hour. The pre-boil gravity was 1.082, and post boil gravity was 1.100 (which is consistent) and yields  $82 \times 7/24$  or  $100 \times 5.75/24$  or about 24 pts/lb/gal. Normally I get about 27-28 pts/lb/gal with a regular strength beer.

The wort was fermented using a 3 quart starter of The Yeast Culture Kit A1 yeast (a close relative of Wyeast 1056) which took the gravity down to 1.030 in four days. I then racked to secondary, after which there was very little activity. After one week dry hopped with 1/2 oz of Kent Goldings pellets and stirred. I didn't want to pitch more yeast since my secondary (a 5 gallon carboy) was filled to within 2 inches of the brim, so I decided 1.029 was good enough and bottled after two weeks in secondary. The beer was very clear with a deep amber color, had a nice warm alcohol taste but was a little sweet (next time a little more bittering hops). I'll wait a few months to see how it ages before posting the recipe in detail.

Subject: "ISO-KLEER"

Hi all,

I have a quick qestion, Has anyone ever hear of a product for clearing brew called "ISO-KLEER"?

I inherited a couple of bottles and have no idea what it is or how it's used (except that it is a clearing agent -- I assume from the name!) This stuff comes in small (about 100mL) bottles and is a clear liquid. The bottle

is blank except for a "5" in a circle with "ISO-KLEER" under it, stamped on in black ink.

If anyone has ever used/heard of this stuff, I'd like to know what it is and how is it used. (Do you have to boil it, dilute it, how much do you use, etc...) Any help is appreciated.

Thanks,  
Wayde.

Subject: COPS replies:

Soon after the COPS incident was discussed here, I sent a letter to the local FOX station and the producers of COPS explaining that I thought homebrewing had been misrepresented. Today, I received the following reply:

- -----  
Dear Mr. Bickham,

Thank you for your letter regarding the homebrewing episode of COPS.

Please realize that COPS is a video verite show, flimed without a script, rehearsals, narration or whatever. What we see while accompanying the police is what you see -- right or wrong.

In the episode you question, the officer does make the point that home brewing is legal, and nowhere is there any mention of beer. The suspect was, in fact, supposedly making tequila and whiskey.

We have however brought your complaint to the attention of the police, and we truly regret any misinterpretation -- which was not our intent. COPS has never professed to do anything other than reflect actual incidents while following our nation's police departments in carrying out their duties.

Sincerely,

Malcolm Barbour  
Executive Producer

- -----

It appears that COPS is aware of our feeling about this incident, and judging from this, may even respond to similar letters the receive from other homebrewers. I don't think they should be held blameless, since there is obviously a large audience for this type of journalism, but they shouldn't be held responsible for the ignorance the law enforcement officers display on camera.

Subject: Juice jar starters, squeezing out an extra quart

In hbd #1062, Tony Babinec wrote about making starters from Wyeast:

>...American Science Center, for example, has 250, 500,  
>and 1000 ml flasks that can be fitted with a stopper and fermentation  
lock.

>...

>...If you don't have flasks, use a 12 oz beer bottle!

In most supermarket, you can buy 48 and 64 ounce juices in dark  
brown bottles. Their wide mouths accept #8 and #8 1/2 stoppers.  
You can make a quart-sized starter in either of these bottles;  
almost 1/2 gallon in the larger size.

Misers (like me) will appreciate the following feature of this  
system: leave a few drops behind in the juice bottle when when you  
pitch the yeast and fill it up with trub from your cooling/settling  
vessel. It will settle and you'll get an extra quart or more of  
beer which, in my limited experience, is hardly more raunchy than  
the good stuff. [I came up with this idea in early December after  
reading the experiences of a clever person whose name escapes me.  
He used a 2 l. pop bottle.]

Cheers,

Rob (bradley@adx.adelphi.edu)

From: TiM@world.std.com  
Subject: Low Pilsner Yield(?), GOTT Cooler Conversion

This year (the second year I've been brewing) I decided to try a lager since I now have a new unheated area below an addition to the house which keeps an ambient 40-45 degree temperature during the winter. (I'm in the market for a used fridge...just haven't got one yet).

My question is: I bought 'Pilsner' malt, and according several sources including the calculations in Darryl Richmond's (c) shareware spreadsheet, for brew 1 I should have received a 1.044 O.G. However I ended up with 1.038 (pilsner light?). For brew 2 I compensated and 'aimed' for 1.052 and ended up with 1.043.

Both times I rested at 130 degrees for 45 minutes, then through a combination of adding some boiling water and heating existing mash brought the temperature to 156. I mash using a GOTT water 'cooler' which tends to lose only about a degree in 30 minutes (after which I heat a little of the mash and bring it back to proper temperature). I mashed for 90 minutes, then poured the mash into a kettle, broke at 168, poured the mash into my sparging setup and did about a 45-50 minute sparge with 168-170 degree water.

I guess my question is: Is Pilsner grain typically low-yeild? Did I do something wrong (this is my first attempt at lagering).

Just for the detail, the first beer used Danish Lager Wyeast. The second used Wyeast #2206.

Every other all-grain brew I've made to date (15) hit the O.G. within .02, except both these using Pilsner malt (from the same homebrew supply shop).

Also, does anyone have info regarding converting the water-outlet in a GOTT cooler painlessly into a grommet-and-hose assembly for a combo mash/sparge bucket? The false bottom from my Phils unit fits PERFECTLY into the GOTT cooler...can I get away with simply using a big grommet to seal a piece of tubing (I've never had the problem experienced by some people on this BBS of mash crimping the plastic tubing coming from the top of the false bottom)?

Thanks.

When I found out that the World's Greatest judge of beers was unable to re-arrange his honeymoon plans, I decided that it just was not worth my effort. Had I known you were going to be there, I most certainly would have been there to frustrate you. Imagine have to pick which of my three beers really was the World's Greatest.

A WARINING to all: Do NOT trust to random luck. Phone ahead!

>From: Jeff Frane <70670.2067@compuserve.com>  
>Subject: Barleywine Yeast Method

>On the subject of proper yeasts for barleywines, I'd like to offer my own suggestion, having brewed a couple successfully.

This is probably not (maybe?) related to yeast but it is a good segue anyway.

This past Sunday, I took a customer to lunch at the Goose and we did their sample program. All the beers were interesting and worth the taste. However, the barleywine was absolutely vile. My guest says this is what barleywine tastes like and I politely dissented but did not argue. The customer is not always right but there is little to be gained by arguing with one.

I am not sure of the correct nomenclature but it tasted like the screenprinting ink I use smells. Back in the days before I cultured yeast, I had made beer with that taste, more than once. I recognize it as a defect and not just something unique to barleywine because I never have made barleywine.

Anybody have barleywine at the Goose lately?

Subject: Beer Survey

MHS: Source date is: 26-Jan-93 09:21 EDT

John Isenhour asks about the bright yellow choose-a-mug beer survey. I can report that one arrived at our house last week, and that we took a similar tack in answering it (i.e. listing "most often" brands of some obscurity rather than Xing the mug of some megasuds). However, I can't help anyone figure out where the names came from; though I've got my name on several beer related lists, the survey came addressed to my wife, who is on no such thing. Of course, we queered the results by making her name answer to my habits, but that's a risk you take when you just mail out your surveys. I should add that they promised a "free mystery gift" for completing the survey - the bait did its trick, as I would never have bothered with it if there weren't something in it for me. I just hope this isn't something to help research Zima ClearMalt, or something equally horrifying; I expect my mystery gift will be a voucher for a beverage I'd rather not have, in any case. Anyone else?

From: gjfix@utammat (George J Fix)  
Subject: Nitrosamines

The work that first showed that nitrosamine is a potential carcinogen is summarized in the following:

Environmental Aspects of N-nitroso Compounds, Proceedings of a Working Conference held at the NE Center for Continuing Education, Univ. of New Hampshire, 22-24 Aug. 1977, IARC Publ. No. 19 (1978)

Following this report, a technical committee was formed and headed by Dr. W.A. Harwick of Anheuser-Busch, Inc. This led to various procedures that could be used to control N-nitrosodimethylamine (NDMA) levels in malt. Their findings were published in the MBAA Tech. Qr. (Vol.17, No.4, 1980)

For the record, the highest NDMA level reported was in Bamberg Rauchbier. It contained 5-15 parts per billion, and not 5 ppm as reported in HBD. This also was the level reported in their malt. The NDMA levels of beer is typically 9-10 times lower than in the malt used.

I feel it is perfectly legitimate to raise the possibility that beer with higher than normal nitrosamine levels could be a health hazard. Nevertheless, there are many aspects of this issue I do not fully understand. For example, population data shows that Bamberg has one of the highest rates of beer consumption in Germany (no small feat!), yet its cancer and death rates are near (and in fact slightly below) the average in Germany. I conjecture if the fair citizens of Bamberg smoked cigarettes at the same rate they consume Rauchbier, and if at the same time everyone else in Germany did not smoke, then the Bamberg cancer and death rates would be 5-10 times the German average. This is a fair comparison since most German beer has very low NDMA levels. While a formal linkage between cigarette smoking and cancer has not been established, just about anyone's data shows that it is indeed real. If Rauchbier is a health hazard, why doesn't this show up in the data? People in Bamberg have been drinking this beer throughout the 20th century, and in fact even longer.

There has been a serious "social cost" associated with the ban on smoked malt. One casualty has been a beer called "Smoked Porter". It is a natural for brewpubs. For example, it and smoked salmon are a marriage made in heaven, especially if capers are added as well. It is possible for a brewpub to buy regular malt, and then smoke it themselves. Alaska Br., a micro, is doing just that, and at the same time winning all sorts of ribbons at the GABFs for their version of smoked porter. Nevertheless, the brewpubs I have been associated with have been reluctant to brew a version for fear they would be accused of poisoning their customers.

It doesn't take much of this sort of thing to totally trash a small commercial operation.

For the record, the Belgium base malts have very low NDMA levels, and in fact are lower than most US malts. Other than that, they are perfectly fine for brewing!

From: korz@iepubj.att.com  
Subject: Corona versus JSP MaltMill

This post may come as a surprise to those who have followed my battles with JS over the last year, but being a BJCP beer judge teaches you the importance of being just and unbiased, which is what I feel compelled to do regarding this point also.

Roy writes:

OBTW, blind side-by-side comparisons between grists crushed with a corona mill and a "you know who" rollermill have shown the corona crushed grist to be superior. The Corona Mill produced less flour and smaller starch granules and the husk was left more intact. Analysis was done by several professional brewers and scores of accomplished homebrewers.

I find this so incredibly hard to believe, I find it difficult to avoid calling it a lie. With the proper adjustment, the Corona can, indeed, produce smaller starch granules, but contrary to Roy's statement, this will invariably produce *\*more\** flour and *\*shred\** the husks into very small pieces.

Jack and I have this on-again/off-again war going on and during one of the cease-fires, I purchased a JSP MaltMill. I have compared the crush with the MM against the crush done by various other means, including the Corona, and I must honestly say that the MM crush is *\*far\** superior to the Corona and all other methods short of a \$5500 professional rollermill. I have used the MM with over 17 different varieties of malted and unmalted barley and there has *\*never\** been any splintering of husk material by the MM as is *\*always\** the case with the Corona.

I'm not the only one who thinks this way... on March 31, 1992, George Fix wrote:

>Jack has built a first rate mill that is  
>worth every penny he is asking for it. The metal work, the  
>heart of any mill, is extremely impressive. When the mill first  
>arrived, the first thing we did was to compare the quality of the  
>crush with that obtained from the commercial mill at the Dallas  
>Brewing. For the record the latter cost between \$5000 and \$6000.  
>There was absolutely no difference between the two.

Al.

P.S.

Roy also writes:

>9:40 Added the 6 gal of 180F mash water to picnic cooler mash/lauter  
> tun. Plastic tubing manifold system. Igloo 36 Qt.  
>  
>9:45 Doughed in grist when temp of strike water is ~175F.

For the record, "doughing-in" is the addition of water to the grist (which is highly recommended) not vice versa. Adding the grist to the strike liquor will work, but will create much more balled starch than the opposite (see Noonan's "Brewing Lager Beer").

Date: Tue, 26 Jan 93 12:07:08 CST  
From: tony@spss.com (Tony Babinec)  
Subject: brown ale or porter?/samuel smith's

In the last HBD, Shreefal presents the following recipe for comments:

brown ale recipe

4 # light liquid extract  
2 # english 2-row malt <--- lager or ale malt?  
1/4 # chocolate malt  
1/4 # black patent malt  
1 # light brown sugar  
  
1 oz Goldings in the boil  
1/2 oz Cascade boiling hops and finishing <--- is that 1/2 oz  
each for boiling and  
finishing?  
ale yeast

I'd like to comment on the recipe and the brown ale style. This is not a flame!

The AHA style guidelines for the english brown ale are:

1.040 - 1.050 SG  
15 - 25 IBUs  
15 - 22 color

Assuming the usual 5 gallon batch, the above recipe will produce a beer in the mid-to-high 1.050s. I played with it a bit in Chris Campanelli's BRF program, but the gravity math would go approximately as follows:

32 - 36 points of gravity for the liquid extract  
10 points of gravity for the 2 pounds of malt  
5 points of gravity for the highly roasted malts  
8 - 9 points of gravity for 1 pound of sugar

So, strictly speaking, the beer is too big to be a brown ale. In gravity and color, it is more like a porter. 1/4# each of chocolate malt and black malt will give the beer a dark brown-red color.

What about hops? As indicated, I don't know whether the hopping is intended as:

1 oz Golding in boil 1 oz Golding in boil  
1/2 oz Cascade in boil OR 1/2 oz Cascade for finish  
1/2 oz Cascade for finish

Assuming a one-hour boil, the left hop schedule will produce something like 30 IBUs, which is better suited to a porter, while the right hop schedule will produce something like 25 IBUs, which is suited to a brown ale.

A brown ale is brown in color and malt-accented in flavor. While there are different variants of brown ales, sample some Newcastle Brown Ale or Samuel Smith's Nut Brown Ale.

How about getting some color and flavor from dark crystal malt?  
For example, assuming a 5-gallon batch and 75% extract efficiency:

7-8 # pale malt (OR 5 # dry malt extract)  
1 # 80L (dark) crystal malt

should produce an appropriate flavor and body. For an attempt at  
a "nut" flavor, try instead:

7-8 # pale malt (OR 5 # dry malt extract)  
1 # 10L (light) crystal malt  
2-3 ounces roasted barley

In either of the above, you can substitute some brown sugar for the  
pale malt or dry malt extract. I wouldn't use more than 1 pound of  
sugar. While pure refined sugar will ferment perfectly, brown  
sugar has some added molasses that will leave some residual  
unfermentables and their flavors in the beer.

Samuel Smith's Nut Brown ale is very nicely hopped. To get some  
hop flavor, which I think I taste in this particular beer, try a  
hop addition at 20 minutes to end of boil. Samuel Smith's uses a  
unique yeast and fermentation setup. For a bit of diacetyl  
(butterscotchy) flavor in the beer, perhaps Wyeast Irish ale yeast  
might be tried.

Subject: Keg pressures/hose lengths

Michael writes:

>because of the high pressure. Well, the first glass of Weizen looked like  
>airport runway foam, and I was not about to go through the 1/3 keg ritual with  
>this one. I could see the beer leaving the keg ok, but about 5" into the hose,  
>the foam was starting and by the cobra tap - foam-a-rama. The hose was ~24"  
>long. I cut my hose with the cobra tap so it was only 2 inches long, and  
>viola! no more foam! Needless to say, this really made my weekend...so much,  
>that we tapped a second keg ( an IPA ) on Sunday to see if it was a fluke,  
>and it also poured great from the start...

It seems that many, many brewers have problems getting their keggings systems to work properly. What is often forgotten (as Michael noted) is the length of the liquid-side hose. David Miller has a great article in the 1992 AHA Conference Proceedings on keggings systems.

The CO2 dissolved in the beer will come out of solution eventually. We would like most of it to come out of solution in our mouths, not earlier. \*When\* the CO2 comes out of solution is based upon many things, including:

the temperature of the beer,  
the pressure on the gas-side of the keg,  
the length of the liquid-side hose,  
the diameter of the liquid-side hose,  
the smoothness of the walls of the liquid path  
(note this includes any gunk on the inside of the walls of the pickup tube, fittings, hose and faucet),  
the amount of constriction of flow in the faucet, and  
the cleanliness of the glass.

I dispense my 54F ales at between 7 and 12 psi (depending on the style), down a 6 foot, 1/4" ID FOXX SUPERFLEX hose and (as Michael said) let the keg cool for a good 24 hours so the force-carbonated beer can dissolve the CO2 you pressed against it.

From: tony@spss.com (Tony Babinec)  
Subject: brown ale quick correction

Here is what a portion of the brown ale post should say:

32 - 36 points of gravity for the liquid extract  
10 points of gravity for the 2 pounds of malt  
2 points of gravity for the highly roasted malts  
8 - 9 points of gravity for 1 pound of sugar

Sorry!

I think you're talking about the Whitbread yeast. SNPA yeast and Wyeast #1056 are both single-strain yeasts, whereas Whitbread and Wyeast #1098 are three-strain yeasts. Slow fermentation from SNPA dregs might be attributed to under-oxygenation by brewers used to dry yeasts (which require a lot less oxygen than Wyeast or dreg-cultured yeasts) or by extended lag times resulting from temperature shock (be careful that your starter and wort are as close to the same temperature as possible).

From: rak@mayo.EDU (Ron Karwoski)  
Subject: FAST Fermentation

I've seen articles in the past that suggested pouring a new batch of wort over the trub remaining in the fermenter after racking off for bottling. I gave this a try last weekend and recommend it if for nothing else than the entertainment value. Fermentation started in less than an hour, and after four hours the fireworks had commenced. I have never seen such a vigorous fermentation! The blowoff tube resembled flowing lava and I kept getting up during the night to see if disaster (overflowed blowoff jar) had struck. Luckily, the blowoff tub was longer than normal and the height of the bend never allowed much wort to be blown off. I'm sure that at least a gallon would have been blown off under normal conditions. Fermentation was basically complete in less than 20 hours. I'll be racking to a secondary soon and I'll let you know how it taste after bottling. Lag time is definitely not a problem with this method.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: freezing pellets, low pilsner yield

Hi All,

In HBD #1063, Peter Maxwell asks:

>Al gives us some interesting figures for hop storage which apply for, I  
>presume, whole hops. I'm wondering what the figures would be for hop  
>pellets stored at -18C (i.e. in the freezer).

>In fact, is storing pellets in the freezer a good idea? Is any harm  
likely  
>to come to them?

I use pellets exclusively, and always store them in the freezer.  
Pellets  
tend to keep better than whole hops, storing them in the freezer seems to  
prolong the shelf life even further. I've used pellets that were stored  
in  
this manner for 4 to 5 months, the beers came out fine, I didn't \*  
notice\*  
any funny flavors or effect on hop utilization. On the other hand, I've  
read that sub-freezing temperatures can rupture the lupulin glands.  
Assuming for the moment that this is true, how much of a problem would  
this  
be with pellets? IMHO, the milling and pressing processes used to make  
pellets would rupture the glands anyway. Comments, anyone??

\*\*\*\*\*

Also in HBD #1063, Tim Roaix asks:

>This year (the second year I've been brewing) I decided to try a lager  
>since I now have a new unheated area below an addition to the house  
>which keeps an ambient 40-45 degree temperature during the winter.  
>(I'm in the market for a used fridge...just haven't got one yet).

>My question is: I bought 'Pilsner' malt, and according several sources  
>including the calculations in Darryl Richmond's (c) shareware  
>spreadsheet, for brew 1 I should have received a 1.044 O.G.  
>However I ended up with 1.038 (pilsner light?). For brew 2 I compensated  
>and 'aimed' for 1.052 and ended up with 1.043.

>Both times I rested at 130 degrees for 45 minutes, then through a  
>combination of adding some boiling water and  
>heating existing mash brought the temperature to 156. I mash using  
>a GOTT water 'cooler' which tends to lose only about a degree in 30  
>minutes (after which I heat a little of the mash and bring it back to  
>proper temperature). I mashed for 90 minutes, then poured the mash  
>into a kettle, broke at 168, poured the mash into my sparging setup  
>and did about a 45-50 minute sparge with 168-170 degree water.

>I guess my question is: Is Pilsner grain typically low-yield? Did I  
>do something wrong (this is my first attempt at lagering).

>Just for the detail, the first beer used Danish Lager Wyeast. The  
>second used Wyeast #2206.

>Every other all-grain brew I've made to date (15) hit the O.G. within  
> .02, except both these using Pilsner malt (from the same homebrew  
supply  
>shop).

Tim, do you know to what extent the pilsner malt was modified? I get German pilsner malt that has a very low degree of modification. On two occasions in the past, I used this malt as a base malt for light colored ales. Both times, I used a step mash with rests roughly similar in times and temperatures to what Tim described. The first batch, I got 27 pts/lb, and 26 for the second. I consistently get 30-32 pts/lb using step mashing and highly modified malts, 34 pts/lb using decoction mashing and undermodified pilsner malt. IMHO, the combination of undermodified malt and step or single infusion mashing will produce lower yields, the use of these malts calls for decoction mashing.

If the modification rating cannot be obtained from the supplier, there are a couple of other ways to determine the degree to which a malt has been

modified. Chew a few grains, if the malt is undermodified, the tips of the grain will feel hard and steel-like against the teeth. The degree of modification can also be determined by examining the length of the acrospire. Use a razor or penknife to scrape away the husk, there will be

a fibrous looking growth that's a slightly different color than the rest of the kernel. If the length of this growth is 1/2 to 3/4 the length of the kernel, the malt is undermodified. If the length of the acrospire is 3/4 or more the length of the kernel, the malt is highly modified.

There are pilsner malts available that are highly modified, I know Munton & Fison produces such a malt, I'm sure there are others.

Cheers,  
Jim

From: Mike Zulauf <zulauf@orbit.Colorado.EDU>  
Subject: wort chiller questions

Howdy All!

I have a few questions regarding wort-chillers. I am interested in making my own chiller. The type I have decided on is a copper coil immersed in an ice-water bath. The reason for this style is the desire to conserve water (Colorado being a fairly arid state.)

I am curious if anyone else uses this type of chiller. If so, how well does it work? How long does it take to chill 5 gallons of wort to a reasonable temperature? How much ice is required? What length of what diameter tubing was used?

Anything else I should know before leaping in and just making the thing? Enquiring minds want to know!

Thanks for any and all replies,  
Mike Zulauf

Date: Wed, 27 Jan 1993 12:27:01 +1030  
From: Murray Robinson <robinm@mrd.dsto.gov.au>  
Subject: Colour Units

I have just found a new supplier for my grain requirements who has data sheets on the malt available. Specifically, it mentions a colour rating expressed in degrees EBC as opposed to degrees LOVIBOND. What is the conversion factor between the two units.

Also the product specification mentions the following:

SPECIFICATION PALE MALT WHEAT MALT

|                 |                      |                      |
|-----------------|----------------------|----------------------|
| Colour          | 2.7 degrees LOVIBOND | 4.5 degrees LOVIBOND |
| Total protein   | eg 11.5%             | 14.5%                |
| Soluble protein | eg 5.0%              | 8.5%                 |
| Kolbach index   | eg 43 (no units)     | 61 (no units)        |
| Diastatic power | 70 degrees L         | 160 degrees L        |
| Viscosity       | 1.65 cp              | 1.60 cp              |

Need I concern myself with any of these quantities? If so which ones are important and what do the units mean? Does the above specification indicate a malt of good or average quality?

Cheers,

Murray.

xBeer Judge Certification Program Ex

am

x

xFellow Homebrewers,

xIn Texas, the bluebonnet is a symbol of beauty and pride, especia  
lly during

xthe spring when they blanket the countryside. The coming of spring in  
1993

xis no

exception, as we usher in that time of year with this year's edition  
xof the BLUEBONNET BREW-OF

F. In a few short weeks, the judge's score sheets  
xwill be in, and the mugs and ribbons awarded.

This means that NOW is the

xtime to gather your brews and make travel plans.

x

xThis ye

ar's competition will be bigger and better than ever with an expanded  
xformat which will include sp

eakers, demonstrations, and activities to

xsupplement the greatest collection of homebrews we have  
ever known. Did I

xhear somebody say "Pub Crawl!"?

x

xWe invite homebrewers everywhere

to join the Cowtown Cappers, the Arlington

xHomebrewers, and the North Texas Homebrewers Associatio  
n for two days of

xadventure such that has not been experienced before.

x

x

Thank You,

x The 1993 Bluebonnet Committee

x

xClubs: Please make copies of th

is brochure and its enclosed entry forms

xavailable to your members.

x

xEligibility

x

The 1993 Bluebonnet Brew-off Homebrew Competition is open to all  
xnon-commercial, home- produced

beers. Beers produced on the premises of

xcommercial breweries are ineligible.

x

xEntri

es

xEach entry shall consist of three (3) bottles, free of commercial labels  
or

xother ident  
ifying markings which are not part of the entry label.  
xThe minimum size for entry bottles is 10 ounces.  
xconform to these standards will be disqualified. The preferred bottle  
for  
xentries is the 12-ounce brown longneck.  
x  
xBrewers may enter any categories, with  
the restrictions that only one entry  
xmay be submitted for any one sub-category, and that no more than two entries  
xmay be submitted for any one overall category.  
x  
xAll bottles should be  
clean, with a properly completed entry label attached  
xby rubber band. Please do not use tape or  
glue! Bottles will be presented  
xat the judging tables, and the use of any material which may cause a label  
to be difficult to remove during entry logging may cause it to be  
ineligible

xfo  
r awards. The sole purpose of the bottle label is to match an entry to a  
xrecipe form, so that we  
may assign an entry number to it. Once this is done,  
xthe label is removed.  
x  
xBe sure  
that each entry has an accompanying recipe form which is completely  
xfilled out, since this is our  
source for all information concerning that  
xentry. With the expanded category list we are using this  
is year, it is  
ximportant that you designate exactly the category and sub-category on  
this  
x  
form so that your beer will be judged according to the style you wish.  
x  
xEntry Fees and Deadlines  
xEntry Fee for entries received by 1:00 PM, Feb. 20 (Saturday) is

From: finette!tamsky@hub.ucsb.edu (Marc Tamsky)  
Subject: Propensity Pilsner Lagering Questions

I am posting for a friend, but he made the following, and has a few questions:

Propensity Pilsner (from Papazian's NCJOHB)  
Wyeast #2007 (I think it's a bavarian lager, but the # is definitely correct.)

OG: 1055

Primary Ferment for one week @ 52F.  
Racked to secondary.  
Secondary Ferment is currently on it's NINTH week @ 40F.  
Still getting glugs every 60 seconds from normal 3-piece airlock.

Bottom of carboy currently has ~1 inch of all-one-color trub.  
Color is crystal clear.

Questions:  
Is this too long of a ferment?  
Should this be re-racked into a third carboy to get it off the trub?  
With 60sec/glug does he need to wait any longer before bottling?  
If he bottles now, should he use less priming sugar since it's not finished?

Thanks

From: zentner@ecn.purdue.edu (Mike Zentner)  
Subject: Semi Annual Wort Chiller diatribe

Mike Zulaf asks about tubing in ice chillers.

Mike, while I haven't built one of these specifically, I have seen one work and can offer some general advice which may be of use to other readers as well.

In general, don't go with any tubing smaller than 3/8" OD unless your tubing length is very short (I built a counter flow chiller with 1/4" and was sorry I wasted my time). Because I use tap-temperature water, I have a 30' length counterflow chiller. If you are going to use ice (and keep it icy) you can get away with less. If ever in doubt about your length, install a valve at the outlet of your copper coil so you can slow down the flow if the outlet is not cold enough. A friend of mine who uses a chiller of the type you mentioned is convinced the 10' length he used is too short.

**MOST IMPORTANT!** Before you coil any tubing, take a q-tip, dip it in rubbing alcohol, and swab around on the inside of the tubing. If you get black goo on the end, you've got machining oils inside and don't want your beer to be in contact with that. You need to clean out the tubing by snaking a very stiff wire through it, lubricated with lots of dish soap. Pull a string through the tubing, tie cotton balls on the string and pull them back and forth to scour the inside of the tubing. Rinse the soap out (leaving the string in) and repeat the cotton ball exercise.

If anyone wants my plans for a counter-flow chiller, send me email.

Date: Wed, 27 Jan 93 08:55:44 EDT  
From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: Culturing Sierra Nevada Dregs

Someone says:

) Rob Bradley asked about culturing Sierra Nevada dregs. Isn't there  
three  
) different strains involved in the fermentation, as well as three  
initially  
) in the Wyeast 1056 pouch? The first strain starts rapidly, but isn't  
) tolerant to ethanol and settles out rapidly, and then a second strain  
takes  
) over. The third strain starts very slowly, but is responsible for the  
) bottle conditioning. I have heard of very slooow fermentations from  
) yeast cultured from SNPA dregs, so maybe only the third strain is  
viable  
) at that time. Any comments?

My experience with 1056 and cultured Sierra Nevada is that they both  
perform similarly (at least when neither is infected), are more  
attenuative  
than 1098 and 1028, and generally finish more quickly than less  
attenuative  
yeasts, particularly when the wort is dextrinous.

Even if your SNPA is a little old, you can still make a fine culture  
from it. The last one I did took several days to start up in a small  
culture flask. Fresh ones take only a day or two, or so they tell  
me. I've never seen a brand new SNPA out this way, although they  
still taste just fine. :-)

As another poster said, you must be confusing the Whitbread yeast  
with SNPA/Chico/1056. Now, what I remain confused on is whether the  
real Whitbread triple strain is used in the Wyeast cultures. My current  
understanding is that it is not, that 1098 is a single strain. I  
know I've heard the answer to this several times over the past year  
here, but it just doesn't sink in ... :-(

Finally, on a slightly different topic, has anyone here tried using  
1084 (Irish) for purposes other than stouts and porters? I feel like  
trying it in bitter and mild ... perhaps it might make a good alt  
yeast, too?

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: re:doughing in water onto malt

In the last digest Al Korz wrote:

<For the record, "doughing-in" is the addition of water to the grist  
<(which is highly recommended) not vice versa. Adding the grist to  
<the strike liquor will work, but will create much more balled starch  
<than the opposite (see Noonan's "Brewing Lager Beer").

This is indeed what Noonan preaches. I have always wondered about  
the importance and significance of adding water to malt as opposed  
to the converse. Ok, so one can get "balled starch", wont it then  
hydrate and become "non balled"? Cant you just stir enough to  
completely mix the mash? Since I do an upward step mash, the  
protein rest provides a 30 minute hydration period for the grains.  
Wont this hydrolyze the grains and liquify the starches? Also, who  
has ever seen a professional brewery doing this?? All of the breweries  
I can recall visiting do what most homebrewers do, raise a volume  
of water to a given temp, and add the crushed grains onto the  
water. This is one of the "Noonanisms" that I feel is rather un-  
important to the overall beer quality. There are so many other  
places for brewers to make significant improvements to quality  
in brewing like malt/hops/yeast choices and even water chemistry.

Maybe I missed something somewhere....

>than the opposite (see Noonan's "Brewing Lager Beer").

Curious. I add the grist to the liquor, and get what seems to be a fine  
dough-in. It seems to allow for better mixing -> no dry spots. How does  
Noonan determine that it creates more "balled starch"? Just what is  
"balled starch"? Obviously I don't have the book.....

From: KLIGERMAN@herlvx.rtpnc.epa.gov  
Subject: nitrosamines

To continue the thread concerning nitrosoamines (specifically N-nitrosodimethylamine), they are indeed potent carcinogens but their level in beer is relatively small (ave. 2 ppb) compared to such products as frankfurters (0 - 84 ppb), fish and fish products (4 - 26 ppb), cheeses (2 - 26 ppb), and various meat products (1 to 80 ppb). They are also found in tobacco smoke and are produced in the human body from reactions between nitrates and protein. In reality, some of the more prominent carcinogens we should worry about are tobacco smoke both main and side-stream, grilled meat and fish products which contain potent heterocyclic amines, alcohol in excess, mycotoxins found in moldy grain, and UV light.

From: rxh6@po.CWRU.Edu (Randall Holt)  
Subject: Old trub, New wort story

Had to add my data point to the re-usable trub methodolgy.

Made a nice lager in my 50 degree basement, and decided to try out the method of trub recycling. First I dumped the trub into a sterile pot, and covered it, then washed and sterilized the fermenter (I use plastic for the first stage, but only have one usable bucket). Brewed up another batch, let cool, and pitched the wort. Okay so far.

As reported, the first stage takes off like a house afire, even at 50F, it looked like it would be ready within 5 days to rack to secondary.

But, around the fifth day, while making my customary wort check, I noticed that the whole basement smelled of dirty diapers. And when I stepped into the little side room that I keep my fermenters, the smell was overpowering.

(insert sound of sinking spirits)

Well, loathe that I am to dump \$20 of malt down the drain, I waited one more day and then racked it to secondary. And while checking the gravity, I tasted the tube full of beer, and no odd flavors! The secondary seemed to be clearing just fine, BUT, the odd smell persisted in the fermentation room.

To make a long story short, the ferment room is right next to the downstairs bathroom, which we almost never use. The p-trap in the shower had dried out, allowing sewer gas to seep out into the ferment room through the plumbing access hole. Running the shower for a few minutes solved the problem.

The end of the story, is that the final product, a bitter lager turned out beautifully, and I'm convinced that re-using trub is a viable alternative but I would recommend it only for low temperature fermentation because of the extremely fast start.

And run your basement shower every month or so to keep the p-trap primed.

Bibo ergo sum.

From: cbacco@ursa5.cs.utah.edu (Corby Bacco)  
Subject: Source for caps for Champagne bottles.

Greetings,

I was wondering if anyone can give me a source for caps for Champagne bottles (28 mm?). My roommate works at a restuarant and has been bringing home a nice supply of champagne bottles which I would love to be able to cap. My capper does have the proper fittings to handle the larger caps (as well as the standard ones) so all I need are the caps and I'm in business. I've checked with my local shops (all 2 of them) and with William's mail order and so far have struck out. Any ideas?

Cheers,  
Corby Bacco

> copper? positive/negative comments? anyone? anyone?

I am using a six gallon Ropak bucket with a PVC manifold at the bottom for my lauter tun. There is a half inch adapter for PVC that screws directly into the small spigot sold at my local brewshop. This piece, a cross fitting, three end caps and the 12 or so inches of PVC needed cost me a grand total of about \$2.50. I slotted the bottom similarly to the copper coil method. It works fine, and seems to have improved my yields over the Zapap method. I attribute this to the elimination of the 1-1.5 gallon space between the two buckets in the Zapap system. Then again, I've only got about 6 all grain batches under my belt :-), and experience may be what is increasing my yields.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: And now, a beer for cats!

HBD readers might be interested in the following, which was distributed by the Associated Press:

"Brewery Markets Energy Drink for Pets  
"Strasbourg, France: A French brewery hopes to capture the pet market with its latest product--a non-alcoholic, high energy drink for cats and dogs.  
"The Pecheur brewery's latest creation is made from ingredients left over from the beer-making process and enriched with vitamins and mineral salts, said Marc Arbogast, the brewery's technicaltechnical director.  
"The drink will be marketed in Japan. If Japanese pets give it a paws-up, it will be introduced in France in March, then in Germany.  
"The drink comes in cartons and costs about the same as mineral water.  
"Pecheur has previously experimented with a beer containing malt whisky and another promoted as an aphrodisiac."

I've seen what I believed is the last product mentioned, which is packaged in a contain I could easily have mistaken for a men's cologne.

Unfortunately I can't say which paper this appeared in or on what date. I received this clipping from a relative.

In fact, Pellet hops have all the glands ruptured by the pelletization  
process. The reason pellets are more stable is that they are highly  
compressed and that naturally excludes oxygen infiltration. The  
completely ruptured glands are the reason pellets have higher utilization  
rates in the boil.

conversion

>factor between the two units.

>

>Also the product specification mentions the following:

>

>SPECIFICATION PALE MALTWHEAT MALT

>

>Colour 2.7 degrees LOVIBOND 4.5 degrees LOVIBOND

>Total protein eg 11.5% 14.5%

>Soluble protein eg 5.0% 8.5%

>Kolbach index eg 43 (no units) 61 (no units)

>Diastatic power 70 degrees L 160 degrees L

>Viscosity1.65 cp 1.60 cp

I don't have a conversion, but here are some L/EBC pairs from Siebel's -

-

perhaps you can figure out your own conversion factor:

| Lov   | EBC  |
|-------|------|
| 3.21  | 8    |
| 7.83  | 15   |
| 25.7  | 55   |
| 7.87  | 15   |
| 21.65 | 45   |
| 77.5  | 155  |
| 221   | 500  |
| 22.5  | 55   |
| 497.5 | 1100 |
| 557.5 | 1400 |
| 601   | 1400 |

Looks slightly non-linear at the ends, but roughly 1:2 in the middle.

Regarding the quality of this malt, I'd say it's quite good. To compare, the DeWolf-Cosyns Pale Ale Malt is:

3.21 degrees Lovibond  
10.00% total protein  
3.94% soluble protein  
60 degrees Lintner (diastatic power)

Schreier 2-row Brewer's Malt is:

1.78 degrees Lovibond  
12.4% total protein  
5.10% soluble protein  
131 degrees Lintner

Al.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: re-using yeast in fermenter

Ron Karwoski writes about his experiences in pouring new wort over existing yeast in the fermenter. My questions relate to doing the same thing with the secondary fermenter:

1. If the secondary has been sitting a while (say a week or two) is the sediment still viable yeast?
2. After I've racked off for bottling, how long could I safely leave the remnants? I thought of just putting back the airlock and leaving it untouched until the next brew.
3. If I do 2 above, will it be necessary to "start" the yeast by adding a small amount of sterile wort as per WYEAST starters?

From: hmcook@boe00.minc.umd.edu (Hardy M. Cook)  
Subject: Yeast Culturing Questions

I'm a new reader of HBD, and some recent discussions about culturing yeast prompt me to ask a few questions. I started culturing yeasts a few weeks ago.

I began with an ale and a lager strain that I purchased in slants from the mail order supply store I use. I then had a microbiologist make me slants and petri dishes of solidified worts as per Paul Farnsworth's culturing article in the ZYMURGY Yeast and Beer Special Issue. I inoculated two petri dishes with these strains, but of course I didn't want to stop there.

Next, I took the sediment from a Trippel I had brewed using Wyeast #1214 (Belgium Ale), cultured it, and inoculated another petri dish.

Then, I brewed a lager with a Whitbread Dry Lager Yeast and an ale with a Whitbread Dry Ale Yeast. I first inoculated slants from the starter cultures

I had made by rehydrating these two in sterile wort. I had inoculated slants of the other three strains too, but all five of these slants were not as solidified as the petri dishes and I did not like what saw, so I disposed of them. I still, however, wanted cultures of the two Whitbread varieties, so I inoculated petri dishes from the slurry I collected after the primary fermentation.

I also inoculated a petri dish from a starter culture I made from a Dry Edme Ale Yeast.

Now, my questions.

Concerning the Belgian Ale Yeast from the Trippel, what are the chances that it has mutated or was a multiple-strain yeast? (I am currently making a starter culture to use over the weekend.)

Are the Whitbread's Dry Ale and/or Lager Yeasts triple-strain yeasts, and if they are, does that mean that I have cultured only the third strain because I used the slurry from the primary fermentation?

Is there anything I should know about the Dry Edme I cultured?

I would appreciate any response from those more experienced than I in yeast culturing.

Thanks,

Hardy M. Cook

>4 months but it could take a year -- don't worry... the alcohol level  
>will keep nasties at bay.  
Al.

I disagree. Let me be more specific: what Al says about higher alcohols may well be true. We don't really know what's wrong with Scott's beer. I have, however, on three or so occasions over the years had awful, unexplained (unexplainable?) solvent tastes/smells. Similar to the problem that JS mentioned in the Goose Island Barleywine (I tasted the stuff in early January and agree (!!)) with arf) in today's HBD, but more pronounced. In my private lexicon, this solvent taste is "clinical". I posted about it in the HBD in 1989, wondering about possible connections with diacytel (consensus: no connection) and how to avoid it (be careful with fermentation temperature and cleanliness, I seem to recall).

At any rate, I twice bottled such beer, and the solvent never went away, not even after a year. It got worse, in fact, as the other flavors mellowed.

So keep us posted, Scott.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: mmlai!lucy!gildner@uunet.UU.NET (Michael Gildner)  
Subject: brewpots

After some thought I've decided to invest in all grain brewing. The problem seems to be that the start up costs for the equipment could be over \$100. I can get access to a corona through my local homebrew club and the cost of converting my cooler for mashing is minimal. The main cost remains, a large 7-10 gallon brewpot. So does anyone have any ideas on where to find a good deal on a large pot? I've been eyeing one at the local "PACE" store recently. It is a 13 gallon oval shaped "Revere" copper boiler for \$80. I was hoping to find something for under \$50.

Any ideas?

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: dough in correction

In the last digest I made the comment regarding dough in methods in many breweries based on adding malt to water. It occurred to me last night that many BIG breweries and small breweries with pretty high tech malt feed systems do indeed have a spray system where the malt entering the mash tun is showered with hot water mixing both as they enter the tun. This is indeed about the best way to dough in, but I still assert that for homebrewers this is a bit of overkill. But then, most of you probably were aware of this anyway.

Subject: re:blond doppelbock

In the last digest hosehead@acs.bu.edu (Michael Reinhorn) asks about making Blond DoppelBock. HE also notes that the bock from the Chapter house was pretty good. This bock used to be produced by the now defunct Clement Brewing Co. It was indeed a fantastic blond doppel, weighing in at 9.5% alcohol by Vol!! For a try at the brew: Use 100% pale pils malt, possibly adding a bit of Munich, but this is not required. Push the OG up to around 1.090. Use quality imported german hallertaur hops. A double decoction mash would be good. Keep the IBUs in the 20 range. Ferment with a very clean lager strain, keeping the ferment temp at 48F. After primary for about 1 week, rack to secondary and slowly (2F per day) drop the temp to 31F. You may want to do a 2 day diacetyl rest at 39F. LAger at 31F for at least 6 weeks, 8 is better. Prime with fresh yeast and wort, or force carbonate. This is not a simple beer to make well, but can be very rewarding.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: doughing-in

Hi All,

In the last few digests, an interesting thread on dough-in. Al Korz writes:

>>For the record, "doughing-in" is the addition of water to the grist  
>>(which is highly recommended) not vice versa. Adding the grist to  
>>the strike liquor will work, but will create much more balled starch  
>>than the opposite (see Noonan's "Brewing Lager Beer").

Jim Busch answers:

>This is indeed what Noonan preaches. I have always wondered about  
>the importance and significance of adding water to malt as opposed  
>to the converse. Ok, so one can get "balled starch", wont it then  
>hydrate and become "non balled"? Cant you just stir enough to  
>completely mix the mash? ....

>This is one of the "Noonanisms" that I feel is rather un-  
>important to the overall beer quality. There are so many other  
>places for brewers to make significant improvements to quality  
>in brewing like malt/hops/yeast choices and even water chemistry.

I tend to agree with Jim. Quoting from the source in question:

"More than 10 percent flour is undesirable because it balls or cakes readily. Balled flour results in unconverted starch that is inaccessible to enzymes; some would surely wash into the wort during sparging, causing an irreversible haze in the beer."

So, Noonan says that the problem with balled starch is that it leads to incomplete conversion, and to unconverted starch getting into the wort and causing a starch haze. While I believe this is true in general, I don't think dough-in procedure is the determining factor in creating balled starch.

I say this because I always do it "backwards", fill the mash tun with water at ~130F, add 2-3 pounds of grist, stir thoroughly, repeat until all the grist has been added. The temperature settles in at ~118F-120F, just right for the protein rest. I don't have any problems with either complete conversion or starch hazes, my lagers come out brilliantly clear.

IMHO, a too-fine crush of the malt is far more likely to cause the above mentioned problems, due to large amounts of flour and pulverized husks. Comments, please?

Cheers,  
Jim

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: re-use slurry

Re-using yeast slurry is easy, efficient, cost effective, and taste effective; I do it often. Some things to keep in mind:

1) Sanitation - especially wrt. the very first primary (meta-primary?) ferment. Anything "bad" you introduce here will be propagated through all the successive batches. Once you get to the point of using the slurry, sanitation is \*not as\* important, because there is such a relatively enormous amount of yeast being pitched for primary ferment that other organisms cannot get a foothold.

2) Pitch a large healthy yeast starter for the meta-primary ferment.

3) Use the slurry from the secondary. The primary has trub, hops, and dead yeast that can add off flavors. However, you may use the primary slurry if it fits your brewing style. If you are unsure of your sanitation in transferring from primary to secondary, you may be better off using the primary slurry.

4) Don't overdo it. All yeasts mutate; some more (and more quickly) than others. Often the mutation is to become more attenuative (making a dryer beer). I've found this to be true of Sierra Nevada/Wyeast 1056 yeast; after 3 batches the beer is too dry for my tastes. Whitbread ale yeast, otoh, had been reported to be able to be re-used many times (20+ ?) without much change in character.

Try it, you'll like it. Oops, gotta go to work.

| 497.5 | 1100 |
| 557.5 | 1400 |
| 601   | 1400 |

Fred Eckhardt's well-known book on beer styles contains an equation for converting EBC to Lovibond.

$$\text{EBC} = \text{Lovibond} * 2.65, \text{ less } 1.2$$

Implying that to convert from EBC to Lovibond, add 1.2, then divide by 2.65. Here's what I got when I ran the numbers Al provided:

|                        |
|------------------------|
| EBC = 8, L = 3.47      |
| EBC = 15, L = 6.11     |
| EBC = 55, L = 21.21    |
| EBC = 15, L = 6.11     |
| EBC = 45, L = 17.43    |
| EBC = 155, L = 58.94   |
| EBC = 500, L = 189.13  |
| EBC = 55, L = 21.21    |
| EBC = 1100, L = 415.55 |
| EBC = 1400, L = 528.75 |

EBC = 1400, L = 528.75

Hmmm, a couple of interesting observations here. First, from looking at the pairs Al provided, it would seem that whatever the conversion formula is, it's not linear, so I'm not terribly surprised the equation from Eckhardt doesn't quite hold. Second, there are three pairs where the

EBC rating is the same (15, 55 and 1400), yet the equivalent Lovibond ratings are different. What gives?

I would be very interested in an accurate method of converting these units. If anyone knows how to convert the two, please jump right in.

Cheers,  
Jim

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Isolating pure yeast

Hardy M. Cook ask some questions about yeast culturing.

There exists a agar called "WL nutrient agar" that is great for isolating pure yeast from wild yeast strains. This agar is green in color. The pure yeast take up the green color when grown up on Petri dishes and the wild yeast remain white. I personally have never used the stuff, but have know about it for years and was looking at some yeasts that were grown up of the media this last weekend at the Bay Area Brewoff. A friend of mine uses it to always check his yeast and grows up yeast taken from slants on the stuff. I like these type of eyeball sort of tests. Maybe some microbio type out there could post the availablity and cost of the media for those interested.

I think this is a mistake. They have brewed a beer using whisky malt called Adelscott which (according to Mr. Jackson) "imparts a very light smokiness." I have spoken with the US importer about this product in the past only to learn that they do not plan to introduce it here. Some problem with the labeling.

From: gjfix@utamat (George J Fix)  
Subject: Bluebonnet Brew-off

I hope everyone caught Bryan's announcement in HBD#1064 of the Bluebonnet Brew-off which will be held on 5-6 March. The organizing committee has really worked hard on this one, and it looks like it is going to be a very interesting and fun conference.

I hope to organize a tour during the conference. This will be carefully coordinated with the organizing committee so that it does not conflict with the exciting events they have planned. The conference will be held in the central part of the Dallas-Ft. Worth metroplex (better known here as the Arlington metroplex). This is within striking distance of two commercial breweries (Dallas Brewing & Miller/Ft. Worth), and I hope to include some interesting homebrewing setups as well. It would be great to have people on this network join us. Technical discussions tend to have a lot more meaning when they are done in the context of an actual brewing configuration.

Anyone interested should contact me via private e-mail.

From: Chris McDermott <mcdermott@draper.com>  
Subject: Repitching yeast.

Repitching yeast.  
First off lets clear up the terminology here. Several post in last few digest have mentioned repitching "trub". In most cases I assume that this was simply a mistake and what the writer meant was "yeast". However in #1065 Randall Holt says:

>Made a nice lager in my 50 degree basement, and decided to try  
>out the method of trub recycling. First I dumped the trub into  
>a sterile pot, and covered it, then washed and sterilized the fermenter  
>(I use plastic for the first stage, but only have one usable bucket).  
>Brewed up another batch, let cool, and pitched the wort. Okay so far.

While I am sure that this will give him a good quantity of viable yeast, I'm also sure that it give him of bunch of crap (trub - yeast = crap) that I wouldn't want to pitch into my beer. So before anyone takes that advise to heart unadvisably - the more accepted method, at least in my mind, is to repitch the sediment from the secondary which should be mostly yeast and should contain several orders of magnitude less crap.

Also in #1065, Peter Maxwell asks:

>1. If the secondary has been sitting a while (say a week or two) is the  
>sediment still viable yeast?

At least some portion of the yeast should still be viable.

>2. After I've racked off for bottling, how long could I safely leave the  
>remnants? I thought of just putting back the airlock and leaving it  
>untouched until the next brew.

With no food left the yeast will begin to autolyze. This is not good. My method for saving yeast in this situation is to dilute the sediment in the carboy with some sterilized water and then dump that slurry into a steril jar that gets stored it in the refridgerator. The cool temperatures slows down the autolyzation and should keep the yeast good for a week or more. I use a pressure cooker to prepare "canned" jars of yeast starters. Using the same method I make up a few jars of "canned" water that serves to produce a sterilized jar for storage as well as sterilized water.

>3. If I do 2 above, will it be necessary to "start" the yeast by adding a  
>small amount of sterile wort as per WYEAST starters?

Most of the "old" yeast may have died, but again there should remain some portion of healthy yeast. By using a starter you can insure that you will get

a large population of viable yeast for pitching. I usually assume that the portion of viable yeast is large enough that I can build up a large starter (1 - 1.5 qt) in a single step, but depending on how old the yeast is you may want to do it in stages.

> untouched until the next brew.

The yeast should still be viable even after a long secondary. I believe  
that many of the yeast cells go dormant, rather than die (the more  
biologically inclined can correct me on this point if I'm wrong).

I suppose you could leave the remnants in your fermenter, but once you  
remove the beer, you introduce a lot of air and accompanying microbeasts.  
My technique is to pour the sediment into a small sterilized (boiled)  
jar,  
cap it with an airlock, and put it into the fridge. The small CO2 output  
you'll get will quickly purge the smaller jar of air, and the colder  
temps  
inhibit any bacterial growth and slow down the yeast activity.

I find that my yeast stored this way will last 2-3 weeks.

> 3. If I do 2 above, will it be necessary to "start" the yeast by  
> adding a  
> small amount of sterile wort as per WYEAST starters?

I don't think so. If you have half a cup of thick yeast slurry like  
that, you already have more yeast than you would in a 1-qt starter.  
I simply let the yeast warm to room temperature until it shows signs of  
life again, and then dump it right into my wort.

| 40                                     | 2.430 | 2.347 | 2.268 | 2.195 | 2.127 | 2.062 | 2.002 | 1.944 | 1.890 |  |
| 45                                     | 2.868 | 2.769 | 2.676 | 2.590 | 2.509 | 2.433 | 2.362 | 2.294 | 2.230 |  |
| 50                                     | 2.995 | 2.892 | 2.796 | 2.706 | 2.621 | 2.542 | 2.467 | 2.396 | 2.330 |  |
| 55                                     | 3.198 | 3.088 | 2.985 | 2.889 | 2.798 | 2.713 | 2.634 | 2.558 | 2.487 |  |
| 60                                     | 3.198 | 3.088 | 2.985 | 2.889 | 2.798 | 2.713 | 2.634 | 2.558 | 2.487 |  |

To use this table estimate (or measure) the gravity of the wort, and find the number corresponding to the time of boil. Multiply this number by the HBU's to get IBU's. For example to compare Jim's two recipe's for an extract pilsener, let's assume a full boil with a gravity of about 1.050 (and neglect the increase in gravity as the wort is concentrated). Then recipe 1 yields

5.75 HBU @ 60 min = 5.75 \* 4.477 = 25.7 IBU  
 +3.5 HBU @ 15 min = 3.5 \* 1.194 = 4.2 IBU

-----  
 29.9 IBU (from the boil).

Recipe 2 calls for

10.0 HBU @ 30 min = 10.0 \* 2.283 = 22.8 IBU

which is less than recipe 1. Of course if you are only doing a partial boil (heaven forbid) the gravity of the boil will be about

1.125 and the IBU counts will be reduced to 21.4 and 16.6 respectively.

In Rager's article the utilization rates are based on a maximum of 30% at 60 minutes and these numbers should probably be reduced by about 20% for hop flowers.

In HBD1064 Mike Zulauf asks about immersion in ice-water chillers:

> I am curious if anyone else uses this type of chiller. If so, how  
>well does it work? How long does it take to chill 5 gallons of wort to  
>a reasonable temperature? How much ice is required? What length of  
>what diameter tubing was used?  
>Anything else I should know before leaping in and just making the  
>thing? Enquiring minds want to know!

I made such a chiller out of 25 ft. of 3/8 od copper last summer because during the summer my tap water is 80 degrees F making the counterflow or immersion in kettle type less attractive. It works great, chilling 5 gallons of boiling wort down to 60-70 degrees F in 15 to 20 minutes. When you factor in the latent heat needed to melt the ice you will find that equal amounts of 10 deg F ice and 212 degree boiling water will come to equilibrium at about 52 degrees F. So as a rule of thumb you should use about the same amount of ice as the wort you're trying to cool. I also add about 1 or 2 gallons of cold water to the ice. You should constantly stir the ice water while the wort is passing through for the ice water and wort to more efficiently equilibriate the temperature.

On the other hand since my tap water now is about 52 degrees F I have also made an immersion in kettle chiller which cools the wort to about 70 deg F in about 25 minutes. Since we don't have a water shortage in Maryland, I prefer this method because I don't have to save all that ice.

Subject: Propensity Pilsner Lagering Questions

>I am posting for a friend, but he made the following,  
and has a few questions:

>Propensity Pilsner (from Papazian's NCJOHB)

>Wyeast #2007 (I think it's a bavarian lager, but the # is definitely correct.)

>OG: 1055

>Primary Ferment for one week @ 52F.

>Racked to secondary.

>Secondary Ferment is currently on it's NINTH week @ 40F. etc...

>Still getting glugs every 60 seconds from normal 3-piece airlock.

>Is this too long of a ferment?

I have made this beer 3 or 4 times and it is excellent but the flavor depends on the source of honey. My advice to you is relax and have a homebrew. Your lagering is more than ample but you probably have a lot of dissolved CO2 which is slowly coming out of solution. I would raise the temp. 5 degrees/day until your beer is up to room temp. and let it either finish fermenting (doubtful) or degass a bit. Also it would be wise to take a gravity reading and/or measure the residual sugar to see if the gravity is low enough to bottle safely.

From: "Sadvary, Bill" <SADVARY@DICKINSON.EDU>  
Subject: My Shuttle Buddy

My Shuttle buddy, Dan Vosel (some of you may know him) sent me a case of Pabst Blue Ribbon today for my birthday. I thought it was a rather unusual choice of brew and thus it got me wondering...

The label states:

This is the ORIGINAL Pabst Blue Ribbon Beer. Nature's choicest products provide its prized flavor. Only the finest of hops and grains are used. Selected as America's Best Beer in 1893.

A few questions:

1. Why would they specify Original? Did they have forgery problems at one time?
2. Nature's choicest products, is choicest a word?
3. Prized flavor, would anybody know the prizes awarded? ..besides a Blue Ribbon.
4. Only the finest of hops and grains. How would I attempt to duplicate such a beer? Rice would be one, right?
5. Selected as America's Best Beer. What other american beers were around available in 1893?

If anyone can answer any of these I would greatly appreciate it. Thanks!

From: Tom Rush <trush@mhc.mtholyoke.edu>  
Subject: Scientific American: Absinthe

If anyone is interested and has access to the back issues of SA the June 1989 issue, pp 112-117, there is an article on the liqueur "Absinthe".

I know this is not a forum for discussion of distillates but bear with me :-). ... it is well researched and proposes a chilling theory on the use (abuse) of various herbs particularly *Artemisia absinthium* the common herb, Wormwood and other herbs found in herb gardens (mine) and many times in herbal outlets (herbalists?).

I understand the herbs in absinthe are distilled \*essences\* but it is food for thought when someone discovers an old beer recipe some of the herbs it could require may contain some powerful compounds which invite the cautionary phrase "more is not always better".

Other interesting sections touch on relationship of absinthe with Van Gogh, Degas, Manet, etc. - the "absinthe spoon" which I have seen but never knew why a spoon would have slots cut thru it. Also a sidelight on the invention of the alcoholmeter (works like a hydrometer), and a 19th century still. Ironically in the bibliography of the author, Prof. Wilfred Niels Arnold specializes in yeast research but his avocation is 19th century medicine and art history. Please do not consider this as "breaking new ground" it is meant to be read and taken for face value, I am not a scientist or engineer (liberal arts and MBA).

Now that I am admitted scientific layperson, would someone be kind enough to send me the method used to "wash" yeast? I would prefer a simple explanation where I don't have to put on a laboratory "white coat" :-). ... Thanks,

Tom Rush

Subject: nitrosamines in beer

Just to add a little to the talk about nitrosamines, they are found in beer and wine, but as has been noted, they are found at very low levels.

They are formed under acidic conditions in our stomachs by the nitrosation of ingested secondary amines by nitrite (generated from nitrate). It has been shown that vitamin C prevents nitrosation by competing with the amines for the nitrite. So everyone drink their O.J. so you get your C's.

Finally, nitrosamines require metabolic activation to exert their toxic and carcinogenic effects. It just so happens that ethanol increases levels of the enzyme responsible for the activation of N-nitrosodimethylamine, the major nitrosamine found in beer. Whether increasing the metabolism by raising enzyme levels is good or bad regarding toxicity is currently being studied by a lot of people.

This is great, we all need a little chemistry now and then. Enjoy.

From: "Kevin (K.W.) Golka" <golka@bnr.ca>  
Subject: Mai Bock Strike Temp and Chillers

I have read a couple of recipes for Mai Bock that call for a mash temperature of 150F for 2 hours. This temperature seems too low. The Mai Bock which we made had a strike temperature closer to 156F and it turned out pretty much as expected.

With a mash temperature of 150F how do you end up with the characteristic sweetness of a Bock? There was a pound or so of crystal malt in these recipes but I wouldn't have thought that this would be sufficient on its own for the style.

I thought that a two hour mash at this temperature would give you Mai Dry :). Am I missing something here?

On another note...

I have an immersion wort chiller but a friend of mine is planning on building a counter flow chiller. Is there a FAQ with pipe diameter, length and so on?

Has anyone built a counter flow chiller that looks like a coil in a big coffee can? Advantages/disadvantages over the garden hose method?

Thanks for any info,

Kevin Golka, 613-763-3474

These opinions are my own and not necessarily those of NT or BNR.

From: MARK TARATOOT <SLNDW@CC.USU.EDU>  
Subject: cyser yeast

Greetings.

I am going to give my first cider a couple of months in the bottle and I am sure it will get better. It already seems to be improving and I am less disappointed than I was at first.

In the meantime, I am in the process of starting a batch of cyser and am in need of a few comments. The basic recipe is:

~ half a gallon of snowberry honey (5-6 pounds)  
4 + gallons fresh cider (mostly macintosh and delicious)  
12 oz seneca granny smith apple juice concentrate (no preservatives)  
3 tsp acid blend  
3+ tsp yeast nutrient  
10 campdon tablets

O.G. = 1.082

I have several yeast varieties at my home, and I am wondering which I should use/start with/finish with/etc. I have:

Pastuer Champagne (red star)  
Montrachet (red star)  
Epernay 2 (red star)  
Ale (williams)

My last cider was made with Epernay 2 and it finished quite dry. I would like a sweeter beverage, but I don't know if the ale yeast will poop out too soon (I want to sparkle some of it). Also, I don't know if the ale yeast will ferment more vigorously and scrub some of the more subtle flavors from the must. If anyone has information on the characteristics of the first three yeasts above, I would like to hear it.

When I rack this, should I increase the sugar (honey) if I go with one of the wine yeasts?? My first cider started around 1.050. What about lager yeast? What are the advantages/disadvantages in using one type of yeast and adding another at a later time (or starting with more than one type)?

How about juicing some other type of apples and tossing that in at one of the rackings?

I plan on pitching late tonight or more likely tomorrow morning after the majority of SO2 has been thrown off, so timely comments would be helpful.

BTW... the Clinton Ale is Delicious!!

Thanks for the help!

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Nitrosamines, Dough-in

>From: gjfix@utammat (George J Fix)

>For the record, the highest NDMA level reported was in Bamberg  
Rauchbier.  
It contained 5-15 parts per billion, and not 5 ppm as reported in HBD.

Just testing to see if you read my articles as carefully as  
I read yours :)

> This also was the level reported in their malt. The NDMA levels of  
beer is  
typically 9-10 times lower than in the malt used.

One would think that it would be many orders of magnitude lower than the  
malt  
resulting from the dilution by water. Would not the fact that this one  
is an  
exception point to the possibility that they are creating new NDMA (I  
bow to  
your term) in their brewing process?

>I feel it is perfectly legitimate to raise the possibility that beer  
with  
higher than normal nitrosamine levels could be a health hazard.  
Nevertheless,  
there are many aspects of this issue I do not fully understand. For  
example,  
population data shows that Bamberg has one of the highest rates of beer  
consumption in Germany (no small feat!), yet its cancer and death rates  
are near (and in fact slightly below) the average in Germany...

A dilemma indeed. (Potentially resolved by the suggestion today that,  
maybe  
it's the saurkraut) However, someone decided that NDMA is carcinogenic  
and  
without further evidence, I am not about to waive the condemnation based  
on  
one anecdotal experience. It's a bit like the CDC claiming that  
mosquitoes  
can't spread AIDS because a study done in a swampy town in Southern  
Florida  
showed no higher incidence than the population at large.

>For the record, the Belgium base malts have very low NDMA levels, and  
in fact are lower than most US malts.

Their literature claims that all their malts are indirectly kilned and  
the  
major US supplier (Bries) still uses direct fired kilns. No doubt this  
is  
what skews the data.

Personally, I was delighted to find a source of indirect malt that  
didn't  
compromise overall quality and taste. The Belgian malts seem to be the  
best

of all options. By using them I do not have to care who is right on the NDMA issue.

>From: Jim Busch <busch@daacdev1.stx.com>

>This is indeed what Noonan preaches. I have always wondered about the importance and significance of adding water to malt as opposed to the converse.... This is one of the "Noonanisms" that I feel is rather unimportant to the overall beer quality.

>Maybe I missed something somewhere....

I think what you missed was Rudebusch's reference to "doughing-in" with water at a temperature on the order of 175 degs.

Doughing-in is the initial mixing of malt with water in such a way as to assure that it is thoroughly mixed BEFORE the water is raised to ANY strike temperature. It is done with a small quantity of water at or near room temperature and the result is what is described in the name, i.e. a dough or very thick paste. It is more easily accomplished by adding the water to the malt but the important point is to break up the starch balls before they are heated up as they can then form clumps that water will never penetrate.

The value of all this can be debated ad nauseam but one point that should be clear is that it really can not be done with a single step infusion mash.

The amount of water used to doughin, in addition to the grain itself, could never be brought to saccharification temp by adding the rest of the water, regardless of the temp. It is a concept that really only applies to kettle mashing on the stove.

This also explains why brewpubs and micros do not do it. I would also caution that as micros are in a grey area economically, between large commercial brewers and home brewers, they are not necessarily the paragons of technology or quality a homebrewer wants to aspire to. They do lots of things for reasons of cost that we do not have to be concerned with. The majors can do things that seem costly but have a positive effect on the bottom line for other reasons. They also have the option of "adjusting" the bottom line by adding more water to the "beer concentrate".

>From: KLIGERMAN@herlvx.rtpnc.epa.gov

>-nitrosodimethylamine), they are indeed potent carcinogens but their level in beer is relatively small (ave. 2 ppb) compared to such products as frankfurters (0 - 84 ppb), fish and fish products (4 - 26 ppb), cheeses (2 - 26 ppb), and various meat products (1 to 80 ppb).

Interesting numbers but so are the ranges. They all have a low end below the

FDA limit for beer. I don't know what the limits are for the other products but I think we all know that BIG Brother seems as interested in protecting the economy and big business as they are in protecting the consumer.

Having said that, I guess I have to add, so what? Only a fool would intentionally choose to eat products with higher levels of carcinogens if given reasonable choices. In malt we have a choice. If we let the industry trample our health interests and defend them in doing it, whom have we served? If we insist on the safest product they can produce, we serve ourselves.

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: Hop\_aroma

In a recent issue Darryl Richman laments:  
>If only there were a way to describe hop aroma with a number...

Well, Darryl (choir music...) there is a way, and the good folks at O.S. U. Ag. Chem. (Gail Nickerson) and Blitz Weinhard Brewing (Earl Van Engel) have published a couple of papers on it in the Journal of the American Society of Brewing Chemists (Vol. 50, No. 3, 1992). The number you hoped for is called the hop aroma unit and is Rquantitatively measured as 1 nanoliter per gram of hops (1 ppm, v/w), of 22 hop oil compounds that have been reported to affect hop aroma.S The individual measurements of these 22 compounds make up the Hop Aroma Component Profile (HACP). The researchers hope that the hop aroma unit will end up being as useful as the alpha acid % is now.

The 22 aroma-active compounds are divided into three groups, oxidation products of humulene and caryophyllene, floral-estery compounds, and citrus-piney compounds. The oil is obtained via steam distillation and taken apart with a gas chromatograph.

What does this mean to the average homebrewer? Not a heck of a lot, unless youUve got some state of the art instrumentation hanging around the garage. I sell hops for a living and have had a \*real\* hard time getting anything but vague average values from the brokers. So for a specific lot of hops from a specific grower (which could be any of many), you are better off relying on your nose than making any assumptions based on the R1992S crop data.

In the same issue Al (Korz) asks about his hop stats and whether anything useful can come of them. Here are some common assumptions for hop RnobilityS: AA % less than 7, alpha/(alpha+beta)=.4-.6, cohumulone <25%, myrcene content low, humulene/caryophyllene >3, farnesene may or may not be present. So you can get quite a bit from the numbers you have.

I have a \*lot\* of other info on hops, hop analysis, Rhoppiness potentials, yeah I went a little crazy with my copy card at the library, heck, no one else reads those beer journals but me. Give me a yell if you want more in depth hopitude. IUm on the net only on Tues and Thurs.

End of HOMEBREW Digest #1066, 01/29/93  
\*\*\*\*\*

-----

Date: Fri, 29 Jan 93 02:38:20 MST  
From: Chris Kunath (Chicago) <cjk@denver.ssds.COM>  
Subject: malt mixing

Dear Hopheads,  
I've followed this reflector group for several months, and am finally motivated enough to try my first batch of homebrew. Whilst doing my homework, though, I've stumbled across a few contradictions. After I figured out the difference between a single-stage and two-stage fermentation (thanks to "Better Beer & How to Brew It") after about ten books, I have only one conceptual block (so far): mixing the malt.

Mr. Beadle ("Brew it Yourself\*"), and at least two other British 1960s-type books abhor boiling:

"Do not bring the water to a boil. You will remember from the section on commercial procedures that the malt was kept at a temperature of 153 degrees Fahrenheit to allow the diastase enzyme to convert starches to sugar for correct fermentation of the malt. If you allow the water temperature to approach the boiling point, you will upset this sugar conversion and cause it to re-fix at a stage that will not allow the yeast to convert all the malt sugar to alcohol and and carbon dioxide. The temperature of the mixing water must not exceed 153 degrees F. Every other book on home-brewing has incorrectly given instructions to boil the malt in the water to dissolve it. This will only guarantee that some of the malt sugar will not be converted. This single bit of misinformation from those who should know better has caused many beginners to become unnecessarily discouraged in their attempts at brewing."

Tenth-grade chemistry was many moons ago. Every book I've stumbled across published since then (c1971) recommends boiling, even up to an hour for porters and stouts. Since that is what I'd like to brew, I have a few questions:

1. Has brewing chemistry advanced since then, proving this guy and my library of 1950-70 homebrewing books wrong?
2. Am I treading on rwar territory? If so, don't waste bandwidth, flame me direct at cjk@denver.ssds.com.

Perhaps I should not "Don't Worry," and instead "Don't Panic!" :-)

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Dough in, yeast, all Munich brew, barley wine

I have had some trouble with the mailer. My last 2 postings bounced after several days...

Congrats to js for finally giving an accurate description of dough in, i.e. adding the minimum COLD water to form a dough. This is not just to prevent dough balls, but to allow enzymes to leach into the water before the rests. It assumes a poorly converted malt. Normally the temp is raised to ACID rest with an infusion of boiling water, but who does an acid rest anyway? I will dough in for my barley wine this weekend, mostly because I don't know how thin my mash can be (24 lb in a 7ga cooler), and because I'll be using Pilsener malt.

I often reuse yeast and have had few problems, except that occasionally fermentation will start so quickly, I won't have a chance to rack off the trub before it gets dispersed. I will reuse the yeast from the primary of a stout made with yeast cultured from a Guinness bottle for my barley wine.

I made a beer with all Munich and 1 lb of Ireks-Arkady crystal. My suppliers has been having trouble getting analyses, so I was shooting in the dark. Rather than a dunkel, the beer is a Vienna. Now I am wondering what the supposed Vienna I made with 3lb Munich and 6lb lager will be - a Muenchener Helles - my attempt at the latter became an award winning Helles Bock (maybe I'll brew what I intend to sometime!).

Someone asked about agar - 1.5% is normal for slants i.e. 15g/liter. Convert from these units to those you like perhaps 1/2 oz per quart would be close.

From: steve\_T@fleurie.compass.fr (Steven Tollefsrud)  
Subject: Old Porter Brewed using Salvaged Yeast

In response to someone's not so recent interest in this story, I dug around in my dusty archives and found a copy of an article which I clipped out of the Int'l Herald Tribune (Nov. 29, 1991). The story is written by Steven Prokesch of the New York Times Service.

It is about the successful efforts of a microbiologist, Dr. Keith Thomas, to cultivate yeasts taken from two bottles of Porter recovered from a ship that sank in the English Channel in 1825. He is now brewing Porter from this yeast with a Porter recipe from the same era taken from the archives of Whitbread. The significance of this beer is that it is an example of what true Porter was like in the early 19th century and how, over time, yeasts have changed through genetic mutation and brew recipes have changed in response to consumer mutation.

The name of this brew is Flag Porter and Bottle Green. At the time of the article, only about 4000 gallons per year were being produced. Flag Porter and Bottle Green were being wholesaled by Vinceremos Wines Ltd. and most of it was being sold through restaurants, specialty liquor stores, health food shops, and pubs in the UK, though, according to the article, they were hoping to start exporting to the U.S. in 1992.

This is a very interesting story for this forum, and I have not done it justice with the scant details I have included here, but I don't know whether it is legal to transcribe it without permission from the publication or the author. Can anybody advise me on this?

I hope that this info has been useful for the person who was asking about it.

Subject: Aluminum brain death?

Is there anything wrong with using an Aluminum brew pot.

I don't know if this is related, but it seems that everytime I try to make a beer with any spices or special ingredients it turns out horrible. All the simple ale's with only malt, sugar, and hops turn out great, but with the addition of even just cinnamon it turns into icky beer.

Some of the bad spiced brews seem to have the presence of another form of alcohol or solvent, that the non-spiced ones lack. The procedures are the same for both spiced and non-spiced. The only thing that could be different (besides the presence of spices) is maybe I boil longer when I add spices.

Any ideas would be greatly appreciated.  
Am I making Alzheimer brew?

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: re: reusing yeast & open fermenters

Since the yeast reuse thread has popped up again, I thought I'd add my two cents worth. I am most likely in the minority of homebrewers in that I am currently utilizing open fermentation techniques. I ferment in a SS vessal with a heavy lid that in no way could be construed as a closed system. One of the great advantages of open fermentation is the ability to skim a lot of trub junk off the fermenter during the first 8-24 hours of fermentation. The resulting krausen head can be quite strikingly clean and white. Since I brew mostly ales, my yeast tends to rise to the top of the fermenter around day 4 or 5. I skim this yeast off and since I usually have more yeast available to me than I can ever use, I throw it away, or give it to fellow brewers. Top cropping ale yeast is a more effective and viable technique to reuse yeast than waiting to harvest off the secondary. Yeast allowed to sit in the secondary will invariably be less healthy than fresh top cropped yeast. This is due to autolysis and alcohol effects on the yeast cell.

I have generally been quite pleased with the ease of open fermentation with respect to skimming and harvesting of the yeast. If you are a careful clean brewer, using quality yeast, open fermentation is great.

Subject: EBC -> Lovibond conversion

Sorry if I've lost track of who said what in this thread.. I think it went like this:

Murray writes:

```
>>> I have just found a new supplier for my grain requirements who has
data
>>> sheets on the malt available. Specifically, it mentions a colour
rating
>>> expressed in degrees EBC as opposed to degrees LOVIBOND. What is the
>>> conversion factor between the two units.
```

Al Korz adds:

```
>> I don't have a conversion, but here are some L/EBC pairs from Siebel's
--
>> perhaps you can figure out your own conversion factor:
```

```
>> Lov      EBC
>> 3.21     8
>> 7.83     15
>> 7.87     15
>> 21.65    45
>> 22.5     55
>> 25.7     55
>> 77.5     155
>> 221      500
>> 497.5    1100
>> 557.5    1400
>> 601      1400
```

Jim Dipalma says:

```
> Hmmm, a couple of interesting observations here. First, from looking
> at the pairs Al provided, it would seem that whatever the conversion
> formula is, it's not linear [...] Second, there are three pairs where
> the EBC rating is the same (15, 55 and 1400), yet the equivalent
> Lovibond ratings are different. What gives?
```

Looks to me like the EBC has just been rounded off to the nearest convenient number -- for all intents and purposes, though, 557L and 601L are identical, no?

```
> I would be very interested in an accurate method of converting these
> units. If anyone knows how to convert the two, please jump right in.
```

Take a look at the data on a log-log scale.. the relationship

p

```
Lovibond = M * EBCp with M = 0.5 and p = 0.98
```

works well, even in the range of pale malts. I don't know if this is an "exact" conversion, but it does a good job on the data given.

```
/* In case the notation is confusing.. */
double Lovibond (double EBC)
[
double M = 4.9950570e-01;
double p = 9.8024579e-01;
```

```
return (M * pow(EBC, p));  
    1  
/* */
```

Happy brewing,  
Greg

From: Darryl Richman <darrylri@microsoft.com>  
Subject: re: EBC to Lovibond

Yesterday, James Dipalma expanded on Al Korzonas' observation that the conversion between EBC color units and Lovibond (SRM) is not linear. This is indeed true. Both would like to find some kind of relationship between the two. Unfortunately, there is no real conversion between the two. The problem is that they represent two different ways of measuring color in beer, and they react differently to different coloring agents. The widely quoted conversion of  $2.65 + 1.2$  does work passably for pale beers where there isn't a lot of coloring material. Even if you could work up a curve fit for readings against one set of beers, other beers might not lie on that line because their coloring comes about from different materials.

The problem stems from the fact that the EBC has specified measurements at one light frequency while the ASBC has opted for a different one, with a fudge in it to try to approximate Lovibond. Although two beers might appear to be the same color to our eyes, these differing measurement techniques might come up with strongly different numbers. To use a rough analogy, it's like watching a B&W TV; although red and green are being transmitted, to the observer they are both gray.

From: davep@cirrus.com (David Pike)  
Subject: Lagering in the Fridge

This comment is in response to the lagering question where the beer had been in the fridge for 9 weeks and still 'glugs' slowly....

Refrigerators inject cool/cold air INTO its interior while cooling. This means that the ability of CO2 to be released into the air from the beer will be less than if the beer is outside the fridge (ie. the air pressure inside the fridge is a \*bit\* higher than the outside air pressure.

Now you open the door, and the air pressure drops, but slowly. If you stand and look at your beer, perhaps a minute or two, one or two glugs may appear, so...(to repeat what we already know) the best way to tell if fermentation is done is to take an SG. Get some beer, let it stabilize re. temperature, and perhaps even release some CO2, then take the SG.

This may not be exactly a question for the Digest, but here goes.

This stuff sounds interesting and useful, but it also sounds strange.  
What is the difference in "pure" and "wild" yeast that determines  
whether they will pick up the color?

I mean, at some point they were all wild yeast.

>Noonan determine that it creates more "balled starch"? Just what is  
>"balled starch"? Obviously I don't have the book.....

Noonan's book is the first place I've seen this "add the liquid to the  
dry" procedure recommended regarding brewing, but I believe that most  
food cookbooks recommend adding the liquid to the dry so you can work out  
the clumps. Theoretically, I believe the problem is in that little  
"pockets" of the dry material can become encapsulated (like lumpy  
gravy). This is probably less of an issue with the relatively stiff  
mashes that we use in our infusion mashes, than with the much "watery-  
er"  
mashes that Noonan uses in his decoction mashes.

I don't agree that it is overkill -- I don't think it's that hard to add  
3/4 of your water at first, smush-out (a very good technical term... see  
DeKlerk ;^) the clumps and then add the balance of the water. I feel  
that the biggest problem may not be the loss of extract rather the  
possibility of these clumps un-clumping during the mashout and releasing  
starch into your runnings (say goodbye to any hope of crystal-clear beer)

.

Al.

**Subject: Spraying the grist**

Both Jim and Donald mentioned the spraying of water on the grist as it enters the mash tun. I suspect that this has the additional benefit of reducing grain dust which is explosive.

Yes, both methods (liquor-to-grist and grist-to-liquor) will work, but I, personally am always looking for ways to improve my methods -- I get a great deal of new ideas from the HBD and other digests and this is what keeps my brews constantly improving. Thanks to all!

Al.

> 1084 (Irish) for purposes other than stouts and porters? I feel like  
> trying it in bitter and mild ... perhaps it might make a good alt  
> yeast, too?

I used the "Irish ale yeast" in an ESB--strong, fairly light in color,  
and aggressively hopped--pretty un-stout like. It was really tasty,  
and probably my favorite of all the batches I've brewed (it was  
rated pretty highly by a random sampling of friends too, who  
said things like "your best yet," and "can I have another?").

I can certainly recommend it for bitters--and it seems like it  
would be good for beers calling for some residual sweetness,  
like milds and Scottish ales. Go for it.

OK

From: mark@verdix.com (Mark Lundquist)  
Subject: Weird beer flavor

I have some extract ale that is ready to go into bottles, but it tastes wrong. I'd like some help in identifying what the wrong flavor is, and how to eliminate it!

The best way I can describe it is: have you ever tasted malt extract syrup right out of the can? There's a molasses-like malty sweetness up front, followed on by an unpleasant aftertaste (at least, I find it to be unpleasant). Well, the weird flavor component in this batch of ale is very much like that aftertaste in malt syrup.

Here's the specifics:

Two cans (8 lbs) Alexander's Pale malt extract syrup  
13 AAU (1 oz.) Chinook hops (boil)  
1 oz. Cascade hops (finish)  
W. #1098 (British), recultured from dregs of a  
homebrew (1st generation)

O.G. 1.058  
F.G. 1.017

Does this taste description ring any bells? Is it something that will go away with time? (Please don't bother with "Well you're using all this malt extract, so of course your beer is going to taste like malt extract, why don't you switch to all-grain, blah blah blah". I'm sure I'll switch to all-grain someday soon, OK? But I have never had this problem with an extract batch before, and I want to find out if anyone has had any specific experiences with it).

Thanks for any help,

> yeast; after 3 batches the beer is too dry for my tastes. Whitbread  
> ale yeast, otoh, had been reported to be able to be re-used many times  
> (20+ ?) without much change in character.  
>

This datapoint on WYeast 1056 is very appropriate for me right now. I've been repitching the same yeast for several batches and used some stored 1056 to ferment out the extract beer I made in my Beginning Homebrew class. When I measured the specific gravity the other night, the hydrometer dropped right through like it was in water -- and the beer doesn't taste too good. :- (Don't worry, I've got plenty of other good stuff in kegs so I won't die of thirst.) I was surprised by this, as the yeast strain I used to use regularly never performed this way; Russ' observation answers my concern.

On 'tother hand, Ballantine Brewery supposedly used this yeast strain over and over, repitching hundreds of times without any problems. So I'm still scratching my head over this one.

One thing the yeast was very good for was the barleywine I brewed on the 10th. As I mentioned previously, I ran the wort in on top of a deliberately created yeast pack (after racking out a "starter" ale); the specific gravity dropped from 1.095 to 1.030 in 15 days, which is pretty damn good. So, by the way, is the barleywine.

James Dipalma asks:

> Subject: RE: EBC to Lovibond  
>

> units. If anyone knows how to convert the two, please jump right in.  
>

I can only reiterate what I was told by the lab folk at Great Western Malting: There is NO conversion formula, and I've told this to Fred, too. According to the lab folk, who should know, the only way to get an accurate Lovibond figure is to test the sample on equipment calibrated in Lovibond. A few years back they ran some tests for me on British

malts and the figures didn't come out anywhere near where they would have using Fred's calculations. Fred's calculations, by the way, as much as I love the man, are not always, um, completely reliable.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: keeping properties of yeast slurry

There have been a few replies to my earlier questions regarding reusing the slurry from the secondary fermenter. Comments like "it should keep for a few days" or "a week or two" appeared as did something to the effect of leaving it longer would result in autolysis, which is bad.

Given that several people have indicated that they leave their brew in the secondary for months sometimes, why don't they suffer from autolysis also?  
What's the difference between leaving it in the secondary for months and leaving it in a separate bottle for months? In particular I was thinking of filling a beer bottle with the slurry, capping it (because fermentation is finished) and putting it in the refrigerator. Then all I'd have to do is warm this up to wort temperature and pitch, then wait for the fireworks.

Does this sound viable?

Peter

From: MEHTA01@SWMED.EDU

Subject: Alternative yeast re-use method

i sp  
spoke to a fffriend here at UTSouthwestern Medical Centre where  
we are students about culturing yeast, as she is doing her Ph.D. on yeast  
genetics and is always culturing all kinds of yeast (nasty mutated ones  
though).

i had previously done the re-use slurry trick successfully and told  
her about it, asking her why it can be re-used only a few times...  
One main reason, she said, is that alcohol kills yeast or at least causes  
severe damage to the poor beasties. Thus, resuing the yeasties that have  
been  
exposed to alcohol for a long time (in the secondary) is not a good idea.  
The ones that are left are the ones that are more tolerant of alcohol  
(hence  
the fact that the Sierra Nevada culturer noticed severe attenuation after  
3  
life-times... in theprevious HBD # 1066 Jan 29).

So, the solution is to take off some yeast during the aerobic  
fermentation period and store them in a cold (0 to 5 C) fridge in  
whatever  
kind of wort they are in. They should stay well for quite a long time  
(settling  
into their cyst mode due to thte cold) and every time you make a starter,  
you can just store a little bit before you pitch, for next time.

i would recommend carryinmg out the std sanitary procs with these  
yeast viz. flaming the mout of the containers, and all other things that  
touch  
the yeasties...

Good luck. If you have any more qs, pls email me, i have a real informed  
source  
who can help me answer these qs.... :-) (for the price of a good HB, she  
says)!

Ciao

Subject: World's Worst Brewer

Sorry, Jack, this isn't a flame :)

I have a friend, who shall remain nameless to protect the guilty, who claims to be the World's Worst Brewer. I think it might be amusing to outline his process:

He is, of course, an extract brewer. He doesn't have a big enough pot to boil the whole brew, so he squirts the extract into his carboy with some of the water. Some of the rest of the water goes into his kettle with the hops, which are boiled for an hour or so. This water is then dumped into the carboy, bringing the level up to something less than full. The (dry, of course) yeast is pitched and a lock fitted. When the krausen falls, he tops up the carboy with more water, thus avoiding the need for a blow off tube and such. When fermentation is finished, he syphons the beer into plastic soda bottles primed with sucrose. The result is not too bad.

One side effect of this process is that there is no coagulation and precipitation of protein, so the brew never clears. He has two solutions to this: The first is to brew mainly dark beers so he can't tell. The second is to refer to the stuff as "high protein sports drink." I don't think the brewing supplies shop keeper likes him hanging around talking to the other customers.

He claims his next project is to use only a small amount of dark extract for color and to make up the rest of the fermentables with table sugar.

and the  
wild yeast remain white... I like these type of eyeball sort of tests.

Me too but this one sounds like a wet dream.

> Maybe some microbio type out there could post the availability and cost  
of  
the media for those interested.

Maybe some microbio type could tell us how it works.

.....

One more pass at dough-in. Two batches back I doughed-in a batch before  
going to bed and mashed in the morning just to see if it made any  
difference.

I thought it might improve the conversion by solubilizing the starch  
better

but did not know what effect it might have on the taste.

The conversion was at the high end of typical for me (31 pts/gal/lb) but  
it  
might be more helpful on poorly crushed malt than on properly crushed.

It is now in the keg and I have been drinking it for about a week and  
completely forgot about the experiment till this dough-in thread jogged  
my

memory. I can't find the slightest clue that the taste was affected and  
I

passed around a liter at a recent CBS meeting and at the last report, no  
one  
has died from it.

Subject: Keg problems

Hello,

I have made the leap into kegging but I can't get the thing to work properly.  
Every time I try to pour a beer there is nothing but foam. I have tried some of the ideas mentioned last week in the digest and none work.

I have chilled the beer before taping, tried a long [6ft] and short [10in] liquid out hose, bleeding off the excess pressure in the keg before pouring, let it sit for a week after force carbonating.

What I have noticed is that the beer is not losing CO2 in the liquid out hose, it remains a liquid until it gets to the cobra tap and all I get is foam coming out of the tap.

I have a few ideas what the problem is but I could use some input from the ever knowing HBD crowd. I think I might be over carbonating the beer or the beer comes out too fast and foams up when it hits the glass.....any suggestions at fixing these things or other insights to what the problem may be.

Thanks for the help

From: "M. Mitchell Smith" <mms7r@ascus.micr.virginia.edu>  
Subject: W L Nutrient Medium

In HBD #1066 Bob Jones asked about WL Nutrient Agar. Here's what I could find:

"Wallerstein Laboratory Nutrient Medium" was devised by Green and Gray, Wallerstein Lab. Comm., 13:357, 1950. I couldn't find it as pre-poured plates, but you can get the powder ready to mix and autoclave from suppliers of Difco microbiology products; it is Difco catalog number 0424-01-7 and lists for \$43.00 per pound in my Curtin Matheson Scientific, Inc. catalog. From the recipe below, I'm guessing 1 pound would make about 5.5 liters of medium. That should keep you in green for awhile :-).

Here's the recipe from "Products for the Microbiological Laboratory", Baltimore Biological Laboratory, Inc. (BBL). [The book lists it as BBL product no. 01-388 but I couldn't find it in the BBL section of current suppliers.]

Formula in Grams per Liter of Distilled Water

```
-----  
Yeast Extract      4.0  
Trypticase        5.0  
Dextrose          50.0  
Monopotassium Phosphate  0.55  
Potassium Chloride  0.425  
Calcium Chloride   0.125  
Magnesium Sulfate  0.125  
Ferric Chloride    0.0025  
Manganese Sulfate  0.0025  
Brom Cresol Green  0.022  
Agar              20.0
```

Preparation

```
-----  
"Suspend 80 grams of the dehydrated material in a liter of distilled water.  
Mix thoroughly. Heat with frequent agitation and boil for about 1 minute.  
If a final pH of 6.5 is desired, the pH may be adjusted with one per cent aqueous sodium carbonate, using about 30 ml. per liter of water. ...  
Dispense and sterilize the medium by autoclaving at 121C. (15 lbs. steam pressure) for 15 minutes. Avoid overheating and unnecessary remelting."
```

Use

```
-----  
"W L Nutrient Medium is recommended for examination of worts, beers, liquid yeast and other materials. At a pH of 5.5, reliable counts of variable brewer's yeast cells may be obtained. With the pH adjusted to about 6.5, the medium becomes suitable for obtaining counts on baker's and distiller's yeast."
```

The same medium can be used for counting contaminating bacteria with the addition of cyclohexamide at 0.004 grams per liter to inhibit the growth of yeast. This then makes it "W L Differential Medium".

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: WL nutrient agar update

A few additional details on the WL nutrient agar. As I understand the media it changes color primarily do to Ph reactions. Yeasts turn green and other things turn pink or white. The term "wild yeast" in my last post, wasn't the best possible description. What one would do is plate out an unknown yeast source from say a bottle of beer. Then by eyeballing the growth shapes and colors one can easily identify the different types of yeasts. Then each different type is picked up and built up and used to ferment a test batch of beer or wine. The desirable ones are saved and re-used. I have a paper from a talk given about 10 years ago by a person from The Winelab. As I recall this media was used to isolate and culture all their yeast strains.

I hope this short explanation better describes the way I think this media is supposed to be used. And JS your are welcome for the "Wet Dream".

>  
>1. Has brewing chemistry advanced since then, proving this guy  
> and my library of 1950-70 homebrewing books wrong?

Don't confuse the MASH with the BOIL. In all-grain brewing, you MASH,  
LAUTER, BOIL, CHILL, FERMENT and PACKAGE. In extract brewing, you simply  
BOIL, CHILL, FERMENT, and PACKAGE.

Our knowledge of brewing chemistry may have advanced, but the physics  
involved and therefore the chemistry is still the same. If Mr. Beadle  
and  
your 1950-1970 homebrewing books are saying that you should not boil your  
wort, then indeed they are wrong. The passage Chris has quoted and which  
I have included here, on the other hand is referring to mashing. If you  
begin from malt extract, where the producer of the extract has already  
done  
the mashing and lautering for you, so you start the process from the boil  
onwards. It appears that Mr. Beadle is perhaps confusing infusion  
mashing  
with decoction mashing or is mis-reading "every other book on home-  
brewing."

I suggest that any beginner first read Charlie's book, "The New Complete  
Joy  
of Homebrewing." This book is all you really need to begin brewing. If  
you  
want to continue your studies, I recommend then reading Miller's "The  
Complete  
Handbook of Homebrewing" followed by Noonan's "Brewing Lager Beer,"  
followed

by George's "Principles of Brewing Science." The reason I recommend the books in this order is because Charlie's tone and language de-mystifies brewing and concentrates on stressing how easy brewing really is. I feel that the other books dive into complicated procedures and science much too early for a beginner -- they could really scare a beginner away from starting.

Once you've read the four books I mention above, you can then go back and read older books and see if you can't find little bits of useful information hidden among all the stuff you already know. Saturday night I was reading Foster's "Porter" and ran across something I had yet to read in any other book (alas, I can't remember what it was, but it's stored away in my brain somewhere and I'm sure it will come to me in the right situation).

Good observation. I have recycled slurry from my primary that was  
sitting  
for over 7 months in the refer at 50f (my delivery box). Of course it  
needed  
to be rejuvenated: I added fresh wort, shaken vigorously, let settle for  
a  
day, poured off the liquid into some more fresh wort and waited until it  
took off. Easily 99% of the slurry was dead, but there were a few live  
ones  
in there that took off.

My experience is that within two weeks the slurry can be directly pitched  
into  
the fermenter and a violent start will be observed, followed by complete  
fermentation in an unbelievably short time. Good tasting beer follows.  
Longer  
than that and you need to restart the yeast by adding fresh wort, let it  
start  
to ferment and separate out the live yeast (as described above) and build  
it  
up again.

The reason yeast might survive eons in a secondary or keg or bottle is  
that  
there is lots of wort (beer) on top of it with residual sugars that the  
yeast  
can slowly work on. With reclaimed slurry, usually it is topped with  
plain water (in my case) so there is nothing but their neighbors to feed  
on.

Assuming your pressure is correct for the temperature you're using, I  
have  
two suggestions: 1. Are you opening your faucet all the way? Note  
that if you only open it part-way, the constriction will cause foaming,  
so  
\*always\* open the faucet full blast. 2. Could your faucet be dirty or  
have something stuck in it? Take it apart and soak it in bleach for a  
few  
hours then rinse, reassemble, rinse, rinse and rinse again. Even though  
my faucets are stored inside my beer fridge, when I don't pour from a  
particular keg for a week or so (I can have four on-line at one time)  
sometimes  
a glob of mold forms inside the faucet (YUK!).

>procedures are the same for both spiced and non-spiced. The only  
>thing that could be different (besides the presence of spices) is  
>maybe I boil longer when I add spices.

I have had good success with spices added to the fermenter, \*not\* during  
the  
boil, for a Christmas Ale I made last November. I put all the spices  
(cinnamon,  
clove, ginger, orange zest, and nutmeg) into about 2 quarts of water,  
boiled  
them long enough to feel confident that they were sterile, cooled to room  
temp.  
I added them to secondary, then racked wort on top, from the primary. If  
you  
use one step fermentation, I would add after pitching yeast. Beer came out  
very  
good, a bit ginger heavy, but was drinkable after two weeks (orange was  
strong,  
after about 4 weeks ginger was the winner), it is wonderful now,  
if only, I had more of it :( It was real popular with the Christmas  
Guests...

Hope this helps.

>Am I making Alzheimer brew?  
how would you know, who made this beer anyway? :)

Subject: Mixing beers

OK, I would like to hear peoples views on mixing beers. I used to really  
be  
rather stiff shirted about this whole affair. I figured that if the  
brewer  
made a beer certain way, then by damn it shouldn't be messed with! I have  
become a little more relaxed about these things in the recent past, and  
as  
a result have had rather good mixes. How about Sierra Nevada Celebration  
ale  
with a floater of Anchor Old Foghorn? Yum, yum. Their both great beers,  
but  
the two mixed create a third beer that is as great and different. I  
realize  
that there are a few of you that live in "the beer waste land" and this  
discussion could drive you mad. I have found some interesting mixes on my  
home draft system. I usually go through and squirt alittle beer from each  
tap into a common glass to keep the taps from sticking (this IS mandatory  
work you know). I of course drink this mix of beers, and some interesting  
combo's have come up. I remember the Vienna lager and the Scotch ale mix,  
sort of a Robust Porter. Have I gone off the deep end, or am I finally  
relaxing? One thing is for sure, when you mix about five draft beers  
while  
lubing those taps, the mix sure don't lack complexity!

From: Phil DiFalco <pdifalco@fnma.COM>  
Subject: Brewing Sake

From: Japan Times, January 29, 1993 --

"Brewing fuzzy for sake's sake,  
Computer helps make up for dwindling makers' ranks"

FUKUSHIMA (Kyodo) A computer system for controlling the fermentation of malted rice, the most important process in brewing sake, has been developed by a technical center here.

Fukushima Prefectural Aizu Wakamatsu Technical Support Center spent four years working on the system, which it claims will help the industry, hit by a shortage of skilled brew masters.

A local sake brewer is now experimenting with the system to assess its feasibility for commercial use.

In brewing sake, malted rice, or "moromi," is fermented in a tank to turn starch into alcohol.

The trick is making the precise temperature adjustments during the process. This has been difficult to automate.

The center developed the technology to automatically measure the specific gravity of moromi and its alcohol content during fermentation.

The technology permits a temperature gradient to be maintained between the surface and bottom.

The center talked to many chief brewers about temperature adjustments and computerized the data collected.

The outcome has been a fuzzy-control system for adjusting temperature.

The art of brewing takes years of experience to master. A fully qualified brew master needs to spend more than 10 years in the business.

But many chief brewers are farmers who work in breweries in their spare time.

According to the Central Association of Sake Brewers Cooperatives, the average age of chief sake brewers across the country rose by about 10 years to 60 over the past 14 years.

The aging of the brewers and lack of successors have cast a pall over the future of the industry.

Tadashi Sato, chief of the Fukushima Prefectural Aizu Wakamatsu Technical Support Center's brewing department, hoped the new fermentation control system will alleviate the problems.

Subject: Homebrew Digest #1066 (January 29, 1993)  
I've been reading various techniques and opinions for re-pitching yeast ( trub ? ) from a previous batch to start a new one. While common sense tells me that pitching the contents of the 2ndary is better than the gunk typically found in the primary. One evening a couple weeks back I was getting ready to make a yeast starter by consuming a few SNPA's and just coincidentally killed a 3-gallon cornbellius keg of some very tasty pale ale. It occurred to me that a potentially very stable source of yeast would be the residue at the bottom of this keg, since I prime the beer before racking into the keg. I made up the starter as usual, dumped it into the keg, and pumped it back into my 500 ml flask. By morning, the contents had fully fermented. I haven't tried the resulting beer yet. The flash fermentation of the starter resulted in it going dormant but I did have active fermentation in my beer within 18 hours. I plan next time to simply hold the pressurized dregs and draw off some wort during the boil, add it to the keg, shake the s--- out of it and pump that directly into my wort. My only question is: would the cold temps which this ale yeast endures while in my refrigerator cause any off flavors, etc in a finished beer ? BTW. I've found that 1 bottle of good home brew, or 3 of fresh SNPA makes a great starter.

From: dwatson@as.arizona.edu (Dan Watson)  
Subject: BUGS!

Yo Y'all,

Not long ago, I got geared up to make a batch of I.P.A. Rummaging around in my shelves I found a tupperware bin of about two lbs of pale ale malt which I promptly added to the grain bill. This stuff had been sitting for a couple of months. Humming a happy tune, I milled all of the grain together into a big clear plastic bag (keeps the dust down), and proceeded with the preparations. With everything ready and HB in hand, I grabbed the bag and found it teeming with thousands and thousands of tiny black bugs!! Talk about a terrible sinking feeling! Horrified and discusted, I threw the whole ten lbs out to the chickens (who thought this was QUITE the treat), and went and begged some grain from a friend (thanks Ken!) and the day was saved.

These guys look like beetles and on close inspection there were tiny holes in the husks of the grains. Has anyone else had experience with these monsters? How can one avoid them? I was thinking about storing the grain under CO2 in kegs, maybe these things can't grow without O. Any tips would be appreciated.  
Thanks, Dan

> to find something for under \$50.  
>  
> Any ideas?

I have just gone through the process of acquiring the bits and pieces for an all setup and have found some particularly good sources for large brewpots (ie larger than 10 gallons).

1) Try your local software manufacture for secondhand kegs. Places like Coca Cola not only have the 5 gallon Cornellius Kegs that brewers use for their draft beer systems but they also have 10 gallon Stainless Steel Kegs.

These 10 gallon kegs allready have handles welded onto them so all you need

to do is cut a hole in the top of it to convert it into a pot. In Adelaide the

10 gallon SS kegs sell for \$45 secondhand.

2) Phone you local beer manufacturer and go through the same process with them.

If you can purchase secondhand kegs from them you will not only need to cut a hole in the top of it or cut it through the middle but you will also need to put some handles on it.

3) Try a few scrap yards. In Adelaide, one of the local scrap yards bought all of

the secondhand 18 gallon kegs from the Coopers Brewery for \$18 and was reselling them to the public for \$40. Quite a markup, but, still reasonably cheap for a brewpot if you can do the metal work yourself.

4) In Australia, the dairy industry used to use 10 gallon SS drums for transporting the milk. This has now changed and their are a lot of old drums to be had from local dairy farmers. As far as price goes it depends on the farmer you talk to and the condition of the keg laying around his farm. From my experience prices go from free to \$50.

Hope this helps. I chose to buy the 10 gallon kegs from Coca Cola.

Cheers ,

Murray .

From: rogers%scsd.dnet@gte.com (JOHN - GTE - (617) 466-3681)  
Subject: recirculating runoff

I have been easing myself into all grain brewing. I have done a few batches with varying amount of grains. I have found that keeping the temp. constant during mashing is easier than I expected but that lautering is more of a pain than I expected.

My question: just how important (\*really\*) is re-circulating the runoff? I am using a grain bag with a very fine mesh, and it seems to catch everything of real substance. Also note I am not concerned with extracting every molecule of fermentable from the grain. I would be happy to get 25-27 points per pound, and add an extra pound or so of grain to reach the specified OG.

Thanks for any advice!!

From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
Subject: Mixing beers

Mixing beers has a long history in England, where the Black and Tan, Light and Dark, or 'arf 'n 'arf are all quite common in pubs. One of my fond memories involves drinking with friends from MIT at the Muddy Charles, a graduate student hangout on campus. At that time, they only had Bud on tap :-), but they did have Guinness in bottles. Being cheap, but not quite cheap enough to drink Bud straight, I'd buy a bottle of Guinness, and use half a Guinness per pitcher of Bud to give the stuff some flavor. It worked pretty well - it made the Bud into something you could fool yourself into believing was beer....

A floater of barleywinne on a good pale ale... Hmmm....

The best way I have found to achieve sweet cider is to artificially carbonate with kegging equipment after using potassium sorbate to kill off the yeast. After the yeast are dead you can sweeten to taste. I know of no yeast with low enough attenuation to achieve sweetness anywhere near something like Woodpecker (I have not had Woodchuck).

May I suggest you subscribe to the Cider Digest. Requests should be sent to "cider-request@expo.lcs.mit.edu".

From: bickham@msc2.msc.cornell.edu (Scott Bickham)  
Subject: Update in solvents in homebrew

Last week, I posted (indirectly) some worries about solvent-like flavors and aromas in my latest brew - a Strong Belgian Ale. It was a mash/extract recipe, with about 45 gravity points coming from the mash and another 35 from a kit that was given to me. The wort was pitched onto the Belgian Ale yeast slurry left behind when I bottled a wit.

When I bottled the strong ale, there was a terrible flavor similar to turpentine. But now, after only one week later, this seems to have vanished, leaving behind lots of banana esters and some spicy phenolics. The finish was slightly bitter, but that should mellow with age and blend with the esters to create a nice complex balance. I did notice the solvent-like aroma when I was washing the bottle, so whatever the culprit was (maybe the yeast?), it seems to have settled out of the beer's way.

From: gdmcconn@mspe5.bll.ingr.com (Guy McConnell)  
Subject: Irish Red Ale

As a result of my post on using Wyeast #1084 Irish Ale yeast in an Irish Red Ale, I received several requests for the recipe. Here 'tis:

Dana's Smilin' Irish Eyes Red Ale  
5 Gallons

6 pounds Alexander's Pale Malt Extract Syrup  
1 pound Orange Blossom Honey  
1 pound ( 4 cups ) Belgian Special B ( 200 L )  
3 ounces Cascade Hop Pellets  
1 tsp Irish Moss  
1 pack Wyeast #1084 Irish Ale

Place cracked grains in 2 quarts cold water and bring temperature up to 170 degrees. Steep for 15 minutes and sparge into brewpot. Add malt extract and 1 oz. hops and boil for 45 minutes. Add Irish moss, 1 oz. hops, and honey & boil for 15 more minutes. Remove from heat & add remaining 1 oz. hops. Cool quickly, add to 3 gallons cold water in primary fermenter, and pitch yeast. Rack to secondary after vigorous fermentation subsides. Bottle when fermentation completes.

I bottled this one with gyle I saved before pitching the yeast, my preferred priming method now. I did it as a quick and easy way of making a decent Irish Red Ale and it turned out quite well. An all-grain version could be done with 2-row malt (I'd use the Belgian), a little carapils, and the special B. Maybe a little toasted victory malt would also add a nice "toasty" character. The two best commercial examples of this (non?)style IMHO are Boulevard Brewing Co. (of Kansas City MO.) "Irish Ale" and Birmingham Brewing Co. "Red Mountain Red Ale". I know the guy who started the Birmingham Brewing Co. and he gave me the details of his recipe. It has 2-row pale malt, Carapils, and Belgian Special B with "18-20" IBU of hops (he didn't tell me what type but I believe Cascades are used) and Irish Ale yeast. After trying either of these, you will realize just how pale a reflection Killian's is of this all but forgotten style. Another victim of the American Mass Brewing monster.

I was also asked for my blackberry ale recipe which used #1084 yeast:

Cat's Claw Blackberry Ale  
5 Gallons

6 pounds Alexander's Pale extract syrup  
1 pound Orange Blossom Honey

1 pound ( 4 cups )Crystal Malt, 10L  
1/4 pound ( 1 cup ) Victory Malt  
1 ounce Cascade Pellets ( bittering - 60 mins )  
1/2 ounce Cascade Pellets ( finishing )  
1 pint WYeast #1084 Irish Ale Yeast ( recultured )  
8 pounds Blackberries  
2/3 cupOrange Blossom Honey ( for priming )

Place crushed grain in cold water and steep for 45 minutes at 155 degrees. Sparge into brewpot and bring to a boil. Add extract and bittering hops and boil for 50 minutes. During the boil, mash berries through a strainer to extract the juice. Add honey and boil for 10 more minutes, skimming off any scum that forms. Remove from heat and pour blackberry juice into the hot wort. Stir well and allow to steep for 15 minutes. Cool and pour into primary containing 3 gallons cold (previously boiled) water. Pitch yeast and aerate well. Rack to secondary when vigorous fermentation subsides. When fermentation completes, make a "hop tea" with the finishing hops. Cool, add to bottling bucket along with honey priming solution, and bottle.

This brew turned out quite well too with a nice blackberry nose complimented by a floral note from the Cascade hop tea added at bottling. Enjoy!

>this malt extract, so of course your beer is going to taste like malt  
>extract, why don't you switch to all-grain, blah blah blah". I'm sure  
>I'll switch to all-grain someday soon, OK?

Later, McHarry sez:

>

>Subject: World's Worst Brewer

>...

>He is, of course, an extract brewer.

Well, I know McHarry couldn't have planned that, but ouch! Talk about rubbing salt into an obvious wound.

I posted about how much fun the CBS "First Thursday" meeting was last month (I wish I could be in Chicago tomorrow.... >plug< 7:30 at Goose Island). The first people I talked to were a couple who brewed a nice pale ale, and very good holiday ale and stout. And they were so apologetic about it being extract brew!

The homebrewing community is generally guilty of snobbishness when it comes to extract vs. grain. It is assumed that all extract brewers will eventually "grow up" and go all-grain. (When I was younger, it was assumed that pot leads to harder drugs....) I'm sure many do, but there's no reason they need do, and grain brewers shouldn't try to make them feel small.

That said, Mark may not like my advice. Based on many extract brews, I think the problem is not extract, but too much extract. Somewhere around 1050, I've found that the "extract tang" (Dave Line's words) becomes evident. With ~6.5 pound (3kg.) you can make VERY\_GOOD beer like OG 1045-1048, FG 1010-1012. "Ordinary strength" beer. Of course, one reason for homebrewing is to try out stronger styles. If you want to do that with extract, consider:

- partial mashes

- a pound of adjunct (brown sugar for a darker ale, brewer's corn syrup for a lighter one)
- dark malt both to boost the OG a little and to mask other flavors
- overhop :-)
- long bottle aging

Alternate versions of Mark's ale:

- replace 1.5 lb. Alexander's with a 2 lb. partial mash -- this can be done with equipment already available in most kitchens.
- Replace 2 lb. Alexander's with 1 lb crystal and 1 lb. brown sugar (darker, Bass-like ale).
- Less popular with "Enemies of BudMilLob" would be to replace 1.5 lb Alexander's with a brewer's grade corn syrup. Unlike corn sugar, these syrups have a sugar spectrum similar to wort and won't change the OG-FG balance. Of course the beer will be 80-20 malt-corn, but (heresy coming!) I'm not sure that's so bad when the amount of malt present was already sufficient to make good beer. And, your non-beer-snob friends may find it a kinder, gentler untrouction to high gravity brew.

Finally, and more practically for the present batch, Mark. Just let it age for a while in the bottle. You've used good yeast, so it won't go dry and over-carbonated. The stuff is gonna be great on Paddy's Day...just don't put any green food coloring in it!

Cheers,

Rob (bradley@adx.adelphi.edu)

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: pH electrode, copper pot, rye

In hbd 1066 Michael Gildner complained that the only suitable pot he could find was a 13 gallon copper one for \$80. I drooled. Wher could I find one? I have the cheapo option - an 8gallon enameled canning pot I bought at a local housewares store called Waccamaw, but I believe they can be specially ordered at Ace hardware. Its cheaper <\$30, but I am fed up of the poor heat transfer of steel, which I would also have with stainless, so more information like manufacturers names for big copper pots would be appreciated.

I bought a chcheap pH electrode/meter from Cole-Palmer for \$30. It is called the Champ and has a resolution of .1 and an accuracy of .5 (mine reads .1 high). I am satisfied. If anyone is interested Cole-Palmer's number is 1-800-323-4340 and the "Champ pH Tester" catalog number is G-05941-10. Usual disclaimers.

Carlo Fusco wanted Rye Malt. It used to be available from the Malt Shop in Cascade Wisconsin. I don't have the phone number, but you could try 800-555-1212 for it, or email me tomorrow.

Subject: NDMAs (the last little bit)

In HOMEBREW Digest #1066, Fri 29 January 1993, a few folks kept on flogging the nitrosamine horse:

>From: lencell@unmc.edu (Lance Encell)  
>Subject: nitrosamines in beer  
>  
>Just to add a little to the talk about nitrosamines, they are found in beer  
>and wine, but as has been noted, they are found at very low levels.  
>  
>They are formed under acidic conditions in our stomachs by the nitrosation  
>of ingested secondary amines by nitrite...  
>It has been shown that vitamin C prevents nitrosation by competing with the  
>amines for the nitrite. So everyone drink their O.J. so you get your C's.  
>  
>Finally, nitrosamines require metabolic activation to exert their toxic  
>and carcinogenic effects.

Thanks for a little research on the metabolisation of NDMAs. Since I drink OJ the way caffeine-heads drink coffee - I drink it by the liter - I'm not going to worry about the NDMA levels in any of my beer, either store-bought or home-made.

>From: arf@ddsw1.mcs.com (Jack Schmidling)  
>Subject: Nitrosamines, Dough-in  
>  
> >From: gjfix@utamam (George J Fix)  
>  
> >For the record, the highest NDMA level reported was in Bamberg Rauchbier.  
> It contained 5-15 parts per billion, and not 5 ppm as reported in HBD.  
>  
> Just testing to see if you read my articles as carefully as  
> I read yours :)

Cute, but disingenuous. Given the orders of magnitude between ppm and ppb, this is important. The point is, there are plenty of sources of health risks, carcinogenic especially, that are far nastier than the few ppb's of NDMA found in, say, the California & Alaska Street Brewery's Rauchbier. These days, you stand a bigger risk from the second-hand smoke of a typical cigarette-filled pub than from any beer you'll drink.

> > This also was the level reported in their malt. The NDMA levels of beer is  
> typically 9-10 times lower than in the malt used.

specialty beer-and-wine-retailers here. Adelscott was sold in smallish  
(25  
cl) clear-glass bottles, and mentioned the smoked-whisky malt on the  
label.  
The smoky flavour was quite subtle, and over-chilling it masked it  
completely; it was also paler in colour than the Bamberger-style  
Rauchbier.  
The closest Bamberg beer to it in flavour is the lightly smoky  
Greifenklau  
Rauchbier, with just a hint of smoke in the background. Adelscott's not  
hard to find in France and Belgium, and I've seen it in the Netherlands  
also.

As a homebrewing-related aside, the company that imports the only German  
Rauchbier (Kaiserdom) available here (Seattle / Pacific Northwest) is  
Merchant du Vin, of Seattle. The founder of MdV is also involved with  
the  
Pike Place Brewery and the Libery Malt Supply homebrewer's shop. As a  
result, Liberty Malt has Bamberger Rauch malt available, imported from  
the same company that makes Kaiserdom.

Two Seattle brewpubs have also made Rauchbiers, both top-fermented. Big  
Time Alehouse's Rauchbier was smooth, but had a curiously "slippery"  
mouth-  
feel. West Seattle's brewpub is up-front in flavour, but also has a very  
hoppy astringency to it; they serve it mixed half-and-half with a more  
conventional bitter ale, unless you ask for it "straight".

From: rxh6@po.CWRU.Edu (Randall Holt)  
Subject: Grain Weevels

D. Watson tells a sad tale of finding weevily grain and asks for advice.

My father used to store large amounts of wheat and oats in 50-gallon drums (as part of a two year food supply in preparation for the coming nuclear holocaust, a byproduct of the Cuban missile thing).

Anyway, weevils were a problem back then, because irradiated food didn't exist. His solution was to fill up the grain barrel, then toss in a large brick of dry ice, put the lid on loosely, then seal the barrel with wax to keep airtight after the CO<sub>2</sub> had sublimated. Result - bug free after 10 years.

I guess this technique could be modified to store barley using CO<sub>2</sub>(g).

A word of warning, once you find weevils in your pantry, you will never get rid of them, short of completely replacing all dry goods, and then fumigating.

Sounds like you have grain beetles. These nasty suckers will eat anything: flour, spices, sugar, dried pasta, malted barley 8~)  
Your best bet for eliminating this infection is to clean EVERYTHING. If you have a second nest of these beetles anywhere near your stored grain, they'll return. To prevent entry of these beetles, you need very tight closing containers. Ordinary jars apparently don't work too well; my girlfriend had to throw away most of her spices after the beetles got to then through the threads of the lids of the screw-top jars. Clean everything; you may want to consult with an exterminator. Empty every cabinet; examine everything they could possibly eat. Don't assume that an item is uninfested just because it's closed or unopened.  
Good luck.... Terminate with extreme prejudice.

Subject: Re: Bad Luck With Spices

I don't know if your trouble with spices has anything to do with an aluminum brewpot, I do know however that spices can quickly overwhelm the other flavors in your wort. It's REAL easy to go overboard, thinking such small quantities will have no effect. They do! ginger root is especially strong, I've found.

Typical quantities I use in making an excellent spiced ale are: 1/2 teaspoon (tsp.) powdered nutmeg, 1.5 tsp. powdered cinnamon, 1/2 tsp. powdered clove (all 8 minutes from end of boil), 1 tsp. liquid vanilla (5 minutes from end). Add to this 1 lb. honey, 6 lbs. light extract, a pound or two of pale-to-crystal grains, hops of your choice, and barring infection I promise you a winner. This recipe has been called "the best homebrew I've ever tasted" by anyone who's tasted it. If you get the same reaction, just give credit where due! :-)

From: russo@carlos.sps.mot.com (Russell L. Oertel)  
Subject: brewpots

I noticed a couple of people mentioning that they need brewpots big enough for all-grain brewing, and particularly one person who was concerned about cost. My solution to this problem is to have two smaller brewpots.

When I started brewing with extracts, I used a 3.5 gallon SS pot which cost about \$15. I figured the easiest thing to do would be to buy another identical pot, so that's what I did. 3-3.5 gallons is about all my electric stove will boil on one burner, anyway, and it's easier to move around ~25 lbs. of wort than ~50 lbs. if your setup requires moving pots around.

Subject: H-BAIRD MALTS

Howdy HBDers

1) Is anyone out there (George Fix?) familiar with the Hugh Baird malts? I would like to know what beer they are generally used in and its characteristics such as points per pound of extract (theoretical maximum).

2) How does one go about converting Theoretical Maximum Extract (ie 82% TME for Klages malt, for example) to points per pound of extract, excluding the brewhouse efficiency factor?

If this has already been discussed in the past, maybe someone could point me in the right direction.

Thanks for the help,

Mark Simpson, The Harmonica Brew-Cat

From: atl@kpc.com  
Subject: Drew's Brew Wheat Beer

I've gotten a number of complements on my extract wheat beer, and a request for the recipe, so I thought I'd post it here.

2, 4 lb cans Alexanders 60% wheat 40% barley unhopped extract  
1 lb 80L crystal malt, crushed  
2 oz 5.3 alpha Styrian Golding hop plugs  
2 oz 6.1 alpha Cascade whole hops  
Wyeast #3056 Bavarian Weissen yeast

3 days before brewing, pop the Wyeast package.  
2 days before brewing, pitch Wyeast package contents into a starter made from 2 cups water, 1 cup light dry malt extract, and 1 Tettnanger pellet. I use this type of starter on all my batches and pitch \*after\* high krausen.

BrewDay:

- 1) "Teabag" the Crystal malt, and add to 3 gallons cold water.
- 2) Bring almost to a boil and remove the "teabag".
- 3) Add malt extract and bring to a boil.
- 4) Add Styrian Goldings hops and boil for one hour.
- 5) Add Cascade hops, return to boil and remove from heat.
- 6) Steep 15 minutes.
- 7) Chill with immersion chiller to 80F.
- 8) pour into clean fermenter and top up to 5.5 gallons total volume with cold water.
- 9) shake up starter, pitch and vigorously stir wort.
- 10) Ferment ~3 days at ~68F.
- 11) Rack to secondary.
- 12) bottle when clear (~1 week) with 1.25 cups light dry malt extract.

This is about the simplest recipe I've ever made, and it tastes great. Clean and refreshing, and a little on the light bodied side. I might lower the lovibond rating of the crystal malt to get a color that more matches the flavor. I'll be attempting to recreate this with all grain this weekend :-)

From: acarvin@casbah.acns.nwu.edu (Andy Carvin)  
Subject: A marvelous accident

Not too long ago I brewed a five-gallon batch of beer that somehow turned into something it should never have been in the first place. Lemme explain:

In November I brewed a basic batch of John Bull Wheat Beer. Nothing really exciting -- three cups of sugar, one ounce of hallertau hops. Then, I decided to add one pound of oats, just to see what would happen. When the time came for bottling, I realized I forgot to sparge the oats, and they had swollen so much I was stuck with a gallon of beer, yeast, and wort that was unseparable.

I didn't want to throw this stuff away, so I immediately brewed five gallons of Telfords Nut Brown Ale, added 2 cups of sugar, 3 cups honey, 2 ounces cascade hops, and a quarter cup of maple syrup. Now, I honestly did not think this would amount to much, and my fears worsened when I noticed that most of the wheat beer bottles were infected. Praying for the best, I bottled the nutbrown monstrosity anyway.

Well, two weeks ago we cracked a few open, and amazingly enough, it tastes almost exactly like Chimay Premiere, except with 8% alcohol. Just to confirm my surprise, I brought samples to fellow brewers and beer afficianados, and they also said the same thing -- Chimay.

Does anyone out there have any clue what I did right to make such a great beer?

Feel free to email me directly, or post on the net. Thanks a bunch.

From: dduane@kestrel.win.net (Diane Duane)  
Subject: "Irish Red Ale"...

It may amuse (or horrify) some of you to know that at present, there are almost NO red ales sold in Ireland. Killian's, which I've seen while visiting in the US, is not sold here. Just about the only ale brewed in Ireland at the moment, to the best of my knowledge anyway, is Hilden Ale, brewed by Hilden up in the North. And it doesn't get down into the south - -- whether because of import problems, or no one here knows it exists, I'm not sure.

The most popular beers here are, by and large, Irish brewed ones: Guinness has a stranglehold on the market (and likes it that way, so that foreign beers, especially the German ones, are coming into the country only very slowly. My husband danced and sang for about a week when he was able to get some weissbier in, just before Christmas.). American beers are oozing in...heaven help us. Miller Draft is sold in bottles: so are Pabst (some places) and Schlitz. There is better news, though: Budweiser is brewed here under license by Guinness, and "Uncle Arthur's" version is two and a half times stronger than the US article. Astonishingly, it actually tastes like something.... Otherwise, the most common brews found here would be (for stouts) Guinness, Murphy's, and Beamish: for lagers, Harp, and some German ones like Kronenbourg, Carlsberg, and Louwenbrau.

PS: the weird beer called "Guinness Gold" is not sold here. They wouldn't dare. (grin)

#### WL NUTRIENT AND DIFFERENTIAL MEDIA

##### INTENDED USE

Bacto WL Nutrient Broth and Bacto WL Nutrient Medium are recommended for the cultivation of yeasts, molds and bacteria encountered in brewing and industrial fermentation processes.

Bacto WL Differential Medium, also used in the microbiological control processes in the fermentation industry, permits the unrestricted growth of bacteria and inhibits development of yeasts and molds.

##### HISTORY/PRINCIPLES

Bacto WL Nutrient media are prepared according to the formulae described by Green and Gray. In their study of various fermentation processes, Green and Gray pointed out the inadequacy of the microscopic count in fermentation control procedures. An exhaustive study of the method of examination of worts, beers, and liquid yeast and similar fermentation products led to the development of two media; one containing no selective agent and the other, a differential medium containing the antibiotic Actidione (cycloheximide) as a selective agent.

Bacto WL Nutrient media permit the development of yeast. In those instances in which the number of yeast cells is comparatively small, certain bacteria can be detected. Green and Gray reported that counts of viable bakers' yeast may be made on the WL nutrient medium at pH 5.5. If the reaction is adjusted to pH 6.5, the count of bakers' and distillers' yeast may be made. In making microbial counts using these media, the temperature and time of incubation will vary depending on the various materials under investigation. Temperatures of 25C are generally employed with brewing materials and 30C for bakers' yeast and alcohol fermentation mash analyses. Incubating periods run from 2 to 7 days, depending on the flora encountered. Incubation periods of 10 to 14 days may be used in some cases.

Bacto WL Differential Medium has the same formula as Bacto WL Nutrient Medium, with the addition of 0.004 g of Actidione per liter. This inhibits the development of yeasts without interfering with the development of bacteria generally encountered in beers.

A reliable count of bacteria can be obtained at pH 5.5. To obtain estimations of beer cocci and lactic rods, plates should be incubated under anaerobic conditions. For estimation of acetic acid rods and termobacteria (very small rods occurring in wort as described by Linder in about 1900 as *Termobacterium lutescens*, *iridescens* and *erythrumum*) incubate under aerobic conditions. To analyze bakers' yeast and alcohol fermentation mash, the reaction is adjusted to pH 6.5. Plates containing dilutions of bakers' yeast are incubated aerobically, while those from alcoholic fermentation mash are incubated anaerobically.

FORMULAE

BACTO WL NUTRIENT BROTH  
DEHYDRATED

Ingredients per liter

|                             |          |
|-----------------------------|----------|
| Bacto Yeast Extract .....   | 4 g      |
| Calcium Chloride .....      | 0.125 g  |
| Bacto Casitone .....        | 5 g      |
| Magnesium Sulfate .....     | 0.125 g  |

| Manganese Sulfate .....     | 0.0025 g |
| Potassium Chloride .....    | 0.425 g  |
| Bacto Brom Cresol Green ..  | 0.022 g  |

Final pH 5.5 + 0.2 at 25C.

One pound will make 7.5 liters of final medium.  
Rehydrate with 60 grams/liter.

BACTO WL NUTRIENT MEDIUM  
DEHYDRATED

Ingredients per liter

|                             |          |
|-----------------------------|----------|
| Bacto Yeast Extract .....   | 4 g      |
| Magnesium Sulfate .....     | 0.125 g  |
| Bacto Casitone .....        | 5 g      |
| Ferric Chloride .....       | 0.0025 g |
| Bacto Dextrose .....        | 50 g     |
| Manganese Sulfate .....     | 0.0025 g |
| Monopotassium Phosphate ... | 0.55 g   |
| Bacto Agar .....            | 20 g     |
| Potassium Chloride .....    | 0.425 g  |
| Bacto Brom Cresol Green ..  | 0.022 g  |
| Calcium Chloride .....      | 0.125 g  |

Final pH 5.5 + 0.2 at 25C.

One pound will make 5.6 liters of final medium.  
Rehydrate with 80 grams/liter.

BACTO WL DIFFERENTIAL MEDIUM  
DEHYDRATED

Ingredients per liter

|                           |         |
|---------------------------|---------|
| Bacto Yeast Extract ..... | 4 g     |
| Magnesium sulfate .....   | 0.125 g |
| Bacto Casitone .....      | 5 g     |

Ferric Chloride ..... 0.0025 g  
 Bacto Dextrose ..... 50 g  
 Manganese Sulfate ..... 0.0025 g  
 Monopotassium Phosphate ... 0.55 g  
 Bacto Agar ..... 20 g  
 Potassium Chloride ..... 0.425 g  
 Bacto Brom Cresol Green ..... 0.022 g  
 Calcium Chloride ..... 0.125 g  
 Actidione (cycloheximide) .. 0.004 g

One pound will make 5.6 liters of final medium.  
 Rehydrate with 80 grams/liter.

METHOD OF PREPARATION

1. To rehydrate suspend appropriate amount in 1 liter cold distilled water and heat to boiling to dissolve completely.
2. Sterilize in the autoclave for 15 minutes at 15 Lbs pressure (121C).
3. To obtain a final reaction of pH 6.5 add the amount specified on the product label of a 1% solution of sodium carbonate per liter distilled water used for rehydration; dissolve and sterilize as indicated above.

Subject: Re: all-grain snobs

Sorry if I offended extract brewers with my reference to my friend, the World's Worst Brewer, as, of course, an extract brewer. He is mainly trying to produce beer by the simplest possible means.

We are all extract brewers. Some of use make our own extract. Whether that is worth the bother (it more than doubles brewing time) is a matter of what you are trying to brew and how much effort you want to put into it. Some of my better beers have been extract brews. It seems to me that one can make a lighter colored beer from all-grain, and a lighter bodied one as well, if the mash temperature is right. One can also play with adjuncts such as rice or rye with interesting results. Whether that is worth shooting a whole Saturday, I am not sure.

The World's Worst Brewer is satisfied with what he produces and the time he puts in on it. As I said, the stuff is actually quite drinkable, in fact I may drown my sorrows in a liter plastic pop bottle of the stuff this evening--I need the protein!

Date: Wed, 3 Feb 93 08:00:50 PST  
From: greg@bandit.Berkeley.EDU (Greg Jesus Wolodkin)  
Subject: Culturing lager yeast

Greetings!

In getting ready to brew my first lager, last week I attempted to culture the yeast from a commercial brew. I've cultured SNPA (Wyeast 1056) several times without any problems, so I figured it'd be easy..

I re-read the "Yeast" chapter in Miller, and then headed down to Liquor Barn and picked up 3 pints of Paulaner Hefe-weizen. My technique was as follows:

- 1) 1.020 SG starter wort, just off the boil, cover and cool in a sink full of ice water to 80F.
- 2) Sanitize a one gallon glass jug and funnel (20 minutes with chlorine solution, then rinse).
- 3) Take a butane lighter to the exposed rim of the pot, then transfer 1/2 gallon of starter wort into the jug and fit with (sanitized) airlock.
- 4) Open a bottle of hefe-weizen, flame the mouth, decant beer into pitcher, sending the last 1/2" of dregs into starter. Repeat until beers are gone and pitcher is full ;-)
- 5) Place the starter jug at room temperature (70F) covered with a t-shirt to keep out the light.
- 6) Drink the hefe-weizen and don't worry!

Well a typical culture (at least in my experience) would be bubbling merrily within 48 hours, with visible signs of activity within 24. This one has been \*much\* slower. At four days there was \*nothing\*. At five days a very small ring of bubbles on the surface. Now at six days, it has reached kraeusen stage.

I can think of a few possible mistakes -- first the beer was chilled (it was unavailable warm at the store), and I guess that would slow things down. Second I discovered that Miller actually recommends Spaten, not Paulaner, as a stable, reculturable lager yeast. (Oops..)

Whatever I have in my starter is a bottom-fermenter. It even smells good, so after it finishes I plan to taste the result and give it another feeding. If it seems OK at that point, I will most likely brew with it. I wanted to ask those of you who culture yeast on a regular basis:

- 1) Is six days such a long lag that I should expect a wild yeast, rather than the yeast I was attempting to culture?
- 2) What behaviour can I expect from the Paulaner hefe-weizen yeast, assuming that's what I've got? Anybody ever use it?
- 3) Should I eventually move the starter to fermentation temps (~50F) or should I leave it at 75F until pitching (since I will most likely pitch at 75F)?

As always, thanks in advance for any suggestions/comments.

Greg Wolodkin

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Re: BUGS!

I would think that canning jar lids, screwed down tightly, would keep the bugs out. After all, they can hold a vacuum seal for years, even without the screw band holding the lid down. Of course, there is one major difference: the vacuum seal is formed at high enough temperatures to deform the "rubber" on the lid to exactly conform to the rim of the jar.

I get bugs every summer, and consider it a good excuse to throw out the old stuff in the cupboard. If it's more than a year old, I'm not sure I want to eat it anyway. I've got too many uncontrolled insect sources entering the house to keep them all away. (Birdseed is the worst, even after freezing it at 0F for a few weeks before using it.)

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Lager...

Disadvantage is that you almost are required to add new yeast to get reliable carbonation when you bottle. Also, you tie up a carboy for a long time.

Advantages: you can put off bottling. A carboy takes less space than two cases of beer(?). Purportedly, you get better flavor characteristics. I've only done one (sort of) test on this -- a friend and I split 10 gallons of wort (Vienna lager), pitched the same yeast (2308, from the same starter), fermented at the same temperature (in our respective fridges) for the same length of time. He clarified with Polyclar, bottled, and lagered in the bottles. I lagered in carboy, didn't clarify, then bottled. Both were good (an understatement!), mine had a more malty flavor, but that may have been because he used polyclar and I didn't.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: BUGS!

Rereading your post, it appears to me that the bugs (or, rather, their eggs) came in the grain (a not unlikely occurrence). The tightest container in the world won't prevent these suckers from growing. The CO2 idea sounds good, as I don't think they can grow without oxygen.

I've had this problem with birdseed, and sometimes with flour(!) back in the days when I bought 25lbs at a time. Freezing them for a month in my chest freezer (or even storing them there) seems to kill most of the eggs.

From: Chris McDermott <mcdermott@draper.com>  
Subject: FAQ/RFC on Recirculation.

FAQ/RFC on Recirculation.

Since many topics come up in cyclical manner it would be nice if they could be answered in a FAQ format. And since some topics have more than one accepted answer the FAQs should try to show all sides of an issue.

So to get the ball rolling here is an example:

FAQ #0000-000:

[Note that 0000 indicates the number of the FAQ and -000 indicates its version.

The version mechanism allows mistakes and inaccuracies to be corrected and newer information to be included in newer versions of the FAQ.]

\*\*\*\*

FAQ #0001-01: Recirculation: What is it, and should I do it?

Recirculation is a practice employed in the lautering of mashed grains where the turbid sweet wort is collected, as it is runoff, and recirculated through the grain bed until the runoff becomes clear.

Most sources of homebrewing information will tell you that you should employ the practice of recirculation to avoid significant amounts of chaff in the boil. Chaff in the boil is considered by these sources to lead undesirable effects in the finished beer including astringency and cloudiness. (Ref. Miller, Papazian)

However, others believe that some amount of chaff in the boil is desirable in that it helps to coagulate large protein molecules producing a better hot-break and thus a clearer finished product. Furthermore, some think that the hot side aeration (HSA), or oxidation, of the sweet wort during recirculation outweighs any benefit that may be gained by clearing the wort. (Ref. Fix)

\*\*\*\*

Please consider this FAQ as a kind of HbD Request For Comment (RFC). Please feel free to make any additions or corrections.

>numbers in the table by 5/X.

Well thanks, now that I just wasted 35 oz of hops in my latest barleywine :-)

AA units = oz hops \* %AA and HBU = AA units / gal. wort (right?)

so that was really a AAU to IBU table, or do I have them backwards?  
I also noticed that the rows for 55 and 60 minute boiling times  
were identical. Was this a typo?

Nonetheless, the table is among the things that I saved from the HBD  
for future reference and is greatly appreciated.

From: bliss@csrd.uiuc.edu (Brian Bliss)  
Subject: fresh hops

The freshest hops I have found are hops plugs from GW Kent. They come vacuum packed in gold foil, in packs of 10 - 1/2 oz plugs. At around 8\$ per pack (\$1.60/oz) they are about twice as expensive as normal leaves or pellets, but they are so fresh that you will probably have to reduce your hopping rate by about 30% over "regular" leaf hops. They can survive a 60 minute boil without scrubbing out all their aromatics (which isn't always what you want).

From: pointon@m2c.org (Joel Pointon@staff)  
Subject: How Long Is Too Long

Greetings fellow brewers. Being a fairly new convert to HB, I have a question that I realize most of you WON'T be able to relate to. Although I enjoy my HB, I'm not a big drinker, so subsequently I have a stockpile building up of my brewing efforts. The beer cellar presently contains the following extract brewed product: Porter, (3 months), Pilsner (2 months) and English Bitter (1 month old). The cellar is approximately 55 degrees F at this time of year and will increase to about 65 by the beginning of summer. How long can one expect to keep each of these before the flavor falls off? I know, I know - "drink it or loose it", but seriously if I had to focus on which would decline first I would guess Pilsner, Porter and Bitter in that order.

As long as I've tempted your wrath already - I'm heading to San Diego 2/13 - 21 for a sailing course and \*\*\*\*\* brew pubs, etc.\*\*\*\*\*.  
(Please send replies on this portion via email.) Thanks.

Date: Wed, 3 Feb 93 16:15 MTS  
From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: A survey of the readership

Are you an all grain brewer or an extract brewer?

Lately, there have been quite a few highly technical discussions about mash techniques, kegging setups, and hopping rates, to name a few. This has been a real boon for most of us, whether advanced or beginners. Advanced brewers get an opportunity to discuss, with others at their level, the challenges that they're facing in their home breweries. Beginners can read these discussions and learn. Everyone wins.

With one exception. Beginner brewers, or even intermediate brewers, are likely being intimidated by the high level of this discussion. How many posts in the last few weeks have started with "I'm only a lowly extract brewer. . ." or "Sorry for taking up bandwidth with such a simple question..."? And, I wonder how many questions have not even been asked because the author is afraid of being labelled "not a REAL brewer" by more advanced brewers. (Remember that discussion a while back about real brewers?) I believe that Rob Bradley was referring to this in HBD #1069, when he wrote about all-grain snobs. I'll bet that the progress of many beginners is being slowed by this thought. I hate to think that people are being intimidated from asking questions, because the HBD has helped me so much in the three or so years that I've been reading it. (There used to be lots more "lower level" discussions.)

I think it would be interesting to take a poll to see how many readers are extract brewers, or all-grain brewers. I suspect that the readership consists of more beginners than are represented by the questions posed in the HBD. And I think that, if beginners realized that they make up a substantial part of the HBD community, they would be more likely to pose "lower level" questions, and therefore, improve their comprehension and brewing.

Therefore, I invite everyone reading this post to send me a brief note indicating your level of expertise. Please use the keywords:

All Grain if you rarely use extract for your brewing, other than for yeast culturing,

Intermediate if you do some mashing, partial mashing, some yeast culturing, etc., but you don't consider yourself very experienced, or

Extract if you are relatively new to the brewing process, haven't

tried mashing, or in general, consider yourself to be on the steepest part of the learning curve.

I know that this classification is too simple, but it should prove to be informative, nonetheless. (It should also give some kind of a count of the number of readers, as well as swamping my mail utility.) In about a week, I'll post the results.

Cheers,  
Chuck coronellrjds@che.utah.edu

P.S. Sorry if this gets posted twice, we're experieingnce nicaltech ultiesdiffic iwth our ermail.

From: Richard Cox <rcox@hsc.usc.edu>  
Subject: Dry Malt Extract vs. Syrup Malt Extract

One of my homebrew suppliers strongly maintains that dry malt extract provides better flavor and less extract "tang" than the syrup variety. He has encouraged me to use all DME in my recipes whenever possible.

I'm too new to homebrewing to have an objective opinion on this, although my last batch -- using all DME -- does taste \*much\* better than my first, which was made with syrup extract. There may have been other factors at work in that case, though. I have wondered whether or not the syrup cans impart any detectable metal taste to the extract.

Does anyone have any advice?

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Beadle, Open Fermenting, arf n snobs

>From: korz@iepubj.att.com

Chris writes:

>>Mr. Beadle ("Brew it Yourself\*"), and at least two other British  
>>1960s-type books abhor boiling:

>> "Do not bring the water to a boil.... This single bit of  
misinformation from those who should know better has caused many  
beginners to  
become unnecessarily discouraged in their attempts at brewing."

>Don't confuse the MASH with the BOIL. In all-grain brewing, you MASH,  
LAUTER, BOIL, CHILL, FERMENT and PACKAGE. In extract brewing, you  
simply  
BOIL, CHILL, FERMENT, and PACKAGE.

I also have this book in my library and HIS statement far better fits my  
definition of the "single bit of misinformation" that caused me no end  
of  
confusion. That page was dog eared in my book and the paragraph  
underlined.

I assure you the he was referring to extract beer as there is not a  
single  
reference to whole grains in the entire book.

Several times he describes the process of mixing extract with water  
between  
151 and 155 F and maintaining it there for the duration.

Another example of his misinformation is on page 53, also underscored  
and  
burnt into my early data base on brewing.

"If you look into the fermenter, you will see a rich foamy head bubbling  
on  
top. This head is composed mainly of resins from the hops, which are  
forced  
up ty the carbon dioxide bubbles. Some books advocate skimming off the  
head  
but this should never be done because it contains all the oils and  
resins  
that will give the beer its body, aroma and characteristic beer taste.  
"

Certainly, there is a legitimate debate on the importance of skimming  
the  
foam but no one but Beagle argues the merits of leaving it there.

I also note on reviewing the book again for this posting that there is  
no  
mention anywhere of hops. His recipes simply call for light or dark  
extract  
as though hops did not exist.

The book also has no index so it is difficult to find anything but I  
think it

is safe to say that it is one of the worst of the generally lousy books on homebrewing available in the 60's and 70's.

It is not hard to understand why homebrewing is now rapidly expanding as a hobby and why it stagnated before. I have no problem admitting that I never really made a good batch of beer till I spent several months digesting the Digest and much of the other information currently available. It's truly is a New World Order for home brewing.

>From: Jim Busch <busch@daacdev1.stx.com>  
>Subject: re: reusing yeast & open fermenters

>I am most likely in the minority of homebrewers in that I am currently utilizing open fermentation techniques.

You're in good company. The only thing you need to do to complete your joy is to add a spigot on the bottom so you can take QC samples on a regular basis to determine how it is progressing before sending it to the secondary.

I find that for some strange reason, the primary fermentation seems to take much longer this way and I always seem to come up about a half a gallon short:)

I am sure you have also figured out how simple it is to sterilize with a bit of water boiling in the bottom.

I also suspect that you, like the rest of the enlightened ones, simply yawn at all the discussions about "blow-off" tubes and related mess.

>From: korz@iepubj.att.com  
>Subject: Spraying the grist

>Both Jim and Donald mentioned the spraying of water on the grist as it enters the mash tun. I suspect that this has the additional benefit of reducing grain dust which is explosive.

I suspect that it might have a negative effect if Fix's hypothesis on HSA is correct. What say George?

>From: Tom Dimock <RGG@CORNELLC.cit.cornell.edu>  
>Subject: Mixing beers

>Mixing beers has a long history in England, where the Black and Tan, Light and Dark, or 'arf 'n 'arf are all quite common in pubs. One of my fond memories involves drinking with friends from MIT at the Muddy Charles, a graduate student hangout on campus. At that time, they only had Bud on tap :-( , but they did have Guinness in bottles. Being cheap, but not quite cheap enough to drink Bud straight, I'd buy a bottle of Guinness, and use half a Guinness per pitcher of Bud to give the stuff some flavor. It worked pretty well - it made the Bud into something you could fool yourself into believing was beer....

This is amazing. I was going to point this out in response to the original question but I could not resist noting that ARF was drinking arf 'n arf long before he gained world wide acclaim as the World's Greatest Brewer. I did this when I was stationed in Bermuda in the 60's. Guinness and Bud was the poor man's real beer.

> >For the record, the highest NDMA level reported was in Bamberg Rauchbier.

> It contained 5-15 parts per billion, and not 5 ppm as reported in HBD.

>

> Just testing to see if you read my articles as carefully as

> I read yours :)

<Cute, but disingenuous. Given the orders of magnitude between ppm and ppb, this is important.

Just cute. George and I discussed the orders of magnitude issue in email and it was a private joke in public. When researching the subject, I got that sort of ambiguity from the maltsters themselves. Not one of them could tell me for sure whether it was ppm or ppb so I asked George.

>The best reason to use the Belgian malts is 'cause you like 'em - sorry if that seems a bit simple-minded, but I'm not planning on being part of this world forever...

It is not only simple minded but puts everything else you say in the same perspective. Part of being cultured and civilized is controlling our likes to conform with not only our own well being but the needs and interests of others. I may very well like the taste of smoked Scheidt on a bagle with cream cheese, but I am not simple minded enough to assume that justifies eating it.

From: dbreiden@dsuvax.dsu.edu

**Subject: All-grain snobs**

Wasn't it Rob B. who had some remarks about all-grain snobs? Well said, Rob! I recently made the switch to all-grain -- I will admit that I was always a bit apologetic about being an extract brewer.

My friends (hi guys) had all gone all-grain long before I did, but I wouldn't call them all-grain snobs. While I do agree with Rob about keeping down the snobbishness, I also believe that all brewers should seriously consider doing the all-grain bit. I was always encouraged to take the plunge, and I'm oh so happy I did. The beer isn't orders of magnitude better (yet), but the magic of the mash is just TOO cool!

The best situation is for extract brewers to be able to dabble in all grain without purchasing the equipment (which may or may not cost a fortune). I personally believe working with an experienced person is the best way to manage all aspects of brewing though.

Brew-on!

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Irish Ales

Being Irish I was more than a little surprised to read a posting from Ireland saying that there was no ale sold there and began to wonder if I had grown up in and visit a different place. In hbd 1070 Diane Duane never mentioned ales in her list of beers and even said there were none apart from a minor Northern brew. While ale sales have been falling to lager (with stout relatively constant) sales of Smithwicks are still high. MacArdles is also sold nationwide in bottles and can be got on draft in local areas. In Waterford one can even get Phoenix Ale in large bottles produced at the small Cherry' brewery there. All 3 of these are sold by Irish ales, which is a group coowned by Guinness and Grand Met. Bass is also produced in Belfast and is an Irish Ale having slightly different taste than British produced Bass. Unfortunately the virtual monopoly Guinness have on the Irish market, and indeed on malt and hop industries has meant that there are fewer small brewers than elsewhere.

Another point I would question was Diane's statement that Irish Bud was 2.5 times stronger than American stuff. While it does taste a little better (It would be hard not to), it is 4.3% by vol as against US Bud which is 4.6%.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: beginners,extract

As one who has flooded the HBD with "beginner" questions, I have to agree with Chuck C. about the tone lately. I'm now exclusively an all-grain brewer (it's easy, really), but no less than 2 years ago I was an "extract brewer without a clue". So I asked questions, \*lots\* of questions, to the HBD. Some were really clueless; I cringe when I look through some of the HBD archives. But, hey, just \*asking\* the questions forced me to think about what I was doing, and of course the quality and depth of the answers has always been startling. So go ahead and ask "beginner" questions; they often lead to more advanced topics, so everyone wins. For instance.....

It was mentioned that extract brew tastes better if it is made from 100% dry extract. In my e.brewing days, my standard batch was 1 can of syrup with and equal amount of dry extract, which seemed tastier than 2 cans of syrup. Perhaps, as was said, the canned syrup does pick up some of the metallic flavor of the can, and might be (one of) the source(s) of the extract "tang". Those box/bags of syrup from BME always produced a nice (if expensive) brew.....HMMMMM....

Russ G.

BTW, \*HIGHLY RECOMMENDED\* - Read \*all\* the HBD archives. Yes, all. IMHO, the HBD archives are perhaps the richest source of homebrewing info available.

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: re: HB Shelflife, Irish Bud

In HBD1070 Joel Pointon asks about the shelf life of homebrews

>The cellar is approximately 55 degrees F at this time of year and  
>will increase to about 65 by the beginning of summer. How long  
>can one expect to keep each of these before the flavor falls off?

From personal experience, I've had some of my beers about one year after brewing and they were still good, with some being better than when younger. My beers are kept in similar conditions as yours, perhaps even 2 or 3 degrees warmer. Someone told me that HB will keep up to 5 years, but I've only been brewing myself a little over a year and a half. In general, beers with more alcohol, and more hops should keep longer than weaker brews.

The only danger comes from beers with an infection or wild yeast which can cause the beer to overcarbonate and gush upon opening. (This happened to me with an octoberfest last year.) In this case, which will be obvious, I would recommend drinking these fast (if drinkable) or dumping them out before any explosions occur. With my batch the beer was actually not so bad, but the caps were bulging outward and half the beer gushed out when I opened a bottle.

Also, Diane Duane writes

>(some places) and Schlitz. There is better news, though: Budweiser  
>is brewed here under license by Guinness, and "Uncle Arthur's" version  
>is two and a half times stronger than the US article. Astonishingly,  
>it actually tastes like something....

Does stronger mean greater alcohol content? If so since Budweiser is about 4.8% alcohol by volume this would put the Guinness version at about 12%, stronger than most barleywines. Maybe we should try to get the Irish Bud imported back to the US.

-----

Date: 04 Feb 1993 09:07:45 -0600 (MDT)  
From: MARK TARATOOT <SLNDW@CC.USU.EDU>  
Subject: more lager questions

I have two more questions regarding lagering. If I choose to lager my lager in the bottle, should I:

1. Prime, put in warm (room temp) place for a week to carbonate, put in cold place to finish lagering.

or

2. Prime, put in cold place to finish lagering, put in warm (room temp) place to carbonate.  
????

Will the latter give the beer a dicetyl rest after lagering (during carbonation)?

Second Question:

Concernig pitching extra yeast at bottling. What if I just "grab up" some of the yeast sitting on the bottom of my fermenter? What are the chances that these yeasts are mutated and what will that do to the final product? This particular batch is in a tertiary fermenter (racked from secondary to get WAY away from yeast/other stuff that flocculated out) so all the "stuff" should be yeast. This yeast will be mostly dormant, to be sure, but shouldn't it just hop back to life if more fermentables are added?

Any comments?

thanks!

-toot

Date: Thu, 4 Feb 93 10:20:21 CST  
From: tony@spss.com (Tony Babinec)  
Subject: chimay yeast/recipe idea

I had success culturing up Chimay yeast by using a large bottle of Chimay Red. If you examine the cork closely, you'll see a date code. In the Chicago area, the currently available bottles are dated 10/92, which means that they're reasonably fresh. Perhaps you have access to this beer wherever you are. I would use Chimay Red rather than Cinq Cent or Grand Reserve because it's the lowest gravity of the three.

You can drink the beer (!) and pitch the dregs from the bottle into some starter wort. The yeast ought to take off relatively quickly, that is, within a couple days. If you get no activity or very slow activity, then discard the starter wort and start over. Once you have an active culture, you can taste and smell it to see whether it's good. At this point, you have a choice. You can either brew a beer and pitch your starter culture, or you can plate out the yeast, isolate a single cell, build it up, and then brew the beer. The advantage of the more labor-intensive approach is that you can isolate the yeast and build it up minus whatever bacteria or other stuff might be in the dregs, provided you're sanitary in your yeast culturing. On the other hand, if you're satisfied from your taste and smell test that the starter culture is good, you can pitch it straight into the beer, albeit at some slight risk.

The Chimay yeast is a very important component of making a Chimay clone. You might try to get your hands on Wyeast Belgian ale yeast, though to me it doesn't taste like Chimay's.

For recipe ideas, Rajotte's book has a recipe called St. Humulus. I don't have the book with me now. Note that Chimay Red has a starting gravity of 1.063, which, while high, is not whopping. What an incredible beer!

Here's a recipe suggestion:

Abbey Beer in the style of Chimay

9 pounds U.S. 2-row  
1.5 pounds Munich malt  
0.5 pounds 60L (or darker) crystal malt  
1-2 ounces of chocolate malt  
1 pound of honey or dark brown sugar

6 - 7 AAUs bittering hops, a mix of hallertauer and kent goldings, added at 60 minutes before end of boil. You are not looking for high hop bitterness, nor should there be noticeable hop aroma.

Chimay yeast, of course

If you're not an all-grain brewer, then don't use the 2-row or munich malt but use, say, 7 pounds light, unhopped dry malt extract instead. Use crystal and chocolate malt for color. The honey or brown sugar will boost the starting gravity as well as contribute to the flavor and body of the finished beer. You might try doing the fermentation at a relatively "warm" temperature, say, 70 to 75 degrees F. This should lead to more of that Chimay flavor in the finished beer. And, don't drink the beer all at once, as its

flavor will evolve in the bottle over time.

Good luck!

From: gdmcconn@mspe5.b11.ingr.com (Guy McConnell)  
Subject: Re: "Irish Red Ale"

Diane Duane writes:

> It may amuse (or horrify) some of you to know that at present, there  
are  
> almost NO red ales sold in Ireland. Killian's, which I've seen while  
> visiting in the US, is not sold here.

Actually, that was part of the point in my posting. That is why I  
used  
the terms "(non?)style" and "all but forgotten style" when describing it.  
My  
history on Killian's is a bit foggy but I seem to recall that they were a  
brewery in Ireland (brewing an Irish Red \*Ale\*) and they experienced  
financial  
difficulty (probably due in part to the preference for stouts and  
[increasingly]  
lagers) in Ireland. A "kind-hearted" American megabrewery decided to  
help them  
out and gobbled them up. They moved production of the Irish Red over  
here and  
de-characterized it almost completely, decided it should be a \*lager\*,  
and  
kept the name. I don't intend this to be regarded as absolute fact as I  
admit  
that my recollection of the details is a bit rusty, but I think the truth  
is  
pretty close to what I remember. Anyone with access to the Real Truth,  
please  
feel free to step in.

This is another case where microbreweries and homebrewers are  
responsible  
for reviving (rescuing?) a beer style, much in the same way as Porter.  
The  
two examples I mentioned are, I'm sure, not the only ones left  
(hopefully!)  
but they are the two I am familiar with and both are microbrewed ales.  
Now,  
I love a pint o' Guinness with a passion and my tastes tend toward the  
darker,  
heavier beers but I occasionally like something a little lighter. A good  
Irish Red Ale fits the bill nicely.

From: billm@scorpio.sps.mot.com (Bill Moyer)  
Subject: idophor, rinse/reuse

I've just recently tried using idophor instead of a bleach solution for sanitizing ( .5oz idophor/gallon water, ~12.5ppm free iodine) and have 2 questions.

- 1) if a rinse is omitted at bottling time, will the brew condition properly, or will the yeast be affected? I'm assuming no air drying of the bottles.
- 2) how long will the solution remain stable, and what indication (if any exists) can be used to guage the remaining sanitization potential of the solution?

thanks,

Bill Moyer

Subject: RE: lager questions, recirculation

Hi All,

In HBD #1070, Greg Wolodkin writes:

<description of culturing yeast from Paulaner Hefe-weizen deleted>

>2) What behaviour can I expect from the Paulaner hefe-weizen  
> yeast, assuming that's what I've got? Anybody ever use it?

My understanding is that Paulaner uses a non-flocculating lager yeast to bottle condition the hefe-weizen, it's not the same yeast used to ferment the beer. I'm fairly certain a top fermenting strain is used for that purpose.

That said, I believe you'd end up with a cloudy beer due to the poor flocculation, and you would likely not get the clove phenolic/banana ester character that's desirable in a German weizen.

Disclaimer: I've never actually cultured this yeast and brewed with it, so the above comments should be taken with whatever quantity of salt seems appropriate :-).

\*\*\*\*\*

Also in HBD #1070, Ron Karwoski asks:

>At what temperature should the wort be when the yeast is pitched  
>and how soon should the whole thing be brought down to lagering  
>temperatures? Do you wait for active signs of fermentation before  
>cooling?

This seems to be a major issue, I see a lot of posts in this forum and r.c.b regarding pitching temperatures for lagers, and long lag times that result from pitching liquid yeast at reduced temperatures.

According to Miller, pitching at temperatures in excess of 50F results in increased diacetyl production. He states that the traditional method is to pitch when the wort is between 40F-48F. While this produces minimal diacetyl, it does cause longer lag times. To counteract this problem, Miller recommends pitching large amounts of yeast, 0.67 to 1.3 ounces of \*slurry\* per gallon. (Source: Miller's Continental Pilsner)

IMHO, the one pint to one quart starters that most of us use simply do not contain enough yeast to initiate lager fermentations quickly. I've been experiencing the problem of long lag times with lagers, and confess to pitching at slightly higher temperatures (~60F) in attempting to reduce lag time. For my last batch, I used a somewhat larger starter than usual, and fermentation did start more quickly. For my next batch (also a Bock), I'm going to grow the yeast in a one gallon starter, let it ferment out in order to get a large sediment of hungry yeast, pour off most of the liquid, and pitch the slurry at 50F. I'll post the results.

>Should the starter be cooled?

The starter should be as close in temperature to the wort as possible, as temperature shock is detrimental to yeast performance. I've pitched

starters into \*slightly warmer\* worts with good results, but I wouldn't recommend pitching a starter that's at 70F into wort at 50F.

\*\*\*\*\*

Also in HBD #1070, Chris McDermott writes:

FAQ #0001-01: Recirculation: What is it, and should I do it?

Recirculation is a practice employed in the lautering of mashed grains where the turbid sweet wort is collected, as it is runoff, and recirculated through the grain bed until the runoff becomes clear.

Most sources of homebrewing information will tell you that you should employ the practice of recirculation to avoid significant amounts of chaff in the boil. Chaff in the boil is considered by these sources to lead undesirable effects in the finished beer including astringency and cloudiness. (Ref. Miller, Papazian)

However, others believe that some amount of chaff in the boil is desirable in that it helps to coagulate large protein molecules producing a better hot-break and thus a clearer finished product. Furthermore, some think that the hot side aeration (HSA), or oxidation, of the sweet wort during recirculation outweighs any benefit that may be gained by clearing the wort. (Ref. Fix)

For what it's worth, I recirculate about 1 - 1.5 gallons. The runoff is still a little cloudy at this point, but it is free of any large chunks of husk or grain material. Coincidentally (or perhaps not so), 1.5 gallons is exactly the volume of "dead space" under the false bottom in my lauter tun.

Not to change the subject, but this brings to mind something I've been wondering about for some time. Exactly how much of a problem is HSA during sparging? The wort will be boiled within an hour, which will drive off the oxygen, so I guess my question could be phrased "how quickly do HSA reactions occur?" Comments, please.

Cheers,  
Jim

Subject: All-grain Snobs

>From: bradley@adx.adelphi.edu (Rob Bradley)  
>Subject: all-grain snobs

>The homebrewing community is generally guilty of snobbishness when it comes to extract vs. grain.

I can't speak for the "community" and you may be right but it is also worth while to put the issue into proper perspective.

Keeping in mind that lots of people stick with extract because they are lazy, paranoid or il-informed and further keeping in mind that the industry, as opposed to the "community" has a vested interest in maintaining the status quo because it would just about dry up without extract sales, it is worth noting that some extract beers are excellent beers, so I am told. One also presumes that lots of extract brewers use extract because they know how to make said excellent beers.

Having said that, I suggest it is the extract brewers' insecurity, sensitivity and paranoia that creates the image that all-grain brewers are snobs.

>Based on many extract brews, I think the problem is not extract, but too much extract. Somewhere around 1050, I've found that the "extract tang" (Dave Line's words) becomes evident.

This is an interesting point and may very well be true and important to those who wish to continue brewing with extracts.

The reality is that once a brewer makes the switch, invests in the equipment and learns the process AND becomes aware of the economies that accrue, he has little incentive to go back and try to make good extract beer.

If looked at objectively and without emotion, I see nothing wrong with the notion that brewing extract beer is a step in the overall experience of brewing beer. That is not to put a value judgement on it or to belittle it but simply to put it in proper perspective. It is by any definition, a shortcut to brewing beer and hence, not the total process.

I have been castigated in the past for comparing it with baking with cake mixes but it is hard not to draw the comparison.

Perhaps a better analogy is instant versus brewed coffee. A batch of coffee is made after which it is concentrated down to a convenient extract, to which hot water is added by the consumer and we get coffee again. Judging by all the TV commercials, ha ha... some of it may actually be good but it is a hell of a way to treat coffee. They same could be said for a nice batch of wort that gets concentrated.

The bottom line is we brew beer the way we do because it suits our needs and personalities and we brag about what we do because we are human. There is just no point in trying to impune evil motives into our hobby.

>  
>-- End of excerpt from Chuck Coronella

I fit into your definition of "Intermediate", I guess, since I use extract and often do partial mashes. However, I've been brewing on and off for about 13 years.

I really consider myself a "beer connoisseur" - my primary reason for brewing is to understand the subtleties of flavor and appearance imparted by variations in the process, and I find HBD a valuable way to supplement this experience. Oneday I'll probably get around to doing a few all-grain brews, but I don't consider the extra effort a necessity in achieving my main aims. As a Englishman, and a member of CAMRA, I find the discussions on HBD of pressurizing beer with CO2 (e.g. in soda kegs) far more disturbing than any distinction between extract and all-grain brewing.

P.S. I've sampled Celis White a couple of times now and been very impressed. Anyone know of anywhere in San Francisco selling it that is more "comfortable" than the Toronado and Midtown (both lower Haight Street)?

P.P.S. Beer snobs can drink all-grain snobs under the table any day! ;^)

Subject: convert cooker to natural gas...

Greetings All,

I have a question about cajun cookers. I have put an addition on the ol' homestead, and moved the laundry room into the addition. I now want to turn the old laundry room into my brewery :-[>

I have a double sink, a floor drain, and the gas line and vent from the dryer. What I want to do is convert my cajun cooker from a propane unit into a natural gas unit. Can I do this?? If so, does anyone know what is involved? How much it might cost?? Where to get parts???

Any help would be very welcome!!!

Thanks,

Subject: homemade wine

I have noted with curiosity that while there is discussion of sidelines to beer brewing that shows up on the digest (cider, mead), there is almost no discussion of homemade wines. I have never read about or experimented with homemade wines, but I have the idea that people just dump concentrate and water in a carboy and add yeast. Is wine making discussed here so seldom because the process is uninterestingly straightforward or because the results are so inferior to commercial wines or both?

From: SynCAcct@slims.attmail.com  
Subject: Leaf Hops?

I've been using leaf hops from a west coast distributor for a while now, satisfied with the results. I purchased some GW Kent Saaz yesterday and mentioned the West Coaster to him and he scorned "sweep-ups!". I asked him to elaborate, he said that the hops purchased from this particular western hop vendor were bale drop offs, swept into a nice pile and sold to us as fresh from the farm hops.

I was skeptical, but was told that I could tell that they were "sweep ups" because they never came in cones, rather they come in loose petals. I rushed home, looked in one bag and would estimate that 95% of the hop volume is loose petals as I was told.

I've picked wild hops here in Ontario and they generally fall apart after kilning, which is what I attribute the "individual hop petal" phenomenon to, but I would be curious if anyone would have the "inside scoop" on leaf hops, whole cones vis-a-vis petals.

Incedently, the GW Kent foil wrapped babies are actually perfectly preserved whole cones, unadulterated and compressed into a plug. Upon re-expansion in the boil pot they look like they just fell off the vine.

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: All-Wheat Beer

I made the following brew on 20 Dec last year. It has turned out to be a \*fine\* beer, and I recommend it to you.

All-Wheat American Pale Ale

To make 3 US gallons:

6# US Malted Wheat  
3oz toasted malted wheat -- in 350F oven until brown/dark tan through  
several pounds spent barley for sparging, boiled and drained.

Crack grains. Add hot (150F) water to make a very stiff mash at 120-125F.

Let rest 1 hr. Add infusion of boiling water, plus direct heat if necessary, to bring to 150-152F. Let rest 30 min. Add spent barley, raise to 158F for 10 min, then to 168F for 10 min.

Sparge to collect 4-1/2 gallons or so of wort at 1.035+.

Add 3/4 or 1 oz 5AAU Cascade hops (the original used 1-1/4 oz, but this is pretty darn hoppy) for 1-1/2 hr boil. Add 1/2 oz Cascade when removing kettle from heat, cover, let sit for a few minutes.

Pitch with cultured SNPA yeast or Wyeast 1056. Volume should be 3-1/2 gallons at about 1.048. Ferment at 65-70F. Rack off primary after a few days. When fermentation has dwindled in secondary, add 2-3 tbsp Polyclar in boiling water.

The finished product was bottled a little over two weeks ago. It is still not fully conditioned, but that will pass. The aroma is unique. It smells like the crust of a freshly-baked loaf of bread. (With notes of hops and the usual Chico yeast bouquet.) The beer is crystal clear, still throws a light to moderate chill haze (less than many weizens), and has a fine, fine American Pale flavor. Even an experienced sipper would have difficulty distinguishing it on the palate from barley beer. There certainly is no "tang" or overt fruitiness to it.

I offer this as food for thought to those who wonder whether American wheat malt has sufficient enzyme activity to convert itself. For the rest of us, it's just good beer ....

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: Re: IBU table

In HBD1070 Brian Bliss first quotes me:

>>In HBD1066 I submitted an HBU-IBU conversion table  
>>but forgot to mention any volume relationships.  
>>That table assumes a 5 gallon batch.  
>>To adjust for a volume of X gallons simply multiply the  
>>numbers in the table by 5/X.

and responded

>Well thanks, now that I just wasted 35 oz of hops in  
>my latest barleywine :-)

>AA units = oz hops \* %AA and HBU = AA units / gal. wort (right?)

>so that was really a AAU to IBU table, or do I have them backwards?  
>I also noticed that the rows for 55 and 60 minute boiling times  
>were identical. Was this a typo?

Well, after Brian's note I wasn't sure myself so I looked up  
AAU's and HBU's in Papazian (TCJoHB), Miller (TCHoHB) and  
the Zymurgy Hops special edition V 13 No. 4. I don't have  
Papazian's new edition and his old one mentions alpha units  
but does not mention either HBU or AAU. Miller only defines  
AAU = oz hops \* %AA as Brian stated above.  
I found HBU mentioned twice in the Zymurgy issue. The first mention  
was at the bottom of page 44 on the AHA Guide to Hop-Flavored  
Mald Extract page where they say

"The expression "HBU" refers to homebrew bittering units.  
HBU equals the number of ounces of hops multiplied by the  
percent of alpha acids in the hops."

Also, in Jackie Rager's article he writes

"If I understand what I've read, AAU and HBU are calculated by  
multiplying the weight of hops (in ounces) by their alpha acid".

So I think HBU and AAU are the same thing, at least I assumed they  
were based on my readings. However, I think Brian's definitions  
make more sense - Why define two different terms to mean the  
same thing with neither depending on the volume?

The lines for 55 and 60 minutes of boil are identical because  
according to the utilization table I used (from Rager's article)  
the utilization of 30% for a boiling time between 51 and 60 minutes.  
Actually, my table should have listed boiling times as intervals  
<5 min, 6-10 min, 11-15 min, etc. instead of 5, 10, 15 which I  
listed for simplicity.

I think you've also invented a new beer style-barhopwine.

Bill Szymczak

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Irish Ale, lager pitching, dryer gas stove

Guy McConnell reproduces a blurb from Coor's about Killian's Red. Much of it is true other than the fact that it paints Old Adolphus and family as being something other than Ogres. Ireland has had its own ogre family dominating the brewing industry (now a largely English owned company that also produces whisk(e)y in Scotland) and throughout history has gobbled up all competition it could, blackmailed Pubs to keep Harp taps when they wouldn't have been able to give the piss away, and now that they do replacement lagers under licence (having stolen the Carlberg franchise from Beamish after they spent years building it up) are forcing pubs to retain Smithwick's taps (Smithwick's is an Irish Ale, but a pretty poor one) whose sales are slumping. Blackmail is easy. Guinness do their own distributing and own all their own taps. So they will offer to remove all their taps or none, including the Guinness stout tap. This beer represent about 1/2 of all beer sold in Ireland.

A small brewery called Dempseys who produced an ale set up a few years ago in Dublin and didn't last long. Killians decided to close down in 1955 rather than sell their property including name to the big G. Now they licence their name to Coors and Penforce (sp) in France. The latter is supposed to be good. Hell, they get money for nothing.

James dipalma discusses lager pitching rates. I always pitch much yeast, like the entire primary sediment at 40F. recently I pitched a batch at 40F with my cleaned sediment, racked off all trub including dead yeast, and I guess much of my live yeast and waited 5 days at 48-49 for Krausen. Disconcerting to some, but recently when I tasted the Vienna I was making it is was exceptionally clean and good tasting for a beer in primary. Relax, don't worry, pitch much sediment cold and wait. Remember yeast do much better at cold temperatures than bacteria, and I would much prefer to slowly build up a heawlthy yeast stock than rush things for the sake of less worry.

Todd Williams considers using a cajun cooker indoors. Best of luck! I believe the modification for propane to methane is simply replacing the flow nozzle with a narrower one, but getting the part other than from junk would not be easy because nobody will sell it to you, justifiably so, IMHO, for liability reasons. Also I would not recommend it. Cajun cookers have a 200,000 btu/h output, don't they, which is much too much for indoor use. What I use is the burner from an old water heater I picked up in a junk pile. Just remove the regulator and burner, connect it with the necessary valves and nipples to your dryer output, and get a stand for your pot that will nestle the burner nicely. I use an old table stand. This is then a 25,000 btu/h burner designed for indoor methane use with no problem. It even has a pilot light that will go out if the flame fails. 25,000 btu output is fine. I would boil 7 gallons from cold in about 15 minutes.

Subject: krausen,iodophor,lagers & snobs

From: Jim Busch  
Some comments regarding recent digests:

<From: MARK TARATOOT <SLNDW@CC.USU.EDU>  
<Subject: more lager questions

<Concernig pitching extra yeast at bottling. What if I just "grab up"  
<some of the yeast sitting on the bottom of my fermenter? What are the  
<chances that these yeasts are mutated and what will that do to the  
<final product? This particular batch is in a tertiary fermenter (racked  
<from secondary to get WAY away from yeast/other stuff that flocculated  
out)  
<so all the "stuff" should be yeast. This yeast will be mostly dormant,  
<to be sure, but shouldn't it just hop back to life if more fermentables  
<are added?

While it is true that the dormant cells could be revived, I have to wonder  
the rational in carrying over these cells into the bottling process.  
These  
cells are certainly not as healthy as freshly grown ones. The question  
to  
ask yourself is: are there enough residual cells in the beer to wake up  
after priming? Has the beer been lagered to the point of doubt about the  
viability of the dormant cells? I would recommend the traditional german  
technique of adding krausen beer and/or young yeast slurry. Yeasts at  
this young stage of growth will have higher glycogen levels and will be  
more able to ferment the remaining sugars without worries about  
mutations.  
If there are enough cells already, the yeast will merely die off as soon  
as the fermentables are gone.

<From: billm@scorpio.sps.mot.com (Bill Moyer)  
<Subject: idophor, rinse/reuse

<I've just recently tried using idophor instead of a bleach  
<solution for sanitizing ( .5oz idophor/gallon water, ~12.5ppm  
<free iodine) and have 2 questions.

I believe Bill meant to state 1oz per 10 gallons!!! At this level,  
I never rinse, I just pour off the fluid in whatever I am sanitizing.

That said, I DO rinse when I am kegging. A brief hot water rinse  
of the iodophor prior to kegging does the trick. So far, no problems.  
I believe if the ferment is clean, it is fairly difficult to infect the  
beer at packaging time.

<From: dipalma@banshee.sw.stratus.com (James Dipalma)  
<Subject: RE: lager questions, recirculation

<My understanding is that Paulaner uses a non-flocculating lager yeast  
<to bottle condition the hefe-weizen, it's not the same yeast used to  
<ferment the beer. I'm fairly certain a top fermenting strain is used  
for  
<that purpose.

Yes, it is lager strain in the bottle. But I do believe it is a flocculant one, that is one of the reasons lager yeast is used. If you want a Hefe-weizen poured clear, the lager yeast will tend to cling to the bottom of the bottle. Even if you pour it "correctly" the yeast tends to floc in the bottom of your glass. The top fermenting strain is filtered out prior to addition of the krausen beer.

James goes on to comment on pitching temps of lager yeasts. The important thing to remember is that once fermentation is active, the temperature will rise significantly. Thus, if one pitches at 60F, the yeast could kick in and boost the temp up to 70F! Obviously, one of the tricks is to get it in the fridge at the right time, so the temp is dropping as the yeast temp is pushing it up. You really want to be below 52F during primary fermentation, so it is important to be careful about when you pitch and when you put it in the fridge. Pitch at 55-60F with LOTS of healthy yeast, move it to the fridge and begin lowering the temp. It will take a 10 hours or so for the fridge to cool the wort below 50F, and if you have enough yeast, activity should have commenced.

RE: All grain snobs:

Very excellent beers are produced using extracts. The key is the quality of the extract (I believe dry IS better) and the yeast & hops. That said, while I will not claim to call it "cake mix" I do often refer to extract brewing as "home fermentation". Dont take offense at this, the more you know about brewing, the more you realize that fermentation is the most important part of the process. After a few hundred batches, the quality of the wort is pretty consistent, but the challenge of the fermentation remains :-).

Jim Busch

PS: to JS- My lauter tun/open fermenter does indeed have a spigot. The only problem with taking ferment SG readings is that what comes out is yeast sludge! Thats what you get when you have a bottom grant. Maybe when I have a Unitank made, I will add the side outlet, about a foot up from the cone. Of course, it is quite simple to open the lid and scoop out a sample.

From: neilm@juliet.ll.mit.edu ( Neil Mager )  
Subject: Special Archive Proposal

A few months ago, I started seriously considering taking the step from extract to all-grain brewing. I downloaded the indices of the archives from the last ~15 months to find information about all-grain brewing and cooler mash-tun/lauder-tun construction. After several pleasant evenings sorting through the archives of interest, I ended up with about 70 messages (~200k) of interest.

I'm sure I'm not the only one doing this. If we create a few Special Archives, readers could download the special archive, then ask specific questions later if the needed to. Sort of like a very detailed FAQ. Since the archive contains the reasonably complete thread, the reader would get different opinions and options from which they could draw their own conclusions (and confusion).

This could also help reduce the bandwidth on the daily hbd since we wouldn't have to rehash how to build a cooler mash-tun/lauder tun or how to culture yeast, or how to brew a barley wine (I'm still sorting through that thread - thanks!). And hopefully, these wouldn't overload our current archive site since I don't foresee all that many of these...but I could be wrong!

The Special Archive could be compiled by whomever has been following a particular thread. Consider the Special Archive the HBD version of a Zymurgy special issue.

Thats the proposal...

Neil (Still an extract brewer and proud of it!)

>What I want to do is convert my cajun cooker from a propane  
>unit into a natural gas unit. Can I do this?? If so, does anyone  
>know what is involved? How much it might cost??.....

It couldn't be easier! Just remove the brass cap from the cooker and  
drill  
the orifice to 1/8 for natural gas. Sounds like an great brewery in  
progress. If you are indoors make sure that you are **\*\*extremely\*\*** well  
vented. This will cost some cash. (A bathroom fan/vent **\*won't\*** be  
sufficient  
to provide air exchange and remove all of the steam). A couple of good  
fire  
extinguishers would not be out of the question either.

>connell@vax.cord.edu

>I have the idea that people just dump concentrate and water in a carboy  
>and add yeast. Is wine making discussed here so seldom because the  
>process is uninterestingly straightforward or because the results are  
>so inferior to commercial wines or both?

Ouch. This is a beer forum. I know that there are also cider and mead  
forums,  
and assume that there is one for homevintners. In any case, the process  
that  
you have described is a lot like the instant coffee analogy of Jack. IMHO  
you  
need (good) grapes to make (good) wine.

Subject: Extract brewers are lazy?

WARNING: this is long.

Once I saw this thread reappear, I knew it was only a matter of time before Jack Schmidling would chime in with something like this:

> Subject: All-grain Snobs  
[...]

> I can't speak for the "community" and you may be right but it is also worth while to put the issue into proper perspective.  
>  
> Keeping in mind that lots of people stick with extract because they are lazy, paranoid or il-informed and further keeping in mind that the industry, as opposed to the "community" has a vested interest in maintaining the status quo because it would just about dry up without extract sales, it is worth noting that some extract beers are excellent beers, so I am told. One also presumes that lots of extract brewers use extract because they know how to make said excellent beers.  
>  
> Having said that, I suggest it is the extract brewers' insecurity, sensitivity and paranoia that creates the image that all-grain brewers are snobs.

This 'perspective' smacks exactly of the 'snobishness' that we have seen discussed here on the HBD. Lots of people extract brew because they are lazy, paranoid, or 'il-informed'? That's rich coming from a semi-retired homeowner. Why do I mention this? Because economic status is part of my personal reason for not going all-grain.

Right now I am spending many thousands of dollars going to school nights while I work during the day. Being older than me Jack, and having some savings in the bank (plus whatever revenue you derive from selling tapes of brewing and bats) you may have easily forgotten that some of us cannot immediately afford the startup costs for all-grain.

If, for a minute, we consider extract brewing to be, from one possible perspective, "training wheels" to the art of brewing, then it makes sense that someone start off by extract brewing to learn the art before moving on. But things happen - you buy the equipment and put in the time to brew and, if you are like me, you spend some money here and there to improve your beers and increase your equipment holdings.

Before you know it, you're looking at all-grain wondering when you can afford the cajun cooker and the 7 gallon Vollrath plus all these other goodies that make all-grain fly.

At this point you, Jack, would seem to argue that in the end you'll actually save money from the all-grain process. Sure you might, I respond, but this involves the concept of breaking even first. I cannot economically justify making all the purchases right now when I have tuition, rent, car, and cat food payments to make.

Oh, but am I really just scared, and not wanting to make the plunge? I think not. I spend my brewing time trying to learn more about the process.

I try things that I haven't tried yet - simple things that you have to try at some point like dry-hopping, wort-chilling, making yeast starters, or going for full-gravity boils. I read HBD looking for new techniques, and

I talk with the more experienced brewers asking them what I can do to improve my beers.

Ah, you say, but you aren't really doing anything but avoiding all-grain.

No. In the meantime I am investing piecemeal in the equipment I need to start all-grain. I've got my pot, and I'm saving up to buy my cooker. Then

I will consider all the other goodies.

So far, then, I am neither lazy nor ill-informed. And I think that my curiosity cancels out any notions of being paranoid.

Does this mean then, that you are still right and that I am really just an exception - someone on his way to reaching full enlightenment in the hallowed halls of all-grain brewers? No.

I happen to have a number of friends my age who have decided to take up brewing too. Both of them are now extract brewers. One of them was on his way to going all-grain until he suddenly found himself on academic probation and out of a job. He cut back on his brewing activities for a little while and certainly killed any notions of going all-grain.

The other friend found himself in the middle of layoffs back when DEC decided they would give him the ultimate X-mas gift. For some reason his priorities are not set on going all-grain anytime soon. Both of them still feel, BTW, that they have more to learn and enjoy in extract brewing anyway.

Quite frankly, I've never met anyone who avoids going all-grain because they are lazy, paranoid, or 'il-informed'. Usually they avoid it for the cost, time, and b/c they feel they have more to learn and enjoy from extract brewing. (Note: using time as a factor does not automatically mean you are lazy. Laziness doesn't apply when you have plenty else to do in your life.)

With this rather long diatribe on your premise in mind, lets look at your conclusion:

> Having said that, I suggest it is the extract brewers' insecurity,  
> sensitivity and paranoia that creates the image that all-grain  
brewers are  
> snobs.

Hmmmm. The only time I have ever heard extract brewers complain about all-grain brewers' snobishness is really in this forum, the HBD. I've never won over a scared extract brewer's confidence at a club meeting or at the supply store b/c we held some heavy burden of shame due to the all-grain brewing community's snobishness.

It seems to me that people are really complaining about people like you Jack, who make unfounded general statements like:

>Keeping in mind that lots of people stick with extract because  
>they are lazy, paranoid or il-informed. . .

These statements are so arrogant. You make it sound like a foregone conclusion that this is the truth. You, a middle-aged man living in Chicago who never talks about going to competitions or meeting up with fellow brewers at club meetings yet who seems to have plenty to say on this forum. Where does your experience base come from?

I've explained mine.

Finally (at last) I am not ignoring the rest of your post to HBD. I agree that brewing extract is a part of the "overall experience" but I don't agree with your premise which pretty much says that once you know extract brewing, you should move on to something else.

You see, your approach concludes that since extract brewing is nothing more than a reduced set of steps in a process, you are therefore not a legitimate brewer. This is patently false: would you suggest that C programmers are not "real" programmers and that only Assembly language programmers do "real" programming since Assembly programmers don't need reduced shortcuts like compilers? It makes about as much sense as you do in approaching brewing - fewer steps = illegitimate worker.

I don't hold you to growing your own hops. That's not unreasonable since many here have tried. By your reasoning, you are missing out on a step and cannot be the authentic brewer you keep whining about being.

Your logic is poor; your reasoning arrogant. Give it a rest.

From: davidr@eeecs.ee.pdx.edu  
Subject: Beginner wants to make SMALL batch...

First of all, is there a FAQ available?

Secondly, I am a beginner who has been reading for approx. two weeks now. I've never made homebrew. Hell, I hardly ever even drink beer. However, I AM interested in the process, and do enjoy a nice frosty one now and then. In the past, I have made some hard cidar, and a batch of wine... both with natural yeasts. I used a gallon jug with a piece of aquarium air tubing attached to the top. I ran the other end of the tube into a glass of water, thus establishing an air lock. Anyhow, I would like to try making some brew, but on a much smaller scale than what I've seen. Can anybody suggest \*ANY\* recipe to use for a One-Gallon batch?? (I'd like to use the same fermenting apparatus I just described.) Also, since I am a beginner, I have no idea as to the terminology. I don't know what "secondary", "pitch", etc. means! I understand "yeast" and "fermentation," and that is the limit to my technical brewing dictionary. Eventually, I would like to read some of the books described by others in HBD, but by the time I have more than 30 min. free time, I'll have obtained my MSEE. I'd like something to just get me started without having to read a great deal.

SUGGESTIONS???

Thanks,  
David Robinson

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re: iodophor, rinse/reuse

Bill Moyer asks about iodophor rinse/reuse:

I tried out iodophor for the first time last weekend. How well does it work - who knows? I found that the iodophor I purchased (brand named 'iosan') tended to foam a fair bit when agitated. Hence, bottles that were simply emptied tended to contain a fair bit of foam. I was not prepared to leave this amount of residue unrinsed (while the 12ppm concentration is considered safe when used on dairy equipment without rinsing, I should think the volumes of milk that would dilute the residue would be larger than the volumes of beer going through my brewing equipment). My incentive for using an iodophor was the hope that it could be reused more than bleach (iodine less volatile than chlorine?) and hence less would go down the drain (and into the air I'm breathing!).

It's also cheaper than the brewing sanitizers.

My jug of iosan states that the amber colour of the solution is a self-indicator. The bulk of the solution I mixed up is in a stoppered carboy and is still amber. I put about a pint in a blowoff bucket for a batch of wine. After a few days, the amber colour has disappeared. The iodine has either reacted with the plastic bucket/hose, organic gases expelled from the fermentation (no actual krausen has come down the tube), or simply evaporated (scrubbed by the constant stream of CO2 bubbles?). This would seem to verify the self-indicator feature. The iodophor quickly stained my bottle/carboy brushes and hoses, but has had minimal effect on my buckets. This doesn't worry me though.  
Cheers,  
Rick C.

Subject: Re: FAQ/RFC on Recirculation

RE>FAQ/RFC on Recirculation.  
In an e-mail message, Spencer Thomas says:

>I like the idea. Now someone has to archive them specially?

Now thats a bit of a trick. I suppose that the latest version of each FAQ could be maintained as a seperate file in the archives on sierra. Then all that would have to be done would be to maintain FAQ# vs. subject index.

Might there be some concensus on this? How about other suggestions? Volunteers? Would someone like to write a FAQ on writting FAQs?

Spencer also points out:

>An addition to your FAQ: There is evidence that suggests that >recirculating for a long time can raise extraction rates. (Ref: >Miller/hearsay (via Fix, I think), personal experience, Fix)

So:

\*\*\*\* HOMEBREW Digest FAQ #0001

FAQ# 001-002  
Subj: Recirculation: What is it, and should I do it?

Date: February 4, 1993

Orig: Chris McDermott (mcdermott@draper.com)

**Subject: Re: FAQ/RFC on Recirculation**

Recirculation is a practice employed in the lautering of mashed grains where the turbid sweet wort is collected, as it is runoff, and recirculated through the grain bed until the runoff becomes clear.

Most sources of homebrewing information will tell you that you should employ the practice of recirculation to avoid significant amounts of chaff in the boil. Chaff in the boil is considered, by these sources, to lead undesirable effects in the finished beer including astringency and cloudiness. (Ref. Miller, Papazian) Recirculation may also contribute to increased extract efficiency.

However, others believe that some amount of chaff in the boil is desirable in that it helps to coagulate large protein molecules, producing a better hot-break and thus a clearer finished product. Furthermore, some think that the hot side aeration (HSA), or oxidation, of the sweet wort during recirculation may outweigh any benefit that may be gained by clearing the wort. (Ref. Fix)

Subject: Brewing a Weizenbock -- Need Ideas

Hello Homebrewers!!

I have discovered a truly fantastic beer called "Erdinger Pikantus Weizenbock". It is a Dark Weiss Bock beer with incredible body and a taste unlike any other Weiss beer on the market. It is available locally in Chicago at the Weinkeller, a microbrewery/bar/german restauraunt which serves 8 different brews of their own along with 500 different beers from around the world.

>From reading other posts, I believe that I would be able to cultivate the yeast from several bottles of Pikantus, but I need help in finding a mixture of malt extracts which would yield the proper starting wort for this type of beer. Also, I would appreciate any ideas on proper brewing technique (temperature, specific gravity, fermentation time, etc..) for this type of beer.

The Wienkeller (plug) is located on Roosevelt Road, just east of Harlem Ave. in Chicago (actually in Berwyn). I highly recommend this place to anyone who is planning on making a visit to the area. In fact, drop me a line and I'll meet you there!!

Thanks in advance,

From: Joe Boardman <boardman@amber.Colorado.EDU>  
Subject: cold break in or out....second try

\*\*\*\*OOOPS\*\*\*\* Sorry about that "subject only" post yesterday.  
Brevity is a commendable, but it was an accident. Here's the whole  
letter:

G'day HBD'ers,

After returning to Boulder from a 15 month stay in Australia,  
I got reacquainted with my grain mill et al last weekend. I brewed up a  
10  
gal batch, everything went well. Then I ran it through my counter-flow  
chiller  
and really ZAPPED it with Boulder's near-freezing tap water, causing a  
great  
cold-break. I had a semi-slow moving 1056 Wyeast starter going so I  
pitched  
the two carboys and went to bed. My wife just gave me a copy of Miller's  
Complete Handbook, and he seems to go to great lengths to get the wort  
off  
the trub, racking soon after pitching. I left the stuff in there and it  
settled out and formed a semi-solid layer on the bottom, even the  
churning  
ferment of the last few days has left it pretty much undisturbed  
EXCEPT  
it seems to have all these little "worm-holes" in it. It's as if during  
the  
active primary ferment some part of the trub has been used by the yeast.

What's the collective wisdom?

- 1)does leaving the cold-break in the primary (a feature of a counter-  
flow  
chiller) harm the beer?
- 2)does it help the yeast, nutrients etc.?
- 3)is a beer-style thing (lagers no, ales yes)
- 4)can anybody tell the difference?
- 5)any ideas on what has been taken out of the trub to make the worm-  
holes?

Maybe next time I'll rack one carboy and not the other. But it was 9.5  
hour  
session as it was and I just couldn't make myself sanitize another carboy  
and  
go through all the hassle. Or maybe I should just chill the hell out of  
it,  
no problem to get it below 50F, and let it sit overnight before pitching.  
All my instincts say "NO DON'T LEAVE YOUR WORT OVERNIGHT WITHOUT YEAST  
YOU  
FOOL".

So.....

Cheers,

Joe "Leave dead dogs alone"

From: tima@wv.MENTORG.COM (Tim Anderson)  
Subject: All-graiWorld's Worst All-Grain Snobs

I nominate "All-grain snobs" as the most insipid HBD thread of the year.

On the other hand, "The World's Worst Brewer" is delightful, and I have a suggestion:

Tim's Bucket Conditioned Brew

Pour a 5 lb bag of cane sugar into a 5 gal plastic bucket with a spigot in the side near the bottom. (Don't buy the bucket, just walk out the door of the home-brew supply store with it under your arm. Say something about wanting to see if it's the right size. Drive off with tires squeeling.) Add room temperature tap water, stir. Pitch several packets of different kinds of bread yeast. Stir again. Before putting on the lid, (Oh My God, did you forget to steal the lid? Well then use plastic wrap.) put your face close to the surface of the wort and softly whisper the word "hops". Wait a couple of weeks. You now have beer for the rest of your life. Just pour from the spigot directly into your glass. Or if you haven't gotten around to stealing any glasses, directly into your mouth. Every now and then add some more sugar and water. If it starts tasting sweet, add some more yeast. If anything fuzzy or smelly starts growing on top, skim it off (you don't want to DRINK that shit!)

It's obvious to me that your method of brewing is only a step toward my method of brewing. It couldn't possibly be the case that you actually enjoy doing it your way. Therefore, I want everybody who reads the digest to start making bucket conditioned beer immediately. And email me with all sorts gratuitous testimonials, and grovelling for my approval. As long as there's any difference in the way we make beer, you won't get it, but it will do wonders for my ego.

Ready, begin.

tim  
"Just kidding. Use ale yeast."

From: DLAMARPL@ucs.indiana.edu  
Subject: Sanitizing Copper; All-Grain Snobbery

Several sources indicate the hazards of using alkaline solutions (e.g. chlorine) to sanitize copper. None I have seen, however, suggest alternatives other than boiling. What are effective sanitizing agents for equipment that cannot be boiled (e.g. counterflow wort chillers)?

\*\*\*\*\*

In HBD 1071, Jack Schmidling implies that, in its "proper perspective," extract brewers' "image that all-grain brewers are snobs" is the result of the neuroses of extract brewers themselves. As a former rhetorical critic, I feel compelled to note the contradictions in Mr. Schmidling's statements.

In laying blame on extract brewers, Mr. Schmidling, an all-grain brewer, describes them as "lazy, paranoid or ill-informed" and refers to their "insecurity, sensitivity and paranoia." Such epithets appear to me to be "all-grain snobbery" of the most inelegant sort. Although he is entitled to his interpretation of the "proper perspective," his articulation of it lacks internal validity. Mr. Schmidling's attempt to exonerate the more "sophisticated" brewers instead indicates that some of the perceptual inadequacies felt by extract brewers may, in part, be instilled and perpetuated by \*some\* advanced brewers.

Any time we discuss advanced topics with those less informed, we must be careful not to confuse or offend them, else we snuff out their desire to learn.

Without more empathy in our attempts to share our knowledge and experience with beginners, we risk alienating potential new members of our hobby. As I used to tell my students: "THINK about what you say; you never know when your words will come back to haunt you."

From: SCHREMPP\_MIKE/HP4200\_42@pollux.svale.hp.com  
Subject: All grain snobs

After reading all the snob stories, I had to throw in my two bits. I believe a big part of the snobbery is the snob appeal... "sure you can make better beer if you're willing to take the BIG STEP and go all-grain".

It's the mystique of the BIG STEP that makes brewers fear taking it and puffs up those that have. The fact is, the BIG STEP is NO BIG DEAL. My second batch was all grain and yours can be too.

Read a book, use a washed out cooler as a mash tun, make and use a \$5 sparge system (window screen on the end of a siphon tube (EASYSiphonPipe tm), and use as many pots as necessary to boil the wort.

It's just not difficult enough to make those that do it into snobs. And it's more fun too.

Mike Schrempp

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Smooth Hop Utilization Function

Hi fellow beermakers:

I've come up with a formula to approximate hop utilization in a continuous fashion by fitting a curve to the data from the "Hops" issue of Zymurgy. The article is "Calculating Hop Bitterness in Beer" by Jackie Rager, and is found on pages 53 and 54. (Thanks, Jackie.)

I know what you're saying: "Overkill". But in preparation for the "do-it-all" spreadsheet that I hope to write sometime in the near future, I've been trying to create a formula for all those little brewing calculations that don't generally have one.

The main reason for fitting a curve, is to have an easy way of calculating IBU's with a spreadsheet, or programmable calculator. The secondary reason is to have some reasonable interpolation of intermediate boiling times. Of course the smooth function is only as good as the original data; but I think that it would provide more consistent results-- especially for someone like me who likes to add hops at different times (other than the standard :60, :30, :05).

The graph approaches 5% utilization towards zero boiling time. This might seem strange at first until you assume that "zero" boiling time means that the hops were boiled for zero minutes, but they were still added to the wort. In other words, I take the point zero to mean dry hopping; or probably more correctly, putting the hops in at the very end of the boil (steeping). Dry hopping and steeping does (in my limited experience) add to the bitterness a little. (About 5%, right? :-)

Here's the data from the article:

| boil (minutes) | Hop Utilization (percent) |
|----------------|---------------------------|
| < 5            | 5.0                       |
| 6 - 10         | 6.0                       |
| 11 - 15        | 8.0                       |
| 16 - 20        | 10.1                      |
| 21 - 25        | 12.1                      |
| 26 - 30        | 15.3                      |
| 31 - 35        | 18.8                      |
| 36 - 40        | 22.8                      |
| 41 - 45        | 26.9                      |
| 46 - 50        | 28.1                      |
| 51 - 60        | 30.0                      |

>From that, I created a data point for each minute:

(0, 0.05), (1, 0.05), (2, 0.05), (3, 0.05), (4, 0.05), (5, 0.05), (6, 0.06), (7, 0.06), (8, 0.06), (9, 0.06), ...

Then, I fit a smooth function to the data. Here's the function that I came up with:

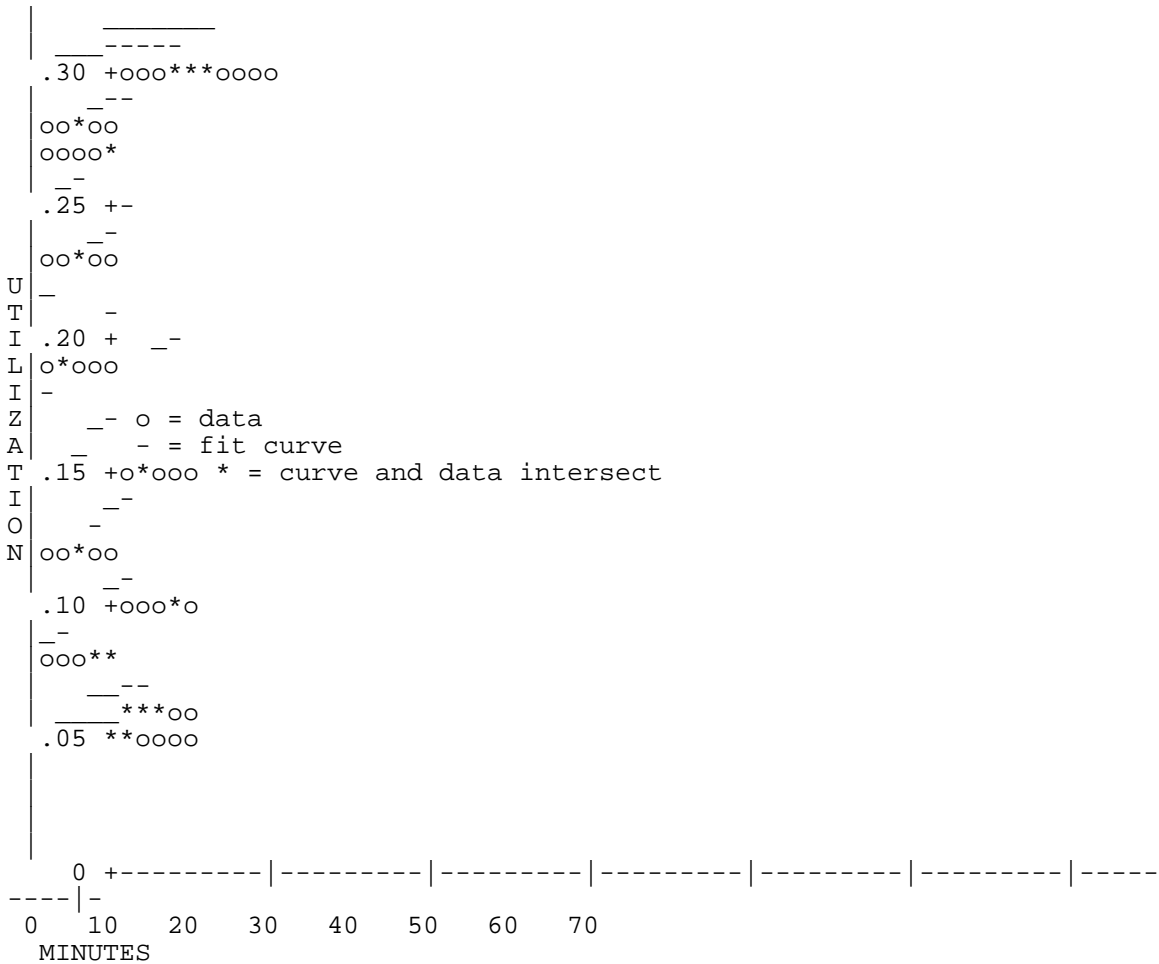

---

```
utilization = 18.109069 + 13.862039 * hyptan[(minutes - 31.322749) / 18.267743]
```

(The hyperbolic-tangent may be expanded to it's exponential definition if your calculator or spreadsheet doesn't have hyptan.)

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \quad e = 2.71828182844\dots$$

This formula was fit with the least-squares method. I realized that a hyperbolic-tangent fit much better than a polynomial, because the data implies an "s" curve. Here's the data and the curve superimposed:

As you can see the curve fits pretty well with the data. Of course the data is to be questioned; but it's the best that I've seen so far. (I especially suspect the data for the 41-45 range, it looks a little too high to be consistent.)

Here's a table that the function generates:

---

| Hop Utilization per Boiling Time |     |     |     |     |     |     |     |     |     |     |
|----------------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| +                                | :00 | :01 | :02 | :03 | :04 | :05 | :06 | :07 | :08 | :09 |

:00 .051 .052 .053 .054 .056 .057 .059 .061 .062 .065  
:10 .067 .070 .072 .075 .079 .082 .086 .090 .095 .100  
:20 .105 .110 .116 .122 .128 .135 .142 .149 .156 .164  
:30 .171 .179 .186 .194 .201 .209 .216 .223 .230 .236  
:40 .242 .248 .254 .259 .264 .269 .273 .277 .281 .285  
:50 .288 .291 .294 .296 .298 .300 .302 .304 .306 .307  
:60 .308 .309 .310 .311 .312 .313 .314 .314 .315 .315

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Calculating IBU's with the Utilization Function

Here's an example of how to use the hop utilization function in my previous article, using the calculations in Jackie Rager's Zymurgy article:

```
UTILIZATION = 18.109069 + 13.862039 * hyptan[(MINUTES - 31.322749) / 18.267743]
```

(Of course, you can drop a lot of those significant figures.)

```
    If the gravity of the boil exceeds 1.050:  
ADJUSTMENT = (BOIL_GRAVITY - 1.050) / 0.2  
    otherwise,  
ADJUSTMENT = 0
```

```
IBU_PER_OZ = UTILIZATION * ALPHA * 74.62 / (VOLUME * (1 + ADJUSTMENT));  
    ALPHA is the percent alpha acids (eg. 5.2--don't divide by 100)  
    VOLUME is the final number of gallons in the batch (usually 5).
```

To calculate IBU's if you know the number of ounces of hops to be used:

```
IBU = OUNCES * IBU_PER_OZ
```

To predict the number of ounces needed to hit a targeted IBU:

```
OUNCES = IBU / IBU_PER_OZ
```

I've packaged those formulae into a nifty calculator for those of you who are on a Unix machine, or a PC that has Perl installed. (If there is a demand, I can convert it to a C-shell script or a C program.)

It will calculate IBU's (International Bittering Units), given only:

- amount of hops
- alpha acid rating
- length of boil
- gravity of boil (if over 1.050)

It basically does what that mess of calculations in the Zymurgy article does (but you don't have to think about it). It will also do the inverse--return the amount of hops required to reach a target IBU level.

If I typed:

```
ibu 1.5 8 45
```

The output would be:

```
1.50 ounces of hops with 8.0% alpha acid, boiled for 45 minutes  
will produce 48.2 IBU's.
```

In the "inverse" mode:

```
ibu -i 49 8 60
```

would produce this output:

```
1.33 ounces of hops with 8.0% alpha acid, boiled for 60 minutes  
will be required to produce 49.0 IBU's.
```

Here's the Perl script (called "ibu"):

---

```
#!/usr/bin/perl

require "getopts.pl";

# set option variable defaults

$boil_gravity = 1.050;
$volume = 5;

# read command line

if ((!&Getopts('iv:g:')) || ($#ARGV != 2))
[
    printf STDERR qq/
Usage:
    ibu [-v volume] [-g boil_gravity] ounces percent_alpha minutes
    -v Final volume in gallons. The default is 5.
    -g Gravity of boil if over 1.050.
or
    ibu -i [-v volume] [-g boil_gravity] target_ibu percent_alpha minutes
    -i Inverse. Return number of ounces required to hit target IBU's.

Example:
    ibu -g 1.082 1.5 8.3 30
    /;
    exit 1;
]

$inverse = $opt_i;
$boil_gravity = $opt_g if ($opt_g);
$volume = $opt_v if ($opt_v);
$ounces = $ARGV[0];
$ibu = $ARGV[0];
$alpha = $ARGV[1];
$minutes = $ARGV[2];

if ($boil_gravity > 1.050)
    [$adjustment = ($boil_gravity - 1.050) / 0.2;]
else
    [$adjustment = 0;]

# calculate utilization from exponential equivalent of hyperbolic tangent
$exp = ($minutes - 31.322749) / 18.267743;
$utilization = 0.18109069 + 0.13862039
    * (exp($exp) - exp(-$exp)) / (exp($exp) + exp(-$exp));

$ibu_per_oz = $utilization * $alpha * 74.62 / ($volume * (1 +
$adjustment));

unless ($inverse)
    [$ibu = $ounces * $ibu_per_oz;]
else
    [$ounces = $ibu / $ibu_per_oz;]

printf("%.2f ounces of hops with %.1f%% alpha acid, boiled for %d
minutes",
    $ounces, $alpha, $minutes);
printf(" in %.3f wort", $boil_gravity) if ($opt_g);
```

```
printf("/nwill");
printf(" be required to") if ($inverse);
printf(" produce %.1f IBU's./n", $ibu);
```

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: Extract and Proud

As one who has gotten a great deal of information out of HBD, and who finds it a great way to forget about work for twenty minutes a day, I really hate it when it degenerates into silly stuff like Pub-Info-Request-Wars and Extract-vs.-Grain wars.

PLEASE LET'S NOT LET THIS GET OUT OF HAND, PEOPLE!

I have thought about doing the all-grain route, but frankly my present financial condition prevents me from investing in the additional equipment, and the fact that I have three children under the age of six lurking around my house makes the extra time involved impractical for me. I also suspect that if I didn't know all-grain methods were available to the homebrewer, I would continue to drink my extract brews in complete bliss (o.k., and ignorance too). Most of us extracters have very good reasons for staying with our present methods.

My inquiries regarding extract brewing have always been received gracefully and enthusiastically by readers of the HBD. I would say that if there really ARE extract brewers who are intimidated by the level of discussion by all-grainers, yeast-culturers, etc., they should do as I have done: ask anyway! It's your right. If someone actually does respond "snobbishly," then flame the idiot by private e-mail and go on asking your questions publicly.

Relax, don't worry -- have an extract brew.

Jonathan

Subject: RE: soda kegs on tap

Hi All,

From HBD #1071:

>Anybody have advice on how (and how long) to keep soda kegs on tap? I  
have  
>not tried it for more than about two weeks, and there was a noticable  
>change in the beer at the end. I did not take stringent measures against  
>leaks, so I presume the deterioration was due to air getting into the  
keg.

I'd say your presumption is probably correct. I've kept beers in soda  
kegs for over two months with absolutely no ill effects, the last pint  
tastes  
as good or better than the first. Sealed in a keg at a constant 45F,  
protected from heat, light and air, beer should keep for quite some time,  
certainly longer than two weeks.

The poster didn't mention whether or not the kegs were kept  
refridgerated,  
but I'm not sure this is a critical point. Keeping them in a reasonably  
cool  
place like a basement should be OK. I believe the problem is the kegs  
were  
not well sealed, allowing air to get in.

Try keeping a maintainence pressure of 12-15 psi on the keg when not  
dispensing. This will help provide a tighter seal along the large O-  
ring.

Also, disconnect the CO2 tank and the cobra tap when not in use. Leaving  
the  
hose barbs installed keeps the check valves in the fitting open. The  
only  
remaining seal is the small rubber gasket between the hose barb and the  
fitting, which I would not trust to keep the keg airtight over an  
extended period.

Cheers,  
Jim

From: brian@bio.cor2.epa.gov (Brian Spence)  
Subject: Hops Cultivation

Short time listener, first time caller. When my spouse and I purchased our home, we had the good fortune of inheriting a rather prolific hops plant. Now that I've begun brewing, the plant is no longer just and attractive ornamental, but offers practical benefits as well.

The Problem: I have no idea as to what variety these hops might be. We live in the infamous Willamette Valley, so I at least have the obvious first guess. Does anyone out there know of a good reference book that would allow me to key out this beast. Perhaps a "Peterson's Field Guide to Hops and Grains."

Other Questions: Papazian suggests that the soil for growing hops should be loamy and kept continually moist during the growing season. We have excruciatingly high clay content in our soils and have never watered at all.

Nevertheless the plant has done quite well. Will the quality of the hops be affected by my lack of care? Or should I follow the adage "If it ain't broke, don't fix it?" Also, how much will AAU vary with time of harvest, amount of watering, etc. And lastly, is there any moderately low-tech way of determining AAU of homegrown hops?

A good reference book on this subject would satisfy my needs, should you not wish to clutter the e-waves.

Thanks in advance. Spence.

>Subject: WL media (extracted from the Difco Manual)

>Bacto WL Differential Medium has the same formula as Bacto WL Nutrient Medium, with the addition of 0.004 g of Actidione per liter. This inhibits the development of yeasts without interfering with the development of bacteria generally encountered in beers.

A most enlightening article. However, if this is in response to the discussion about a medium that rejects or encourages "wild yeast", it seems

to confirm my opinion that such a medium is a wet dream.

The two described here simply control yeast and/or bacteria.

>From: Chris McDermott <mcdermott@draper.com>

>Subject: FAQ/RFC on Recirculation.

>Since many topics come up in cyclical manner it would be nice if they could

be answered in a FAQ format. And since some topics have more than one accepted answer the FAQs should try to show all sides of an issue.

A couple of points here. Many of us barely literate computer users have no idea of how to access a FAQ, if indeed it is something we can get at will.

CompuServe stores just about everything of any value in library files that are easily accessible but cost an arm and a leg to retrieve or even find out what's there. I have not read the header lately, but if such a thing exists for HBD readers, instructions on accessing it should be part of the HBD header and in terms even I can understand.

.....

>Recirculation is a practice employed in the lautering of mashed grains where the turbid sweet wort is collected, as it is runoff, and recirculated through the grain bed until the runoff becomes clear.

>Please consider this FAQ as a kind of HbD Request For Comment (RFC). Please feel free to make any additions or corrections.

My comment is that there exists a commercially available product for mashing (name and availability upon request) that runs clear in something less than one cup and the whole discussion becomes academic.

.....

Having said that, the RFC aspect for a FAQ library is important and seems to be lacking in the current system. For example, I have badgered the person who maintains the FAQ to include videos in his list of sources and the request has been ignored for several years.

>From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
>Subject: A survey of the readership

>I wonder how many questions have not even been asked because the author is afraid of being labelled "not a REAL brewer" by more advanced brewers. (Remember that discussion a while back about real brewers?)

How could I forget? I suppose my more objective posting yesterday will also be interpreted by some as intimidation but that was not my intent.

I simply think it's time to call a spade, a spade and get on with brewing. How one reacts to someone else's opinions, views and statements is his own responsibility. If one chooses to run away because some windbag uses big words, I guess that's life.

I would like to point out that before stumbling upon the HBD, I had spent over twenty years (off and on) making barely drinkable (and mostly not) rubbish. And now look at me... the World's Greatest Brewer! If I can glean what is needed out of this forum, so can anyone else and I have little sympathy for people who claim to be intimidated.

>I suspect that the readership consists of more beginners than are represented by the questions posed in the HBD. And I think that, if beginners realized that they make up a substantial part of the HBD community, they would be more likely to pose "lower level" questions, and therefore, improve their comprehension and brewing.

That is a good point but I think it is already happening at a reasonable level. Compuserve deals with this problem by dividing the forum into Basic and Tehnical message groups but that can't be done on the Digest so one just has to wade through the stuff they are not interested in but fortunately it's "free" here. Someone could start up a beginners' digest but I think it would be counter-productive.

I don't doubt that some people may be intimidated but there are enough that are not, to get out the questions and keep the discussions going.

Back to spades.... "real brewers" was a poor choice of words and perhaps trying to come up with a more appropriate one will still offend some but pushing it under the rug doesn't help either.

I still contend that mashing whole grains is another step up the ladder to becoming the "complete brewer". If many/most opt out, so be it. We opt out of many steps in the process but there is no reason to get paranoid about any particular one of them. Nor is there any reason to criticize those who crusade for or against, any or all of them.

>From: Richard Cox <rcox@hsc.usc.edu>  
>Subject: Dry Malt Extract vs. Syrup Malt Extract

>One of my homebrew suppliers strongly maintains that dry malt extract provides better flavor and less extract "tang" than the syrup variety. He has encouraged me to use all DME in my recipes whenever possible.

I can't offer anything other than intuitive reasoning. Wort is converted to extract by evaporating the water. In the case of dry extract almost all and in the case of liquid much less. It seems that whatever they do to the wort to get rid of the water has nothing to do with what we do to wort to make beer and therefore, less is better.

From: colvin@hayduke.cs.utah.edu (Tom Colvin)  
Subject: Bud % alcohol / Ridding oil from plastics

After reading the posts of Ulick Stafford and Bill Szymczak, I realized that Bud % alcohol must vary greatly from region to region even in the US.

In this "wonderful" state of Utah it is law that beer exceeding 3.2% alcohol by volume must be sold in liquor stores. However, Bud is available in any grocery store around here.

Our brewing club recently brewed a beer with chocolate in it. Does anyone have any idea on cleaning the oil out of the plastic tubing and buckets easily? We were trying to avoid using dish washing detergent since they normally leave behind stuff for anti-spotting and who knows what else. We also were trying to avoid using a lot of water since we going through a major drought in the area.

thanks for any advice in advance,

I've been absent for a while, so I don't know what the last time was  
that this was discussed.

The yeast in Chimay is not a single strain. It is either 3 or 5. I  
forget which, but I think it is 3. If you plate it and isolate a  
single cell for building a culture, you will only get one of the  
three.

Of course, you also avoid any other nasties that snuck into the bottle  
in small numbers.

It was an ale. When Coors started making it (1978?) it was an ale.  
Somewhere along the way, they started making the lager.

When I first was drinking it ~1986, it was an ale and I liked it. I  
stopped buying it for a while (shifting to Bass), and when I bought it  
again, I didn't like it much. I later noticed that it was (in tiny  
print) "lager" now.

>The cellar is approximately 55 degrees F at this time of year and  
>will increase to about 65 by the beginning of summer. How long  
>can one expect to keep each of these before the flavor falls off?

Well, there are at least some of us out there who don't drink much beer.  
I probably drink about 2 or 3 beers a week. There are at least 12 cases of homebrew in my basement.

Like yours, my basement doesn't get below 50F during the winter nor much above 60F or so in the summer. Also, I store all my beer in cardboard boxes with covers, so there is no exposure to light.

I brought a three-year-old holiday ale to a December homebrewer meeting. It had been seriously overhopped originally and now tasted like an OK ale-- none of the spice character was left, and only a normal amount of hop bitterness could be detected. It wasn't oxidized, either.

I recently uncovered a two-year-old raspberry ale six pack. Figured it would have none of the overpowering raspberry aroma and flavor of the original brew. Boy, was I wrong! Still smelled and tasted great! I \*would\* say that it was past it's prime, though.

For that matter, I still have some 1990 Anchor holiday ale down there and it is starting to get a little worse but is still just fine.

What general rules or conclusions do I have?

1) Most beers will keep fine for at least a year under such conditions. Many will keep for two or three just fine.

2) Invite friends over to help you drink it if you like to brew as much as

I do. Everyone is happy this way.

Subject: Re: wine making

in HOMEBREW Digest #1071 connell@vax.cord.edu asks:

> I have noted with curiosity that ... there is almost no discussion  
> of homemade wines ... Is wine making discussed here so seldom  
> because the process is uninterestingly straightforward or because  
> the results are so inferior to commercial wines or both?

The charters of the Digest and rec.crafts.brewing exclude wine making for some reason. As both brewer and wine maker, I will risk flamage to comment here on wine making. As far as wine kits go, I can't comment; I tend to avoid anything that looks like a recipe. I don't see why you can't make a decent wine from kits, though. I make fruit wines, which can't really be compared to commercial (grape) wines. For example, I tend to like dry wines ("Hey, Stiles, you call this good wine? I call it gagging in the Sahara."), but fruit wines generally exhibit their fruit character better if they have some residual sweetness.

Wine making skills/equipment overlap considerably with those of brewing, but there are differences. Also, the time scale is a lot different (I don't have TIME for instant gratification, dammit!). Get a good book on wine making. A browse through the library is a good start.

ObBrewing: No takers on my question about flavor/aroma properties of Chinook hops, huh? Do any commercial brews use them?

From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: Spiced Ale

Now, here's a question that could be answered by extract brewers and all grain brewers alike.

There was a \*thin\* thread (not quite overwhelmed by all the philosophizing and speculation about snobbishnes) recently about spiced ales.

Part of the discussion prompts me to wonder: has anyone tried BOTH the technique of adding whole spices at some point to the boil AND adding powdered spices at the end of the boil? (Obviously, in different batches.)

I made my first spiced ale this year and boiled orange zest, ginger root, cinnamon sticks and whole cloves for about the last thirty minutes. It has a bit more bite than I intended, although the beer does taste quite good. I am wondering whether I boiled the stuff too long and whether powdered spices at the end of the boil would produce a "kinder, gentler" brew.

If anyone has a response of general interest, please post. I would also be happy to summarize and post e-mail responses.

Not Worrying, and Having a Spiced Extract Ale With a Little Too Much Bite,

Jonathan

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: Leaf Hops?

I have to agree about the freshness and general wonderfulness of hops plugs. I bought some recently (imported by Crosby & Baker, according to the package) at Brew 'N' Grow (same as Alternative Garden Supply, but in Detroit instead of Chicago). I made a Bock with Hallertau & a little Saaz. What an aroma! This was the first time I really understood what is meant by the "spicy" aroma of Saaz. Wow!

And the hops looked beautiful after I drained the wort. Full cones that half-filled my brewpot.

The beer is still lagering, so I can't report on the taste, yet.

Hi yall

Well well well! There are quite a few of you out there with opinions on Beer Across America. I tried to reply to each of you to thank you for your time in replying to my query. But jeez, I got better response than I ever anticipated. So, I'll waste everyone's bandwidth and just do a global THANKS. :)

I just gotta be careful what I ask for, I just might get it ;)

I think I'm gonna join this thing, at least for a little while. Spencer had a good suggestion about "sharing" the cost. I may do that with a friend or 2 to help defray some of the expense. But we-uns here in the southland don't got much other choice. Maybe some day.

Oh yeah, Michael G., thanks for the fax, I guess that means you're my sponsor. Only one more for a free 6er :):) Think maybe you could send ME a bottle? :)

From: Lee Menegon <necis!lmenegon@transfer.stratus.com>  
Subject: Diacetyl ?

I have recently begun brewing all grain batches, 5 or 6. A constant comment about my beers is that they contain noticable levels of diacetyl. I have done some research in the Zymurgy trouble shooting issue and in Miller's CHOB and found:

- 1) Diacetyl is a by product of the early stage of fermentation when oxygen is available to the yeast.
- 2) Its level of production is directly related to wort temperature, i.e. warmer = more diacetyl.
- 3) Yeast will eventually reduce the diacetyl in the later stages of fermentation.

I discussed my brewing process with an experienced all grain brewer who too was having this problem with his beers. We decide that since the yeast strains we were using 1056 and 1098 are not noted for high levels of diacetyl in their flavor profile that the following could be flaws in our brewing process:

- 1) Pitching into wort that was much warmer than the target fermentation temperature. We did this to reduce lag time.
- 2) Adding finings immediatley after racking to the secondary. We did this to induce CO2 generation to purge the head space. This would cause the yeast to prematurely fall out of suspension thus reducing the quantity and the time in which the yeast was reducing diacetyl.
- 3) Since we artifically carbonate our beer in soda kegs we would not bolster the yeast population which could reduce diacetyl in the conditioning phase.

What besides pitching to wort at fermentation temperatue and finning after the yeast has settled or not at all what can we do to reduce the production of diacetyl and increase its reduction later? I still plan to artificially carbonate it seems to make for clearer beer and I can drink it sooner, 3 days after keggng.

What can I do to produce high levels of diacetyl and minimize its reduction if I want to brew something with a Samuel Smith profile? Is a warm ferment with a yeast strain noted for diacetyl production and fining immediatley after primary fermentation the way to go ?

Richard writes:

>One of my homebrew suppliers strongly maintains that dry malt  
>extract provides better flavor and less extract "tang" than the  
>syrup variety. He has encouraged me to use all DME in my recipes  
>whenever possible.

I know that the two most popular dry malt extracts, Munton & Fison and Laaglander, are both made from 100% malt (note that the Laaglander is a bit less fermentable, so use that to your advantage). Many syrups contain all kinds of other sugars, like corn and even sucrose. I certainly would not want to simply dismiss all syrups -- there are a great many that appear to be of very high quality. I've narrowed my use of extracts to a few that I feel are good (Northwestern, Munton & Fison, John Bull, Alexander's, Coopers, Ireks and a few others) and my extract batches have been par with my (and other's) all-grain batches.

>I'm too new to homebrewing to have an objective opinion on this,

I've done empirical analysis of two batches of beer split into blowoff  
and  
non-blowoff (non-skimming, also) sub-batches. Beagle is partly right  
about  
the hop resins, but is dead wrong in saying that:

1. \*all\* of them are in the foam, and
2. the oils and resins give the beer its body.

Part of the result of my blowoff/non-blowoff experiments was to determine that

I may lose some hop bitterness and a bit of hop flavor by using blowoff, but

I don't really want a lot most of what gets blown-off in my beer. The blowoff sub-batch was smoother, cleaner, less astringent and a bit less bitter (note that I'm not a lupulophobe -- my last IPA had 80 IBU and I thought it was a bit underhopped). I urge you to try the blowoff method for a beer or two and compare.

Oops. I think there's some miscommunication here, Jack -- the mash isn't hot at this time so Hot-side Aeration (HSA) is not an issue.

Feb. 3, 1993

John Harvard Brew House  
33 Dunster Street  
Cambridge, MA 02138

617-868-3585

Timothy Morse Mark Palmer Ray Kall  
Master Brewer Manager and tour guide Bartender, Waiter, Homebrewer

The first impression of this place might be oops I've stumbled into Cheers. It's down stairs under the THE GARAGE building at 33 Dunster Street, Just a half block from Harvard Square and one block East of J.F. Kennedy Dr. It used to be a restaurant called 33 Dunster Street.

The first thing you notice is the long bar with the stainless steal serving tanks enclosed in glass behind it. The bar has three sets of four towers, each having two taps. One hand pulled pump for either the casked Stout or the J.H. Pale Ale. They seemed to alternate between the two brews. Lots of back lit stained glass against the back wall which was left in place from when it was 33 Dunster Street. At the same end of the building and enclose behind the glass is a big copper mash-tun and fermentor from The Pub Brewing Company.

They get their pre-crushed malt from England and Hops from California, mashing with 700 pound of malt at 165 degrees. Gypsum is added to Cambridge's soft water. Extract is generally 430 gallons. The wort is counterflo chilled and then fermented for three to five days. The secondary is then racked to stainless steal cellar tanks for 10 to 21 days at 50 degrees. Some of their ales are dry hopped with whole hops. When aging is done they drop the temp to 36 degrees and run it through a DE filter and then to the serving tanks behind the bar. They use Krausing for carbonation and no CO2. They brew 14 barrels every three days.

The dining area is large and comfortable. I first arrived there Sat. night at 11pm and the place was so packed I had to squeeze into the hostess stand to get a Nut Brown Ale. The next morning I came back for Sunday brunch. It was great! I had an Omelet that was stuffed with made-on-the-premise pork sausage in a BBQ sauce and a little jack cheese. Served with home fries that were quartered new potatoes sauted in a garlic & onion sauce. Also served was a basket of baked goods from a local bakery, hot and wrapped in linen with a generous scoop of raspberry jam.

This brew house started nine months ago and has only been open about six months. Timothy Morse, Master Brewer who started out at Anchor Brewing, then went to Hope, WI and on to Commonwealth Brewing before starting at John Harvard's Brew House, has yet to pour his own brew here. It's been done under contract at Massachusetts Bay Brewing (Harpoon) due to hassles with the city of Cambridge over the zoning. Apparently Cambridge viewed brewing as a fire hazard. Tim finally got to do his first brew Sat. Jan. 30,1993.

O-K now for the good stuff. Ray Kall the bartender, who is also a home brewer was very helpful, informative and friendly. In fact the entire staff here is well trained and friendly. He said that once Tim gets going with his own brew there should be some improvements. He hopes to brew traditional British (Burton on Trent) style.

I had a five brew sampler.

1. Was a nut brown ale: Color was very good. I didn't get much aroma. It was drinkable but not exceptional. Not a Samuel Smith by any means.
2. Was a Highland Ale-a scotch: My first taste of Scotch Ale so I can't comment other than the FG (final gravity) seemed high but maybe normal for the style?
3. Was NEW TOWN LIGHT ALE: Light golden color. Well carbonated. Good Fuggles hopping. My wife would love this one.
4. Was JOHN HARVARD'S PALE ALE: Nice copper color and hoppy. Served either 'cold draught style' or 'cask conditioned and hand pulled' in the British manner and the Brew House's biggest seller. Had a nice sweet aftertaste.
5. Was an IRISH EXPORT STOUT: This also was poured in two ways. Draft and cask. The cask was hand pulled and served warmer and less carbonated. Both were dark, malty, with a rich roasted flavor. True to style. A full bodied, but

less bitter version of the famous Dublin Ale. This was my favorite.

The bill of fare for this very memorable Sunday brunch and the five brew sampler was \$12.50. I went back one more time for dinner and the food was again excellent. I highly recommend the John Harvard Brew House.

From: ng570@andechs.pnl.gov  
Subject: culturing Paulaner yeast

In #1070 Greg Wolodkin writes about perhaps having problems culturing yeast from the dregs of a bottle of Paulaner Hefe-Weizen. According to Eric Warner's wheat beer book, the Paulaner Weizen that is shipped overseas is first pasteurized! I doubt that this is very good for the bottling yeast. Maybe Spaten is a better bet, but I haven't seen it around my area.

good luck!

said,  
> Rob! I recently made the switch to all-grain -- I will admit that I  
was  
> always a bit apologetic about being an extract brewer.

The insight into the brewing process and the complete flexibility  
in recipe formulation are what do it for me. You can bake fine cake  
from mixes and buy top-notch frozen puff pastry, but until you make  
your own from scratch you are not fully educated. Similarly, a complete  
education in homebrewing must include lots of all-grain beer ....

> The best situation is for extract brewers to be able to dabble in all  
grain  
> without purchasing the equipment (which may or may not cost a fortune)  
.

Really, it's not too expensive. The beer is much cheaper (1/2 or less),  
too. I have spent much more on books and things like autoclaves and  
culture tubes than I have on the equipment just needed to make all-grain  
brews. All you must have is a big pot (even the 20 qt Revereware  
is ok, though a little small) and a lautering system. <\$100.

> I personally believe working with an experienced person is the best way  
> to manage all aspects of brewing though.

Don't be shy. There is no need to brew from extract before working  
with all grain. When you get down to it, the process *is* forgiving.  
The only thing it isn't is, er, quick.

..

> >The cellar is approximately 55 degrees F at this time of year and  
> >will increase to about 65 by the beginning of summer. How long  
> >can one expect to keep each of these before the flavor falls off?

At that temperature, well-made pale or amber beer will keep at least  
a year. Two or three, or more, wouldn't surprise me. I don't recall  
the last time I had a staled pale or amber brew, and I tend to keep  
a few of almost every batch for 6-18 months. Dark beers will eventually  
start to stale quite suddenly.

Room temperature storage is OK for most homebrew, too. Again, I've  
kept bottles for over a year at room temperature with no problems.

...

Jack says:

> Keeping in mind that lots of people stick with extract because they  
are lazy,  
> paranoid or ill-informed [...], it is worth  
> noting that some extract beers are excellent beers, so I am told.

There weren't many extract-based first place winners in the Nationals this year, but they keep on coming ....

> Having said that, I suggest it is the extract brewers' insecurity,  
> sensitivity and paranoia that creates the image that all-grain brewers  
are  
> snobs.

Jack, Jack, Jack! It's the fact that some of us all-grain brewers ARE elitist snobs with a superiority complex. Furthermore, we know we are, and we love it. We demonstrate our affluent, care-free lifestyle by spending 4-8 hours tending a process that saves us all of \$10 per 2 cases of beer. We buy grain by the 50lb/25kg sack and smile while grunting past the open-mouthed folks carrying 11b bags of crystal malt.

The process is longer and harder and more rewarding TO US. I really don't believe, though, that it is much more likely to produce a prize-winning beer than extract brewing is in the hands of someone sufficiently skilled ... or lucky.

I personally wouldn't have it any other way. :-) :-)

...

connell says:

> I have never read about  
> or experimented with homemade wines, but I have the idea that people  
> just dump concentrate and water in a carboy and add yeast.

Oh, my. <asbestos clothing at ready>

.....

And finally, Jim Bayer says:

> I'm just beginning to mash and I have a question about the practical  
shelf  
> life of CRUSHED grain.  
> [...] If for some reason all of my ingredients arrive for brewin'  
> on Saturday but something happens and I can't get to it, how long can I  
store  
> the grain and still have fresh grain and how should I store it?

A very long time. So long as nothing is moving around inside it, it is still OK. I've heard people say it goes stale after a while, but I've not noticed this in some fairly old precrushed grain I've gotten from a friend.

It WILL pick up moisture from the environment if the humidity is high enough. I think that this is responsible for the apparent loss of yield seen by brewers who have let crushed grain sit for a day or two. The effect is on the order of 10%.

(Now, I once made a fine stout from a grain bill that accidentally included a pound of flaked barley infested with weevils. So even a few bugs won't hurt you.)

> So far someone told me to freeze it, but that sounds wrong to me.

Works fine.

> BTW, I'm thinking of weeks for storage, not days. I know it's best if  
I don't  
> have to store the grain, but I like to have my bases covered.

Use a reasonably airtight enclosure (tub or tightly folded bag is fine) and everything will work out swell.

From: Martin Lodahl <gueuze!mal@PacBell.COM>  
Subject: A New Journal

If you read the Celebrator this may be old news to you, but a new magazine devoted to the technical side of homebrewing, pub-brewing or microbrewing is about to make its debut. Called "Brewing Techniques", it will break new ground in homebrewing (as far as I know) by being an honest-to-goodness "peer review" journal. The Editorial Advisory Board (the peers who do the reviewing) consists of Patrick Baker, Byron Burch, Fred Eckhardt, Teri Fahrendorf, George Fix, Terry Foster, Mary Anne Gruber, Dave Miller, Greg Noonan, David Ryder and Bill Siebel. Impressive! The clear wort of usable brewing information certainly seems unlikely to be beclouded by the trub of unsupported speculation presented as fact, with a panel like that reviewing submissions.

The magazine will be published 6 times a year, at a subscription price of \$30. For an unspecified time there will be a \$24 introductory rate for "charter" subscribers. To subscribe, send a note with your name and address information to:

Brewing Techniques  
P. O. Box 3076  
Eugene, OR 97403

You'll be billed after the release of the first issue, scheduled for May. To discuss advertising rates or editorial questions, call Stephen Mallery, Editor, at 503.683.1916.

I think this may be the magazine many of us have been waiting for ...

From: dduane@kestrel.win.net (Diane Duane)  
Subject: Irish Ales and other matters

Hi all.

Re Ulick Stafford's post of the Digest before last:

> While ale sales have been falling  
>to lager (with stout relatively constant) sales of Smithwicks are still  
>high.

I may get in trouble for this, but Smithwicks doesn't taste much like an ale any more. One of the things interfering with this is the excessive carbonation. It now tastes more like a red lager: to me at least. (Granted, this is all very subjective.) What with my husband's and my writing careers, we spend a fair amount of time in the UK, and a lot of it staying in pubs, by preference: and we drink a fair amount of ale, "real" ale by preference, others as desired. The carbonation in them is always minor -- you might get a "petillant" pint, but nothing that fizzes like our present Smithwicks. And again, to me, it simply doesn't taste ale-like. It had never even occurred to me to think of it as an ale until Ulick called it one.

> MacArdles is also sold nationwide in bottles and can be got  
>on draft in local areas.

Ulick, where did you find it on draft? We are in and out of Dublin a lot, and hit many of the major pubs in town, and I haven't seen McArdles on draft anyplace. In bottles, yes, and I thank you for reminding me of it. But down here (Wicklow), it's thin on the ground.

> In Waterford one can even get Phoenix Ale  
>in large bottles produced at the small Cherry' brewery there.

I never heard of this, and would very much like to try it. Thanks for mentioning it!

> Bass is also produced in Belfast and is  
>an Irish Ale having slightly different taste than British produced  
>Bass.

Mmmm...true, and I dislike both forms of Bass immensely, so probably I am not equipped to critique it.

> Unfortunately the virtual monopoly Guinness have on the Irish  
>market, and indeed on malt and hop industries has meant that there are  
>fewer  
>small brewers than elsewhere.

True, but maybe with the trade barriers down between us and the North, we'll see at least some Hilden coming down here. The Hilden Ale is extremely nice. They are also now brewing a stout (Great Northern, I think it's called).

>Another point I would question was Diane's statement that Irish Bud  
>was 2.5 times stronger than American stuff. While it does taste a  
>little better (It would be hard not to), it is 4.3% by vol as

>against US Bud which is 4.6%.

(grin) This one I'm going to blame on my husband. (Truly, though, I think I must have misheard him. He's been going around the house muttering

"A \*time\* and a half stronger, not two and a half times....") I will pop down to the pub and pull the specific gravity and other figures. But certainly it is stronger...one of the local spectator sports is watching the American tourists come through, and see Bud on the pull, and say, "Looka here, Marge, they got Buuuuud here," and proceed to drink as much of it as they would have drunk in front of the TV at home. And then they fall over, and then we stack them up by the wall and put a tarp or something over them until they wake up. Ah, my poor countrymen!

Best to everyone, and thanking Ulick again for his advice. D

Subject: homemade wine

hello all. my last message seems to have disappeared (come back rob, all is forgiven). However someone else replied to the question of how to make wine, and correctly said that extract + water doesn't make the best wine. However, he then went on to say that you can only get good wine from grapes etc. How wrong! We regularly see recipes for beer that do not conform to the german purity laws, but still taste excellent.....

.... possibly because they don't (I'll take an industrial example : most english bitters contain types of sugar, eg mollasses). Well it's the same with wine. Wine making started long before the french made it their own. People have been making blackberry, strawberry, in fact hundreds of NON-grape wines for centuries. It is the "grape wine snobs" and a very powerful french industry which has meant that you can't buy them (a few companies in britain sell them, including Gales - the brewery).

True this is a beer forum, and also true there are (sorry is) a digest for wine, but please don't tell people off for asking! If anyone wants info

or wants to flame me please email me direct.

My wife and I have been both brewing and wine making for quite some years now, and can safely say that both are extremely enjoyable, not least because of the choice of drinks it gives us.

Sorry about the length of this rant, and sorry to the HBD - content - purists. but I had to get my word in!

Subject: Info needed on Cincinnati brewpubs

I'm headed down to Cincinnati this coming weekend for a business trip and was wondering if there were any good (or bad) brewpubs in the area. I've heard that there is one right across the boarder in Kentucky, but that is the only one that I have heard of.

If you know of any in or around the Cincinnati area please send email ASAP.

Thanks,

Juli

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: yeast reuse correction & all grain costs

In the last digest I made a somewhat erroneous statement regarding glycogyn reserves in dormant yeast cells. IF the yeast has been treated well and not shocked, then the dormant cells will have plenty of glycogyn reserves afer sitting in the secondary. The cells should wake up fine when fed fresh wort. An important issue is to avoid "yeast shock" which could lead the cells to excrete nasties back into your beer. So, just be careful handling the yeast and it should wake up fine.

RE: Costs of all grain brewing.

JS has again fired up the snobbery issue and generated a lot of wasted bandwidth in the process. I am sure jack is pleased. What I want to comment on is the response that implied the reason to avoid all grain brewing is cost. It has been noted in this forum before that going all grain does not mean going broke. To sum up the costs needed (a low budget, workable setup):  
2 plastic buckets with the holes drilled in one, plus a spigot-\$10  
used 7 gallon SS kettle - 35-50\$.  
(maybe-corona mill-45\$,new)  
wort chiller, built at home, \$25.  
total- 65-130\$

now look at the savings-dry malt extract at my local store was \$9/3 lbs! So an extract brew would cost between 15-20 for malt, plus hops & yeast, 23-27\$/5 gallons.

All grain- 8lbs domestic 2 row at 30-50 cents/lb, 3-4\$. Add 2-5\$ for hops & yeast, \$5-9 per 5 gallons. The average homebrewer brews 10-20 times a year. At 10 per year, the extract cost would be between 230 and 270\$ per year. At 20, 460-540 per year. The same all grain brewer would spend ~50-90\$ at 10 per year, or 100-200 at 20 per year. So the cost would be recovered in 10 batches or so. Not bad, eh??

Subject: Brewcap

I just bought a BrewCap last weekend and I would like to know if anyone has any advice before I try it (including "you wasted your money" :-). One thing I found curious is the warning against dry hopping with pellets since they might clog the blowoff hose. I don't see why this is true. Would it be better to put the pellets in a hop bag which would contain most of them? Any advice is most welcome.

From: mtavis@gemini.hyperdesk.com (Mike Tavis)  
Subject: Increasing Yields and Yeast

After all the great advice I received on my "Diminishing Yields" post, I wanted to report back to the digest with my solution. For those who don't recall, my post detailed the drop in my extract rate as a function of the size my grain bed (the bigger the bed, the lower the extract rate).

One important piece of information that I left out in my original post was that I use a 5-gallon Rubbermaid cylindrical cooler with slotted copper tubing for my mash/lauter tun. My basic problem was that I wasn't raising the temperature of the grain bed enough during mash out.

Someone (sorry I forget the name) with the same setup said he/she adds near boiling water to raise the temperature of the grain bed to the 168-170 range during mash out. Naturally, the amount of mash out water that you add (restricted by how much room is left in the cooler) determines the temperature of the water required. At some point there isn't enough room left in the cooler to raise the temperature even with boiling water. Someone else (sorry again) said they get around this problem by draining the cooler, heating the removed liquid, and adding it back to the lauter tun.

I didn't have to resort to draining the cooler. I used the first technique and was able to bring my grain bed up to 167. Previously, I used the sparge water (at 170) to do the mash out. I never took the temperature of the grain bed in my old process, but I would guess that it was in the mid to high 150's.

The result of the new process was a much faster sparge as well as an extract rate of 29 pts/lb/gal. Also, the wort come to a boil noticeably faster. I want to thank everybody that contributed their thought and experience to my problem.

On another note, I've noticed that certain yeasts strains have characteristic fermentation styles. For example, WYeast 1056 seems to have an very active start and ferment out quickly. WYeast 1007, on the other hand, seems to have a slower drop off and continues to ferment for longer. These observations are based on the highly scientific glugs per second model, but they do seem to be reproducible. I was wondering if there was any real analysis of the fermentation styles of different yeast strains? Thanks again.

Subject: Wine

>From: connell@vax.cord.edu  
>Subject: homemade wine

>I have noted with curiosity that while there is discussion of sidelines to beer brewing that shows up on the digest (cider, mead), there is almost no discussion of homemade wines.

While HOMEBREW Digest should provide the answer, it does not really explain why cider and mead are discussed far more frequently than wine.

My guess is that it has something to do with the universal availability of apple juice and honey vs the regional availability of grapes. The other lies in the beer vs wine drinking statistics of Americans.

>I have never read about or experimented with homemade wines, but I have the idea that people just dump concentrate and water in a carboy and add yeast.

If that is the standard ritual, it is no wonder few people do it. It hardly is a program for great wine.

I have made wine for years and used everything from dandelions and sugar to home grown grapes.

With the proper grapes and scientific procedures one can make excellent wines. Using concentrates and your procedure, one has a hard time improving on the cheapo jug wine and concentrates are very expensive.

I am sitting on my most recent batch which I described in detail here during the startup stages but there is little to say about it while it sits for months on end. I don't expect the final report in less than ten years and it does not make for great discussions. Furthermore, as good wine requires fresh grapes, it is a seasonal project and I won't start another batch for another year.

However, as long as you brought it up.... I do think I learned something from this batch that seems to confirm what has been said before.

The wine contains 5 gals of home grown apple juice, and 11 lbs home grown elderberries, grapes and mulberries.

I heated the apple juice to 170F and added the fruit and thus sterilized everything. The wine tasted terrific all through the process but now it is

obvious that it is never going to clear properly. I tried gelatine,  
betonite  
and now honey and oak chips.

The word is that the heat destroys the enzyme that reacts with pectin  
and the  
pectin will remain in suspension forever. One can add a pectin  
destroying  
enzyme during fermentaion to overcome this evil but I took my chances  
and  
seem to have lost. I am going to experiment with a small amount of the  
wine  
and the enzyme at the present stage and will report what I learn.

Well there you have it. Be back in a year or so, on wine, that is.

EXCEPT  
>it seems to have all these little "worm-holes" in it. It's as if during  
the  
>active primary ferment some part of the trub has been used by the yeast.

> 1)does leaving the cold-break in the primary (a feature of a counter-  
flow  
> chiller) harm the beer?

Yes. Side-by-side tests done by a reader of this forum concluded  
that the effects were most objectionable when combined with the lack  
of a blow-off for the primary. Personally, I feel that I can tell  
the difference, but one cannot be objective about it without side  
by side comparisons. I can say that not racking detracts from the  
clarity of the beer, if not corrected by cold aging or the use of  
clarifiers.

> 2)does it help the yeast, nutrients etc.?

Yes. The yeast will feed on the cold break, and leaving the wort on  
the break will help the yeast get started. Miller claims that after  
fermentation begins, the hop resins in the break will cause fusel  
alcohols to be produced. Possible solutions are:

- a) pitch the yeast, let it sit on the break for a few hours, then  
rack off into the primary. disadvantage: if you use a quick starting  
yeast (i.e. Whitbread) and wait too long, it will stir up the trub  
at the bottom before you have a chance to rack. Also, if the yeast  
starter has fermented out (post high-krausen), much of the yeast  
will settle to the bottom and never make it to the primary.
- b) let the break/trub settle (possibly overnight in a refrigerator)  
this corrects the disadvantages of (a), but adds to the risk of  
infection, as the yeast is not pitched immediately after cooling.  
If you chill the wort below 60F or so you will sufficiently inhibit  
any foreign bacteria and there is nothing to worry about, assuming  
you have been sanitary in your procedures. The yeast does not  
get to initially feed on the trub, but I would argue the advantages  
of letting it do so, anyway.

c) use an immersion chiller and leave the trub in the brew kettle. This saves on time and the number of fermenters required (and the time to clean them). disadvantages: the wort is more prone to foreign bacteria in an open kettle while cooling than when using a counterflow chiller, and you will not be able to see the dividing line between the wort and trub (unless you are using a pyrex boiler \$\$\$). When I use this method I squeeze the hops to get the last little bit out, then transfer this with the remaining trub in the kettle into 1 gallon glass jug(s) and let sit in the fridge. After a day at really cold temps you can recover quite a bit more clear wort (typically .5-1 gallon for me) and either re-boil it and add it to the fermenter, or add it to the next batch. This is mainly a problem when using lots of leaf/plug hops.

> 3)is a beer-style thing (lagers no, ales yes)

At colder temperatures the yeast will not stir up the sediment on the bottom of the fermenter, so there will be less contact between live yeast and the trub, as in your case. You can still rack the beer off as long as this layer remains undisturbed (though you may have to restart the siphon several times if CO2 keeps stopping it). The cold temps used in conjunction with lager yeasts will usually leave the trub layer intact, but fusel alcohols are much more objectionable in lagers than in ales.

> 4)can anybody tell the difference?

See (1)

> 5)any ideas on what has been taken out of the trub to make the worm-holes?

Some clumps of yeast which were trapped in the layer became active and created them as they rose back into solution. Alternatively, they may still be trapped in the layer, but the escaping CO2 bubbles created the holes.

From: CCASTELL.UNIX11@mailsrv2.eldec.com (CCASTELL)  
Subject: Summer Skiing at Mt. Hood

The Northwest division of the Professional Ski Instructors of America (PSIA-NW) holds three summer race camps each summer at Mt. Hood. The dates for this year are:  
3-day camp July 23-25  
5-day camp July 28-Aug 1  
3-day camp July 30-Aug 1

I haven't seen pricing information yet for this year, but it normally costs around \$200 (if my memory is correct) for the lessons and lift tickets for a 3-day session. The 5-day sessions are a little more. Food and lodging are up to you. (Some people take a tent and camp out.)

Most of you are reading this thinking that I've sent mail to the wrong digest. However, consider the dates:

3-day Summer Race Camp, Mt. Hood July 23-25  
AHA National Convention, Portland July 26-30  
Oregon Brewers Festival, Portland July 30-Aug 1

Looks like quite a week. Its been on my calendar for quite a while now, and I thought that I would share this opportunity with any skiers out there.

The camp is offered to instructors first, and if it doesn't fill up by some date (not announced yet this year), they open up registration to anyone. Email questions/requests for more information directly to me so as not to take up any more space here. Send to: ccastell@eldec.com

ignore whatever my mailer says my return address is. (I am a yearly participant in the race camp, not an organizer, so I have no financial interest in the program other than having spent money on it!)

From: CCASTELL.UNIX11@mailsrv2.eldec.com (CCASTELL)  
Subject: Slow WYeast Growth

I have packet of Vintner's Choice (WYeast) Champagne yeast from last September. I've had it in the refrigerator until I could find suitable apple juice to make this year's cider. (Actually, I've had a tough time finding suitable juice this year, so I guess I just go with what I have.)

I whacked the pouch the evening of 2-2. By morning on 2-3, there was SOME growth. By morning of 2-4, it was where it normally would have been after 12 hours. Now on 2-8, it has hardly changed since 2-4. The envelope is not tight at all, and I am in no fear of going home and finding yeast all over the walls of my kitchen.

Prior experience with beer and champagne WYeast has been similar to what has been reported here, namely that the activity seemed strong in spite of an extra month or three. Since nothing has happened lately, should I:  
1) assume the nutrient isn't nutritious, and pour it into some starter?  
or  
2) toss the packet, not wanting to throw good cider after bad yeast

Subject: Irish Red Ale (again)

Ulick Stafford writes:

> Guy McConnell reproduces a blurb from Coors' about Killian's Red.  
> Much of it is true other than the fact that it paints Old Adolphus  
> and family as being something other than Ogres.

Well, I didn't reproduce anything except nuggets from a fading memory. I don't even recall for sure where I came by this information but it wasn't from Coors directly. I called Coors a "kindhearted" megabrewer, an oxymoron if ever there was one. I even put in the quote marks as above. I mentioned the fact that Coors had removed virtually all of the beer's character and decided that it should be a lager (I'm still not sure about that part - \*was\* it an ale when it was brewed in Ireland?). I also mentioned that micros and homebrewers were responsible for reviving the Irish Red Ale style, much like porter. I don't credit Coors with doing anything except making Killian's fit in the American mass market by sucking the very life out of it. That is why I would violently oppose Budweiser getting their hands on the real Budvar. The one saving grace of Coors is that they are the only megabrewer still producing a decent, all barley beer, albeit seasonally, in Winterfest. We couldn't even get that here in Huntsville this year. I don't count Miller's "Special Reserve" because there is not a dime's worth of difference between that and "Genuine Draft" in spite of the "all-barley" hoopla. How anyone could use all barley and produce a beer so lacking in any sort of beer character is beyond me. I guess I expected too much. Anyway, I was being quite sarcastic in my treatment of Coors' motives and if I painted them as "less than Ogres" it was not intentional.

By the way Ulick, I found your posts on the state of Irish brewing most enlightening. It is a shame that the producer of so fine a beer as Guinness Stout would use such tactics to keep a stranglehold on the market.

From: korz@iepubj.att.com  
Subject: Sanitizing counterflow chillers/All-grain snobs

DLAMARPL writes:

>Several sources indicate the hazards of using alkaline solutions (e.g.  
>chlorine) to sanitize copper. None I have seen, however, suggest  
alternatives  
>other than boiling. What are effective sanitizing agents for equipment  
that  
>cannot be boiled (e.g. counterflow wort chillers)?

Ahh, but you *can* sanitize a counterflow chiller with boiling water.  
Boil  
up some water and siphon it through the chiller with the cooling water  
turned  
off.

\*\*\*\*\*

Regarding all-grain snobbishness, I'd like to say that indeed, it's a  
stupid  
thread and those who still care about it should all take it off-line.

But before we do, I want to get in my two pence ;^):

I spoke with Jack yesterday at the CBS US Ale Fest at Goose Island and it  
appears that he has gotten lots of private email regarding his post. I  
feel that this is the best course of action when you disagree with a  
person's  
post in the HBD. Let's not all overreact here. I agree that Jack's post  
took an abrasive tone but so did Greg's. Are we counting wins and losses  
here? Let's not let our egos get in the way of brewing beer. Let's not  
take every post as some kind of life-threatening situation. It's not.

Personally, lately I've been so busy these days (I've recently opened  
a homebrew supply store *in addition to* working at AT&T) that it's hard  
to find the time to brew an extract batch let alone the time to brew  
all-grain, so virtually all my recent competition entries have been  
extract beers. In fact, my last 12 prize-winners were all extract +  
specialty grain beers. It just goes to show that good beer *can* be  
brewed without mashing.

Note that I asked Micah (in private email, via Bob Jones) to give me sources for more info on this "need for lipids," but I guess he was (understandably) too busy with his new venture. It's not that I don't trust Micah, but when someone introduces something so different from what I've read before (why haven't I read \*something\* about this before?), I have a tendency to doubt first and read up on it. Can anyone (George? John? Mike?) substantiate this "need for lipids?"

From: WESTEMEIER@delphi.com  
Subject: Extracts knobs / overkill

On the subject of extract v. all-grain, I can't resist adding a data point. I've been a homebrewer for five years, all-grain for three. I have a friend who has been an extract/adjunct grain brewer for 15 years. I would give a lot to brew beers as good and as consistently as he does. It's practice and technique, I think, more than ingredients and method, that make for success.

On another topic, I'd like to thank Alan "Overkill" Edwards for his tables, charts, curves, and assorted efforts to put nice, neat numbers to our squishy, seat-of-the-pants approximations. I certainly appreciate it, and so do the other members of my local club.

From: Kieran O'Connor <OCONNOR%SNYCORVA.bitnet@CUNYVM.CUNY.EDU>  
Subject: I need info on a research paper!

Hi all,

I am working on a research paper for my MA in History. I sleazed a coupling of brewing and research and managed to convince my professor that a paper on the consolidation of the brewing industry would be a good topic.

What I'd like to write about is how the United States, chiefly through prohibition, changed form a country with many breweries to one with a few super regionals and national breweries.

I'd also like to look into the resurgence of micro-brewed and homebrewed beers as a result of the bland offerings of the commercial giants.

I guess what i could use is some help in some sources. i can certainly search the New York Times index, and I've done some searching for texts. Any thoughts on places to look?

I will be sending letters to the Federal Bureau of Alcohol, Tobacco and Firearms (hopefully they wont haul me away on COPS) :-(. Could folks help me with addresses for the big breweries? Or other places out there which might have a treasure trove of material? Anything at UC Davis?

If anyone is initerested--I'll gladly upload a copy of the finished product--as long as I earn a decent grade ;-).

Thanks for all the help--could you reply via personal mail or via this forum with the header of "BREW PAPER". It makes life a lot easier. Thanks in advance.

Kieran O'Connor

From: dcheck77@Jade.Tufts.EDU  
Subject: Shipping Homebrewed Beer?

I am almost considering myself an amateur brewer at this point, having brewed two batches so far (both coming out surprisingly excellent -- luck?). I'm brewing up in the Boston area (Framingham specifically), and I was looking to send (heh heh) some of my beer to Santa Rosa, CA.

- a) Is this legal?
- b) Possible?
- c) Advisable?

If anybody wants to laugh at me directly, or possibly enlighten me as to some great news about my shipment dilemma, please do.

Thanks much,

From: SynCAcct@slims.attmail.com  
Subject: Whole Hops

In HBD1071 I posted a comment regarding leaf hops in reference to the loose hops I was purchasing from Freshops (not named in the post) and information I received indicating that they were sweep-ups because they were loose petals instead of whole cones. I received this email from Glenn Tinseth and am posting it with his permission.

I will continue to use Freshops with no reservations tnks to Glenn's legwork.

I continue to be baffled as to why some brewers insist that their methods or opinions are exclusive. I have a hard enough time with life without this kind of crap in my hobby.....Glenn Anderson  
gande@slims.attmail.com

USUAL DISCLAIMERS.....

\*\*\*\*\*  
To: internet!attmail!slims!gande

Glenn,

First of all let me compliment you on your name. I am a not yet prominent west coast hop retailer (The Hop Source) who deals exclusively in whole hops, imported and domestic. In a recent post you mentioned some alarming info about a "west coast hop vender" that you had received from the salesperson who sold you some Saaz hop plugs. I am a competitor with Dave Wills (Freshops) if that's who you mean, and would benefit if his business diminished. That being said let me tell you the following.

What you were told is complete and utter bunk, Freshops buys whole bales from Hopunion and repackages them in ziplock baggies. The floor is never involved except as a place for the person filling the bags to rest his/her weary feet. I suspect that the person who told you this does not know what they're talking about and may have a grudge against Dave although I can't imagine why. I really did check into this and representatives from Morris Hanbury, Hopunion, and GW Kent all said virtually the same thing, that the person who told you this is misinformed and also not a very nice person :-0

Whether or not a hop cone breaks into a bunch of loose bracts is dependent on many factors including the care the grower takes in harvest and drying, the subsequent handling received at the hands of the broker, and even the variety and weather conditions. I get hops directly from the UK (actually they are the hops that go into the 1/2 oz plugs) and they range from quite broken up to pretty whole depending on the lot and the variety. In any event there is \*no\* loss in brewing value when a hop breaks into pieces although it is definitely less aesthetically pleasing ;^)

Since you didn't mention the name of the hop vendor or the salesperson, I decided to e-mail this, if you want you can post all or part. I \*am\* very interested in knowing who said this so if you are OK with it let me know. There is no room for this kind of crap in this industry!!

Wow that feels lots better getting this off my chest. Thanks.

Take care,

Glenn Tinseth

From: David Schleef <dschleef@lclark.edu>  
Subject: Paulaner Hefe-Weizen

The yeast in the bottom of imported and domestic bottles of Paulaner is very hard to re-propagate since all Hefeweizen at Paulaner is pasturized. This piece of information I know as a fact, since working on the bottling line (and in the brewhouse) was part of an one-month internship I did last March at Paulaner. I donot know, however, the exact difference between the yeast used for bottling and the yeast used in the primary ferment (never thought to ask) but I would imagine that the bottling yeast is a special bottom fermenting strain and the primary yeast is a top fermenting weizen strain.

From: thutt <thutt@MAIL.CASI.NASA.GOV>  
Subject: Garumph. Enough with 'real brewers'!

In regards to the vapid discussion about 'real brewers', let me pose the following questions.

- o Do you drive?
- o Do you know how to set the points for your car?
- o Can you overhaul your engine?
- o Do you know how to do brake work?
- o Can you use Bondo? (have you tasted it?) (can you get the catalyst off your hands? if so, how?)

If you have not answered 'yes' to all these questions, you are obviously an amatuer driver, and a danger to those of use who CAN, and DO, all of these things. Please stay off the road.

My point? Get a life people.

This is getting to be more stupid than alt.sex.wanted. There are different levels of interests for hobbies. (ex: My mother collects porcelain dolls. Other people collect barbies. Both collect dolls, but neither is better nor worse than the other).

You began making beer because of some personal reason, for your own consumption. Quit comparing yourself to other people. If you are happy with the beer you make, then drink it, and share your experiences.

If you are not happy with your beer, give it away, tell us what you did wrong, ask for advice on how to fix it, and share your experiences.

The discussion on bees was much more entertaining that this crap.

From: Jim Grady <jimg@hpwarga.wal.hp.com>  
Subject: hbus & ibus

First of all, thanks for all the charts and formulae for hbus -> ibus given boiling time, S.G., etc. I do still have a question however. I have seen that pellets have different utilization than whole hops (both in this forum and in some of the homebrew books); indeed hop plugs have yet another utilization rate. Yet, none of the charts nor formulae contain any reference to the form of the hops. Does anyone have any suggestions here? Am I worrying too much? Should I just use what I have as a starting point and see how I like the results?

>Fm: Jim Busch

>PS: to JS- My lauter tun/open fermenter does indeed have a spigot. The only problem with taking ferment SG readings is that what comes out is yeast sludge!

True but my "QC" samples were tongue in cheek. They never get near a hydrometer. The first squirt is a bit yeasty but with the you-know-what screen at the other end of the spigot, I get a fairly clear "sample" to taste.

>From: neilm@juliet.ll.mit.edu ( Neil Mager )  
>Subject: Special Archive Proposal

Let me make another proposal. How bout explaining what an archive is and how one goes about accessing it before you expand on a special archive.

.....

> Various, Snobs...

Again, I am forced to defend my statements on "all-grain snobs" but prefer to do it without personal references because this thread is simply going the wrong way again. I am sure that I could benefit from sensitivity training but I wasn't able to sell my business at 40 and retire to a life of leisure because I was a fool or a tyrant. One key to success is to find out what people really intend, want and mean and not try to explain to them what they mean.

I listed many reasons why people make extract or all-grain beer, some positive and some negative and some with a value to be assigned by the brewer or reader. To isolate the meanest and thrash the messenger with it is not only unfair but deflects the discussion into an endless stream of useless personal attacks instead of getting to the bottom of the issue.

Viz..... The economics is one major factor in the issue and it certainly is true that one can make a batch of extract beer with less initial expense than a single batch of all-grain beer.

However, as one refines his extract process, he ends up within a few dollars of an all-grain brewery. When you get right down to it, the only thing one

really needs to do all-grain is a large enough kettle to boil it in.  
These  
are available for \$30 at ACE Hardware and \$5 more will get you a  
homemade  
Easymasher in the same store. I am sure if one haunts garage sales, one  
could get it down even further. That and less than \$10 for ingredients  
will  
put you in the all-grain business. Most of the rest of the gadgets  
and  
gizmos are just as useful and important to the serious extract brewer as  
they  
are to the all-grainer.

One final point, I posted the same article to Compuserve and received  
not a  
single negative comment. Again, I am not sure what this portends but it  
is  
food for thought.

>From: "Rick (R.) Cavasin" <cav@bnr.ca>

>My incentive for using an iodophor was the hope that it could be reused  
more  
than bleach (iodine less volatile than chlorine?) and hence less would  
go  
down the drain (and into the air I'm breathing!).

Precisely my reason (breathing) for trying it. That is, in addition to  
the  
fact that I got a free sample in the mail. However, I don't think that  
it  
has anywhere near the useful life of bleach.

I do not feel comfortable with the 1 minute contact time with a  
sanitizer so  
I always used bleach full strength or at least 50:50 and I use this  
stuff, 1  
oz to the gal. There is no shortage of clean water around here so I  
have no  
qualms about thorough rinsing.

I don't like the chlorine fumes and I usually wear a respirator when  
doing a  
keg or my pump and hoses. I like being able to do a simple one time  
rinse  
with the iodophor and not having to worry about the fumes or pitting my  
kegs.

I was a bit disconcerted when a fresh batch came through the pump almost  
clear. I suspected oxidation so I did some experiments by shaking  
samples in  
closed testubes and the color does not change no matter how much or over  
what  
period I shake it.

I have no idea where the iodine goes or why it changes color. The is  
not  
enough water in the system to dilute that much.

I guess, untill I have a bad batch of beer, I will continue to use it.

As as aside, I tried using it for the starch test and it is totally  
ambiguous  
and unsuited for the test.

Subject: Malted Barley

OK,

I've got my 10 gal. cooler with false bottom and associated plumbing, I've got my 8.5 gal pot, and I've got my immersion chiller: I guess I'm ready to mash. I am going to get 8-10 lbs of British Pale Ale malt this weekend and do "it". However, I recall (please pardon my poor memory) a thread (hey, a real thread and not a flame thread!) pertaining to high quality malts (Belgium?). Could someone with a good handle on that thread please point me to the appropriate HBD issue numbers or email me a summary. I am interested in using these malts. Also, could someone post or email this newbie a description of what comprises a high quality malt (proteins/nitrogen/modification/?)

i.e, what are the important factors. Are all malts fully modified these days? How do you determine this information?

Hey BadAssAstronomer, how about a few bottles of my first all-grain batch?

Subject: DAB recipes? Yeast Culturing, and others.

Does anyone have a recipe for a DAB beer clone? If not, do you know what IBU it has? What type of malt/hops would produce that flavor?

Secondly, what is the general concensus on Bigfoot Barley Wine? I tried it, and felt that it tasted EXACTLY like SN Pale Ale, only more alcoholic; I was not impressed... I expected something different. Is this how a BW is supposed to taste?

Could someone provide me with the number to one of the science houses that sells flasks & test tubes?

Does anyone have any 'caveat emptors' for the mail order places that are advertised in Zymurgy? (Are some less reliable than others? I've noticed some strange variations in price too...)

I've also gotten a book published by G.W. Kent on Culturing Yeast that should be avoided, if you like the English language. The book seems to be technically correct, but is so full of errors (bad editing, grammatical errors) that I will probably write a nasty letter of complaint to the publisher (it's in its third!!!! printing, and it STILL has this many errors).

From: orgasm!davevi@uunet.UU.NET (David Van Iderstine)  
Subject: Re: Spiced Ales, DME vs. syrup

In HBD #1073, Jonathon Knight asks:

|>has anyone tried BOTH the technique of adding whole spices at some  
|>point to the boil AND adding powdered spices at the end of the boil?

I used to add whole spices somewhere mid-boil, and found that, for some of the spices, their aroma/taste was being boiled off, particularly things like orange zest or vanilla. Others, like ginger, would last through and overwhelm completely. I tend to steer clear of ginger now, both `cuz it easily overwhelms, and I just don't like its flavor!

I switched over to powdered spices near the end of the boil (5-8 minutes) and am much happier with the results now. It has become very easy to get consistency from batch to batch with this method, I find. I've settled in on a particular recipe of my own creation which I have made several years running now, and I can be assured it'll "taste right" when done.

There may be some dispute, though, over just how fresh powdered spices might be, and that'd I think affect their utilization in the wort. The only advantage I can see to whole spices over powdered is this "freshness thing". And for certain spices, like orange zest, there is no powdered alternative, nor need there be. Add that one near the end of the boil for best results. And be aware that "oily" spices, like coriander, will severely affect head retention and even bottle conditioning (carbonation) - that is, really retard it!

Finally, I find it easier to control quantities with the powdered versions. And believe me, they're \*small\* quantities! Nothing over 1 1/2 teaspoons goes in, some as little as 1/2 teaspoon!

On the subject of dry malt vs. syrup extract-I use only Munton & Fison dry malt extract, have for 5 or 6 years, make great beer w/it, see no reason to change. Also, I buy it 55 lbs. at a time, to minimize cost. I go w/their lightest variety, & use specialty grains for flavor/color.

From: Ulick Stafford <ulick@schumann.helios.nd.edu>  
Subject: 3.2 a/w, Spaten Hefe Weizen, Never mind the full grainers, d

Tom Colvin regrets that only 3.2 alc beer is available in grocery stores in Utah. 2 points. That is not unusual even in more liberal states such as Minnesota. In Indiana 3.2 are not sold, but grocery stores need a licence to sell beer, and can't sell it chilled. And nowhere can sell it on Sundays, unlike in neighbouring states due to a bible belt part in the south. But at least it is cheaper than neighbouring states, and we don't have an inane law like MI's 10cent return charge (but why can't all beer sale laws and prices be like Wisconsin?).

3.2 is 3.2 by weight ~4% by volume, so it is not gruesomely weak. It is stronger than many European table beers.

Spaten usually sell Hefe Weizen under the brand name, Fransiskaner, which is readily available. I cultured from it once, think I got Krausen, but by the time I was ready to pitch, it was not lively and the culture seemed to have a aa tart lactic acid flavor, so I used a substitute (Fleischman's baking yeast - don't laugh the beer eventually was award winning), but I suspect with proper sanitation it is a viable yeast.

Never mind whole grain snobs, us decoctors look down upon them with an even more snobbish disdain - what they are too lazy to stir a thick decoction and spend up to 8 hours mashing (but then I only do double decoctions and I'm sure triple decoctors think I'm ignorant and lazy, and hop growers and barley malterers think they're lazy, and people who grow and harvest, and malt and mash their own barley and wheat and irish moss look down on them).

RE natural carbonation. I have had a hard time priming lagers even with sterile wort, canned from the batch. The perfectly cleared lagered beers have so few viable yeast cells that carbonations takes 3 weeks or more. I will just prime ales and will now krauesen lagers in future (and us krauseners look down with a snobbish disdain on primers - even those who prime with sterile wort and especially those who think they're krauseners because they've never read a book more advanced than Papazian's work, which of course us advanced snobs know, incorrectly defines Krauesening).

Subject: A New Journal

If you read the Celebrator this may be old news to you, but a new magazine devoted to the technical side of homebrewing, pub-brewing or microbrewing is about to make its debut. Called "Brewing Techniques", it will break new ground in homebrewing (as far as I know) by being an honest-to-goodness "peer review" journal. The Editorial Advisory Board (the peers who do the reviewing) consists of Patrick Baker, Byron Burch, Fred Eckhardt, Teri Fahrendorf, George Fix, Terry Foster, Mary Anne Gruber, Dave Miller, Greg Noonan, David Ryder and Bill Siebel. Impressive! The clear wort of usable brewing information certainly seems unlikely to be beclouded by the trub of unsupported speculation presented as fact, with a panel like that reviewing submissions.

The magazine will be published 6 times a year, at a subscription price of \$30. For an unspecified time there will be a \$24 introductory rate for "charter" subscribers. To subscribe, send a note with your name and address information to:

Brewing Techniques  
P. O. Box 3076  
Eugene, OR 97403

You'll be billed after the release of the first issue, scheduled for May. To discuss advertising rates or editorial questions, call Stephen Mallery, Editor, at 503.683.1916.

I think this may be the magazine many of us have been waiting for ...

Subject: Chinook hops

Kevin says:

> ObBrewing: No takers on my question about flavor/aroma properties  
> of Chinook hops, huh? Do any commercial brews use them?

The books I've read seem to disdain the use of Chinook for aroma and bouquet. I've used 'em for both bittering and aroma and don't recall that the results were particularly good or bad. The complaints are harshness and poor storability, if I recall.

Centennial is far superior in my opinion. Try dry-hopping with a half and half mixture of German Hallertau and Centennial. Fragrant, fresh, and yummy. Wow!

Subject: fining -> diacetyl

Lee M.,

I'd vote that adding finings early on in the secondary is what is causing the high diacetyl in your beer. In fact, this is just what happens

with Samuel Smith beers, except their yeast flocs out because of the nature of their slate fermentation vessels. Give the yeast more time in suspension in the secondary to reduce the diacetyl.

Another source of high diacetyl is low oxygen levels at the beginning of the primary ferment. If your ferments are slow or weak, and finish with a high final gravity, this may also be adding to your problem.

Russ G.

From: Richard Stueven <gak@wrs.com>  
Subject: A Beer Odyssey (Act I)

## A Beer Odyssey

I don't much like sweet beers. The Brown Ale style is not one of my favorites. I'm not so much a hophead as I am a "malthead". I like beers heavy, fairly dry, and very well-balanced. Bitter is fine, flowery is right out. (I point this out so you'll have a handle on my perspective later on. Beer with me!)

Having said that, one of the best beers I've ever tasted is Downtown Brown Ale, from Lost Coast Brewing in Eureka. It's just sweet enough, with just the right level of hops; it's one of my favorite beers of all time.

I had my first taste of Downtown Brown Ale at the 1992 Fort Mason Beer Festival in San Francisco, and I've enjoyed it at a number of festivals since then. I had always determined to visit the brewery and sample their beers firsthand, and one particular weekend in August was finally the right time. My plan: drive from San Leandro to Eureka on Saturday, visit Lost Coast in Eureka and Humboldt Brewing in Arcata (as long as I'm there), spend the night in Eureka, and drive home Sunday morning. Simple enough.

The Friday before the trip, I met my friend Jake at Brewpub on the Green in Fremont. We talked about his recent trip to the Hockey Hall of Fame in Toronto, we had a great dinner (they make some fine hamburgers there, honest!), and we had a taste of all of their beers:

Wheat - 4.0%. Seems to be an American style, but hints of Bavarian (clove) character. Maybe a wheat lager?  
Lager - 4.2%. Same characteristics as Wheat, but not as sweet.  
Amber - 4.2%. Nice color, fruity like an amber should be. Good stuff. Very slight Irish moss (?) flavor.  
ESB - 6.0%. Just like the Amber, only more so. The alcohol really comes through in the flavor.  
Porter - 5.0%. OK - rather light and benign. ("Benign" being the opposite of "assertive".)

Like many of the microbreweries, the brewers at Brewpub on the Green have really improved their beers over the last year or so. So many breweries were making...well, bad beer a year or two ago, and those same breweries are making some of the best now. Brewpub on the Green is no exception.

At eight o'clock in the morning on Saturday, August 15, I got in my trusty Cougar and hit the road. I fought the early weekend Bay Area traffic and headed north on US 101. As usual, I skipped breakfast... why should today be any different? (Little did I know...) Around ten o'clock, I was feeling mighty dry. I checked my map for potential lunchtime stops...and there it was! Just an hour away - the Mendocino Brewing Company of Hopland, California! I had been there before...good beer, good food, and most importantly today, perfectly placed for a lunchtime respite!

I drove into Hopland around 10:45, just a few minutes before opening time. I waited in my car, checking my Celebrator and my map for any more potential stops on the way to Eureka. Hmmm...Anderson Valley is

out of the way, and North Coast is even further. Too bad.

Magically, the clock struck eleven...it's opening time! And would you believe the added bonus: it was the brewery's Ninth Anniversary. The party started immediately; the barbecue was fired up, and the Eye of the Hawk Ale was flowing. There was a geezer at the bar (named "Norm", appropriately enough) who claimed that he had been there every day since the day the place opened. There was a camera crew working on a documentary of Northern California brewpubs. I tell ya, the place was hoppin'! For lunch: a barbecued buffalo steak, done to perfection. I had a round of samplers to go with my lunch:

Peregrine - Thin, yellow. Very light. Certainly a good "transition" beer, useful for the re-education of drinkers of industrial beer.  
Blue Heron - Somewhat better. Slightly more body and flavor, little aroma.  
Red Tail - OK amber ale. Good color, flavor not as strong as it could be. MUCH better on tap than bottled!  
Black Hawk - Good black thick roasty. A little sweeter than I like, but good enough for serious quaffing!  
Eye of the Hawk - I need a pint of this to tell if I really like it.

My pint of the Eye of the Hawk Ale was really remarkable. It's their "special" ale, brewed only for special occasions like today. It's an outstanding, full-bodied ale, darker than the Red Tail, and with a similar but much more assertive flavor. It's too bad this is such a rare beer.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: hops plugs & G.W. Kent (NOT!)

I was at G.W. Kent on Saturday, so I asked them about hops plugs. Randy said they had added them to their catalog this year, but then were unable to get any from the supplier. Something about a bad crop this year. So, G.W. Kent is not shipping hops plugs at this time. If you thought you got some with the G.W. Kent label, you must be confused. The only ones I've seen are imported by Crosby & Baker.

He also said that as far as he knows, any plugs on the market now must be from the 1991 crop. If this is true, then my experience with plugs speaks very well for their keeping ability. As I said yesterday, the plugs I bought recently had the freshest hops I've ever used.

Subject: Re: Wet dream/ridding oil from plastics

Jack writes (quoting Paul):

>Bacto WL Differential Medium has the same formula as Bacto WL  
Nutrient Medium, with the addition of 0.004 g of Actidione per  
liter. This inhibits the development of yeasts without  
interfering with the development of bacteria generally  
encountered in beers.

A most enlightening article. However, if this is in response to the  
discussion about a medium that rejects or encourages "wild yeast", it  
seems

to confirm my opinion that such a medium is a wet dream.

I believe another poster mentioned that the media which contains the  
Brom Crestal Green (sp?) will identify different yeast strains because  
each has its own characteristic pH, thus being stained a slightly  
different  
shade of green. This is the key to the isolation of yeasts using this  
media. But you can still have wet dreams about it if you wish... ;^).

Subject: Worst brew

Tim Anderson's discussion of "bucket conditioned beer" sounded a whole lot like the first time I fermented something (on purpose). A couple of suggestions from my experience:

1. Steal the sugar from a restaurant packet by packet.
2. When the flavor of the brew prevents it from being consumed, add some unsweetened lime Koolaid. (I did this before Jonestown made lime Koolaid famous... or was that grape?)

Brian writes:

>The Problem: I have no idea as to what variety these hops might be. We  
>live in the infamous Willamette Valley, so I at least have the obvious  
>first guess. Does anyone out there know of a good reference book that  
>would allow me to key out this beast. Perhaps a "Peterson's Field  
>Guide to Hops and Grains."

I suggest the Hops Special issue of Zymurgy -- in it there are photos of  
virtually every common hop cone and it's corresponding leaf. Since you  
live in the Willamette Valley, I suggest that you make use of the wealth  
of local knowledge. Take some cuttings to a grower and ask them to  
identify. I'll bet that the big commercial facilities have extensive  
libraries too.

>Other Questions: Papazian suggests that the soil for growing hops should  
>be loamy and kept continually moist during the growing season. We have  
>excruciatingly high clay content in our soils and have never watered at  
all.

I give each plant about 6.25 gallons of water every morning via a  
timer-controlled soaker hose. Water makes a big difference. Initially,  
I gave each hill (4: Hallertauer, Hersbrucker, Nugget and Willamette)  
three 1 foot coils of soaker hose for 15 minutes per day. I soon noticed  
that the Willamette was doing much better than the Nugget, which was  
doing  
better than the Hersbrucker, etc. I noticed that the soaker hose was  
spewing more at the near end than at the far end (I should have known).  
After re-arranging the hose to give the far-end hills more hose, the  
growth rate seems to have evened out.

>Nevertheless the plant has done quite well. Will the quality of the  
>hops be affected by my lack of care? Or should I follow the adage "If  
>it ain't broke, don't fix it?" Also, how much will AAU vary with time  
>of harvest, amount of watering, etc. And lastly, is there any  
moderately  
>low-tech way of determining AAU of homegrown hops?

If you pick too early or too late, you will not get as much AAU as if  
you picked at the right time. It seems to me that the general consensus  
is that when the cones begin to feel light, springy and papery as opposed  
to  
heavier, smushy and damp, it's time to pick. I found that not all the  
hops are ripe at one time. I just set up a ladder and picked-off the  
ripe  
ones once per week.

I've asked about low-tech ways to determine %AA and the only one I could  
come up with is brew experimental batches and use your tastebuds. If  
someone knows how to determine %AA using simple chem, please post!

>cinamon sticks and whole cloves for about the last thirty minutes. It  
>has a bit more bite than I intended, although the beer does taste quite  
>good. I am wondering whether I boiled the stuff too long and whether  
>powdered spices at the end of the boil would produce a "kinder, gentler"  
>brew.

OK, some more opinions:

- 1) Why should it make a difference whether the spices are powdered or  
not,  
as far as your question goes? Does it assume that all the spices are  
left in the brewpot and none get into the primary?
- 2) I am now firmly convinced that the only way to add spices is to "dry  
spice", by adding the spices only to the secondary. After all, we  
know  
that the amount of flavor and aroma contributed by hops boiled a long  
time is much less than that of hops boiled a short time or hops not  
boiled at all (dry hopping). Why should spices be different? And  
since  
I only use spices for flavor and aroma, I dry spice.

Did a real nice job on my Pumpkin Pie Ale. Plus, you don't have to use  
powdered spices if you don't want to, just let them sit longer in the  
secondary.

>forget which, but I think it is 3. If you plate it and isolate a  
>single cell for building a culture, you will only get one of the  
>three.

To the best of my memory, every source I've read says that Chimay is brewed from a single yeast strain. It has been widely publicised that Father Theodore was the man who isolated Chimay's current fermentation yeast and really cleaned up the beer. I've read somewhere, perhaps the bottle, that Chimay adds yeast during bottling - -- I recall that there was no mention from this source of whether the yeast added at bottling time is the same as the fermentation yeast or different. Nor do I recall if they mentioned filtering out the fermentation yeast. The bottling yeast may be the same as the fermentation yeast since maintaining two strains of yeast is twice as hard as maintaining one and it's not like the bottling yeast in Chimay is a particularly good flocculator (like SNPA's yeast is).

Orval is brewed from a single yeast also, but then bottled with a mixture of 5 yeast strains. My source is one of the Jackson books (either the pocket guide or the New World Guide to Beer... I suspect the latter). I feel, from my experiments, that one of the 5 bottling strains is the fermentation strain, the one that produces the characteristic banana/bubblegum nose of Orval.

Another multi-strain yeast is Whitbread. George Fix wrote this quite a while ago that Whitbread is a three-strain yeast. My cousin has noted that along with the change in bottles, Whitbread Ale has lost that characteristic "dark bread" flavor. I have yet to verify this. Anyone else notice this? Note that Wyeast #1098 bears a striking resemblance to Whitbread yeast ;^).

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Malting Wheat

Does anyone out there know anything about malting wheat?

I buy (unmalted) whole wheat (for baking purposes) for about 15 cents a pound. Looking at this the other day, I thought I could make some decent Weizen if I could maybe get a small batch of the wheat malted. In addition to expanding my skills as a brewer, this would save me a bundle over what my homebrew supplier charges for malted wheat (about \$1.50 per pound - an order of magnitude higher!) Anyway, I tried malting a little the other day, and found it hard to determine when the grain was fully modified. The "steely-mealy" test (mentioned, I believe, by Miller) does not seem to work here. The grain, when wet, is soft and mealy, but is completely steely when dried. I even tried mashing several ounces of this malted wheat in a "micro-micro" mash tun (along with about 33% 6-row barley malt), but got very poor conversion.

Does anyone have any experience with this, or know any good references? Email me, and I'll post any significant/interesting information, as well as let you know if I have any success with this. (Or does anyone else really care?)

Too busy to make a fancy sigline...

From: chuck@synchro.com (Chuck Cox)  
Subject: BBW wins again!

Here's an update on the Sam Adams vs Boston Beer Works nonsense.

Jim Koch (dba Boston Beer Company, aka Sam Adams) lost his appeal in Federal District Court. Koch has the right to appeal again, and given his attitude he is likely to do so. His lawsuit against the Commonwealth Brewing Co is still pending.

I wasn't at the trial, but I heard that Koch presented witnesses who claimed to have gone to the BBW, disliked the beer, and blamed it on the BBC. Under cross-examination they were all discredited. One admitted to being too drunk to remember any details of the visit. Another objected to a 'foul aroma' which turned out to be the smell of a batch being brewed (something Sam Adams fans generally have to go to Pittsburg to experience). Like the original suit, the ruling on the appeal was quick and decisive; Jim Koch does not own the word "Boston".

So what happened to me?

Koch never followed up on the subpoena they served me. We had to reschedule it, and they never got back to me with a new date. I think they lost interest when it became obvious that I am not an employee or representative of the Beer Works or the Sunset Grill, and that I was hostile and well-prepared. I got to keep the \$46 federal witness fee, and Koch had to spend some money to file & serve the subpoena, so I did my part to waste Koch's money.

I am still boycotting Sam Adams products, and I urge you all to do the same. Since Koch has introduced more lawsuits than beer styles in the last year, I think it is safe to say that the Boston Beer Company is a law firm and does not deserve to call itself a brewery.

I want to thank you all once again for your letters of encouragement and outrage. I had intended to keep them all in defiance of Koch's subpoena of my personal correspondence, but I ran out of disk space and had to delete them.

By the way, I never heard from the person who is forwarding my posts to Koch. I am not surprised. It is obvious that the weasel doesn't have the spine to stand up for his/her own actions, typical for a Koch crony.

To Koch & his email droid: You are both losers, and the brewing community would be better off without you. I will continue to publicly criticize your business practices, and encourage consumers to boycott your products.

I am thinking of starting a new brewery, "The Adams Family Boston Brewing Company". Any interested investors? Any interested attorneys?

(for those who recently tuned into the HBD: Jim Koch has taken to suing any brewery that uses the word "Boston" in the company name or on any of their products. I, and all my personal correspondence referring to local breweries were subpoenaed by Koch in his appeal against the Boston Beer Works. I have no affiliation with the BBW except as a satisfied customer and friend of the owners. The subpoena was pure harassment meant to stifle my outspoken public criticism of Koch & Co.)

>the yeast to prematurely fall out of suspension thus reducing the  
>quantity and the time in which the yeast was reducing diacetyl.

BINGO. That's your problem, IMO. I feel that you don't have to add  
the finings to generate CO2 production -- by the time you are transferring  
to the secondary you already have some CO2 dissolved in the beer. When  
the beer travels over the top of the siphon hose (just past the highest  
point)

it is at slightly a lower pressure and some of the CO2 will come out of  
solution, taking up your head space. Another method, is to use your  
kegging setup to squirt a bit of CO2 into the secondary before racking.  
It's heavier than air and will minimize oxidation \*during\* transfer too.

>What can I do to produce high levels of diacetyl and minimize its  
reduction

>if I want to brew something with a Samuel Smith profile? Is a warm  
>ferment with a yeast strain noted for diacetyl production and fining

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE: all grain snobs, diacetyl

Hi All,

Just my .02 worth on the issue of all grain snobbery. I think the whole debate is ridiculous. "All grain brewers are snobs" and "extract brewers are lazy, paranoid, and ill-informed" are both groundless, sweeping generalities, neither position is logically defensible.

IMHO, any person who cares enough about good beer to spend the time and effort to brew thier own is a kindred spirit. Slowly but surely, the level of beer consciousness in this country is rising, which is at least partly attributable to the recent growth of the homebrewing craft. That said, what earthly difference does it make \*how\* the homebrew was produced? I for one am not going to turn up my nose at very good beer just because it was brewed using procedures that differ from my own.

\*\*\*\*\*

In HBD #1073, Lee Menegoni writes:

>I discussed my brewing process with an experienced all grain brewer

I should preface my comments by mentioning that I am this experienced all grain brewer. "Experienced" in this case is a relative term, I've been grain brewing for about 6 months longer than Lee, I've done perhaps 15-20 more batches than he. Having tasted his beers on many occasions (YUM!), I consider us as being at about the same point on the learning curve.

>2) Adding finings immediatley after racking to secondary.

I admit to being somewhat obsessive about clarity, I used polyclar when racking ales because I wanted crystal clear beer. While this achieved the desired effect, I did end up with noticeable levels of diacetyl. Polyclar is rather indiscriminate about what it scrubs out of the wort, it will cause the yeast to fall out of suspension quickly. This does diminish the ability of the yeast to reduce diacetyl.

>What besides pitching to wort at fermentation temperatue and finning after

>the yeast has settled or not at all what can we do to reduce the production

>of diacetyl and increase its reduction later? I still plan to artificially

>carbonate it seems to make for clearer beer and I can drink it sooner, 3

With my latest batch of ale, I did not use finings at all. Once the beer had fermented out, I racked to a keg, put a CO2 blanket on it, and left it

in the fermentation room at 65F for 2 days. My reasoning was that racking the beer roused some yeast back into suspension at a time when there were no fermentables, a favorable condition for diacetyl reduction, according to the Zymurgy troubleshooting issue. Leaving it at 65F for two days ensured that the yeast will not settle quickly, providing it with an opportunity to work on the diacetyl. I then chilled and force carbonated the beer as usual.

How well did this work? The brew has been conditioning since Sunday, should be ready soon. Lee, when you come over on Thursday night to pick up the yeast culture, let's tap it and see.

Ah, the joys of experimentation :-)

Cheers,  
Jim

From: mcharry@freedom.otra.com (McHarry)  
Subject: Enzymes and temperature

I know that enzyme activity varies with temperature, but I have never seen discussed whether one can run a mash up to the upper 150s to break down some of the starches, then drop back to 148 or so to finish off the dextrins. Does the higher temperature just favor the one enzyme system over the other, or is the lower temperature system actually destroyed? I have always thought the latter, but the literature is unclear, and it would seem the malting process exceeds those temperatures.

From: mcharry@freedom.otra.com (McHarry)  
Subject: Rye

I have been messing (literally) with a couple pounds of rye in my ale.  
The  
first batch I boiled the rye and dumped it into the mash. The rye failed  
to convert since it has a husk or membrane that failed to burst. This  
stuff needs broken up. I ran it through the Maltmill for the second  
batch  
and that worked much better, but-- when I dumped the spent grain into the  
garden I noted a darker area near the bottom of the bed. It was sweet!  
Apparently this stuff forms some gunky mass that needs roused into the  
sparge water a couple times after the first runnings. I shudder to think  
the yield I might have gotten had I known. As it was, I got 27.

-----

Date: Tue, 9 Feb 93 19:06:19 EST  
From: mcharry@freedom.otra.com (McHarry)  
Subject: Overnight mashing

I have been trying overnight mashing for the last couple batches, and I like the results. For the last batch, I doughed in with 130 degree water from the tap, did the protein rest, and added the rest of the water, still at 130. Then I popped the whole thing in a warm oven and went to bed. By morning the temperature had risen to about 163. I put the sparge water on with the coffee and had at it. The apparent time savings is great, and the extract seems just fine. Of course, this result is dependent on the size of the mash and the temperature your oven will hold. I find that a mash will heat just a little slower than an equal quantity of water, so put a pot of water in overnight and check the results. It might work for you also.

> I've heard that there is one right across the border in Kentucky, but  
> that is the only one that I have heard of.  
>  
> If you know of any in or around the Cincinnati area please send email  
> ASAP.

The brewpub you are referring to in Northern Kentucky is Oldenberg. They make some fairly good beers that you can get throughout most of SW Ohio and N Ky. Up here in Dayton (45min - 1hr from Cincy) there is the "Chickery" off I-675 on Ohio Route 725. They specialize in chicken (hence the name) and do it quite well. They also make three beers on the premises. I don't remember their names off hand but they have a red ale (pretty good), an American light pilner (standard stuff), and a wheat beer (never tried it). Food is great and the beer is good, worth the trip.

There is also a sports bar on Marshall Rd that has an Irish Ale made under contract with Oldenberg. The place is called Harrigan's. They have typical bar & grill food as well. Major meat market on Thurs night.

Subject: Clarifiers and dry-hopping

Hello all, I brewed up a batch a couple of weeks ago and, due to too much HB being imbibed during the process, I forgot to add my usual dose of Irish

Moss during the boil. No big deal, I thought, I'll just use some kind of clarifier before I bottle. Yesterday, looking at my beer sitting in the secondary, I thought about dry-hopping it. This leads to some questions. First, what is the best kind of clarifying agent (are there really any differences between using Isinglass, gelatin, or something else)? Second, will I run into any problems dry-hopping and using a clarifier? I plan to use pellets (in case that makes a difference). Finally, am I correct in assuming that the clarifiers only have an effect on the proteins, and that it will not affect yeast availability for bottle conditioning?

thanks,

Jay

Subject: Lipids in wort

Most of the research on the lipid in wort topic was done by Micah. One of the references used was Declerck. This rather rare text is full of good info.

You may be able to check out a copy from your local library via an inter-library loan. I would really like to have a personal copy for my library, I would also like to have copies of both volumes of Malting and Brewing science. If anyone has unwanted copies for the RIGHT price, please

email. There is a more polished discussion of this lipid topic in the last issue of Zymurgy that Micah and I wrote, complete with references.

From: steve\_T%fleurie@champigny (Steven Tollefsrud)  
Subject: Licorice for better head...

I have a couple of homebrew books which suggest using licorice as a way of promoting better head in beer. In a pharmacy here in France I was able to buy what they call reglisse, which are shriveled up sticks of wood (or root?) with a darkish nut color. They are about 5 inches long. My question is this, is this what I should be using or should I use the sort of black licorice sticks we used to gnaw on when we were kids (which is mostly molasses, I think)? I tried the woodish reglisse (half a stick, pulverized) in my last two batches and had good head, but I'd like to know if this can be attributed to the licorice I used, or if it might be the fact that I used unmalted barley in my wort for the first time (contributing proteins for better head retention?). The problem is I've got two variables and I don't know which helped.

If anybody who knows about licorice in brewing can advise me, I'd be much obliged.

From: THOMASR@EZRZ1.vmsmail.ethz.ch  
Subject: re:wine digest.

hello again.

I've had four requests so far for the address of the wine digest. Well, I'm

going to have to disappoint you. I found a number of mail-ins at rusmv1.rus.uni-stuttgart.de (ip 129.69.1.12) a few months ago while browsing the vast archives they keep. However, since I already have more recipes and less storage space than I can use, I didn't make a note of where in the haystack the needle actually was!

I have a quick look today, and if you're feeling adventurous you might try /soft/kommunikation/news/spool/news and further down.

It is not beyond a shadow of a doubt that I was actually reading rec.food.drink or some such. I'm pretty sure it wasn't rec.crafts.brewing

though. Before you start chasing down the directories or getting teed off by being continually forbidden entry to the (VERY POPULAR) site, I'll let you know that the posts I read were very light on info and rather heavy on banter. This may have been an exceptional selection that I read, but you have been warned.

Rob TH.

p.s. I'll pass on any info I may remember/rediscover as soon as I do.

Subject: A Beer Odyssey (Act II)

A Beer Odyssey (Act II)

And up the road I went, and boy is it a long way to Eureka. I can hear the Downtown Brown calling me through the redwoods. By three o'clock, I was there.

It's a nice place, Lost Coast, with a lot of seating upstairs and downstairs, and a long brass-covered bar. A sign on the wall announces that the brewery was established on July 13, 1990; Friday the Thirteenth! I hope good luck stays with this place, because they make some of the best beers around.

The bar was nearly empty when I arrived, so I got to talk with Marty behind the bar for a while. I asked him if they had beer available for takeout in the plastic gallon jugs like many of the other California brewpubs. He told me that the Department of Recycling told him that those containers are illegal! I find this very hard to believe, because I've been to too many other breweries that offered this method of takeout, and I named many of them for him. I wasn't able to convince Marty, though; he said that all he knows is what the government tells him. I'd appreciate any information that will set either him or me straight.

I had a sample of each of their beers to wash down some mighty fine (mighty HOT) Buffalo Wings:

Pale - Very good pale, heavy body, light taste, well-hopped.  
Hefeweizen - Good smooth American style. Thick, just sweet enough. VGI. (Very Good Indeed!)  
Dunkel Hefeweizen - Very caramelly. If my memory serves me, doesn't it taste a lot like the Brown?  
Brown - Nope, the Dunkel Hefeweizen doesn't taste like the Brown at all...so much for my memory. Brown isn't nearly as sweet as the Dunkel Hefeweizen. An excellent brown! I like it better (side-by-side) than the Hefeweizen.  
Stout - Too burnt/astringent. I think maybe they should cut back on the black patent malt.

As I tasted their beers, and sipped my pint of Brown, I studied my map. I noticed that Highway 299 runs between US 101 and I-5. I also noticed that if I could get to I-5, I could stop at Sierra Nevada Brewing Company in Chico on the way home. I told Marty what I was up to, and asked him if Highway 299 was the best way to get to I-5 from Eureka. He told me that it was possible, but if I was willing to drive four hours or so out of my way, I could visit three more brewpubs along the way! I had to think about it for a few minutes, but not for too many.

Marty's advice: follow US 101 north (being sure to stop at Humboldt Brewing in Arcata) to US 199, continuing to Cave Junction, Oregon. There you'll find the Pizza Deli & Brewery. Continue on US 199 to Grant's Pass, Oregon, and pick up I-5 South. The Rogue Brewery is in Ashland, Oregon. Spend the night in Ashland, and head south on I-5 in the morning to get to Sierra Nevada in Chico. "Sure," says I, "and thanks for the tip!" And off I went.

I got halfway to Arcata (a quick six miles from Eureka) before I realized that I had forgotten the T-shirt that I had paid for at Lost Coast. At twenty bucks a throw, it's not the sort of thing you want to leave behind, so I made my only backtrack of the journey.

But soon enough I was in Arcata. I wasn't real sure what to expect, as I didn't remember tasting their beers anywhere, and I didn't have any lowdown on the brewery before I arrived. It's really a huge place, especially considering where it is! (Take a look at your California maps, and try to find Arcata.) For a very good writeup of the place, see Steve McClenathan's front-page article in the August 1992 Celebrator.

I would have liked to have spent more time here, because the beer was excellent! The real kicker: they were all served from real live hand pumps. In all my travels up to that time, I hadn't seen a hand pump on this side of the Atlantic. I was impressed! My round of samplers included:

Honey and Ginger Ale - 4.0%. It certainly is. Pretty good!  
Light...sweet, the ginger flavor is obvious.  
Gold Rush - 4.5%. OK, fruity light ale.  
Red Nectar - 5.0%. Good amber, well-hopped. I've seen bottles of this at Liquor Barn, etc.  
Redwood Amber - 5.5%. Better than Red Nectar, less hops, more malt flavor.  
Storm Cellar Porter - 5.7%. Pretty burnt, maybe too much for a porter. Pretty tasty, though...  
Humboldt Stout - 5.7%. Not as burnt as the porter, smoother.

Unfortunately, I didn't have more time to spend there; Oregon was calling. US 199 is a twisty path through mountains and redwoods. Beautiful scenery, and I'll bet it's even more impressive when you're the passenger in the car, rather than the driver. Distractions aside, I arrived in Cave Junction around eight o'clock Saturday night, and I found the Pizza Deli & Brewery right along the side of the road.

The name describes this place perfectly; it's a typical little pizza joint with a brewery stuck on the side! I bypassed the "Baitbucket Pizza" (shrimp, oysters and/or anchovies) in favor of a small "Deli Delight" (linguica, mushrooms, pepperoni, olives, beef, and sausage). (So sue me; I'm a carnivore.) I noted in their menu-cum-flyer that they use some imported hops, which I thought was a little strange in Oregon, considering the quality of the hops grown there. They also mention that their beers "are centuries old styles that have been the daily fare of sober, hard-working men and women - not necessarily high in alcohol or strong in flavor". That last clause - "not...strong in flavor" really caught my eye and set my expectations somewhat lower than they might have been. I was pleasantly surprised.

Light - Good pale - good pizza beer.  
Blackberry - It's a good porter. Can't taste the fruit, which is OK by me, since I don't like fruit beers.  
ESB - Not bitter enough to be called an ESB, but not bad at all.  
Dark - Good smooth dark ale. Doesn't taste very strong, though...  
Nut Brown Ale - "High in flavor but low in alcohol" - ain't that the truth.

Overall, five good beers, and some very good pizza. This stop really fortified me for what I thought would be the last leg of tonight's journey.

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: All Grain comments and a recipe

So, I see people have been getting bent out of shape about how they brew their beer. I will simply note that this past weekend I entered a competition sponsored by CAMRA Ottawa, and my All Grain Oatmeal Stout placed third in a field of 14, but that the FIRST PRIZE WINNER WAS AN EXTRACT BASED STOUT. And, it was a good brew, too. So. I brew all grain because that's how I get the most pleasure out of brewing. My beers are good. But, Good Beer is made in many ways, the key being A GOOD ATTITUDE! So maybe we should lighten up, eh?

Anyhow, I recall a request some time ago for more recipes and less babble. So here is my CAMRA Third Prize Winning recipe, with comments for improvement.

"Breakfast of Champions" Oatmeal Stout

Water 35 litres mixed with 0.5 tsp salt and 1.5 tsp chalk to buffer the mash.

English Pale Malt (Munton and Fison 2.5 L) 2.8 kg  
Munton and Fison Crystal (60L ?) 0.8 kg  
Rolled Oats 0.4 kg  
Flaked Barley 0.6 kg  
Chocolate Malt 0.44 kg  
Roasted Barley 0.1 kg

All grains added to mash tun, put first liquor (11 litres) at 80C. Obtained strike temp of 64C (too low). Added 3 litres boiling water to obtain 66C. Mashed for 1 hour. Added 6 litres boiling water to mashout at 70C for 25 min.

Drained and sparged with 85C water (too hot). Collected runoff until SG 1.010. Boiled whole wort with 0.5 tsp powdered licorice, 227 g of lactose, and 7 plugs (0.5 oz, 15 g each) of English Fuggles 4.2 alpha. Boiled 1 hour, then removed as much of the hops as possible. Added Irish Moss, 10 grams, boiled 15 mins more.

Chilled in counterflow system, removing hot break but allowing cold break to settle in carboy. Pitched with active Wyeast 1084 culture. OG 1.050 in 22 litres.

Primary ferment 9 days to SG 1.030.  
Secondary ferment/maturation 24 days to FG 1.020. Both ferments at 22 C in closed vessels with locks or blowoffs.  
Bottled with 2/3 cup corn sugar.

Carbonation took about 3 weeks but gave nice result. Head retention is not optimal (oats are a problem). A bit excessively astringent and roasty, next time add the dark grains only in the mashout, add a bit more crystal. This one got 39.6/50 but the winner, AN EXTRACT STOUT, got 42.4/50!

So, There is my recipe, took all day, I had fun, but the extract product was judged the better beer. Ok by me. How about you folks?  
Cheers, P.

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Protein rest for dextrine malt?

I recently used dextrine malt (carapils) for the first time.  
It was US malt. 6-row I think.

7 # Munton and Fison pale ale malt  
2 # carapils  
1 # dark crystal

I used a one-step infusion mash in the low 150s. The beer is tasty but  
has a serious haze. Should I have given the mash a protein rest?  
The beer is still in the secondary. Can anything be done about the haze?

Cheers,

Date: Wed, 10 Feb 93 11:58:38 cdt  
From: "Knight,Jonathan G" <KNIGHTJ@AC.GRIN.EDU>  
Subject: cold break & pitching

I read Brian Bliss's post on cold break & racking off trub with interest. I've only got twenty batches behind me, but I thought my somewhat heretical methods might be of interest to those with as little or even less experience than myself. If some of you grown-up brewers out there would like to comment too, it would be great.

I boil my beer in a Vollrath pot (borrowed from a friend who is currently not brewing). I generally boil about 4 gallons, losing a gallon or so over the sixty minutes. I have pre-boiled and chilled, first in the fridge and then, while brewing, in the freezer, down to almost-frozen, 2 gallon jugs of water. When the boil is over, I stick the Vollrath in my kitchen sink, filled with ice water and dump the almost-frozen water in on top. I cover the pot & wait about a half hour or until all the ice in the sink melts. Seems to me I get a pretty good cold break from this.

Wort-chillers? We don' need no stinkin' wort-chillers!!!

Then, I rack the beer into my plastic bucket, add the yeast starter (I use the boiled DME + a couple hop pellets method) and stir like nuts, take the gravity reading, and rack into the glass primary (\$18 water bottle - \$8 deposit forfeit, and \$10 for water which made really nice beer once) to which I attach a 1" blowoff hose.

Now here's the heretical part. After having read the discussion of yeast nutrients in trub when it first appeared a few months ago, I decided to rack off not only the beer but just a little bit of break material too (maybe 1/2 cup or so). Also, in spite of all the \*worrying\* about temperature shocking yeast, I pitch at a relatively high temperature - usually in the 80's F. (I brew ales), because, o.k., well, my chilling methods DON'T work as well as a wort-chiller does - but the bottom line is that I always get fantastic starts (under six hours and a lot of crud in the blowoff bucket) and I've been getting some pretty decent beer the last few batches.

I imagine I am just being silly with that little bit of break material I rack off, but it doesn't seem to hurt anything either. And if there might be side effects from pitching at high temps, I'd love to know what they might be. At any rate, I may not be one of the World's Greatest but how

about one of the World's Cheapest (until my friend recalls his pot and I have to go get one)?

Any remarks would be happily entertained.

Jonathan

RE: Costs of all grain brewing.

>JS has again fired up the snobbery issue and generated a lot of  
>wasted bandwidth in the process. I am sure jack is pleased. What  
>I want to comment on is the response that implied the reason to  
>avoid all grain brewing is cost. It has been noted in this forum  
>before that going all grain does not mean going broke. To sum up  
>the costs needed (a low budget, workable setup):  
>2 plastic buckets with the holes drilled in one, plus a spigot-  
>\$10  
>used 7 gallon SS kettle - 35-50\$.  
>(maybe-corona mill-45\$,new)  
>wort chiller, built at home, \$25.  
>total- 65-130\$

Actually I started out for even less. 2 food grade buckets that I managed to get for free. a 32qt enamel canning pot. No wort chiller and precrushed malt. To be honest I was using the canning pot for full boils with extract so my only added cost was the tap on the buckets. Less then \$50 total including the kettle.

Cost isn't the issue but time is! If you don't want to set aside the better part of the day then don't. IMHO liquid yeast did much more for my beer then mashing did.

On the issue of wine making. Here in Toronto you can get US wine grapes in season.[Say late Aug-late Oct]. You can buy them either whole or get them crushed by the seller. A second choice is to buy pre-made musts of imported grape juices which are usually available year round.

If you are starting out with either the premade musts or pre-crushed grapes the effort required is much lower then beer and even simpler then the orginal method posted. [I.E. dump concentrate add water and sugar] At most you will have to add yeast. Of course you could stick to more traditonal methods and use the natural occuring yeasts on the grape skins. IMHO this tends to produce a wine of greater interest.

On the cost issue a standard case of grapes [36lbs] produces 2-2.5Imp gallons of juice [say 10litres+] with prices ranging from \$15-25cdn per case plus crushing costs [I think around \$1 we crush our own so I'm not sure] Must are higher priced.

Has long has you stick to relatively simple methods you will end up with drinkable wines. Avoid doing anything wierd like adding extra sugars or boiling the juice. The main point is to get good grapes.

Nick

From: "Jim Daly, Digital Equipment Corporation, Maynard, MA" <daly@mast.enet.dec.com>

**Subject: Fermenting in Stainless**

Can anyone comment on their experience fermenting in stainless? Specifically, I'd like to get away from using glass and the idea that comes to mind is to use cornelius kegs. For my primary I could replace a valve with a blowoff tube (although the diameter may be too small with the existing hole), and for a secondary I could replace a valve with an airlock or checkvalve. An alternative for the primary may be a quarter keg with the top removed, which would provide more headroom (7.5 gallons). I guess I could get really fancy and put a valve on the center-underside of the kegs to drain off the sediment during fermentation (the base of the kegs are cupped), similar to what is done with commercial tanks.

Has anyone tried something like this? Pros/Cons? Thanks...

From: Bill Ridgely FTS 402-1336 <RIDGELY@A1.CBER.FDA.GOV>  
Subject: AHA Conference Schedule

Yesterday, Charlie Castell brought to our attention the conjunction of a ski race camp with this year's AHA Conference:

>Most of you are reading this thinking that I've sent mail to the >wrong digest. However, consider the dates:

>3-day Summer Race Camp, Mt. Hood July 23-25  
>AHA National Convention, Portland July 26-30  
>Oregon Brewers Festival, Portland July 30-Aug 1

>Looks like quite a week. (Etc).

Well, as long as we're on the subject, here's another amazing conjunction that some of you may find interesting:

AHA National Convention, Portland July 23-25  
Oregon Brewers Festival, Portland July 30-Aug 1  
National Speleological Society Annual  
Convention, Pendleton Aug 2-6

For those not familiar with the latter, it's the national association devoted to caves and cave exploration. I've found over the years that a lot of homebrewers are also cavers (we have several in my homebrew club), and believe me, beer and cavers go together like Scotch and soda. Cavers are also generally crazy and like to party in a major fashion. The NSS Convention is a week-long campout with nightly parties including, among other things, "adult water sports" (sauna, hot tub, etc). Don't get me wrong - some serious science and athletic competition takes place during the day, but evenings are generally devoted to carousing and mass consumption (Does this start to sound like the AHA Convention?).

The fact that the two are colocated in time and space this year is a major reason for an old West Virginia potholer like myself to make the trip (although I'll be at the AHA anyway to co-present one of the talks).

Out of curiosity - any other caving homebrewers out there? Private e-mail preferred.

Subject: Chinook,Lag, Foam

>From: kstiles@aluxpo.att.com

>ObBrewing: No takers on my question about flavor/aroma properties of Chinook hops, huh? Do any commercial brews use them?

A number of brewers use them although at the moment I can not name them but it frequently comes up in trade journals. At last Sunday's ALEFEST sponsored by CBS, there was one that boasted of the use of Chinook exclusive and it was an excellent ale. Unfortunately, I do not recall the brand.

I have used almost nothing but Chinook for the past year in over 40 batches and am just now moving on to other varieties now that I have a bench mark.

I just bought some imported Hallertau to try in my first batch with Belgian Munich malt. I will let you all know if it is worth the expense.

I had routinely used a 1/2 oz plug of imported Saaz at the end of boil but as I could not tell the difference between batches without it, I quit doing it.

As far as aroma goes, I have nothing to compare it with yet but moments after dumping the Chinook into the boiling wort, the aroma that wafts out of the kettle can only be described as what I now consider one of the reasons I make beer. I will be most impressed if an exotic hops can improve on this.

>From: Lee Menegon <necis!lmenegon@transfer.stratus.com>

>1) Pitching into wort that was much warmer than the target fermentation temperature. We did this to reduce lag time.

If your diacetyl taste is coming from fermentation temp and you are concerned about lag time, I suggest you reconsider your priorities.

Presuming that you have a reasonable quantity of well working starter, the lag time will not be excessive if you pitch at or near primary fermentation temp. However, the most benign temperature is always whatever the starter is when pitched. If it is at room temperature, it should be pitched into room temp wort for minimum lag time and to minimize the shock to the yeast.

BTW, you did not mention just how warm "warmer" is so I am shooting in the

dark but I think in general, far too much concern is given to lag time and curing it by pitching "warm" is probably not worth the risk.

>From: korz@iepubj.att.com

> I urge you to try the blowoff method for a beer or two and compare.

I don't think I want to get into blowoff vs skimming again but I think that most people who use "open" fermenters skim the foam which is the equivalent of blowoff. The point made by the author was that removing the foam, by whatever means, severely reduces the quality of the beer. That is the mis-information we were dealing with.

For what it is worth, I tried blow-off once and wrote it off as just another one of those procedures that you either believe in or don't and no amount of discussion will change a believer's mind.

>From: korz@iepubj.att.com

>> I suspect that it might have a negative effect if Fix's hypothesis on HSA is correct. What say George?

>Oops. I think there's some miscommunication here, Jack -- the mash isn't hot at this time so Hot-side Aeration (HSA) is not an issue.

I was under the impression that the spray water being mixed with the grist was hot. As spraying it would significantly increase its surface area, it would dissolve more oxygen than if simple poured in. If cold, it would be even worse but of course become CSA.

>From: orgasm!davevi@uunet.UU.NET (David Van Iderstine)

>>Keeping in mind that lots of people stick with extract because they are lazy, paranoid or ill-informed (blah blah blah) .....

>So, Jack, since \*YOU\* were still an extract brewer right up until the middle of last year, which were you-lazy, paranoid, or ill-informed? Maybe you left one out?

I am sure this will disappoint you but I have no problem recognizing that I was all of the above and I probably did leave a few out. This is precisely the reason I feel so strongly about my position. For the record, my first all grain batch was on Sep 23, 1991 and have not used extract since.

> If anyone else gets as ticked off as I do with stupid statements like that quoted above, I've been advised our only recourse is to FLOOD the poster with private e-mail stating how we feel. Please do; I am!

I much prefer your public comments to your trashy and vulgar email.

If anyone takes your suggestion, they will get the same treatment. As a matter of fact, if you do it again, I will start posting your trash to the Digest.

wishes to try.

The number of known results are far outweighed by the number of unknown results, and this promises rewards to the experimentally inclined.

For example, I'm fermenting some black cherry juice from Napa Valley with Pasteur Champagne Yeast, the same yeast I use to make sparkling cider out of apple juice. I tried natural apple yeasts and liked the champagne yeast much better. Even if it doesn't taste good I can use it as an adjunct to another brewing experiment, like a fake cherry lambic.

Subject: fruit wine making

Hello Rob and others,

> .... possibly because they don't (I'll take an industrial example :  
most  
>english bitters contain types of sugar, eg mollasses). Well it's the  
same  
>with wine. Wine making started long before the french made it their own.  
>People have been making blackberry, strawberry, in fact hundreds of  
>NON-grape wines for centuries. It is the "grape wine snobs" and a very  
>powerful french industry which has meant that you can't buy them (a few  
>companies in britain sell them, including Gales - the brewery).  
>True this is a beer forum, and also true there are (sorry is) a digest

Also here is a big cultural difference between America and Europe then. As I read in another mail that wine makers are people who just take a can and brew something, you hear the same story in Europe but then for beer makers;-)

But that is just for information and like all generalizations it says not much!.

But there have already been more questions about wine and reading the above message I see that there is a forum for fruit wine making (I do not mean cider making (is a type of wine) like mead). Is that correct and could you please information on that.

If not, is it not possible to set up such a list somewhere, who volunteers???

All the best,

Victor

From: Sandy Cockerham <COCKERHAM\_SANDRA\_L@LILLY.COM>  
Subject: chocolate in beer

I for one can't tell you how to clean the mess, but next time perhaps you should try using cocoa instead. In an old Zymurgy, Charlie P. has a recipe for "Slanting Annie's Chocolate Porter". When he made it he spoke of the globs of floating cocoa butter mess produced. He then stated that to get around that one could use a good powdered cocoa. One of the guys in the local brewclub made a chocolate porter with cocoa and it was GREAT!

From: casey@bbt.com (Kevin Casey)  
Subject: Misc. beginner questions

I began my homebrewing experience by brewing "kit" beers in September, and have since brewed at least 4 batches of all malt extract beers. After 9 or so batches, I have some questions that I would like answered.

I made a batch of Pilsener which looks beautiful in the bottle until I refrigerate it. What causes the hazing of the beer when I chill it, and how can I avoid it?

I have experimented with different adjuncts. Are there any items that should not go in Beer that would cause it not to ferment properly?

I haven't had a gushing problem but I do have some of the first beers that I made and they seem to be overcarbonated. They were fine for 4-6 weeks and then began to lose flavor. Is this due to the yeast used?, and how much flavor is a factor of the yeast used?

At what temperature would an average beer of 4-5% alcohol freeze? I would rather store them in my garage than in my closet, but do not want them to freeze.

Any help would be appreciated.

I also have one comment on the all-grain vs extract brewing wars. Even a kit beer tastes better than most domestics.

Kevin Casey (casey@bbt.com)

>  
>Let me make another proposal. How bout explaining what an archive is  
and how  
>one goes about accessing it before you expand on a special archive.

I can't speak for "electronic community" and you may be right but it is  
also worth while to put the issue into proper perspective.

Keeping in mind that lots of people don't know about archives because  
they are lazy, paranoid or ill-informed and further keeping in mind that  
Compuserve, as opposed to the "electronic community" has a vested  
interest  
in maintaining the status quo because its revenues would dry up without  
uneducated users, it is worth noting that some Compuserve users are  
excellent  
people, so I am told. One also presumes that lots of Compuserve users  
use  
Compuserve because they know how to make excellent e-mail.

Having said that, I suggest it is the Compuserve users' insecurity,  
sensitivity and paranoia that creates the image that Unix-freaks are  
snobs.

Apologies to "real" Compuserve users. I couldn't resist :-)

> and how one goes about accessing it before you expand on a special  
archive.

Archives are just a collection of files located on some system  
(with generous owners). All the HBD digests back to 1988 are  
stored on sierra.stanford.edu. They also allow to us  
access any previous digests via email or ftp.

This is at the top of each HBD:

> Archives are available via anonymous ftp from sierra.stanford.edu.  
> (Those without ftp access may retrieve files via mail from  
> listserv@sierra.stanford.edu. Send HELP as the body of a  
> message to that address to receive listserver instructions.)

If you don't have ftp access, simply send mail to  
listserv@sierra.stanford.edu and you can receive the files.

Here's a couple of examples to put in the body of your email:

> index homebrew

The listserver will email you the list of all homebrew related files  
you can  
receive.

> get homebrew 1988.index

The listserver will email you the a file containing the subjects  
of each HBD posting, much like the top of the HBD you receive  
daily.

> get homebrew 1074

The listserver will email the HBD from Feb 10, 1993, HBD # 1074.

Richard Stueven writes:

> In HBD# 1071, ex-beginner Russ Gelinas recommends:

> >available.  
>

I completely agree. One of the advantages of the HBD over a  
book is the discussion that occurs. You get many different  
perspectives rather than the authors favorite.

> Of course, the first things we loaded into the system were the entire

> HBD archive, the ASCII Cat's Meow, the publist, and tons of other  
> net.brew\_stuff, and we update it monthly. Mighty informative! Mighty  
> useful!

Well, I'm jealous :-). Unfortunately, we all do not have disc  
space available for the HBD archives, which is why its so nice  
having the it archived for us on sierra.

This is also why I think it would be nice have a few special  
archives files containing all the threads on some popular  
topics that come up frequently. The FAQ could reference some of  
these rather than briefly answering the questions or  
referencing the many hbd's that discussed the topic.

From: Ulick Stafford <ulick@beethoven.helios.nd.edu>  
Subject: Detergents etc.

Al referred to a previous posting about removing Chocolate oil and made the excellent suggestion to use washing soda (sodium carbonate). I'll chime in and also suggest TSP (trisodium phosphate) readily available in hardware stores as an oil paint stripper, or caustic soda (sodium hydroxide). These strong bases are used in commercial practice for cleaning and sterilizing and by us as label strippers. They should be used according to directions with rubber gloves. These suckers will strip the oil from your hands as easily as from the dirty vessel and you'll need quite a bit of vaseline intensive care to get it back.

Don't use soaps or detergents on your brewing equipment. The reaction that occurs above is basically soap making. The fatty acids that forms the oils (attached to glycols) react in an acid-base neutralization with the base to form fatty acid ions, which are long chains ytpically 16-18 carbons long. In water these will form micelles with the negaticely charged acid group on the outside and the hydrophobic hydrocarbons within. Organic material can dissolve within this micelles, so tha addition of soaps to water allows insoluble organics to be dissolved.

Detergents are similar, except stronger acid groups such as sulponic groups are on the end of the organic chain. There are also non ionic and cationic surfactants to go along with the usual anionic types when an acid rather than basic environment is desired (Pert shampoo and conditioner in one is an household example of this).

Basically domestic detergents and soaps are relatively kind to human skin, or have other additives. But in homebrew equipment they will leave a residue that will knock that head straight out of your beer. It is nearly impossible to remove a soap layer from the wall of a plastic bucket. Stick with strong bases for tough cleanup - and use rubber gloves. They are cleaner and stronger.

Ulick Stafford

PS on thurs all submissions were made on Tuesday. hmmm - and there isn't even a maltmill givaway going on. When the cats away everything goes to hell!

From: wood@ranger.rtsg.mot.com (Dan Wood)  
Subject: Ulick's Criticism of MI Deposit Laws

While I have enjoyed Ulick's posts in the past, and benefitted from the wealth of information he provides to this digest, I must take exception to his description of Michigan's deposit law as "inane".

I live in Illinois, a state with neither bottle deposit nor blue laws. I frequently visit friends and relatives in Michigan. The contrast between the two states is startling in many respects, but let me focus on the difference this is entirely due to the bottle deposit.

In Michigan, you will find very little broken glass, nor will you find litter from empty cans or cardboard packaging. It's rare for people to throw away their empties, instead they return them for cash. In the rare occasions where they are discarded as litter, local kids enthusiastically gather them and return them to collect the deposit. You wouldn't think it would work this well, but apparently the locals have figured out that those dimes add up.

In contrast, virtually no area of Illinois is immune to this litter. Even residential neighborhoods routinely have empties (presumably from "cruising" young drinkers) discarded on street corners and in front yards. Local parks typically have hazardous areas created by broken glass. In my experience, this problem also exists in other states that don't have deposit laws.

Although Michigan's deposit laws have created some inconvenience for retailers, I feel it's justified, since they profit from the sales. It costs the consumer nothing so long as he acts responsibly and collects and returns the empties, which should be done regardless. The deposit simply provides incentive to "do the right thing". Obviously social conscience doesn't produce this incentive elsewhere.

Please excuse the long post, and I certainly don't mean to flame, but the lack of deposit laws in other states is a pet peeve of mine. I can't see condemning such an effective system simply because of minor inconvenience suffered by out-of-state visitors. Should anyone feel they must debate this issue with me, please do so via private email, this is the last HBD bandwidth I will expend on this topic.

Stepping off my soap box now, relaxing, and still brewing great beers  
from extract,  
Dan Wood

Subject: Celis expanding to other States

Roll out the Celis  
Austin brewery to boost sales and production  
Austin American-Statesman Statesman, 2/9/93

Celis Brewery plans to introduce its beers to 30 states and several overseas markets by the end of the year, a move that would more than triple its production from 8,000 barrels to at least 25,000.

The Austin-made beers now are sold in six states and Washington, D.C. This month, the company plans to begin distribution in six more, including Colorado, Illinois, Indiana and New York.

We think 1994 will be a very excellent year," said Christine Calis, brewery president. At the same time the privately held company is contracting with several U.S. distributors, it is working on sales leads in Europe and Asia, Celis said. She said she expects to place the beers in Taiwan, China, England, France and Holland by 1994.

Celis began brewing last year and launched its beers -- Celis White, Cells Pale Bock and Celis Golden in May. A fourth product, Celis Grand Cru, was introduced in December.

Cells' 1992 revenues, which represent about a half year of sales, were \$550,000, brewery officials said. This year, the brewery expects sales to climb to about \$3 million.

From: gjfix@utammat (George J Fix)  
Subject: Wild Yeast

It is my opinion that the major open problem in brewing microbiology today is the formulation of an accurate, practical, and rapid media for the detection of nonculture yeast. The problem is one of a needle in a haystack. We pitch ale yeast at the 5-10 million cell per ml (10-15 for lagers), yet we want to detect contaminants at the 1- 10 cell/ml range. In commercial work, even lower levels of detection are required (typically in the cells per 100 ml. range).

This problem has been solved for bacteria. Cycloheximide, sometimes known as actidione, added in very low levels to any of the suitable growth media (WLN, NBB, UBA, et al) will nicely inhibit yeast (culture and otherwise) without affecting bacteria. What is needed is something like this for wild yeast.

Simply streaking samples from a slurry on a media like WLN is only going to give a plate full of culture yeast. I have done this more times than I would like to admit, and have found in spite of the color indicators, spotting the one in a million is next to impossible. Gross contamination can be detected, but direct microscopy, and in fact one's own nose, work as well in these cases.

The two following approaches have been suggested for small scale brewers:

1. Rodney Morris> Incrementally add actidione to a growth media starting at extremely low levels. This, just like all Rodney's ideas, is terrific. It, however, is an extremely tedious procedure that for a long list of reasons can only be done in a professional lab. I use it only as a last resort, only at my university, and only if someone is paying me to do this work!

2. Other inhibitors> A variety of inhibitors have been proposed like copper sulfate. These have been very effective in the detection of strains like *S. diastaticus*. However and alas, there are *saccharomyces* strains, quite common in both home and pub brewing, which are inhibited along with culture yeast. Murphy's law suggests that these are the folks that bring us the "funky homebrew" taste.

For those at Cornell on this network, you should be aware that some very exciting work is being done in your Food Science Dept. by Dr. Karl Siebert, the Chairman of the program and a very distinguished brewing scientist. His group has come up with a new medium (cadaverine, lysine, ethylamine, nitrate) that could be what we are looking for. Now if you folks could just recruit Dr. Jean-Xavier Guinard from Penn. State, you would start to rival Munich!

From: Raymond Taylor <NU028463@VM1.NODAK.EDU>  
Subject: Dry Hopping

I have been brewing for a couple of years, now, and consider myself to be an intermediate to advanced brewer. However, one topic seems to elude my understanding; that is DRY HOPPING. I have Dry Hopped several batches, with good results, but the hops effect on fermentation is what I can't figure out. Each time I have Dry Hopped (I have always used pellets), seemingly dead fermentation restarts, and continues slowly for quite some time. (This is not to be confused with the rapid release of dissolved CO2 that can occur soon after the addition of the hops.)

I have a list of possibilities I have thought of, and would like to get the HBD's opinions on them:

1. The Hops introduce wild yeasts that can digest the heavy remaining sugars. (I haven't noticed any off-flavors).
2. The Hops contain some sort of enzyme that will break down the heavy sugars, to some the yeast can handle. (I have seen gravities drop further than I expected.)
3. The Hops provide a matrix for the yeast to attach to, and be more exposed to the wort. (Similar to Beechwood?)
4. The Hops contain a yeast nutrient. (Or maybe simple sugars?)
5. YOUR ideas here: \_\_\_\_\_.

Thanks for any ideas.

From: "Spencer W. Thomas" <Spencer.W.Thomas@med.umich.edu>  
Subject: hops identification

There was a question a couple of days ago about identifying unknown hops growing in someone's yard.

If the hops came from seed, the probability is essentially zero that they are one of the "recognized" varieties. Hops are normally propagated vegetatively, that is, from cuttings of a "parent" plant. All hops from a given "cultivar" are genetically identical. Plants grown from seed, even if both parents were the same, will have a different genetic makeup, and therefore different flavor, alpha acid content, and other characteristics.

If, however, the hops were planted by a homebrewer, then there's a chance they are of a recognized variety, so it doesn't hurt to try to identify them.

The bottom line is this: you will probably have to experiment with them to determine their bittering and flavor characteristics.

>have seen that pellets have different utilization than whole hops (both  
>in this forum and in some of the homebrew books); indeed hop plugs have  
>yet another utilization rate.

Hop plugs have the same utilization rate as loose leaf hops,  
but they keep better. i.e. the AA% content stamped on the package  
actually means something. You should multiply the AA% on loose  
leaf hops by anything from .7-.9 (typically) to compensate for the  
drop in AA during storage before plugging the # into the table.

>I was at G.W. Kent on Saturday, so I asked them about hops plugs.

Yes, I was reciting from memory, since my brewery is at home and I  
was at work. The plugs were from Morris & Handbury (sp?). They  
have a blue & white label as does Kent, and...

along the same lines:

I believe it's the highly-flocculent yeast strain that they use at the  
Tadcaster Brewery (Samuel Smith's) rather than the slate "squares" that  
causes the yeast to floc out early. Someone (Darryl maybe?) reported  
that they use some kind of hand-held pumping system to push the yeast  
back into suspension.

>you thought you got some with the G.W. Kent label, you must be  
>confused. The only ones I've seen are imported by Crosby & Baker.

I can verify that this was a bad year for hops in Europe and that the US importer (GW Kent's, Crosby & Baker's, and L. D. Carlson's supplier) is Morris Hanbury, who only sells wholesale by the way, is not shipping large quantities of plugs. They said that since their supply is so small this year, that they could not offer cases as they usually do, so that all their customers could have some. Perhaps because G.W. Kent was not interested in only 25 of 50 plugs, they chose to not stock them this year.

>He also said that as far as he knows, any plugs on the market now must  
>be from the 1991 crop. If this is true, then my experience with plugs  
>speaks very well for their keeping ability. As I said yesterday, the  
>plugs I bought recently had the freshest hops I've ever used.

Indeed they have an incredible refrigerated shelf life, partly due to the fact that their O2-barrier packages are nitrogen-purged before vacuum-sealing. The Morris Hanbury Plugs that I received, however, were marked as 1992 crop. I suspect that the unavailability of whole and pelletized 1992 Goldings is perhaps associated with the fact that they are most attractive in the plug form and thus most of the scarce 1992 export crop was destined to be made into plugs. Just a guess.

Subject: A Beer Odyssey (Act III)

A Beer Odyssey (Act III)

Ashland is a good long way from Cave Junction. You have to drive around a whole lot of mountains to get there. You can work up quite a thirst doing it. I finally reached Rogue Brewing in Ashland around 10:30 Saturday night.

It pains me to say it, but I'm going to plead the Fifth in my description of my visit to Rogue, and I promise the brewers and the staff there that I will give them another go under more favorable conditions. I had been driving for some thirteen hours by then, and it was late, and (dare I say it?) I was in more of a mood to sleep than I was to drink beer. As I walked up to the pub, there were a lot of people making a lot of noise (or so I thought, but what did I expect on a Saturday night?) and a folk guitarist on a stool outside. I went inside to the downstairs bar, and the bartender told me I should go outside to listen to the music. I explained the True Reason that I was there, and ordered an IPA.

I'll be honest: I've had Rogue beers on tap and in the bottle, and I was never very impressed. I found them sour and not very appetizing at all. My immediate reaction to this IPA wasn't much different, and I finished the pint and left.

As I was driving away in search of a motel, the taste of the beer lingered, and I thought, "You know, that beer wasn't bad at all." My state of mind had really distorted my state of palate. Once again, I apologize to the folks at Rogue, and I promise to stop by again and do them up right. Like so many of the beers I tasted on this odyssey, I think they've probably improved immeasurably over the past year or two.

I drove through the streets of Ashland, looking for a motel. "No Vacancy" signs lit my path. Eventually, I came to I-5, and I headed south, back toward California. "There must be some towns nearby," I thought, "and I'll find a place to stay in one of them."

Nobody had bothered to tell me that there are nothing but mountains from Ashland on south, and big empty ones at that. No towns to be found; nothing but dark twisty Interstate Highway. The nearly-full moon rose behind Mount Shasta, some sixty miles away by air (ninety by road). Forty-five minutes later, I was in Yreka, California.

No vacancy. I began to suspect a conspiracy.

I returned to the freeway and continued south. It was plenty late, and I was plenty tired, and about six hundred miles from home. The next town with a streetlight was Weed, California.

No vacancy.

I drove around the streets of Weed, checking all the motels, but they all claimed to be full. Reaching deep into my bag of tricks, I asked myself what I would have done back when I was young and poor.

I slept in my car in a Motel 6 parking lot.

I woke Sunday morning around 6:30 when the fellow in the truck next to me was loading up to leave. (The looks I got from him...) Just up the road was the Hi-Lo Cafe & Motel. The Cafe was a lot more interesting to me than the Motel just now; I was in desperate need of coffee. I mapped out the day's battle plan over breakfast. Since I had come this far, and was now rounding the far turn, as they say, I reasoned that I may as well visit a few more pubs on the way home. I plotted my course.

First up was Sierra Nevada Brewing Company in Chico. As luck would have it, I reached this Mecca of Pubcrawlers at ten o'clock in the morning, opening time, and time for Sunday brunch. It's a beautiful brewery, industrial surroundings notwithstanding, and a beautiful bar inside. It reminded me of the bar at Pacific Coast Brewing in Oakland, but the one at Sierra is even bigger. Sunday brunch at Sierra consists of your choice from their breakfast menu plus a half-pint of the beer of your choice. What a way to start your day. The hardest choice to make was which beer to accompany breakfast. To make a proper choice, I felt that I should have a round of samplers first:

Draught Ale - Like the Pale Ale, but smoother, and more hops.

Pale Ale - Even better when fresh.

Porter - Very smooth, with strong chocolate flavor. Not as highly hopped as I remember it, and that's good! Very thick.

Stout - Heavier in body, but lighter taste than Porter. Also not as highly hopped as I remember.

Celebration Ale - Not available. Too bad.

Bigfoot Ale - Holy cow! This is not your basic breakfast beer! Again, ten times better when fresh, just like the others.

Summerfest - Very smooth, heavy body, light taste. Could use a touch more flavoring hops, but maybe not.

Pale Bock - Not available. Too bad.

I chose the Huevos Rancheros and a half-pint of the Draught Ale. The Huevos Rancheros were served with a black bean sauce and an alarmingly hot salsa, and a fruit plate and various muffins. Not bad for six bucks! There was a good crowd for a Sunday morning; at least two dozen people were there for brunch, and even then the bartender called it a "pretty slow morning". Their prices are better than fair: brunch, the samplers, a pint each of Pale and Porter, a T-shirt, and two pint glasses for \$25. It's a deal! Be advised they're closed on Monday.

Smith's  
>Taddy Porter in particular.

I'm confused. Either your friend got a hold of a bad sixpack or is mis-interpreting something in the Taddy Porter's flavor profile as sour. I have never found markedly more sourness in Taddy Porter than in any other British ale. I suggest your friend get a hold of some Berliner Weiss or Cantillon Gueuze and compare sourness to Taddy Porter.

Granted, any beer with dark-roasted grains will have a bit more acidity than paler beers, so perhaps I'm jumping-the-gun... perhaps your friend is hyper-sensitive to sourness (everyone's perceptions of taste are different -- part of being a judge is recognizing and normalizing your own).

To answer your question, I feel that Charlie Papazian has a very good explanation of sour mashing in the back of the New CJoHB. I don't have my copy here, so I can't help you with the times and temps, but it basically uses naturally occurring Lactobacillus on grain husks to sour the mash. I tasted a pseudo-lambic that made it to the second round of the nationals last year that was made this way and it was quite good (albeit short on Brettanomyces character, but that's a different story).

From: Lee Menegon <necis!lmenegon@transfer.stratus.com>  
Subject: Level of Malt Modification

In reviewing a grain suppliers catalog I noticed that they list the level of modification of the various malts they sell. They range from low modification for the German varieties to highly modified for the British varieties. American 2 rows were in the middle.

I know that when a friend step mashed some German Pilsner malt he would get about 28-29 sg points per pound and his mashes would take 30 to 45 minutes longer than when he mashed British Pale malt. When he switched to decoction mashing the Pilsner malt his yield would be about 34 sg points per pound.

Why are grains modified to different extents?  
How can I use this level of modification information to brew better beer?

I have been experimenting with Muton&Fison Mild Malt. It is kilned a bit higher than pale malt, is slightly darker and adds a nutty flavor to a beer's profile. I have used it in a pale ale and brown ale and recommend its use by partial mashers and all grain snobs, AGS. In the pale ale it was about 10-20% of the grist while the brown ale 40-50% of grist. Partial mashers use 1-1.5Lb for ale 2.5 to 4 lb for brown ale.

I will have some of my most recent brown ale at the 2-12 meeting of the Brew Free or Die Homebrew club. Since it is named: not so Brown Ale I hope that the whinny voice in the Sam Adams radio ads, Jim Koch, does not issue an injunction against me for using the same letters in the word Boston in my beer's name. Incidentally the grain was purchased in Boston.

Some recent posts have mentioned "a lost style " of beer, Irish Red Ales and have mentioned how homebrewing has help resurect styles, like Porter. What is the Irish Red Ale style, its color, beginning and ending gravity, what ingredients are normally used, grains hops, level of bitterness, what yeast is characteristic of this style? Lets discuss it and brew it.

From: Jeff Frane <70670.2067@compuserve.com>  
Subject: Costs / Cold Break

On all-grain snobbery: Jim Busch has offered excellent points on how little all-grain brewing can cost. I'd also like to offer a suggestion -- brew with a friend. Or several friends. If you are in a region with a homebrew club, or have other brewers nearby that you know, pooling resources works very well. It's obviously a lot cheaper for 3 brewers to buy a grain mill or build a wort chiller than for one, and the reality is that this equipment spends a lot of time sitting around. It's also true that a 15 gallon kettle doesn't cost that much more than an 8 gallon kettle, and two brewers can make 10 gallons almost as quickly as one can make five. It also means more than one brain -- which can be a real aid.

On Cold Break:

Brian Bliss has posted some responses to a query about cold break, and I must say his opinion seems well-considered. However, I have to disagree, based both on my own experience and on the research I did last year for a presentation at the AHA national conference. George Fix suggested I post it to the Digest last summer, but I never got around to it. Here, then, are my own conclusions, excerpted from a presentation/article on building a wort chiller:

Hot Break/Cold Break

In addition to getting the wort to fermentation temperature, rapid cooling also causes changes in the wort which encourage good fermentation and brighter beer. At two late stages in the boiling/cooling cycle, there is an opportunity to clear the proteins, hop resins and other organic matter that would discourage healthy yeast growth and cloud the finished beer.

The hot break occurs while the wort is still in the kettle and is, in fact, considered to be the right time to end the boil. It is marked by the appearance of large flakes of "gunk" surrounded by a brilliantly clear wort. The cold break -- which consists of similar organic compounds -- begins after the wort has been cooled below 60°C (140°F). George Fix writes that "by removing most of both precipitates, one can eliminate approximately one-half of the haze-forming material." While it is essential to fine beer to ensure a proper hot break and to rack the wort off the precipitate, some homebrewers are overly cautious about "protecting" their beer from the cold break.

After touring through a few breweries, it is clear that cold break sediment is nowhere near as threatening as it seems at first glance; the most common systems create a cold break but do nothing to eliminate it. Consider, then, Jean de Clerq's statement: "It is therefore essential, that while the sterility of the wort is assured, it should (1) absorb sufficient oxygen during cooling, (2) coagulated protein should be entirely eliminated, and (3) the turbid matter which appears during cooling should be at least partly precipitated, so that it does not remain as a fine colloidal suspension in the beer." (emphasis added). In other words, what's essential is ensuring the break; once precipitated out, the material will only cause problems if it is redissolved by raising the temperature again.

George Fix writes that "in preparing my book on brewing science I tried to carefully study the effects of cold break carryover, and found that as far as finished beer flavors were concerned there were none." In that book, in fact, Fix explains that in adverse conditions such as a shortage of oxygen, trub can be utilized in yeast metabolism. He cautions, however, that bacteria can use trub in the same way. "If bacterial levels are sufficiently low both in the chilled wort and in the pitching yeast, then I believe there will be no problems from cold break carryover." With proper sanitation, then, and the use of pure cultured brewing yeast the carryover from cold break should not prove a problem to the homebrewer.

From: krueger@comm.mot.com (Kevin Krueger)  
Subject: Growing your own hops

Okay, being a homebrewer means never having to say your sorry . . . uh, I mean, it means you brew in a home (whatever that might be) and I finally have one !! So, being a homeowner means owning the land, and owning the land means tilling the land, so I want to grow some hops !!

I am curious what kind grows best in Zone 5 (Northern Illinois). I imagine that there is a reference book that addresses so any suggestions would do instead of advice.

Either way, thanks for any advice.

Kevin Krueger

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re: iodophor, rinse/reuse

JS relates his experiences with iodophor sanitizer:

I've had no problem with my brand of iodophor ('iosan') changing colour during normal use. Phil Hultin confirmed that iodine is fairly volatile (though not as much as chlorine), and so will eventually evaporate if left uncovered. This explains the fact that the iodine dissipated from the blowoff bucket but not from the stoppered carboy (I've reused the solution in the carboy and it's still amber - I guess there's a certain leap of faith you have to take in trusting the indicator colour during multiple reuses).

Coincidentally, while brewing the other night, I decided to check if the iodophor could be used as a starch indicator as well. The mash was already pretty much done and I got no colour change from the mash sample. So I tried adding a little powdered corn starch, and got the typical blue indication. Next time I'll check my mash at the beginning and end of the mash. Maybe it would be better to use the undiluted iodophor for starch tests - will test and post results.  
Cheers,  
Rick C.

Subject: hops in outer space...

More or less what was in the Thursday 2/11/93 Chicago Tribune...

BEER COULD REACH NEW HIGH IN SHUTTLE TESTS

German beer brewers, proud of their medieval roots, will join the space age next month when astronauts aboard the space shuttle test the effects of radiation and weightlessness on hops.

A leading brewery said Wednesday it hopes the experiment will produce new and better types of hops, which give beer much of its unique bitter flavor during fermentation.

"Plants change anyway because of natural radiation. Now we want to see what kind of mutation comes from extreme conditions of space radiation and weightlessness," said a spokesman for Bremen-based Brauerei Beck.

The hops experiment is one of about 90 to be carried out by two Germans flying with a U.S. space shuttle in March to the orbiting space lab.

Todd

Moderation sir, aye, moderation is my rule. 9 or 10 is reasonable refreshment, but after that it's apt to degenerate into drinking

Subject: still more BAA information

Hi all

Since I've had more than a few requests for info regarding my post about Beer Across America, I just thought I would post a few excerpts from the most recent BAA newsletter (kindly provided by our own Michael Galloway).

Here are the 24 different brews sent during 1992.

Jan Geary's Pale Ale  
Harpoon Ale

Feb Millstream Schild Brau  
Oldenberg Premium Verum

Mar Wild Goose Amber  
Boulevard Irish Ale

Apr Eureka Bear  
Alpine Village Lager

May Buffalo Lager  
James Page (not the Led Zeppelin guitarist I guess)

Jun Dock Street  
Old Detroit Ale

Jul Crazy Ed's Beer  
Helenboch Oktoberfest

Aug Wasatch Wheat  
Pyramid Ale

Sep Cherryland Golden Rail  
Elm City Golden Ale

Oct Penn Pilsner  
Dominion Lager

Nov Garten Brau Wild Rice Beer  
Kessler Oktoberfest

Dec Portland Ale  
Sierra Nevada Celebration Ale

They were also some favorites listed from the above:

Honorable Mentions:

Geary's  
Wild Goose  
Buffalo Lager  
Dock Street and  
Pyramid Ale

Winners:

Boulevard Irish Ale

Kessler Oktoberfest and  
Sierra Nevada Celebration Ale

As you may have noticed, all beers were either lagers or ales.  
Specifically, 15 lagers and 9 ales.

The Jan 93 selections were; Mass Bay Brewing Winter Warmer and  
Fisher Brewing Dark Ale.

There is a page of descriptions of each of the featured breweries  
giving locations and other beers available.

It also prints reviews of the last quarter's beers. All are  
favorable in a way because they supposedly have already gone  
through a taste-testing before they are selected. But they do  
offer descriptions of each beer i.e. the color, hopness, finish  
etc.

Another feature is that you can order from past selections. I was  
gonna order a 1/2 case of the SN Celebration, but they had none in  
stock. They did have Fishers Dark Ale, Portland Ale, Kessler's  
Centennial and Capitol's Dark Beer. Just in case you're  
interested.

Lastly and of course \*most\* importantly; if you are a member and  
you recruit new members (they mention your name when they sign up)  
you get a free sixpack, including shipping. So, all you  
prospective new members out there, my name is Scott Storey  
(BadAssAstronomer) ;);)

Subject: Another Mash-out Idea

Subject: Another Mash-out Idea Time:3:48 PMDate:2/11/93  
A thought: If unconverted starch, originating from dry sections of malt,  
might  
be released during the sparge; would it not be prudent to forgo the mash-  
out so  
that the enzymes, which are also in suspension (I assume), can do their  
bit on  
the newly released starch? I realize that the liquid level is greatly  
increased  
so it is harder for the enzymes to find the starch, but still...

Reactions?

=====  
====

Gary,

Very sorry to hear you are between jobs. I know this is not a pleasant situation in your neck of the woods these days. Best of luck with your search; I'll be thinking about you.

Feel free to forward this to the Digest. I guess I should have realized we'd developed a sort of electronic "community" and I should have posted something about my status long ago.

Yep, I'm still here. Still in the same job, same office, same compiler development work. Encore still teeters on the crack of doom but after eight and a half years on the crack I've gotten tired of worrying about it.

I haven't read the homebrew digest in around 20 months and have put my homebrewing on indefinite hold. After my coworker here was severely injured in a hang-glider accident in April of 1991 I had to take over extra work. I then rode through the closing of a plant where half my development group worked and I had to see them through layoffs. That was lots of fun. Those of us at other sites who were not laid off had that much more work to do, so up to about mid-1992 I was totally distracted by being screwed into the ground by the load.

I took up gardening as therapy for this and have become one of those rabid types who views the whole planet as composed of compostable and non-compostable objects :-). Seriously, I was shoveling horse manure off my truck before I went to work this morning. A neighbor came out to see what was on fire (it was composting like mad and creating big clouds of steam). Lately I've been on a self-study kick, trying to reinvent myself as an "object-oriented programmer" and between these two hobbies, all the rest of my time has gone to my wife, whose career has ramped up to full time.

But in addition to all this, I find I simply can't have ten gallons of beer in the house and moderate either my waistline or the tendency to substitute one more beer for a more "worthwhile" activity. So, while I've learned to avoid saying "never", I don't expect to be brewing any time soon and I'm thinking about other things.

Cheers,  
Pete

Subject: apology

In hbd 1071, arf dismissed extract brewers in an off-hand and offensive way. I kept my peace. Over the course of the next few days, Jack referred to his limited knowledge of/access to the net. To amuse myself on a quiet Thursday morning, I took Jack's original post and made a few simple global replacements: Compuserve user for extract brewer, electronic community for homebrew community, etc. I was very amused, and decided to share the results with the hbd. I apologize now, as I did in the original post, to any Compuserve users who didn't realize that this was all in jest. More to the point, I apologize to the HBD for wasting bandwidth with what could be considered a flame. I hope this note appears on the same day as the original joke. And Jack, if you must respond by flaming, please direct it to bradley@adx.adelphi.edu instead of here on the hbd.

Date: Fri, 12 Feb 93 08:52:58 CST  
From: wood@ranger.rtsg.mot.com (Dan Wood)  
Subject: Criticism of MI Bottle Deposit

Note: I sent this in yesterday, and got an emailed assurance that it would be added to the HBD, but alas, it's not in today's issue. My apologies if it appears twice on Monday. Just goes to show, you've got to be careful about trusting daemons. :)

While I have enjoyed Ulick's posts in the past, and benefitted from the wealth of information he provides to this digest, I must take exception to his description of Michigan's deposit law as "inane".

I live in Illinois, a state with neither bottle deposit nor blue laws. I frequently visit friends and relatives in Michigan. The contrast between the two states is startling in many respects, but let me focus on the difference this is entirely due to the bottle deposit.

In Michigan, you will find very little broken glass, nor will you find litter from empty cans or cardboard packaging. It's rare for people to throw away their empties, instead they return them for cash. In the rare occasions where they are discarded as litter, local kids enthusiastically gather them and return them to collect the deposit. You wouldn't think it would work this well, but apparently the locals have figured out that those dimes add up.

In contrast, virtually no area of Illinois is immune to this litter. Even residential neighborhoods routinely have empties (presumably from "cruising" young drinkers) discarded on street corners and in front yards. Local parks typically have hazardous areas created by broken glass. In my experience, this problem also exists in other states that don't have deposit laws.

Although Michigan's deposit laws have created some inconvenience for retailers, I feel it's justified, since they profit from the sales. It costs the consumer nothing so long as he acts responsibly and collects and returns the empties, which should be done regardless. The deposit simply provides incentive to "do the right thing". Obviously social conscience doesn't produce this incentive elsewhere.

Please excuse the long post, and I certainly don't mean to flame, but the lack of deposit laws in other states is a pet peeve of mine. I can't see condemning such an effective system simply because of minor inconvenience suffered by out-of-state visitors. Should anyone feel they must debate this issue with me, please do so via private email, this is the last HBD bandwidth I will expend on this topic.

Stepping off my soap box now, relaxing, and still brewing great beers  
from extract,  
Dan Wood

From: Andrius Tamulis <ATAMULIS@ucs.indiana.edu>  
Subject: Mash temps.

In today's HBD I saw a question about mash temperatures, and as I've had a question about the same that I've been meaning to put to the net, I figure now's the time.

I all concerns Miller's book and his mash temperature recommendations. I don't have the book here, so details may be fuzzy, but in his chapter on "Conducting the Mash" he warns that starch does not dissolve in water at temps. less than 149 F, and therefore you should never mash blow (below, that is) that temperature. Then, in the ale recepie section, he recommends mashing certain ales at 141-150 degrees F. Does anyone know what's going on here?

Subject: A Beer Odyssey (Act IV)

A Beer Odyssey (Act IV, the last)

My next scheduled stops were Willet's and Brown Street, both in Napa. Check your maps - Napa is a good long way from Chico, and the nearest intervening brewpub involves a detour to Davis. (Which wouldn't have been a terribly bad idea, since Sudwerk makes some mighty fine brews.) About halfway there, my human frailties overcame my drive for beer, and around 12:30 I pulled off the freeway at Maxwell for an hour's nap.

I awoke a new man. Before long I was on Highway 128, navigating the hills between the Central Valley and the Napa Valley. (Nobody told me there were mountains there! Whose idea was this, anyway?) Willet's was closer than Brown Street, so I stopped there first. I was shocked and dismayed to read the sign painted in their front window: "Closed Sunday". Fortunately, Brown Street was just up the road.

Brown Street had been my favorite brewpub since my first visit not long after they opened. They always had twelve very good beers on tap, from a very light ale to a very black stout. Their specialties were Ginseng Ale, which was their Porter with a bit of ginseng extract added, and California Chili Beer, which was amazing. Period. My friends and I would make regular road trips to Napa to buy the stuff two or more gallons at a time. It was incredible.

Then the unimaginable happened. I read it on page 13 of the August 1992 Celebrator: "Closed: Brown Street Brewing, Napa CA. The brewery has ceased production but the restaurant is still open." I was stunned. Shocked. Dumbfounded, even. Granted, they have a terrific restaurant, but no more Chili Beer? It was hard to imagine. I was sure I was dealing with a vicious rumor, but I had to find out for myself.

The sign on the door said "Sunday: 4:30-11:00". No mention of the state of the brewery. As much as I would have liked to stay, it was only 2:30, and I had places to go. I have since learned that the brewery is in fact closed. They have five excellent California and Washington beers on tap, but the brewery is closed. A moment of silence, please.

Kelmer's in Santa Rosa is just up Highway 12 from Napa. It's bigger than your average brewpub, with a long bar, a large dining area, and a separate room that looks like it would be a great place for a private party. I was stuck in traffic (Traffic? In Sonoma County?) on the way there, so I didn't arrive until nearly four o'clock. Imagine my thirst. I remembered tasting their excellent Scottish Ale on tap at Pacific Coast, and I hoped to have some fresh at the brewery, but it was out of season. I had to make do with some of their other pretty fine beers:

Krystal (light) - Wheat lager. Very light indeed. Definite wheat sweetness.  
Klassic (medium) - Amber. Also pretty light.  
Klout (dark) - Stout. Good roasty flavor, but a bit thin.  
Independence Ale - "Winner of the Great American Beer Festival". That's more like it! Well-hopped, well-balanced pale ale.

The notes on the menu say that the brewery was established October 1987, and that they have sold over ONE MILLION glasses of their beer! Well done! They also sell those one-gallon jugs that are supposedly illegal. I asked the bartender about them, and he was not aware of any rules prohibiting their sale. Go figure. The fish and chips, while not up to the standards of the Edinburgh Castle in San Francisco, were certainly good enough to soak up a pint of their Independence Ale.

One last stop before the home stretch: Dempsey's Ale House in Petaluma. It's tucked away in the back of the Golden Eagle shopping center, but it's not too hard to find. Once again, the gallon jugs were on sale. (They're everywhere, I tell ya!) One more time, I started with a round of samplers:

Golden Eagle - light pale.  
Red Rooster - Less body but more flavor than Gold...  
Bad Bear Brown - Good brown. Just sweet enough. Could use a bit more "roasty" flavor, but maybe not.  
Henry's Stout - Thin, a little astringent. Doesn't make the cut as a stout, and it has too much burnt flavor for a porter.

The jar behind the bar advertised homemade beef jerky, but the jar was empty. Too bad.

There were more stops to be made before I crossed the Bay on the way home: Marin in Larkspur; J&L in San Rafael; 20 Tank, San Francisco Brewing, and Gordon Biersch in San Francisco; Bison and Triple Rock in Berkeley; Pacific Coast in Oakland; Tied House in Alameda; but I had to admit defeat.

Or was it defeat? Nine brewpubs, samples of forty-one of the best beers in California and Oregon, a thousand miles of driving through some of the most scenic country in America...I think I won after all.

And I learned two very valuable lessons along the way:

- A lot of microbreweries are making much better beer now than they were last year.
- The 1989 Mercury Cougar was not designed to be slept in.

From: Nathan Clark <GRS04736@CONRAD.APPSTATE.EDU>  
Subject: Suggestions for a beginner...

I have recently become interested in HB, and have been reading HBD for a few mos. I am wondering if there are any magazines out there for HB, especially ones with help, hints and recipes for the novice. I have seen some references to "Zymurgy" in articles by Bob Jones and others. Is this what I'm looking for? Also any good literature for the beginner?

Thank you,  
Nate Clark

Subject: RE- Fermenting in Stainless

Subject: RE: Fermenting in Stainless Time:9:37 AMDate:2/12/93  
I have been using a 15.5 gal Sanke keg as a fermenter for the past 18 months or so. I have been quite happy with the results. I have not modified the keg except to remove the valve assembly. I can put 13 gallons of bitter wort in it without a blowoff hose and not worry about overflow. To sanitize, I scrub the interior with my regular carboy brush, inspecting with a small mirror and flashlight. Very little grunge has stuck to the walls of the keg. I then rinse with boiling water, about 3 or 4 gallons. I roll the keg around on its side with the boiling water in it for about 15 minutes. The keg is emptied and stored with some foil over the opening. Prior to filling the fermenter with new wort I rinse it again with the same amount of boiling water as before, rolling again for 15 minutes. I have not had any infection problems.

George Fix uses pony kegs for fermenters. There is some study which says that the proportions of ponies are perfect for the task. Perhaps he'll chime in with comments of his own.

>dextrins. Does the higher temperature just favor the one enzyme system  
>over the other, or is the lower temperature system actually destroyed? I  
>have always thought the latter, but the literature is unclear, and it  
would  
>seem the malting process exceeds those temperatures.

It's a better idea to go the other way around or mash somewhere in the  
middle, say low to mid 150s. It is the latter. Actually both alpha-  
amylase  
(which cuts the starches into dextrins) and beta-amylase (which breaks  
glucose molecules off the ends of dextrins and starches) slowly denature  
at all the temperatures above 140F (or something like that -- I don't  
have  
my books here). Beta-amylase is MORE temperature sensitive and denatures  
quite quickly at temperatures like 158F. Alpha-amylase tends to be  
heartier  
and lasts longer at temperatures like 158F. So the key is how long are  
alpha- and beta-amylase going to be around at your mashing temperature,  
not at what temperature they "like" to work. This is why going into the  
high 150s and then back down won't work as planned. I'll leave the  
answer  
to your other question, about temperatures during the malting process,  
to others since I don't know enough about it (perhaps much of the  
enzymes  
\*ARE\* denatured, but enough is still left? -- that would explain why  
Munich  
malt (kilned at higher temps) has less diastatic potential than Pilsener  
malt).

>ice water and dump the almost-frozen water in on top. I cover the pot &  
>wait about a half hour or until all the ice in the sink melts.  
>Seems to me I get a pretty good cold break from this.  
>  
>Wort-chillers? We don' need no stinkin' wort-chillers!!!

That's exactly what I used to do and it was a BIG improvement over trying  
to get the wort to pitching temperature in the bathtub. I build myself  
a wort-chiller so I could do full boils (better hop utilization) and for  
consistency (sometimes half of the gallon of water would freeze and I'd

have a heck of a time getting it out of the jug!) so my pitching temp was more predictable.

Then later:

>Now here's the heretical part. After having read the discussion of yeast nutrients in trub when it first appeared a few months ago, I decided to rack off not only the beer but just a little bit of break material too (maybe 1/2 cup or so). Also, in spite of all the \*worrying\* about temperature shocking yeast, I pitch at a relatively high temperature - usually in the 80's F. (I brew ales), because, o.k., well, my chilling methods DON'T work as well as a wort-chiller does - but the bottom line is that I always get fantastic starts (under six hours and a lot of crud in the blowoff bucket) and I've been getting some pretty decent beer the last few batches.

There's little problem with pitching into 80F wort if your starter is around 80F also. If your starter was in the 60s, then I'll bet you wouldn't be getting such fast starts (temperature shock). Also, pitching a warmer starter into a cooler wort is a bigger shock to the yeast than going into warmer wort.

Regarding your picking up of trub, if you mean when you are transferring to your secondary, then I feel you would be better off not picking up the trub. Sure there are nutrients in it, but they should only be made available to the yeast during respiration not during fermentation. I've read that fermentation of trub tends to increase fusel (higher) alcohol production. It has also been suggested that these higher alcohols are blown-off if you use the blowoff method (which you do), so fermenting on the trub is allegedly less of a problem if you use the blowoff method.

I ferment on whatever break I accidentally don't leave in the kettle AND use the blowoff method and on most of my beers I feel there's no problem with excessive higher alcohols.

Subject: Spread it on Toast Imperial Stout

I've gotten several requests for the recipes with which I've won awards. I believe all but the Imperial Stout and Dubbel-style have been posted. I won't post the Dubbel-style, since I don't agree with the judges -- I thought the beer was quite a bit worse than they did, but here's the Imperial Stout:

Spread it on Toast Imperial Stout  
by: Al Korzonas

6.6 lbs Northwestern Dark Unhopped Extract  
3 lbs Laaglander Light DME  
1/4 tsp NaCl  
1/4 tsp CaSO4  
1 tsp CaCO3  
1 lb 40L Crystal malt  
1/2 lb Chocolate malt  
1/4 lb Flaked barley  
3/4 lb Roasted unmalted barley  
5 gal Palos Hills, IL (soft) tapwater  
1.5 oz 7%AA Cluster pellets (60min)  
1.5 oz 5%AA Cascade pellets (60min)  
0.6 oz 5%AA Cascade pellets (15min)  
0.5 oz East Kent Goldings whole (dryhop)  
8 oz starter culture from 4 bottles of Sierra Nevada Pale Ale

Steeped grains at 170F for 15 minutes in grain bags.

OG=1090  
FG=1037

Fermented at 65F.

Bottled with 1/2 cup boiled corn sugar.

This Imperial Stout is less alcoholic than many others I've had -- this is partly due to the fact that the Laaglander extract is not very fermentable. The Laaglander is also partly responsible for the high FG. This is a very creamy, smooth beer.

From: johnw@NADC.NAVY.MIL (J. Williamson)  
Subject: aeration and hot/cold breaks

I could use a little help with the subjects of wort aeration and the formation and importance of hot and cold break.

First, wort aeration. On reading beginner's books I get the impression that I should boil up my extract, grains, etc in my brewpot, and then

pour the wort through a strainer into my primary, pitch the yeast, seal and

leave alone. Through this forum and from other sources I've learned that the yeast needs oxygen to reproduce therefore the wort should be shaken, stirred vigorously just before or after pitching. What is the experts' advice? Do I leave the wort alone or not?

Regarding hot and cold break. As I understand it hot break is formed during the boiling of the wort. Cold break must be formed by cooling the wort after the boil. A few questions. I only boil about one and a half gallons and add that to three and a half gallons of water in my primary - does just chilling the 1 1/2 gallons produce a cold break? Does the rate of

cooling affect the formation of a cold break and if so how fast should it be cooled? I'm assuming that cooling my 1 1/2 gal of wort does produce a cold break which settles to the bottom of my pot with the hot break - should

I take care and siphon the wort off the trub into the primary? If I siphon

the wort off the trub am I leaving nutrients in the trub that the yeast need?

Any help would be greatly appreciated as even the beginners books are not crystal clear to the beginner.

Thanks in advance, JW

From: Alexander Samuel McDiarmid <am2o+@andrew.cmu.edu>  
Subject: malt extract

I have just tried a new batch of beer which I brewed with a piltzner kit (M&P?) in which instead of adding only shugar to the malt mix I used malt concentrate. My problem is that the taste is too bitter/(malty?). I would like some suggestions if anyone has any as to why it has turned out so bitter and general guidelines as to the proper use of malt extract. there is definately the appropriate amount of alcohol though (just for the idiotic innappropriate discussion as to what beer has the most kick for the dollar).

My process went as such.  
boiled all the water and the malt shugar (liquid), malt extract, and shugar.  
then I dumped it all in the carboy as usual.  
after cooling I dumped in the yeast ( came with the kit)  
after a week in the carboy I added gelatin as a fining agent  
waited a few more days and racked to bottles. I have since let the bottles sit the required three weeks plus a few days. (because I wanted the beer out of the bottles faster I stuck to the required shugar to pre beer ratio, also gets rid of that over pressurization prob my friends complain about when they put in more.)

I have just opened the beer and drunk some, not bad or yeasty as if it was opened too soon, but definately too bitter.

From: arf@ddswl.mcs.com (Jack Schmidling)  
Subject: Where's Rudebush

I think I have allowed a polite amount of time for Roy to defend his position and as he doesn't seem to be so inclined, I will offer a few comments.

Roy Rudebush has been running ads in various journals claiming that his Corona Mill, "crushes malt better than J.S. rollermill. Proven" and he made the same claim in a recent posting to the Digest.

This claim has been challenged by a HBD participant and he seems to have vanished from the scene. I have written to him several times, both email and US Mail and have never received a response.

As a bit of background, Roy who runs IMO Homebrew Supply in St Louis, purchased a MALTMILL (tm) about a year ago and promptly returned it for a refund. Aside from comments about the Corona being better, he has never responded to any further attempts of mine to resolve the issue.

Upon seeing one of his ads, my wife sent for the "proof" under her name and we received his analysis. Again I wrote to him suggesting that it is probably futile to argue with his data but pointed out that most retailers take advantage of selling to both ends of the market and I do not understand why he is taking this approach. I received no response to this either.

He claimed in his posting here that....

> Analysis was done by several professional brewers and scores of accomplished homebrewers.

In the info he mailed out, he only mentions his wife and himself. He also refers to a "Midwestern micro-brewery" that prefers to use a Corona because of its superior crushing. I would be interested in knowing the name of this brewery. The only one I know of in the Midwest using a Corona, never heard of him and the owner assures me it is a tight budget, not preference that has him using the Corona.

As this is the one and only MM ever returned for a refund, it is important to me to make sure it is understood that something most peculiar is going on here. It happens that the one he purchased was a very early edition (number 5 or so) and many improvements have been made since. All of the improvements have been to enhance reliability or ease of use and there never has been a

problem with the crush quality. Furthermore, all known problems with  
early  
units have been resolved to mutual satisfaction and as far as I know,  
there  
are no unhappy customers out there out of close to 500 users.

I can't tell someone else how to run his business or attack him for his  
ads  
but I can sure jump on him for his hit'n run attack in this forum.

Where are you Roy?

Subject: Reused Ballantine yeast

>On 'tother hand, Ballantine Brewery supposedly used this yeast strain  
>over and over, repitching hundreds of times without any problems. So  
>I'm still scratching my head over this one.

Well since you mentioned it, I gotta relate a story I heard from the head  
yeast guy at SchmidtUs of Philadelphia. I gave a seminar and  
accompanying  
laboratory 8^) on brewing biochemistry while in grad school and got the  
cook's  
tour from him as part of the research.

He said that Schmidt's supplied yeast for another brewer he couldn't name  
but  
I figured out was Falstaff (not "Ballantine") in Cranston, RI. Like  
most  
other commercial ventures, Falstaff tried to keep its costs down, so they  
only  
ordered yeast every few months. Naturally, this boomeranged on them  
often, as  
the yeast mutated or got contaminated, and Schmidt's would get an urgent  
call  
from Cranston: "We need some more yeast, like yesterday!" So the yeast  
guy  
would grab the latest batch destined for mother Schmidt's, and put it on  
an  
airplane. The airplane would come back with a sachel full of money,  
since  
Schmidt's knew Falstaff was over a barrel, and all the money they thought  
they'd save by stretching the yeast eventually always got to  
Philadelphia.

Moral of the story: Recycling yeast usually works (e.g. Ballantine's IPA)  
, but  
sooner or later mother nature is gonna jump up and bite you on the wazoo!

Date: Fri, 12 Feb 93 22:36:37 EST  
From: jdg@cyberspace.org (Josh Grosse)  
Subject: Diacetyl reduction and clarifiers

I was moved to post a response to several related questions in today's issue (1076), regarding diacetyl reduction and clarification.

Clarifiers such as Isinglass or Polyclar (tm) will reduce the yeast population in suspension, which may be a contributing factor in diacetyl levels above the taste threshold. Diacetyl is more likely to be noticeable in lagers than in ales.

Racking from primary to secondary fermentation vessels too early may also contribute to diacetyl flavor/aroma.

Since I'm addicted to Polyclar, I use a procedure called a "Diacetyl Rest" at the end of fermentation before racking to the secondary fermenter. This eliminates diacetyl nose, and I get a beer with excellent clarity.

After fermentation completes, I bring my primary fermenter up to 68-72 F for 24-48 hours prior to racking to the secondary. I add Polyclar, and bring the secondary down to lagering temperature.

One note about clarifiers. Spencer Thomas and I split a batch of Vienna this fall. We pitched the same yeast into the same wort, split the batch, and fermented separately. We even used the same temperature for fermentation. HOWEVER, Spencer didn't use a clarifier, and I did. Yes, I won points on clarity -- Spencer won on malt nose and flavor.

Diacetyl references: Miller: TCHOHB, and Fix: POBS.

Subject: Beer places of interest in Santa Clara, CA?

I'm scheduled to go to the Sun Developers Conference in Santa Clara, CA at the end of March and would, quite naturally, like to spend my free time checking out the local suds venues, i.e. brewpubs, micros and beer bars.

Replies by e-mail graciously accepted. Thanks.

Subject: Overnight mashing

Before you trash the ideas herein, please note that I DO recognize bad beer when I taste it, and I DO know the reasons why the big names in brewing for the most part discourage these techniques. I was an extract brewer for 4 years, and then made the switch to all-grain. I sometimes wished I could return to extract for a quick batch, but frankly I can't afford kits anymore; after the initial expenses (and Christmas presents from Mother in law...) I can brew a bitter for under \$10 (canadian), vs \$20+ for an extract brew. A few recent posts, particularly by George Fix and McHarry got me thinking about overnight mashing and cold sparging. So here it is: the EvenEZ-er OverNiteMash (c)\*.

0. Pre-heat oven to 200 degrees F
1. Heat the mash water to 165 degrees F
2. add the grist slowly, stirring (gently) to ensure no dry spots
3. add heat slowly, stirring gently, until temperature of the mash is an even 155 degrees F
4. Turn off the oven, put the mash pot in the oven. (if you use an insulated tun, or your kettle won't fit in the oven, skip this step, it probably won't make that much of a difference).
5. Go to bed.
6. The following morning, remove the mash from the oven, and take the lid off (if it had one on). This will cool it down quicker.
7. When the mash is cool, dump it in the lauter tun (two bucket type works just fine).
8. Sparge with COLD water.
9. Boil as usual.

(I wouldn't recommend this for a brew which needs step infusion or decoction, this process is for a beer requiring only a single stage infusion mash, such as an English bitter.)

I hear you screaming "But there's no mashout!" "My extraction rates will be way down!" "My sparge will stick!"  
To which I reply: So what, no it won't, and I had no problem, in that order. To qualify, as the temperature drops, the enzymes become less active, plus the alpha amylase has been to some degree inactivated by the high initial temp. Furthermore, part of the reason for the mashout is to eliminate a variable in brewing a specific beer; commercial breweries want to control ALL variables so each batch comes out the same. We're homebrewers, we don't have to listen to the bullies if we don't want to.  
As for extraction rates, mine were virtually identical to my hot sparge rates (which were not spectacular, but a reasonable 26-27 points or so). As for the stuck sparge, I can't say I've EVER had one. When making a two-bucket lauter tun, tape 1cm graph paper to the bottom, and drill the holes evenly.  
You will wind up with almost twice as many holes, believe it or not, and no uneven drainage of the grain bed.

I wonder if one reason for commercial breweries using a hot sparge is that it requires much less energy to heat the sweet wort to boiling

afterwards...

Anyway, this requires about 1/2 hour before bed (not including grain grinding time), and about 3 1/2 hours the following day, making the time consumption much more like making an extract brew. Another major advantage is virtually no hot side aeration (HSA) save for the mash (which is why you stir it GENTLY).

As a disclaimer, I just did this over the weekend, so I don't know yet how the final product will taste, but I will keep you posted.

From: wood@ranger.rtsg.mot.com (Dan Wood)  
Subject: Sour Brew, Part II

First let me say thanks to those who replied in HBD and via email. Experimentation with food grade acid is an interesting thought. Does anyone see problems with adding small amounts to just a few bottles at bottling time? Not that I'm nervous or anything, but I hate to take chances with 5 gallons at a time.

Anyway, my friend Brent tried following Charlie's directions. He placed a quantity (sorry, I'm unsure of amount) of pale malt in a cooler with 5 gallons of water at 130 F. He covered the cooler and left it for 19 hours. The temperature had only dropped 20 degrees to 110 F, and the liquid was sweet, with no sign of sourness (tartness?) and no noticeable growth. It may have stayed too hot, any other ideas about what went wrong?

Also, I had the pleasure of sharing an Imperial Stout and Taddy Porter (Samuel Smiths) yesterday, and they both seemed to have a bit of sourness, perhaps more noticeable in the Imperial Stout. Perhaps I'm misinterpreting something in the flavor, but there does seem to be a much more distinct sour flavor than I've experienced in beers with much more dark grains.

From: THOMASR@EZRZ1.vmsmail.ethz.ch  
Subject: yeast strain selection

hello all.

on this thread about yeast strain selection aka finding a growth medium that will kill everything but the yeast you actually want, I have a few comments.

Firstly, there seem to be two lines of discussion going on at the same time, one concerns getting rid of so-called "bugs" and the other concerns getting rid of "wild" yeasts. So, the bug problem first:

most of the bacteria we are likely to get in our yeast supply can't survive acidic conditions, so if you sterilise (ie boil) your growth medium (eg wort), which you have previously adjusted to pH 4-5 (unnecessary if you mashed your own), the bacteria will not grow anywhere near as fast as your yeast. By the time the sugar is used up, there may well be enough alcohol in there to stop all bacterial growth. (I brew a strong (1085) ale just so that I can get a sample of yeast from the bottled version when I need one).

The wild yeast problem, as far as my research has dug up, is not at all trivial. You can stop the growth of ale (top) yeasts compared to lager yeasts by fermenting them on mellibiose as the sugar source. (this should be available from Aldrich chemical co, etc). There are no other sure fire ways of separating yeasts, unless you know EXACTLY who the stranger in your wort is. How about streaking plates, and doing small scale runs with all the yeast looking colonies that appear, and then isolating the strain you want by taste or rapidity of clearance. This is how they do it in the breweries. (Assuming they mislaid the clean strain or are looking for a better one.

I suppose, having finished this note, that I haven't really said anything new. Oh well.

Rob Thomas.

P.S. More brewing/beer quotes please... "Poe" was great!

BadAssAstronomer writes:

>The Jan 93 selections were; Mass Bay Brewing Winter Warmer and  
>Fisher Brewing Dark Ale.

We tasted these yesterday at the brewclub meeting. "Dark Ale" is a misnomer. This stuff was sort of copper colored. I'd say it's at the dark end of the pale ale spectrum. The flavor was nothing to get excited about, either.

The Mass Bay Winter Warmer, on the other hand was excellent. Nicely spiced, but not overwhelming. So many spiced beers have a sort of sour flavor, but this does not. Our meeting was outside at a local park, and I'd say that the Winter Warmer lived up to its name.

From: Joe Boardman <boardman@amber.Colorado.EDU>  
Subject: an HBD-inspired yeast experiment

G'day All,

This weekend I started a little experiment that was inspired by a thread here a few months ago: "just what are the differences introduced by ale and lager yeasts?".

I brewed a 10 gallon batch of a pretty generic (but leaning towards a lager) wort. Then as it came out of the counterflow I split it back and forth between 2 glass carboys. One of these was pitched with a Wyeast 2007 (Pilsen) lager yeast, and is fermenting away at 50-53F. The other was pitched with a Wyeast 1056 (aka SNPA) ale yeast, and is doing its thing separately at 65F.

The recipe was:

Virginia's Advice Ale/Lager

12 lbs Klages American 2-row malted barley  
2 lbs Hinode Calrose California rice  
5 oz Saaz plugs @3.1 alpha  
2 oz Tettnang pellets @4.3 alpha  
+ the two yeasts mentioned above

I ground the rice, boiled it and cooled it to 130 with ice. Then I mashed in the grain and the rice at 130 and held for 30 minutes, then did a 2 hour mash between 152 and 145F. The IG was 11.8 Brix (about 1.047), which means my extract rate was in the low 30's.

I guess what I've really done is brew a lager and ferment half of it as an ale. I made it very light in color and body so the yeast differences wouldn't be masked. Next time, to be fair, I guess I'll have to brew an ale-type and do it again.

Does anybody want to hazard a guess about the taste differences?  
Does "clean" really mean anything?  
Is anybody going to be in Boulder in about 2 months to try some in person?  
Does anybody "know" they can tell them apart in a double-blind test?  
I'll report back if there's interest.

Cheers, Joe

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: I killed my yeast!

Yes I did, and it was cultured-from-the-bottle Chimay Red yeast :-(  
The bleach-water was most of the way back up the blow-off tube, and when  
I lifted it out of the overflow container to drain it back down, it  
splashed  
back up the tube and into the wort. What looked to be a ferment starting  
is  
now dead, dead, dead. It made me wonder why I had bleach in the overflow  
bucket anyway. Obviously, disconnection the blow-off at the carboy end  
would have been a much better idea.

My plan is to boil it again, to boil off the bleach, cool it, and if it  
still tastes ok, pitch some other yeast. Will this work, or has the  
chlorine  
already ruined it? I'm not happy.....

From: gjfix@utammat.uta.edu (George J Fix)  
Subject: Australian Yeast

This post is a request for information from those who have brewed with strains of active dry yeast from Australia. The strains I am particularly interested in are Mauri Foods Y327 Ale, and Mauri Foods Y497 Lager. It is my understanding that they were (are?) distributed in Canada by Superior Brewing Supplies. I am preparing a talk for the Microbrewers Conference in New Orleans, which will survey the important yeast strains currently available. There are some small operations, which due to limitations of equipment and other reasons, are forced into the use of dry yeast. Thus, I felt it is important to touch on some of the better versions. I have been told that the above strains have very high % cell viabilities, and very low bacterial/wild yeast counts. Private e-mail relating practical experience with these strains would be gratefully received.

Date: Mon, 15 Feb 93 21:42 MTS  
From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: The results are in

The results of a survey of the HBD readership are in! As you may recall, I recently submitted a note to the HBD (about a week and a half ago) inviting everyone to mail me with a descriptor of their brewing level. What a response!! By 10 a.m., I'd received more than 100 responses! Thanks to all for participating. (And what a talkative crowd! Sorry that I couldn't answer messages individually.)

The admittedly inadequately simple categories from which I asked people to choose were as follows:

All Grain if you rarely use extract for your brewing, other than for yeast culturing,

Intermediate if you do some mashing, partial mashing, some yeast culturing, etc., but you don't consider yourself very experienced, or

Extract if you are relatively new to the brewing process, haven't tried mashing, or in general, consider yourself to be on the steepest part of the learning curve.

The tallies are as follows:

All Grain: 55  
Intermediate: 65  
Extract: 69

I'd like to make a few comments regarding the survey.

Categorization: Obviously, as stated above, a categorization of only three simple slots describes the multidimensional brewer only crudely. Some people have never brewed with extract; some have brewed for ten or more years with extract only. And so on. I wanted to conduct this poll only to convince novice brewers that they really should use the HBD, not to annoy readers by forcing them to categorize themselves. Enough said!

Statistical Discussion: The results to this poll are most likely not truly representative of the entire HBD readership. I can think of several readers who regularly post in the HBD who didn't reply. I'm sure that more than 189 people read the HBD. And I suspect that the tone of my original message might have motivated those on the steepest part of the learning curve to reply, skewing the results. Also, bravado or modesty might cause people to describe themselves incorrectly.

Use of the HBD: I did all this for one simple reason. I want new brewers to feel free to use the HBD as a valuable resource for talking with experienced brewers for the purpose of improving their brewing, as I did. Several beginners told me that they were certainly intimidated from asking questions. The HBD has got to be the greatest resource available; use it. From my results, a significant fraction of the readership brews extract only. You're not alone!

A few commented that they're annoyed by such questions as "How do you brew beer?" Obviously, questions like this are inappropriate, but this doesn't mean that all discussion should be on the level of comparative mashing methods. So, use the HBD, but use it wisely.

So there you have it. An incomplete, inadequate survey of the HBD readership. That's my contribution to brewing science for now. (But with a Ph.D. in chemical engineering, I should be able to do better than that!)

Cheers!  
Chuck

P.S. For those who must know, I have never tried mashing. I use extracts and specialty grains (and fruits and spices too, yummm!) Maybe someday when I get a regular job (and a house with a basement).

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: snobs

>  
> In Michigan, you will find very little broken glass, nor will  
> find litter from empty cans or cardboard packaging . . .  
>

Really? Guess you've never been to Detroit.

Lately there seems to be a tendency towards complaining about the various types of snobs that can be found on the Digest. Be it all-grain or unix, I feel that these gripes are small potatoes. I think there exists a more serious type of snob out there which threatens the very foundation of the homebrewing community. And since it looks like no one else notices, I shall take it upon myself to point it out the general HBD community.

I would like to complain about fart snobs.

I'm sure you're aware of whom I speak. Tell me if this sounds familiar: You're at a homebrew gathering, drinking a beer, trying to decipher the subtle nuances of the hop aroma, the malt nose and the estery parfum when all of a sudden: (sniff) Oh man! Who the hell did that? GODDAMMITROGER!!!

We have all suffered from such individuals. You know who they are. Its that special breed of homebrewer who can bust worse than anyone else around.

This is one type of snob I cannot tolerate. It's not enough that a fart snob can emit such a heinous stench and at the same time maintain the facade of calm innocence nor make an otherwise gentle, God-fearing group of people trample one another in a stampede for fresh air. What really irks me is that these people won't share their technique with others.

How do they do it? What's the secret? How can they rip so vile that eyes water, dogs howl and vultures circle?

God knows I've tried. I've eaten all the wrong foods. I've done shots of yeast slurry. Hell, I've even sampled all the novice homebrew put in front of me. The result? Nothing. Oh sure, what I could pass showed promise since it did offend my wife, especially when I wafted the blankets. But I think its more of a female thing than anything else.

Which brings up another question: why don't women fart? Is their anatomy different in that the human female can't physically fart? Lets face it, have you ever heard a woman let one go? I know I haven't. It is my personal opinion that if a woman would fart periodically, and I mean really let loose with a long, loud stinkie, she would feel a lot better. Hell, I'll go one step further to say that most problems in the world today could be solved diplomatically if the two parties involved would just sit down and rip a few together. Who's to say it wouldn't work. Stranger things have happened. But I digress.

After much contemplation, I have come to the conclusion that

maybe, just maybe, I not destined for such greatness. Perhaps I should accept the fact that I'm just a mediocre farter. It could be that these people are not self-made but born to greatness.

From: joseph@joebloe.maple-shade.nj.us (Joseph Nathan Hall)  
Subject: New Brewmaster at Dock Street

I just spent an entertaining evening tasting infected beers at our new homebrewing club (now officially christened B.U.Z.Z. -- Beer Unlimited's Zany Zymurgists, after the store that sponsors it). The guest of honor was Nick Funnell, new (2 mo.) head brewmaster at Dock Street in Philadelphia.

Nick is an entirely pleasant tall, lanky somewhat English fellow who obviously has a great love of beer, and in particular cask ale. I think things are looking up for Dock Street. (Jim Busch, did you hear this? It's about time!)

Nick brought along an ersatz "Framboise," which he claimed had a Flanders brown base. I'm practicing for the BJCP exam and was busily filling out scoresheets as the beers wandered by, and was oh-so-pleased to give his (Dock Street's) brew a 41. Really, the only problem with it was a slight lack of body. Otherwise it was nearly perfectly balanced, with an awesome raspberry nose, tenacious head, clear and tart fruit flavor, and an interesting chocolate-toasted malt finish. One of those beers even your WIFE would love. (Not my words, but we know the stereotypes.)

He plans to import some casks from England shortly, and claims to be addicted to real ale. Judging by the slight shudder and glassy look he gave while saying this ...

It turns out that his apartment is right on my way home. Since he lacks a car at this point, I dropped him off and was invited in to share some cocoa with him and his wife Barbara.

Why do we make it so hard for these people to get work permits? We need MORE of them!

Yes, I think things are looking up at Dock Street!

Have you (or anyone else out there) tried Lin's wild yeast medium? I think it contains crystal violet as a culture yeast inhibitor, allowing wild yeasts to grow (or rather, to grow better). Is it better-worse-same-faster than cupric sulfate? The 8th Edition of the ASBC Methods of Analysis contains a section on this media, so I assume that it has some utility and some brewery is using it. Of course if a well funded individual has the ASBC MOA maybe they could respond. The media is available from Siebel.

Another note:

I have only been on the digest since #999 and in one of the early issues I saw a reference to Micah's Magical (bionic) Starter. Can anyone either publish the recipe again or direct me to the appropriate back issue? Thanks.

From: pyle@intellistor.com (Norm Pyle)  
Subject: Mash temps. / Digest plumbing

Andrius asks about Miller's recommended mash temps. I may be speaking out of turn here, since I don't have my copy of Miller handy, but.... I believe Miller's book is mostly about brewing lagers. If that bit of heresay is actually true, then it may explain something. If he is out to brew the finest lager, he doesn't want any starch haze making him look bad. So, he wants to make sure all starch conversion is complete; if it's not, he's going to get a starch haze.

To the numbers you mentioned: I believe he said (or meant to say) that all of the starch may not dissolve below 149F. In fact, I would bet most of it does, which is something you can probably get away with in a dark, muddy ale. I don't remember him asking for anything as low as 141F but it may be so. I personally like to mash in the 152 - 158 F range for more body, less alcohol. Unfortunately, I always seem to screw up and get a nice variety of mashing temps before it's all over. ;-) :-0

Mike Schrempp posted about some outfeed roller to use in a mill. Thanks, Mike. I have one question: does the catalog mention the diameter of the rollers? (I assume the 14" and 22" are lengths) A larger diameter is better for grabbing the grain.

A note about posting to the digest: If you receive a reply from the daemon that says it will post your article, it will post your article. If it says something like: "there are 42 articles ahead of yours", then it probably won't get in the digest for a couple of days. Anything more than about 30 and there's no way it'll make it in the next digest. Please be patient. My article posted today 2/16 was sent on 2/12. The digest needs a serious dose of liquid plumber, or less posts about snobs, to clear this up. In the meantime, double postings just make things worse, so just cool it and have a beer.

Cheers,  
Norm

Subject: grain bill

Hey ...

I went down to my local brew shop yesterday to but some grain for my first batch of all-grain brew (a SNPA clone). The proprietor looked at me rather dubiously when i gave him the grain bill:

8 lb British Pale Ale Malt  
1 lb British Crystal Malt (50L)

He seemed to think that the grain bill was short. I figured that with 30 pts/lb/gal I would get an OG of about 1050. He made some comments about Dave Millers unrealistic efficiencies and seemed to think that 25 pts/lb/gal was more reasonable. I assumed that 30 was a "good" number considering all i've read here on the digest. My setup is a 10 gal Gott cooler with a Phils Phalse Bottom as a combination mash/lauter tun. Am I being unrealistic? Perhaps I should go buy another pound or two?

From: Mark Cronenweth <CRONEN@vms.cis.pitt.edu>  
Subject: Other Digests

In a recent HBD, I heard mention of the Cider Digest. The address for this digest was posted, I SUB'd, and have received some great info. that I know is going to improve my cider tremendously - thanks Jay. I've also heard rumors of a MEAD DIGEST out there somewhere. If anybody has addresses for any online MEAD info., recipes, etc. please post me at: CRONEN@VMS.CIS.PITT.EDU Some purists will probably flame me for mentioning other fermentable materials on the HBD, but I can't help myself! I love the HBD & look forward to reading it every day. I even check my mail for it on weekends. But I'm just a sleaze-bag when it comes to fermentation. I'm not too proud to ferment anything (once) !

Subject: hops: rec.gardens request (fwd)

James,

I've been getting my hop cuttings froms Freshops in Philomath, Ore. They have given good service and are quite friendly over the phone. Directory assistance for are code (503) should find them...

I don't have any here at work, but you should check out Zymurgy magazine. This is the publication of the American Homebrewers Association. It can be found at large newsdealers and bookstores (usually among the gourmet and food/wine magazines). Everyone that sells hop cuttings advertises here.

If you want more info and contacts, send e-mail message with both the subject and message "SUSCRIBE" to homebrew-request@hpfcmi.fc.ph.com to get the daily internet digest for homebrewers. It has around 1500 members and is better behaved than rec.crafts.brewing where it is also echoed.

cheers,  
Paul de Armond.

Subject: recipe request (maple)

In HBD #1078, Eric Mrozek mentioned a Maple Ale recipe posted "a couple  
o'  
months back". This may have been before I started reading the digest.  
Anyway it happens that I picked up a quart of maple syrup (grade c, dark  
amber, \$6) just yesterday. Any and all suggestions for using this in a  
brew would be appreciated. I would definitely like to be able to taste  
the maple - is a qt too much for 5 gal? For background, I am not an all  
grain brewer, but have done several partial mashes with good results.  
I know that Cats Meow probably contains some good maple beer recipes,  
but I don't know how to access it. Thanks in advance for any help.

I have spoken to that brewmaster from the "Midwestern micro-brewery" and he did say to me that he prefers the crush of the Corona mill (drill-powered by the way) over the MaltMill, but I disagreed with him then and still disagree with him. He and Roy seem to be the only two people that I've heard of liking the Corona over the MaltMill. I have an older model MaltMill and am very happy with it, but the more-recent ones I've seen are, indeed, even better. On the older models, two pieces of plastic blocked grains from "falling off the end of the roller in stead of being crushed" whereas the current design has the rollers going all the way flush with their mounting plates. On my design, I need to put a tray under the outlet chute to catch the grains -- the current design sits over a bucket, which, by the way, reduces airbourne grain dust. As much as I've disagreed with Jack (I've got a few megabytes of off-line arguments on disk too), I've got to admit, he's built the best homebrew-sized grain mill on the market.

>looking for? Also any good literature for the beginner?

Yes, Zymurgy has articles targeted for virtually all homebrewers ranging from beginner to expert. I think that not only a subscription is in order if you are serious about homebrewing, but also get back-issues also (especially the special issues on Hops, Extract, Troubleshooting and eventually All-grain).

I feel the best way to start, however is by reading "The New Complete Joy of Homebrewing" by Charlie Papazian. The articles in Zymurgy will make more sense when you learn the basics and the vocabulary of homebrewing.

>Thank you,  
>Nate Clark  
>grs04736@conrad.appstate.edu

John writes:

> I could use a little help with the subjects of wort aeration and  
>the formation and importance of hot and cold break.  
> First, wort aeration. On reading beginner's books I get the impression that I should boil up my extract, grains, etc in my brewpot, and then  
>pour the wort through a strainer into my primary, pitch the yeast, seal and  
>leave alone. Through this forum and from other sources I've learned that  
>the yeast needs oxygen to reproduce therefore the wort should be shaken,  
>stirred vigorously just before or after pitching. What is the experts' advice? Do I leave the wort alone or not?

If you are doing a full, 5-gallon boil, pouring it through a strainer will aerate it enough, but you should let it cool before aerating. When the wort is hot (over 80F) the oxygen you add during aeration will react with compounds in the wort to oxidize them. This is Hot Side Aeration (HSA) which you've probably noticed lately in HBD and is generally regarded as bad (although it appears that many breweries get away with it). If you are doing a partial boil, as you've noted that you do, I feel you still may need to do some aeration to get a good amount of oxygen in the wort. The warning about letting it cool below 80F before aerating STILL APPLIES.

Make sure you don't use your wooden spoon to aerate -- you just can't sanitize wood well enough and should only use wooden utensils in the boil.

> Regarding hot and cold break. As I understand it hot break is formed during the boiling of the wort. Cold break must be formed by cooling the wort after the boil. A few questions. I only boil about one and a half gallons and add that to three and a half gallons of water in my primary - does just chilling the 1 1/2 gallons produce a cold break?

Yes, the down side is that with a 5-gallon boil you will have to leave a quart of wort behind in the kettle to avoid pouring the break into the fermenter. With a 1.5-gallon boil you will still have something close to a quart of break which is a much bigger percentage of your boil. Some have suggested putting this break-wort in a jar, letting it settle in the fridge and using it, but that's too much to worry about right now.

> Does the rate of cooling affect the formation of a cold break and if so how fast should it be cooled?

Yes. The simple answer is: "as quickly as possible" but to give you a rough idea, in the wintertime, with my immersion chiller, I get from 212F to 70F in about 15-20 minutes, depending on the thickness of the wort.

> I'm assuming that cooling my 1 1/2 gal of wort does produce a cold break which settles to the bottom of my pot with the hot break - should I take care and siphon the wort off the trub into the primary?

I just pour it into the primary and stop just before the trub (break) begins to go in. It's usually 1-2 quarts of wort.

> If I siphon the wort off the trub am I leaving nutrients in the trub that the yeast need?

The yeast CAN use the nutrients in the trub, but if you've aerated well, the yeast can synthesize everything they need -- getting it from the trub is just a shortcut for the yeast. Ideally, you may want to give the yeast a few hours in the wort with the break and then siphon off into your primary, but don't worry about it if you don't.

> Any help would be greatly appreciated as even the beginners books are not crystal clear to the beginner.

Yes and much less interactive than the HBD.

Alexander writes:

> I have just tried a new batch of beer which I brewed with a pilsner kit (M&F?) in which instead of adding only sugar to the malt mix I used malt concentrate. My problem is that the taste is too bitter/(malty?). > I would like some suggestions if anyone has any as to why it has turned out so bitter and general guidelines as to the proper use of malt extract. There is definitely the appropriate amount of alcohol though.

..

There is hopped malt extract and unhopped malt extract, if you added hopped malt extract to your pilsner kit (which, by the way is a bitter style to begin with) you may have made it too bitter for your taste.

>My process went as such.  
>boiled all the water and the malt sugar (liquid), malt extract, and sugar.  
>then I dumped it all in the carboy as usual.  
>after cooling I dumped in the yeast ( came with the kit)  
>after a week in the carboy I added gelatin as a fining agent  
>waited a few more days and racked to bottles. I have since let the  
>bottles sit the required three weeks plus a few days.

>I have just opened the beer and drunk some, not bad or yeasty as if it  
>was opened too soon, but definately too bitter.

Fear not. The bitterness will mellow a little with age. Your process seems okay (except for the hot aeration -- see above) as long as the sugar you've added doesn't become too large a percentage of your fermentables (IMO 20% is the maximum) which will give you cidery flavors.

interesting  
>but I don't think I have the whole story for that either.

Personally, I don't think Irish Red is a real style -- I think it's a recently created idea -- a product of the marketing director of a large industrial mega-brewer. Perhaps I'm wrong, but yesterday I heard a radio ad for Killian's Irish Red Lager, in which "lager" was mentioned prominently at least 20 times.

To create something resembling Killian's, I suggest brewing a lightly-hopped (perhaps 15-20 IBU) pale ale but add 1 ounce of Roasted Unmalted Barley, just for color.

Subject: Birmingham Brewing Tour (Part I)

Jeff Herring and I toured Birmingham Brewing on Monday, February 15th. I had not been in there since they got any of their equipment and, boy, what a difference - stainless steel everywhere! A little history first:

At the turn of the century, Birmingham was an industrial oasis in the rural South. The laborers who worked in its mines and factories came from surrounding farmlands, from the industrial North, as well as every country of Europe. And with them, they brought their taste for beer.

In 1889, The Birmingham Brewery was founded to help satisfy their thirsty demands. This modest brewery was equipped to produce 18,000 barrels of lager beer annually. By 1905, the brewery's annual output increased to 40,000 barrels. The brewery closed its doors in 1908, the victim of nationwide prohibition. Its barrels were smashed and their contents gently flowed through the streets of Birmingham, to the horror of thirsty onlookers. Not until last year had beer been commercially brewed anywhere in Alabama since. That has changed with the opening of The Birmingham Brewing Company and its production of Red Mountain Beers. Their product line consists of 4 brews; a red ale (my personal favorite), a golden ale, a gold lager, and (seasonally) a wheat beer. The wheat will be brewed again this spring for the summer season.

Jeff and I arrived at 2:00 and opened the sliding door around back on the loading dock. The wonderful aroma of fresh beer immediately wafted over and welcomed us. John Zanteson, Brewmaster, was expecting us and walked over to greet us. I asked if he minded my taking notes and pictures and he said "no" so we quickly retrieved our cameras.

John started out, surprisingly enough, as a homebrewer. He developed a desire to brew on a commercial scale and took a job in a brewery pushing a broom. From there he "learned every job in the place". That is reflected in his philosophy about aspiring brewmasters. He says that if you are not willing to start with the "menial" jobs in a brewery to learn the trade, you don't have what it takes to become a commercial brewer. John started brewing commercially in 1988 at the Mendocino Brewpub in Hopland, California. He then went to

Dixie brewing in Louisiana before coming to Birmingham Brewing. I mentioned the "Norm" character that Richard Steuven met at Mendocino (who claimed to have been there every day since it opened) and John immediately said that he knew him. He said that he was a thin, older man in a pith helmet. He said that he could believe that old Norm had indeed been there every day since opening.

More to come...

Subject: Re: wyeast 2308 and other stuff

Chuck,

I can tell you a few things about the "Brewer's Workshop" as I am the author of the program. It was designed to help craft recipes to a particular style of beer, of which there are 33 included in the program. They cover most varieties of ales and lagers, but not specialty beers. As ingredients are added their contribution to specific gravity, color and bitterness are displayed in a style definition area, which also has target values for each of these parameters for the style selected. This way it is extremely easy to see if you are going to end up with a bitter or a pale ale (for example).

There are of course many nice features associated with the program, but for a full run down please send for the brochure. Its on the house and doesn't use up valuable thread space, just write to TKO Software, 423 Greenwood Drive, Arroyo Grande, CA 93420.

Subject: root beer

Hello,

I have a couple of root beer type of questions. I brought some of that root beer extract this weekend and made two six pack of the stuff according to the directions. I used corn sugar instead of granulated sugar as a sweetener. I was wondering how that might change the taste since it didn't seem as syrupy as store brought root beer. Also, I added dry yeast to get carboration after bottling. Will this produce an alcoholic root beer? My kids will be bummed if Dad is the only one who gets to drink it.

Date: Tue, 16 Feb 1993 14:06:43 -0800 (PST)  
From: Peter Maxwell <peterm@aoraki.dtc.hp.com>  
Subject: HELP! Can bottle carbonation take a long time?

I have a problem with my latest batch regarding virtually no bottle carbonation. Before going further, here are the specifics of the brew:

3 gallon batch (so you'll have to extrapolate to get 5G equivalents)

the boil -

3.5 lbs John Bull light extract syrup in 1.5 gallons water  
1.23 oz Willamette for 45 mins  
0.35 oz Willamette for 20 mins

(this batch frothed over when I threw in the hops :-( so not knowing how much I lost I added another 0.25 oz)

After boiling I chilled it to 70 degrees (in about 10 minutes using my wort chiller), let the trub settle for 30 minutes, syphoned into a 5 gallon glass carboy, added water to make up to 3 gallons and pitched the yeast (WYEAST 1056 which I'd made into a 1 pint starter).

OG = 1.036

After 5 days at 68 degrees it was transferred into a secondary with an SG of 1.007.

After 1 week in the secondary it was bottled with FG = 1.006.  
This was looking great! I wanted a light, dry beer.

1/2 cup corn sugar was boiled in some water, poured into a carboy and the secondary siphoned into it. Bottling was done from this mixture. At the time of bottling I noticed it was particularly clear - almost all suspended cloudiness had fallen to the bottom of the secondary.

4 days later, after storing at 68, there is virtually no carbonation. The cap hissed a very little on opening, but the beer tastes REALLY flat, subjectively only marginally, if any, more than there was when it was bottled.

What is going on here? Should I wait longer? If the yeast has mostly all settled out in the secondary, does this mean a longer than normal conditioning time? Is it possible to have too little yeast in the bottles to effectively condition them?

In an experiment I have "modified" three bottles but would like comments as to whether this is the right thing to do or not:

add 1/4 teaspoon extra sugar directly  
add 1/16 teaspoon (roughly measured) of dried yeast directly  
put 1/4 teaspoon of dried yeast in 25 ml water to rehydrate and pour 5 ml of slurry into a bottle

The dried yeast I used was Munton & Fison (happened to have a packet in the fridge).

Any advice would be greatly appreciated. I REALLY don't want to throw this batch out as it tastes great, but do want it carbonated.

Peter

From: u4imdmre@cpc41.cpc.usace.army.mil (Markham R. Elliott)

Subject: Questions From a Newer-Brewer About 2 Stage Fermentation

I write as a relative new-brewer and extract user, I have a few questions to pose to the readership after having read the past three months of the HBD and C. Papazian's TNCJoHB.

This past weekend I finally aquired a second 5 gallon glass carboy. After three successful single-stage extract brewings, I feel comfortable enough to take what I feel is the next step up the brewing ladder: Doing a two-stage fermentation. Additionally, this will be my first go at using no sugar in the process, except for what appears to be the standard use of 3/4 cup for priming.

As I understand the procedure, after the respiration phase has completed, and the blow-off tube has cleared, I am to siphon the fermenting brew into the secondary fermentation vessel (with as little aeration of the liquid as possible), leaving behind whatever sediment is on the bottom of the primary vessel.

Questions at this point:

- 1.) Must the transfer to the secondary be done immediately, or is there a safe window of a day or two? Obviously the transfer doesn't have to be done at all, but ... I am trying to make a better brew.
- 2.) How important is it not to aerate the wort during the transfer from primary to secondary.
- 3.) By leaving behind the sediment, won't there be a tremendous (significant) amount of viable yeast left behind? My observations of the fermentation process show that the CO2 rises from the precipitate at the bottom of the carboy, not from the material in suspension.

Now, all my primings to this point have been by adding a measured amount of corn sugar to each bottle, then filling the bottle, capping, conditioning ... enjoying (er, sort of). Hey, what can I say, I followed the directions that came with the extract, and those supplied with the microbrewery kit ... how was I to know. Beat me, whip me, make me write bad checks! I'm trying to reform myself.

If I understand the literature, about 3/4 cup of sugar/sugar equivalent should be boiled in water or sterile wort, then added to the contents of the secondary, cooled to the temperature of the remaining 5 gal liquid (is it still called wort at this stage?), bottled and conditioned as usual.

It would seem that if I add anything to the remianing 5 gal liquid in the secondary, and mix, all the precipitate will go back into suspension and consequently be bottled. If I don't mix, what will be bottled will not be consistantly primed. I was under the impression that one of the advantages of doing a two-stage fermentation was to eliminate as much particulate from the bottled product as possible.

Questions:

- 1.) What am I missing here? Do I accept putting all the precipitate back into suspension and into the bottles, or,
- 2.) Is there a method of mixing the priming sugar/equivalent without disturbing the junk in the secondary?
- 3.) Noting that the 3/4 cup is not carved in stein, if I

substitute dry malt extract for corn sugar, do I use the same 3/4 cup? What if I substitute liquid extract?  
4.) Lastly, if I use (for conversation sake) a 3 pound can of a hopped liquid extract, and want to use dry malt extract (instead of a second un-hopped can of liquid or [gasp!] sugar) to finish off the ingredient list, what would be a reasonable amount of DME be to use as a baseline starting point for future experimentation?

GUIDANCE, PLEASE

Mark

Date: Tue, 16 Feb 93 15:36 MTS  
From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: The results are in!

The results of a survey of the HBD readership are in! As you may recall, I recently submitted a note to the HBD (about a week and a half ago) inviting everyone to mail me with a descriptor of their brewing level. What a response!! By 10 a.m., I'd received more than 100 responses! Thanks to all for participating. (And what a talkative crowd! Sorry that I couldn't answer messages individually.)

The admittedly inadequately simple categories from which I asked people to choose were as follows:

All Grain if you rarely use extract for your brewing, other than for yeast culturing,

Intermediate if you do some mashing, partial mashing, some yeast culturing, etc., but you don't consider yourself very experienced, or

Extract if you are relatively new to the brewing process, haven't tried mashing, or in general, consider yourself to be on the steepest part of the learning curve.

The tallies are as follows:

All Grain: 55  
Intermediate: 66  
Extract: 70

I'd like to make a few comments regarding the survey.

Categorization: Obviously, as stated above, a categorization of only three simple slots describes the multidimensional brewer only crudely. Some people have never brewed with extract; some have brewed for ten or more years with extract only. And so on. I wanted to conduct this poll only to convince novice brewers that they really should use the HBD, not to annoy readers by forcing them to categorize themselves. Enough said!

Statistical Discussion: The results to this poll are most likely not truly representative of the entire HBD readership. I can think of several readers who regularly post in the HBD who didn't reply. I'm sure that more than 191 people read the HBD. And I suspect that the tone of my original message might have motivated those on the steepest part of the learning curve to reply, skewing the results. Also, bravado or modesty might cause people to describe themselves incorrectly.

Use of the HBD: I did all this for one simple reason. I want new brewers to feel free to use the HBD as a valuable resource for talking with experienced brewers for the purpose of improving their brewing, as I did. Several beginners told me that they were certainly intimidated from asking questions. The HBD has got to be the greatest resource available; use it. From my results, a significant fraction of the readership brews extract only. You're not alone!

A few commented that they're annoyed by such questions as "How do you brew beer?" Obviously, questions like this are inappropriate, but this doesn't mean that all discussion should be on the level of comparative mashing methods. So, use the HBD, but use it wisely.

So there you have it. An incomplete, inadequate survey of the HBD readership. That's my contribution to brewing science for now. (But with a Ph.D. in chemical engineering, I should be able to do better than that!)

Cheers!  
Chuck

P.S. For those who must know, I have never tried mashing. I use extracts and specialty grains (and fruits and spices too, yummm!) Maybe someday when I get a regular job (and a house with a basement).

P.P.S. Our damn mailer is still giving us problems; my apologies if this shows up twice.

From: steve\_T%fleurie@champigny (Steven Tollefsrud)  
Subject: Kicking Dead Horse for Better Extraction

(that NAG-ging question)

I know that this poor dead horse has been kicked so many times that it's beginning to seem a bit sadistic, and I, for one, am starting to tire from all the debate between advocates of extract brewing and proponents of all grain brewing, but I felt I might offer just one more whack at the old quivering nag.

There has been a lot of blatant arrogance expressed by some all-grain brewers, some implying that extract brewers are not in the same league, likening extract brewing to mindless just-add-water cake-mixing, or, even more ridiculous, that extract is analogous to instant coffee! This has left the extract brewer feeling ridiculed in a forum intended to be shared and enjoyed by all home-brewers.

While it was refreshing to see a few all-grain brewers come to the defense of the extract brewer, I have yet to see one come out in favor of extract brewing over all-grain brewing. Maybe, then, all-grain brewing produces a brew of such vast superiority over extract brewing that it justifies all the time, expense and complexity. But this isn't always so, is it? More than a few extract beers have beat out their all-grain competitors in brew contests. If I were an all-grain brewer who had made all the investment in equipment and time, I too would find it difficult to admit, afterward, that it wasn't worth it.

Malt is only one contributor to what makes a good beer, and whether that one ingredient is extracted from the grain in your kitchen or at a factory is less significant to the quality of the final product than what is contributed by the flavor and aroma of the hops selected, the quantity and quality of the grain added during the boil, the quality and purity of the water, the subtle differences between yeasts, or the variations resulting from how the fermenting was conducted (temperature, secondary fermenter, sterilization, etc.). Far from being mindless instant cake-mix brewing, there are more than enough ways of varying the other contributors to the formation of beer, intentionally or accidentally, to keep an extract brewer happily experimenting for years.

One of the most common reasons given by all-grain advocates for making the plunge is for greater control over what goes into the beer. But I have seen so much space in HBD used up discussing problems of inconsistency in all-grain results from one extraction to the next as to make me shy away from having such "control" at least until I've got bored with fiddling around with all the other inputs that can be varied. Being an engineer by profession, one of the attractions of homebrewing for me is scientifically experimenting with the brewing process and understanding how changes in the inputs or process affect the (hopefully) tasty result. Using a good quality extract is one way of controlling one of the inputs when I'm interested in understanding the contributions of another. How can you tell the subtle difference a new hop might make when your

grain extract rate or unfermentable content is varying 10%  
from one batch to the next?

It's nice to know that when I've become bored with all the  
permutations possible in extract brewing, there is still a  
whole new world of grain extraction waiting to be explored.  
In the mean time, I'd like to feel good about my hobby  
and not be belittled by those all-grain mashers who would  
make us extract brewers think that we are not really worthy  
to call ourselves beer brewers.

Subject: Oxygenating Mash

What with all the hooplah about HSA, I thought the passage on p. 277 of Malting & Brewing Science might be of interest:

... Additions of hydrogen peroxide or charcoal to the mash or charcoal to the sweet wort also reduce polyphenol levels [76]. Oxygenating mashes, made with uncured or lightly cured malts, also reduces the wort anthocyanogen levels, probably through oxidations catalyzed by polyphenol oxidase, and can result in beers with enhanced shelf lives [77]. The low levels of anthocyanogens found in worts from mashes of green malt may also be due to their destruction by some enzyme-catalysed oxidative mechanism possibly using oxygen from air entrained in the mash....

Am I to take this to mean that the effects of aeration, at least in the mash, vary depending upon the color of the mash? Perhaps some aeration is even GOOD in the case of light-colored worts? In any event, polyphenols are one thing and melanoidins are another. I would rather have a hazy beer than a stale one. There is also obviously the question of whether any of this applies to fully cured malts.

Hmmm. Interesting. May have some truth to it.

>5. YOUR ideas here: \_\_\_\_\_.

I believe it is fairly well-known that items in the fermenter like hops  
(especially hop pellets) provide nucleation sites for CO2 production/  
release. This can easily account for more bubbling than expected for a  
week or more (in my experience, anyway).

I have never seen an lower-than-expected terminal S.G., though, from dry  
hopping, but if you have there might be other reasons, such as somehow  
rousing the yeast or possibly adding oxygen that the yeast used.

Well, first of all, you should \*cool\* the wort before pouring into the  
primary, to avoid oxidation (HSA) that occurs very quickly at such high  
temperatures.

Otherwise, pouring wort from a height, through a funnel with a strainer  
on  
it, into a fermenter causes \*lots\* of splashing and aeration in my house.  
I can't imagine that shaking or stirring the wort afterwards would do  
anywhere near as good a job of aeration.

From: Ulick Stafford <ulick@bernini.helios.nd.edu>  
Subject: Lager Dry Hopping?, etc from 1079

It is nice to see that posting has caught up. Hopefully it'll stay that way. Anyway, one post that struck me was John Sullivan's asking about lager brewing. Generally rack to secondary (lager vessel) once the froth dies down in the primary. Minor temperature fluctuations will make little difference, but you shouldn't have anything too significant in a basement, but the dry hopping question got me thinking. Traditionally (i.e. Germany, Bohemia) lager finishing hops are added at the end of the boil, although reading George Fix's Brewing Science book last night he mentioned that dry hopping may also be better for lagers. I wonder when would be best - perhaps the whole lager, or add after krausen dies and let them sit in the primary for the second week prior to lagering? I am not a fan of dry hopping as I have had trouble clearing dry hopped beers, but my stema beer that never cleared tasted just like Anchor. Anyone anyclearing suggestions that are Reinheitsgebot?

Rob Thomas mentions keeping a strong ale for culturing bacteria low samples. However, strong beers tend to affect yeast too. My preference especially now that I have a pH meter is to acid wash yeast and culture out to totally eliminate bacteria without worrying about mutants.

Norm Pyle considers Miller to be a lager book. I dispute that. It is a good introductory text on producing many basic beers with typical American Malts. Noonan, despite being error riddled, is a lager book. It covers the essential of lager brewing much better. Hell, Miller recommends priming with corn sugar. What is Miller's Continental Pilsener book like?

Michael Galloway mentioned how his homebrew store recommended he increase his grain bill. Good advice, especially for a first all grain batch. I finally got a Milleresque yield in my last batch. I mashed 12Ib of grain (10 pilsener, 1 each of Munich and Carapils) for my 14B Dortmunder (6 gallons or so), expecting my usual 30 point yield. It ended up as 16.5 (out of AHA style range :-), a yield of 33. But I carefully doughed in, left for an extra long protein rest as I desperately sought acid (I had hardened the water with baking soda and gypsum wasan't cutting it), held the thick decoction for an extra 10 minutes in the 140-150 range, and held the main saccharification an extra 10 minutes while I ate my supper. What was the key factor? Who knows? Will I be back to 30 for my next batch? 25 is a nice conservative target. You should do better, but tales of first mashes are usually disappointed because people end up with light beers because they expected too much.

Al Korz doubts the existence of an Irish Red Ale as a distinct style. I tend to agree. While Irish ale are less hopped than those of the South of England they are not significantly different from Northern English or Scottish ales. But the AHA already has so many styles of that type that I think are practically indistinguishable, what's another? Being Irish I get used to the abuse of that word in the US. The football team

here at ND are called the Fighting Irish. That's a howl. Then there is Irish Spring soap and everyone seems to think Corned beef and cabbage is a dish eaten in Ireland. So what if Coor's abuse the term with their Irish Red Lager. You have as much chance of finding Corned beef and cabbage in Ireland as Irish Red Lager (right now I'm pissing myself laughing :-)

From: gdmcconn@mspe5.bll.ingr.com (Guy McConnell)  
Subject: Birmingham Brewing Tour (part II)

Birmingham Brewing Tour, part II:

The tour started with John telling us that they use exclusively Briess malts in all their beers. The Red Ale originally had some of the Belgian caramel malt in it but John has since changed that over to domestic caramel from Briess. He said that the Belgian malts, while good, were no better than the domestic malts and that he has had excellent results with Briess, both the people and the product. John said that he felt that American beer should be made with American malt. He likes the idea of keeping the jobs and business in the U.S., particularly since the price, and the resulting beer, is right. They also use only Yakima Valley hops with the exception of using some imported Hallertauer in the lager.

We started at the grain mill, a rather small unit for a brewery but keeping with their philosophy of starting small and building up if necessary. He said that they'd likely replace it with a larger unit some time but, for now, it fills their needs. The grain is poured into a large hopper (it looked large enough to handle at least 100 lbs of grain at a time) in the floor above the mill (on the same level as the access ports on the mash tun and boiler). From there the grain is moved up to the mash tun through a semi-flexible plastic hose with an "auger-like" device in it. The mash tun is steam jacketed and has a capacity of 30 bbl. They put ~1500 pounds (dry weight) of grain in for a batch, meeting the incoming grain with a stream of hot water as it goes into the tun. After filling, they do a 20 minute recirculation to make sure the mash water is "turned over" well and the temperature is uniform. The steam jacket is not sufficient to mash on its own but rather acts as an insulator to keep the heat in. The mash is a single step infusion (forgot to ask what temp and if they mash out). They then drain the tun through the false bottom and sparge the grains. The liquor then is pumped into the kettle for a 1.5 hour boil with hop additions done at various intervals by hand. After the boil the sweet wort is pumped into a settling tank in such a fashion as to create a

whirlpool and the trub and break material from the kettle is allowed to settle out into a cone on the bottom. They allow it a 20 minute "rest" here before pumping it through a counter-current heat exchanger into a 60 bbl unitank fermentor. The hot water from the heat exchanger is then reused in the brewing of a second 30 bbl batch to fill up the fermentor. The beer is fermented for 4 - 5 days followed by a 2 week aging period for the ales and 3 weeks for the lager. The beer is naturally carbonated by sealing up the fermentor at a predetermined gravity (and kraeusening the lager) followed by dropping the temperature to 32°F to settle out most of the yeast and to mature the flavor. The finished beer is then pumped through a plate and frame depth filtration matrix into a bright beer tank. There the carbonation level is checked and adjusted if necessary. The beer then goes into kegs or to the bottling line. Their current "comfortable" capacity is 6,000 bbl a year but they could do "considerably more" if need be. Right now, there are just three brewers and John said that a 60 hour week was a "welcome break".

Part III (the final installment) tomorrow...

From: rmolinger@mmm.com (RANDY OLINGER 3-0784 [544-2N-1])  
Subject: Length of carboy aging.

Question here. Let me preface this by saying that I am not worried.

How long can a batch stay in the carboy (after racking once) before bottling? Any stories out there of amazing feats like 6 month storage? I used Wyeast American Ale and it was a slow starter, and even slower finisher, but the FG is around 1009. Due to lack of time it has been basically ignored. I don't want to say exactly how long it has sat, but lets just pretend its around, oh, 3 months. Do I have another month? Will my yeast stay dormant that long? I'm in no rush to bottle since I have quite a stock built up. I was kind of hoping that I'd have my kegging system ready for this batch.....

Any ideas, please respond to rmolinger@mmm.com

Happy brewing.

Subject: re:ale vs lager yeasts

Tom writes,  
<From: THOMASR@EZRZ1.vmsmail.ethz.ch  
<Subject: yeast strain selection

<So, the bug problem first:  
<most of the bacteria we are likely to get in our yeast  
<supply can't survive acidic conditions, so if you  
<sterilise (ie boil) your growth medium (eg wort),  
<which you have previously adjusted to pH 4-5 (unnecessary  
<if you mashed your own), the bacteria will not grow anywhere  
<near as fast as your yeast. By the time the sugar is  
<used up, there may well be enough alcohol in there to  
<stop all bacterial growth. (I brew a strong (1085) ale  
<just so that I can get a sample of yeast from the bottled  
<version when I need one).

Well.....

Some of this is true and some needs clarification. One of the points being missed here is that chemical substances resulting from bacteria are detectable in the finished beer at levels as small as several parts per BILLION (ppb)! Another important issue is that while a yeast rich environment will reduce pH and eliminate oxygen, this will not occur for several hours into the ferment. The yeast must transition from the respiration phase into the "active fermentation" phase for these conditions to be relevant. By the time this occurs, your bacteria could have easily produced a few ppb of nasties that can carry over into the finished product. The source for bacteria in the fermenter is often from the yeast slurry/starter that was pitched, and thus the bacteria can get a small foothold in your beer prior to active yeast fermentation. This is one of the reasons Dr. Fix was pointing out the importance of being able to determine gross percentages of bacteria in your pitching yeast. I would also point out that the flavor profile of the bacteria excrement is quite foul (even at a few ppb).

Also, most brewers would never suggest reusing yeast from a beer of such high OG (1.085). This level of alcohol could definitely lead to poor yeast performance and/or mutation problems. In general, a OG of 1.050 or less is optimum for yeast propagation.

Jim Busch

PS: Just a nit here but boiling != sterilizing. It does mean sanitizing, and that is all we care about as long as we have bacteria free (negligable) starters. This is another reason many people pressure cook thier yeast starters.

Subject: re:ale vs lager yeasts

Pardon my missed subject line on the last post.....

Joe comments on his ale/lager yeast experiment. A very good and interesting test. I would just point out that the Sierra ale yeast that you used is about the "cleanest" ale yeast I have ever used. Also much of the flavor profiles you will create will be dependent on your fermentation technique. For example, the SNPA at 65F is about perfect temp for the ale ferment. In fact, variations from 60-70 will not effect the outcome nearly as much as variations of 3-6F will in your lager batch. Also 50-53 is the "American" approach to brewing lagers. Many Bavarian braumeisters never let the lager primary rise above 48F. Not that it will be "bad", just different, and since this is partly a experiment on "cleanliness" of lager vs ale it could be significant. After primary ferment is complete, try a diacetyl rest at 42-44F for 2-3 days. Then drop the temp 2F per day until it gets to 31F. Lager here for 4-6 weeks and the beer should be excellent.

Sounds like a great test, except the ale will be 2 months old when the lager is ready! Should be fine and tasty though. Too bad Im not near Boulder,I would definetly take you up on the blind test offer.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: re: Great beers from Dock Street!!

Wow, three posts in one day, I must be ahead at work!

Joseph Hall pointed out that Dock Street in Philly has a new brewmaster. What great news! Strange how right after I read a rather heated debate between Lou Ferrell, of Dock Street, and Ron Barchet, of Old Dominion, on the pros/cons of Decoction mashing, Lou leaves Dock Street! I had to laugh about the issue in the DC brews paper, Barley Corn, since Lou was belittling the significance of decoction mashing when he was brewing some of the thinnest weakest micro beers in the nation. This was not just my opinion, several professional brewers have reported the same feedback. Is it true that Lou is opening a micro in the Philly area?

There is nothing that disappoints me more than to travel to a craft brewery and discover that the products are so mediocre. It is a benefit to the entrepreneurial spirit of America that anyone can be a professional brewer without specific training or national certification. It can also result in poor beer quality. I am not trying to bash homebrewers who turn pro, and I do believe Lou has been trained at a reputable US brewing school, but it is not for everyone. I do believe there is a place for well trained brewmasters in the US even though the US Immigration service doesn't agree. I'll never forget hearing that the fantastic brewmaster at Sudwerks was sent home by the INS for awhile because "we have brewers in America", glad he's back and speaking at the next microbrewers conference!

I look forward to a wonderful pint of cask Dock Street when I get to Philly for the next Dead shows!

Obligatory positive comment: Stoudts products have just arrived on tap in the MD area. I don't even think the brewmaster (Tom) is "formally" trained, but he sure makes some outstanding beers! The Export/gold was an amazing "session" beer at 4% V/V with rich malty/hop notes. The Mardi Gras Bock was also outstanding, hiding the alcohol very well while maintaining a rich maltiness. Both of these Stoudts get a solid 4.2/5.0. Bigfoot, SNPA, SA Doppel and three Stoudts beers on tap all in one weekend, we've come a long way in MD!!!!

From: tony@spss.com (Tony Babinec)  
Subject: irish ale

Roger Protz's "European Beer Almanac" gives the following information for Smithwick's Kilkenny Ale:

OG 1052

Ingredients. Pale ale and roasted malt (roasted barley?). Challenger, Fuggles, Goldings, Northdown, and Northern Brewer hops to 32.5 IBUs. Infusion mash. Top-fermenting yeast.

Nose. Malt aroma with pear-drop esters.

Palate. Light malty palate, dry finish with some fruit and hop notes.

Comments. The use of roast malt gives the beer a rich copper color and a pleasing fruity appeal.

\*\*\*\*\*

It seems that Irish ale is brewed somewhat in the Scottish style, that is, malt-accented. Estery yeast and warm fermentation temperatures could be used. Diacetyl flavor note is okay. Beer should be less-hopped than bitter or pale ale equivalent. Color can be gotten from 2 ounces of roasted barley, or 4 ounces of Special B.

I, too, remember that Coors' Killian's Red was an ale and then became a lager. This was probably because Coors decided to "tone down" the flavor profile. In the Chicago market, radio commercials mention "Killian's Red," absent an ale or lager designation, and leave it at that.

Another American Irish ale is Dempsey's--still brewed by Huber?--which likewise is not much like the original.

Date: Wed, 17 Feb 93 9:48:59 CST  
From: cush@msc.edu  
Subject: dry hopping and bottle conditioning

I have observed that every single brew that I have dry-hopped has ended up with, apparently, a higher carbonation level in the bottle compared to non-dry-hopped brews with the same amount of priming sugar. The result is brews with a nice-healthy head. Not necessarily gushers....but one DOES need to pour somewhat quickly after cracking the cap!

Has anyone else noticed this effect? Any guesses as to the cause?

There has been some discussion lately about apparent slow fermentation in the secondary following dry-hopping. The two possible causes that have been proposed are 1) the hops act as nucleation sites for dissolved CO<sub>2</sub>, and 2) bacterial contamination on the hops. Any thoughts as to which of these two causes the higher bottle conditioning? (I am still not convinced that some bacteria, or more likely wild yeast, are not carried in on the hops)

Subject: Wild Yeast Media

Dan asks:

>Have you (or anyone else out there) tried Lin's wild yeast  
>medium? I think it contains crystal violet as a culture yeast  
>inhibitor, allowing wild yeasts to grow (or rather, to grow  
>better). Is it better-worse-same-faster than cupric sulfate?  
>The 8th Edition of the ASBC Methods of Analysis contains a  
>section on this media, so I assume that it has some utility  
>and some brewery is using it. Of course if a well funded  
>individual has the ASBC MOA maybe they could respond. The  
> media is available from Siebel.

The ASBC's MOA is worth its weight in gold. Often I am asked by  
homebrewers  
with aspirations to go into the commercial arena, which of the books on  
brewing  
science should be studied. I have always given a prompt response to  
forget  
about brewing science, and to get a copy of MOA and start practicing  
their  
procedures.

The detection of wild yeast is a very special problem. All of the known  
media including Lin's will not only surpress culture yeast, but selected  
nonculture yeast as well. We are currently working with 10 different  
media,  
including 5 developed at Siebel using a crystal violet base. If one were  
to  
do plates using all 10, then likely one would be able to pick up at least  
95% of nonculture strains in pitching yeast. This, however, is not a  
feasible  
proposition. I consider it a triumph just to get pub brewers to do a  
crude  
and simple test like HLP to check for bacteria! The work at Cornell may  
hopefully change this situation.

From: Andrius Tamulis <ATAMULIS@ucs.indiana.edu>  
Subject: Wyeast data point

I have a tale to tell of my first experience with liquid yeast.

Having expended my entire stock of dry yeast, and deciding that my mashing technique has progressed enough to warrant the expense, I decided to buy a packet of WYeast for the batch of beer I was planning. I went to the local homebrew supply store, bought a foil packet labeled 1098 (or something like that) and 2 oz. of hops, and went home. At this point, insanity, or perhaps pure stupidity overtook me. I tossed the entire purchase into the freezer.

I ate dinner, watched some TV, and thought about my schedule, deciding that I would brew in 2 days, and so realized that I had to start the yeast. Then it hit me - YOU AREN'T SUPPOSED TO FREEZE YEAST!! I ran to the freezer, grabbed the foil packet, and felt it. The liquid inside was slushy, and there was at least one part that was frozen.

I started warming the package against my skin as soon as I realized what had happened, and when it had reached a proper temp., I broke that inner-seal thingy and hoped. Well, the package swelled in less than the 2 days that were suggested (this was last weekend, the date on the pack was Dec 6), and the beer is bubbling nicely.

Just another story to keep people from worrying about yeast mistakes,  
andrius

in with  
>comments of his own.

De Clerck (who else!) was the one who did the most fundamental work on  
fermenter  
geometry. His results are briefly summarized on page 414 of his book.  
Actually,  
his references provide more detail. His ideal fermenter is a shallow one  
like  
that used at Anchor. Subsequent work has focused on the depth to surface  
area  
ratio. This usually gets expressed as the ratio of depth to a  
characteristic  
horizontal dimension. This number is very small for Anchor's fermenter,  
which  
De Clerck felt was highly desirable. It has been my experience that as  
long as  
that ratio is not much greater than 1.0, then effects due to fermenter  
geometry  
will not be significant. With a 1/2 bbl. keg filled to 75-80% capacity,  
you are  
doing just fine. My main interest in using kegs as fermenters is they  
permit  
a closed system of beer transfer from fermenters to storage tanks via CO2  
pressure. I still consider this a more important issue than geometry.

As Russ and Darryl Richman have correctly pointed out, boiling water is a  
natural and effective sterilant. Many small scale German brewers would  
not

touch chlorine or iodophor with a "10 foot pole" due to a hypersensitivity to chemical residues in beer. In the past, it was either boiling water or vinegar for those folks. It should be noted, however, that peracetic acid has found widespread acceptance there, primarily because its residues are totally natural to beer. However and alas, this stuff is explosive (as been previously noted in HBD). It seems like there are no 100% safe sterilants, and this is an area where a "cowboy brewing style" does not find application. Care and attention to detail is needed by all no matter what sanitation procedure is being used.

George Fix

Subject: Meeting with Pierre Celis

I had the honor of meeting Pierre Celis last night at Lyon's Brewery Depot. Pierre is on a world wind tour through Calif. micros. What a nice guy! I got to pick his brain and share a few brews with him for about an hour. I brought along a light lager for our consumption. He took a whiff and said "no problems here", he liked it! He had many photos of his new brewery and lots of photos of Hogarden brewery in Belgium. We did speak about brewing techniques, I ask many questions and he was very open with answers. What a evening for the memory bank!

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Re: Corn Sugar in Root Beer

Mike Gildner asks about using corn sugar in root beer. I've used corn sugar and Equal(tm) [aspartame] to make diet root beer for a friend's father who is diabetic. We used four cups (about a pound +/-) of corn sugar and a huge number of packets of Equal following the substitution directions. It worked fine and was rated as better than store-bought.

Homebrewed soft drinks contain very little alcohol, since the CO2 stomps the yeast after it reaches a certain level. I've also made root beer and force carbonated it in a 5-gal soda keg.

I don't know what the store-bought root beers use to increase the richness of the mouth feel. Small amounts of glycerine or Irish moss (carageenan) are possibilities, but I don't know of anyone who has published recipes for full-bodied root beer.

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Micah's magical yeast starters

For a very short review, Micah advocated using powdered sugar for yeast starters with some Difco nutrient. His claims of greater yeast growth got all interested. I too have used this growth technique for a while with no big obvious problems.

Now for the update.....

I recently decided to compare the two yeast starter techniques. The two techniques being, standard starter (DME and water) and powdered sugar starter. I split a 10 gallon batch of wort for comparison. Both starters were the same gravity (1020) and volume and the yeast was the same (1028)

The two batches were fermented side by side at the same temp. I feed both starters the morning of brew day. The powdered sugar starter (PSS) seemed to

generate much more yeast than the DME starter. The activity in the PSS was

almost zero through the whole growth phase, compared to the DME starter that

looks like a normal mini-fermentation. This is a bit troubling when you observe the two side by side. I pitched them both and waited. The next morning the DME starter batch was at high krausen, the PSS had no sign of fermentation. The PSS started several hours later. The DME batch stopped fermentation at about 3 days, and the PSS continued for several more days.

The terminal gravities were measured at about 1 week. The DME batch had better attenuation than the PSS batch. The PSS batch never reached as low a

terminal gravity as the DME batch after several weeks. I have now kegged them separately and will taste and continue my comparisons. My opinion at this

point in time is that although there may be much more yeast growth with a PS starter the results when compared to a standard DME starter may not be what one desires. I mentioned all this to Micah and he said it could be due

to the lack of Difco nutrient in the PSS. I don't think so. He thought the

results were interesting, too. He agrees now that PSS may not be so good. Personally I am going back to DME starters, and don't recommend PS starters.

I'll post the taste off results when their all in.

From: jason@beamlab.ps.uci.edu  
Subject: yeast nutrition

Ok, say I want to make a quickish mead, but I don't have any yeast nutrients.

I know that malt extracts have the required goodness.

How many lbs of malt extract would I need to add to the boil (for a 5 gallon or 1 gallon batch) so that the yeast will be happy enough to ferment in a reasonable amount of time?

I was thinking of maybe 1 lb honey and 1 lb extract per gallon of water. And using Champagne yeast. Maybe 1lb honey and 1/2 lb extract per gallon will be good enough?  
Or three lbs honey and 1 lb extract for two gallons?

Comments?

Jscum

What happened to the mead digest--is no one posting to it. I never saved the address, so I can't post to it until it is sent to me again.

>rollers that might work. These rollers look like conveyor belt rollers  
and

>are sold to be used to make outfeed supports for table saws and such.  
Here

>are the particulars:

>

I have lots of these rollers. I got them from a local conveyor  
manufacture

for \$5/ea (or may it was \$3.50...) anyway they would be a BAD choice for  
roller mills. A: they are welded thinwall pipe and do not roll true  
enough

for any kind of milling. B: they have internal bearings, so there is no  
decent way to drive them.

Try "Bearings Inc" - you can get conveyor belt drive ends (e.g. shaft  
driven,

not bearing rolling) 4"dia, 10" wide for \$44/each. They are custom built  
because you don't want a crown on your roller mill. The one I had priced  
out included built in hubs. That is cheaper than the standard rollers  
with

two-piece hubs. They also had a precision roller (machined), but I  
didn't

bother pricing it out. I figured I could true up the standard rollers if  
needed.

The company that actually makes the rollers is Van Gorp, in Iowa.  
1-800-Van-Gorp You want to specify a "Finish Bore Drum Conveyor Pulley"  
And you want it "straight faced" not "crowned".

Disclaimer: I have yet to make my roller mill...

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Refrigerators

Over the past year I have thrown away almost half of the beer I've brewed, which is a bummer of such magnitude that only a homebrewer can understand. This has been due to the high temperatures in our house, which typically range from 74-76 degrees F. I can say from long, sad experience that this imparts some highly undesirable flavors to beer, (particularly high-gravity brews), and I have the bottles to prove it. We have no control over this heat, which comes from the various steam pipes located throughout the floors and walls. Nor do we have a basement.

In one of those saint-like gestures sometimes made by spouses of homebrewers, my wife has given me permission to look for a refrigerator I could use for brewing. (Presumably this would be used in a conjunction with a Hunter Airstat or similar device).

The problem--and the reason for her saintliness--is that our house is quite small, and there is absolutely no inconspicuous place to put a fridge. We will have to live with this thing constantly in our faces. I am therefore looking for the smallest possible (presumably dorm-type) refrigerator that can hold a carboy with airlock. I'll buy new if necessary, as I am desperate.

Are any of you familiar with refrigerator models that are currently available, or were available not long ago, that fit this bill?

Please send responses and any other suggestions via E-mail to PSEITZ@MCIMAIL.COM

Thanks!

>chances with 5 gallons at a time.

I tried adding some 88% lactic acid from GW Kent (I double checked to make sure I had the right source this time) to my dry stout a few weeks ago. It tasted great. The only side effect was that I passed out after 5 pints and woke up with every muscle in my body sore as hell...

> Anyway, my friend Brent tried following Charlie's directions. He  
>placed a quantity (sorry, I'm unsure of amount) of pale malt in a cooler

>the liquid was sweet, with no sign of sourness (tartness?) and no  
>noticeable growth. It may have stayed too hot, any other ideas about  
>what went wrong?

The mash probably also stayed too hot. It needs to get into the 80-100 F range. Then it will take only a few hours to sour appreciably.

> Also, I had the pleasure of sharing an Imperial Stout and  
>Taddy Porter (Samuel Smiths) yesterday, and they both seemed to have

>beers with much more dark grains.

The Imperial stout comes in a clear bottle and 50% of the time I buy it, it is light-struck (skunky). I don't drink much of the taddy porter.

>park, and I'd say that the Winter Warmer lived up to its name.

I loved the Dark Ale. The following is palate-subjective, but it seemed to have just enough diacetyl without seeming stale to taste good (not that a beer needs diacetyl, but this one used it to its flavor advantage, as do Smith's and (possibly too much) Young's).

On the subject of staleness, try comparing a bottle of 1992 Thomas

Hardy's to a 1991 version...

-----  
>Nick brought along an ersatz "Framboise," which he claimed had a

Date: Wed, 17 Feb 93 13:47 CST  
From: korz@iepubj.att.com  
Subject: Public service announcement

This is a public service announcement for Chicagoland beer lovers or beer lovers who will happen to be in the Chicago area this Saturday, Feb. 20th:

What: BEER TASTING (11 U.S. Microbrewed ales and 3 homebrewed ales)

When: Saturday, February 20th, from 2pm till 8pm

Where: MAINSTREET DELI AND LIQUORS  
5425 South LaGrange Road  
Countryside, Illinois

(3 minutes north of I-55 (Stevenson) on LaGrange Road)  
(15 minutes south of I-290 (Eisenhower) on Mannheim Road)  
(LaGrange and Mannheim are the same street -- Route 45)

Cost: FREE!!!

The Beers: Grant's IPA  
Grant's Scottish Ale  
Pike Place Pale Ale  
Sierra Nevada Pale Ale  
Pete's Wicked Ale  
Bell's Amber Ale  
Sierra Nevada Porter  
Bell's Porter  
Grant's Imperial Stout  
Bell's Kalamazoo Stout  
Sierra Nevada Stout

Homebrewed Light Ale  
Homebrewed English Pale Ale  
Homebrewed Medium-dry Stout

More info: Call 708-430-HOPS or 708-354-0355

Okay, so there's nothing very extraordinary on the list, but it's free beer (the best kind) and it's an opportunity to compare a number of respectable commercial beers, side-by-side. Actually, the purpose of this tasting is to get some Beck's or Sam Adams (boo) drinkers to be more adventurous. Mainstreet normally does wine tastings on Saturdays from 2 to 8, but this is their first beer tasting. Hopefully the turnout will be good, the owners will be impressed and will do this more often, maybe next time with 11 Belgian Lambiks!

Disclaimer: I'm not denying anything.

See you there.  
Al.

P.S. I brewed the three homebrews.

From: mrozek@gandalf.etdesg.TRW.COM (Eric M. Mrozek)  
Subject: re: recipe request (maple)

Jon, in answer to your request:

Mark and I brewed the maple ale on Labor Day so I don't recall the details of the recipe. I'll pull out my logbook when I get home tonight and give you the actual recipe tomorrow.

If I remember right, we used half a quart of dark amber maple syrup. The end result was a pretty dry beer with a thin body. I really liked it even though it didn't turn out like we intended (a maple flavored PALE ALE). The maple flavor was definitely there, but you can bend your brain trying to imagine what maple sugar tastes like without the sugar.

I think the maple sugar ferments out almost completely, and even seems to increase the overall attenuation. The recipe was based on other pale ales we had done (which had real pale ale gravities and body). The next maple ale we do will have more crystal malt and maybe some carapils (going for more body). Does anyone have any recommendations?

As for the Cat's Meow recipes, I have a hard copy and I can get it via FTP (read the daily HBD header for more info) but maybe someone who already has an electronic copy can volunteer to cut out the relevant recipes and E-mail them to you (southard@biology.UCSC.EDU).

From: bradley@adx.adelphi.edu (Rob Bradley)  
Subject: Irish red ale recipe idea

In #1079, Al (korz@iepubj.att.com) writes:

>Personally, I don't think Irish Red is a real style -- I think it's a  
>recently created idea -- a product of the marketing director of a large  
>industrial mega-brewer. Perhaps I'm wrong, but yesterday I heard a

I agree, that the word `Red' sounds unauthentic and that the lager  
Coors makes likely bears little resemblance to anything that may have  
been brewed in Ireland in years gone by.

That said Irish Red ALE (yes ALE) seems to be an emerging American  
style, based on recent offerings at a variety of microbreweries.  
Ironically, Guy McDonnell mentioned one in the article immediately  
below Al's post! I posted here in January about the Chicago Brewing  
Company's Legacy Irish Ale. I find it a very tasty brew. It is both  
darker and more bitter than Killian's. It's brewed in Chicago, Al;  
you must have tried it. The blurb on the bottle says Irish immigrant  
brewers brewed in this style in 19th century Chicago. It's certainly a  
plausible tale.

>To create something resembling Killian's, I suggest brewing a lightly-  
>hopped (perhaps 15-20 IBU) pale ale but add 1 ounce of Roasted Unmalted  
>Barley, just for color.

I can't imagine too many people really want to duplicate Killian's  
when they can brew something with more character. Here's my suggestion,  
based on my memory of Legacy Red Ale and my experience using smallish  
amounts of more highly roasted malts in pale ales:

pale ale malt or pale malt extract for OG of about 1050  
 (for extract recipes with attenuative yeast, include 1 # crystal,  
 for all-grain with attenuative yeast, mash at a warmer temperature)  
2 ounces roasted barley (up to 3 if no crystal is used)  
Bittering hops for 30 IBU (CBS uses Chinook)  
Fuggles or Willamette to finish (CBS uses Willamette)  
Wyeast Irish yeast or a reliable dried yeast

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: Adams Family Boston Brewery

Subject: Time:6:24 PM

OFFICE MEMOAdams Family Boston Brewery Date:2/17/93  
Chuck Cox had a great suggestion for paying retribution to Jim Koch's  
(Sam  
Adams) bad legal habits. John Adams thought that, being born an Adams,  
he  
could not be denied use of the name. He's wrong, unless the law has  
changed in  
the14 years since I visited the Bully Hill Winery on the Finger Lakes of  
New  
York.

During the tour of Bully Hill, I noticed that there were many paintings  
in  
the tasting room signed by an artist named Walter S. \_\_\_\_; that is, the  
last  
name was obliterated. The same obliterated name was seen on various  
signs  
around the winery giving inspiration to the workers about quality control  
and  
the like. I asked about this and was told that the owner was named  
Walter S.  
Taylor, and he was a descendant of the founder of Taylor Wines. Taylor  
Wines  
had been acquired by Coca-Cola (Koch? could it be??) (or was it Pepsico?  
) , and  
they had obtained an injunction prohibiting Walter Taylor from using the  
Taylor  
name in the marketing of Bully Hill wines. So... Walter complied with  
the  
order to the absurd limit.

Bully Hill also produced bumper stickers stating: "Drink Bully Hill  
wines --

the UN-Taylor" (remember the 7-Up Un-cola campaign?)

Fight back!

**Subject: Re: Kicking that horse**

Just a few data points on Steve Tollefsrud's post, based on experience. My background is 10 years brewing extract kits, now two years all-grain.

I agree with Steve that extract brewing can keep a brewer just as occupied juggling with ingredients. Extract can beat all-grain in competitions. It's easier, quicker and requires less kit. Why do I prefer all-grain? Because all-grain consistently produces better beers for me than extract. Maybe I'm such a useless brewer I can't get a good beer out of extract.

> There has been a lot of blatant arrogance expressed by some  
> all-grain brewers,

I think it was only Jack, who admits he sometimes puts his foot in his mouth. Best thing is to count ten and forget it. Mail direct if you must.

>  
> Malt is only one contributor to what makes a good beer, and whether  
> that one ingredient is extracted from the grain in your kitchen  
> or at a factory is less significant to the quality of the final  
> product than what is contributed by ... [hops, water yeast etc]

Disagree totally here. Factory extract in my experience is markedly inferior to wort extracted at home or brewery. Probably due to the processing required to eliminate the water. Far from being less significant, I consider it to be the most significant factor in poorer flavour compared to all-grain. Only differences in hop rates come near to affecting taste as much. This is why it is essential to use the very best quality extract if you want to beat all-grain brews in competitions.

> One of the most common reasons given by all-grain advocates for  
> making the plunge is for greater control over what goes into  
> the beer.

It's not my reason, and I doubt it is a common reason. Greater scope for experimenting maybe, and even that's debatable. As Steve says, all you do is throw more variables in the pot. I use all-grain, as said before, because it tastes far better. That's the main reason I switched and the only reason I prefer it. Ah! that taste!

> shared and enjoyed by all home-brewers.

Whilst the "grain vs. extract" argument can be taken too far, I must admit I agree with the instant coffee analogy. After all, both instant coffee and malt extract are concentrated forms of the original substance.

I brewed with extract for about 5 years before trying my first all-grain brew, and since then I haven't looked back. I could say the same about using instant and ground coffee, and also about from-concentrate vs. freshly-squeezed orange juice. In all three cases, IMHO, the concentrated product lacks the clean, "zesty" quality of the original. The basic flavour is present, and about right, but it seems somehow to be dulled. I've an idea that this difference is rather more important than any additional flavours that may be introduced by the concentrating process.

OK, malt [extract] is only one ingredient, and not the major one for flavouring purposes, but good fresh malt does make a big contribution to the taste. I've drunk some fine beers made from extract - and some dreadful all-grain brews. But my own experience with homebrew is that it's been well worth the change, if only to hear from fellow imbibers the comment "this doesn't taste like homebrew, it's just like <some commercial real ale>".

At the request of a few people, here's my chocolate porter recipe that Sandy was bragging on a few issues back (blush):

3 lbs laaglander light dry malt  
3 lbs laaglander amber dry malt  
1/4 lb black patent malt  
1/2 lb chocolate malt  
2 1/4 lbs xtal malt (i had 32 deg lovibond laying around; 40 deg would be ok)  
1/2 lb cara-pils  
24 tablespoons cocoa powder

1 oz Northern Brewer hops (6.8% alpha), boiled 1 hour  
1 oz Willamette (alpha not recorded) at finish of boil

Yeast was Whitbread dry ale yeast in a 1 qt starter

Steeped cracked grains in grain bag in 5 qts 160 deg F water. Strained. Brought water volume to 6 gallons, added dry malt, boiled one hour. Chilled with immersion chiller, racked to primary, pitched yeast starter.

OG 1064 FG not recorded. Bottled with 3/4 cup corn sugar to prime.

The beer was great tasting from the beginning, but after a month in the bottle, the hop bitterness had diminished, allowing the chocolate bitterness to come thru. The beer was very rich and thick with a creamy tan head.

My wife is a confirmed chocoholic (and porter lover), and is bugging me to brew another batch.

Cheers!

- -- Paul

Subject: Answers

In HBD #1080 Mark had a few questions:

[snip]

>Questions at this point:

>1.) Must the transfer to the secondary be done immediately, or  
>is there a safe window of a day or two? Obviously the transfer  
>doesn't have to be done at all, but ... I am trying to make a  
>better brew.  
>2.) How important is it not to aerate the wort during the  
>transfer from primary to secondary.  
>3.) By leaving behind the sediment, won't there be a  
>tremendous (significant) amount of viable yeast left behind? My  
>observations of the fermentation process show that the CO2 rises  
>from the precipitate at the bottom of the carboy, not from the  
>material in suspension.  
>

Answers:

1. No, remember there are few hard and fast rules when it comes to making homebrew. My typical fermentation schedule is this: Brew and get the primary going on Saturday ... active fermentation by Sunday. Then I normally rack (transfer) to the secondary the next Saturday. Then I bottle the following Saturday. So ....

7 days

in the primary and 7 days in the secondary. Racking to the secondary gets the beer off the trub and hops and dead yeast and appears to allow much more yeast to flocculate ... this means clearer beer in the bottle with much less sediment in the bottle.

2. It is important that you minimize the aeration at this stage. The dissolved O2 from aeration will lead to premature staling of your beer. All you need to do is get the secondary end of the racking tube (I use 3/8 tubing) under the surface of the beer as soon as possible.

3. Yes, there will be a lot of 'good' yeast left behind but you will also leave behind a lot of dead yeast, trub (break material) and spent hop material. Don't worry, there is plenty of yeast in suspension that will carry over into the secondary.

>Now, all my primings to this point have been by adding a  
>measured amount of corn sugar to each bottle, then filling the  
>bottle, capping, conditioning ... enjoying (er, sort of). Hey,  
>what can I say, I followed the directions that came with the  
>extract, and those supplied with the microbrewery kit ... how was  
>I to know. Beat me, whip me, make me write bad checks! I'm trying  
>to reform myself.

>If I understand the literature, about 3/4 cup of sugar/sugar  
>equivalent should be boiled in water or sterile wort, then added to  
>the contents of the secondary, cooled to the temperature of the  
>remaining 5 gal liquid (is it still called wort at this stage?),  
>bottled and conditioned as usual.

>

>It would seem that if I add anything to the remaining 5 gal

>liquid in the secondary, and mix, all the precipitate will go back  
>into suspension and consequently be bottled. If I don't mix, what  
>will be bottled will not be consistently primed. I was under the  
>impression that one of the advantages of doing a two-stage  
>fermentation was to eliminate as much particulate from the bottled  
>product as possible.

>

>Questions:

>1.) What am I missing here? Do I accept putting all the  
>precipitate back into suspension and into the bottles, or,  
>2.) Is there a method of mixing the priming sugar/equivalent  
>without disturbing the junk in the secondary?  
>3.) Noting that the 3/4 cup is not carved in stone, if I  
>substitute dry malt extract for corn sugar, do I use the same 3/4  
>cup? What if I substitute liquid extract?  
>4.) Lastly, if I use (for conversation sake) a 3 pound can of  
>a hopped liquid extract, and want to use dry malt extract (instead  
>of a second un-hopped can of liquid or [gasp!] sugar) to finish  
>off the ingredient list, what would be a reasonable amount of DME  
>to use as a baseline starting point for future experimentation?

>

>

Answers:

First, once the fermentation is over, its beer, carbonated or not.

1. The normal priming method is this: boil and cool 3/4 cup  
corn sugar (or 1 to 1 1/4 cup dried malt extract, I never use  
liquid extract, too hard to measure at this level) in 1 cup  
water. Place this sugar solution in the bottom of a clean and  
sanitized 5 gal carboy (or what ever you use for a bottling  
container) and rack the beer from your secondary onto this  
sugar solution, again, with as little aeration as possible.  
The sugar solution will go into solution with the beer with  
no difficulty. Bottle and enjoy a week or two later.

2. See 1

3. See 1

4. First, I would recommend that you use un-hopped extract (it  
is difficult to predict the hopping rate in extracts) and hop  
the wort yourself. This way you get the hop rate YOU like  
and you get to use the variety of hops that are pleasing to  
YOU. The amount of DME (dried malt extract?) that you  
would need depends on the kind of beer that you want to  
make. For my 'normal' ales I like an OG of around 1.045,  
and I usually end up using 6-7 lbs of extracts (I like the  
Northwestern extracts) total.

GUIDANCE, PLEASE

Subject: Aeration

I think this was in the gadgets issue of Zymurgy (maybe it was even posted here months ago), but it's a neat idea that bears repeating. It's not original to me, anyway.

I'm one of those who likes to rack (siphon) from the boiling pot into my primary fermenter (maybe because it's hard to pour into the neck of a carboy from a big pot). I made a neat gadget that automagically aerates the (cooled!) wort as it's siphoning. I took some 3/8 OD copper tubing (left over from building wort chiller, sparging manifold, etc.) and cut a piece just slightly taller than the inside height of my carboy. A couple of inches down from the top (far enough down so it's inside the neck of the carboy) I drilled four 1/16" holes. I filed notches in the bottom with a triangular file (this prevents it from sitting flat on the bottom of the carboy and stopping the flow). I then insert this into the end of my racking tube, put it in the carboy, and siphon. The Bernoulli effect (knew that physics class would come in handy some day) sucks air in through the holes, and it gets well mixed with the wort. Makes a nice head of bubbles in the carboy, too.

Assuming you've got some copper tubing lying around, it's free and easy. Even if you don't, a couple of feet of tubing will cost you maybe a buck?

Subject: Birmingham Brewing Tour (part III)

Last we were taken into the cold storage room filled with kegs, cases of bottled beer, and the unmistakable aroma of hops. I thought I'd died and gone to heaven. John then took us back to the front of the brewery (a long walk of perhaps 100 feet), pointed out some cups and two taps and said "help yourselves". They had the golden ale and gold lager on tap. There was no red ale on tap because they didn't have any in kegs at the time. I'll have to recant my previous opinion of the golden ale. I have had it in bottles here in Huntsville and said that it was "good but nothing special". After trying it fresh at the brewery, I'll have to say that it is quite good. It had a wonderful hop aroma and flavor, balanced by good malt taste and topped off with a creamy head. The lager was very smooth and quite good as well. John likened it more to a Dortmunder style than a pils. Being an ale man, I can't comment on that comparison.

I asked if he would tell me what was in the red ale, without giving away the farm of course. He said they use 2-row, Munich, Caramel, and a "small amount" of Chocolate malts in the brew. The chocolate is there primarily to add texture and complexity rather than color as that is derived from the caramel malt. Clusters are used for bittering with Fuggles and Cascades used for flavor and aroma.

When asked about brewing other types of beer he said he'd love to do a stout or a porter but they were afraid that it wouldn't sell here. They do plan to brew a Christmas Ale of some sort this year and are, as yet, uncertain as to whether it would be available only in Birmingham or in all markets. Their beer is currently available throughout Alabama in the "major" cities such as Birmingham, Huntsville, Decatur, Mobile, Montgomery, etc. He wasn't sure how much of it made it into "outlying areas" as they deal only with distributors. It is also available in some parts of Georgia and they are soon going to have it in the Florida panhandle.

Red Mountain Red will be in next month's Beer Across America shipment and John was quite honored by that as they are such a new brewery. He showed us the last of 3200 cases on their way to the BAA people.

They are migrating to twist-top bottles since the ones they use are not returnable anyway. This had an unexpected benefit to us as he gave us a half case of the red ale and a half case of the golden ale to split from their bottling runs. That fresh red ale is something else indeed!

John is justifiably proud of the brewery. He says that, while it is quite small in comparison to most others, "there are no finer micros anywhere, all of the equipment is first-rate".

Quite an enjoyable tour, particularly since I'd never seen the inside of a brewery before. John said that he is happy to give tours of virtually any size, preferring those in the range of 1 - 4 people. Larger tours are also welcome but are not as "personal". Just call to make sure he will be in and will have the time to show you around. The address and phone number:

Birmingham Brewing Company  
3118 3rd Avenue South  
Birmingham, AL. 35233  
(205)326-6677

Enjoy and here's to the return of the brewing industry to Alabama!

From: mattd@software.pulse.com (Matt Downs)  
Subject: Found Beer

All Homebrewers:

Recently, I found a raspberry wheat beer in a fermenter that I forgot about.

Please no flames--I know "stupid"! Any way, it is about 7 months old and the air lock appears to still be intact. What I was wondering is if any one has had an experience like this and what did they do? Did you bottle it any way?

Did it turn out ok? How might have using fruit changed this?

Any answers would be appreciated, but flames would not! There seems to have been an extradonary number of flames for people who have valid questions to this group, we as a group should be more understanding and unless we have constructive answer, we should refrain from wasteing bandwidth in meaningless and unwanted expressions of our own inadequatcies (spelling is probably incorrect).

Thanks.

Matt

From: DJH0@NIOSR1.EM.CDC.GOV  
Subject: is it too late for the secondary?

Greetings-

I tried a partial mash of 1/2 lb. chocolate malt (crushed with a mortar and pestle) with a lager extract, and lacking a wort chiller, poured the hot wort and the hot break (out of ignorance) through a strainer and into a 5 gal. carboy with 3 gal. of water. I let the cold water in the carboy cool the wort and pitched my yeast soon afterward. (My milling "technique" had produced some powdery grains as well as granular grain fragments) . The latest posts in the HBD have given me some concern about my crude methods. Question- Has all the harm been done? Should I bother racking to a secondary ASAP to get the wort away from the hot/cold break which formed a 1 inch layer on the bottom of my carboy? The yeast is just now producing CO2 (very slowly) after 2 days of no activity at 65-70°F. Not worrying- just learning.

Subject: Irish Red Ale

Considering that I am at least partly responsible for starting (as well as carrying on) this thread, and that this (non?)style is near and dear to my heart (as well as my palate), I decided to poke around in my copy of Michael Jackson's 1977 "World Guide to Beer" to see what I could find.

In the section on "Classical Beer Styles" under the "(Burton) Pale Ale" heading:

"...a lively beer, faintly acidic, with a strong tang of hops...also sometimes known as 'India Pale Ale'...France has 'Irish Russett Ale', a copper colored beer..."

Also, in the section on Britain and Ireland, he mentions that Lett's at Enniscorthy, county Wexford, the last small independent brewery in Ireland, ceased to produce its popular ales in 1956. The company has kept up to date its brewing license. Enniscorthy-style beer can be produced under license in France by Pelforth. There is a picture of two beer labels on that page, one from Ireland and one from France. The one from Ireland reads:

"G.H. Lett & Co., LTD., Enniscorthy Ruby Ale"

The one from France reads:

"George Killian's Biere Rousse Brasse Par Pelforth" While the signature on the label under the horse's head is "George Killian Lett". In the fine print at the bottom it says:

"Biere Brasse Par Pelforth Selon De Procede de Fermentation Haute (Irish Top Brewing) De George Killian Lett".

While this certainly does not indicate that "Irish Red Ale" is considered a style unto itself, it does indicate that there exists (or existed) a type of Irish Ale with a distinctively red coloration, possibly brewed only in one area of the country. It would also appear that this type of beer is no longer produced in Ireland.

I checked in the section in U.S. breweries to see if there was any mention of Coors buying the Killian's name but this book was written prior to that. It says that "while most major U.S. breweries brew multiple types of beers,

Coors is adamant that they only need one; their Coors Banquet Beer".

Based on this, I stand by my assertion that "Irish Red Ale" is a type of beer (perhaps "style" is not the correct word) that has been revived by micros and homebrewers in much the same way that porter was. My initial thought was that "Irish Red Ale" was a relative to, or perhaps a decendent of, a British beer style (I thought maybe Special Bitter or ESB). While that may indeed be the case, it seems that the evidence I found would indicate that it is distinctly Irish in origin though perhaps similar to IPA in character. I still found no direct reference to the type of grain used, hopping rate, or strength of this elusive brew but maybe further research will turn something up.

I believe you should let the beer sit in the bottle a little longer.  
You should wait about eight days (or so I've been told). Just because  
you only made 3 gallons doesn't mean you wait half the time.

Great experiment. I would love to hear how it came out.

Also, I have a question of my own: I would like to put fruit flavor  
in my beer. I am strictly an extract brewer (for now). Is this easy  
to do? When should I add the fruit flavor (for example, apple)? What  
form should the fruit flavor take (diced apples, whole apples, apple  
kool-aid?)? I appreciate any help.

Thanks,

Shaheen

From: pyle@intellistor.com (Norm Pyle)  
Subject: Several

Some random ramblings:

Steve brings up several very valid points in the extract vs. all-grain debate. I will explain my motivation for recently going all-grain: FUN. I have more fun brewing with grain than with extract. Everything else (lower cost, more time, less/more control, etc.) is secondary. All homebrewers clearly have more fun brewing beer than people who just go to the store and buy it. I have more fun brewing mine with grain. No big deal; just brew it and have fun (right, gak?)

I saw an article in the Wall Street Journal yesterday about clear beers. It seems all of the big boys are planning to make them but the people who really know beer don't think they'll sell (no color = no taste = no alcohol = no sales), or so the logic goes. The interesting part to me was the method for removing the color: charcoal. They dump a load of charcoal into the beer, filter it out and voila!: clear beer. Any volunteers to ruin a perfectly good batch of hb in the name of science? (not me) P.S. I expect it would be much more difficult to remove the color from a deep amber ale than a piss-colored well-known American swill beer. I'll bet Guinness doesn't try to make Guinness Extra Stout & Clear.

Thanks for setting me straight on Miller, Ulick. Its been several homebrews since I read it...

Joe, I'd be glad to participate in your ale/lager taste test. I don't pretend to be able to add much to the discussion, but it sure would be interesting for me. I live in Longmont.

Just had a Vail Pale Ale last night. It had a wonderful sweet, malty base with a quite well-balanced hop kick to finish it. I've never had a 22 oz. bottle disappear so quickly. In fact, it was so good I immediately went to the store and liberated another.

Cheers,  
Norm

From: Joe Rolfe <jdr@wang.com>  
Subject: pH Meters, Sparge, MM and Extracts

hi all,

whew what a subject (forgot, yeast re-pitch, Belgian Ale Book Comments).

on the subj of pH meters - i recently got one from HANNA (shucks found out it is made in italy :0). anyway does anyone have one of these? do you notice a fluctuation between hot and cold temps of the same sample? i am not sure if mine is defective or what, pH varies by .5 (even after letting it sit in the non-ambient temp sample for 1-2 mins)....the probe was calibrated with the 7 and 4 solutions minutes before....and soaked in a conditioning solution for 30 mins as recomended.... does any one have the temp diffs for pH?

on sparge water - i am just beginning to go all grain (not because i feel less than a whole brewer - but for cost reasons and control over the end product). i am looking for inputs on what types of acids people use to knock down the pH of the sparge and comments on the results brought into the final product (flavour, aromas, color or anything).

on the js MM, i have been using it - mostly on MF crystal - it does produce a good crush, no tearing (to speak of ) of the husks. the thruput may not be high enough for my purposes (at least in a manually operated mode) but both myself and another larger scale brewer are going to put a motor on it with a good sized hopper (in and out). anyone done any motorizing of these? what rpm did you find best (too fast the grains just roll or fall out of the sides).

my 1/2 cent on extracts vs grain - what ever works for you. i think it has been said that yes - you too can make a good beer from extract and grain. one thing i have found in using the extract to date - you have a hell of a time controlling color of the final product. if your looking for the same color it seems very difficult (at least for a very pale to pale colors). the extract does brown over time ( i have yet to figure out MF date coding). i have even seen some difference in SG/lb/gallon of between 3 and 8 pts. again if you try as i do to produce the same product over and over - it makes it less "cookbook" like.

i finally got a re-pitch to work. i had problems with stucks and in conversations with Mike Sharp and SHeri Almeda the major problem was O2 and areation. i never had a problem re-pitching small batches (5-10 gal) but

larger batches (even when over-pitching) got stuck. pH of the wort was fine (5.2 +/- .2). no major temp changes in the yeast.. started warming the yeast up days in advance. yeast never sat for more than 5-7 days in 40F temps. so if in doubt areate the hell out it. i used an oilless compressor with .2 ucron filter and connected to the bottom valve of the fermenter. a hose dropped into the wort should do fine if you can get it to the bottom for top opening vessels. but always use a filter to get "sterile air". i have also heard that using pure O2 is not very good - most bottles o2 contains an additive used to prevent "stuff" growing (for hospital use), it is very explosive and too much purew o2 can be toxic to yeast..... although i have heard that divers O2 should be fine.

as i have posted in the past - i will be travelling to montreal to see pierre rajotte within the next few weeks - the offer still stands about those people who thought the book "missed the mark", "lacked" wahtever... or was good in whatever....both sides of the comments are desired...

so far i have posts from Brian Bliss, Jim Liddil, Jim Busch (hi jim!), Conn Copas

have not gotten any specifics from Martin Lodal (not to put you on the spot:) but in LD 11 for Thur Dec 10 -you mentioned "but many experienced and capable brewers don't feel he succeeded in communicating it" [it being info on brewing beglian ales]. between you and Conn - this was the impetus to get the questions answered....

so martin - do you have any comments?? do any of the other brewers you talked to have them? these can be direct comments of questions that could be answered to remove the vague areas. as i said and pierre has agreed to answer any questions, you post them, i hand carry them and respond to all en-mass....

my god - what a long winded mess i have made - sorry for the wsted bandwidth i have not posted in a while....i feel better now:)

good brewing (how ever you do it)

Subject: Re: Length of Carboy Aging

I brewed an Ale a couple of years ago that had a "stuck" fermentation. It was in the winter in a unheated bedroom. After a couple of months in the secondary I kind of forgot about it and it didn't get bottled till it was 6 or 7 months old. It was great. It didn't carbonate quite as much as I thought it should have, but that didn't bother me. The ale was a nice amber  
with no haze and very little yeast in the bottom of the bottle.

Bryan

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: Re: stuck conditioning

Peter Maxwell says his brew isn't conditioning in the bottle. I've had similar hassles. Is there any visible sediment in the bottles? This is the best gauge (other than opening a bottle) of how the yeast in the bottle is doing. My guess is that the yeast count at bottling was too low.

In my case, I think this was due to fining with Polyclar. Now I swish the racking tube around the bottom of the secondary to pick up a little of the yeast sediment. I have also added 1/4 tsp of dry yeast to the bottling bucket.

That's for later, this is for now: Peter, shake all your bottles and lay them on their sides in a warm (70F) place. Shake every day, until there is visible yeast in suspension. I got this trick from The Cellar in Seattle. I think it works by exposing more yeast surface area. I did this on a batch of Kropotkin Anarchist Ale and it had good carbonation in three weeks. This was after it stayed flat for a month. Let us know how it all works out.

Paul.

Subject: Fermenters

The following are answers to private e-mail from Cush Hamlen. My response to cush@msc.edu bounced.

>A quick question on your posting today on fermenter geometry: If I follow  
>you right, DeClerk (sp?) found a shallow container to be better. However,  
>is seems to me that a large surface area is just begging for increased  
>likelihood of contamination (of course, this is a mute point for closed  
>fermentors). Is he concerned, then, about geometry as it relates to  
>circulation of wort during fermentation?

You are absolutely right about bacteria. Those using open fermenters have to be very careful here. Anchor has theirs in an enclosed area that is under a positive pressure, and where sterile air is circulated.

>If one assumes that the circulation imposed by the CO2 rising through the  
>liquid is akin to uniformly heating the base of a container, then the  
>mean number of convection cells is greater for a container with a small  
>depth to area ratio. This is the typical Rayleigh-Bernard convection  
>pattern (Gee...can you tell that a great deal of my research has been  
>in fluid-dynamics? :- ) The result of increased number of convection  
>cells would be greater contact of unfermented sugars with yeast.

>Is it then concern about convectin pattern in the fermenter that drives  
>the conclusion that 'shallow is better'?

You are exactly right here as well. There is a nontrivial temp. gradient in a tower type fermenter which drives the Rayleigh-Bernard convection cells.

This has been observed empirically, and in addition numerical simulations have been done using the (incompressible) Navier-Stokes equations at appropriate Reynold's numbers which confirm this as well. I have the most relevant references on file at home. I would be happy to send you this list if interested. In modern commercial brewing, stirring devices are added to the tower fermenters to keep yeast in suspension along the length, and to level out temperature gradients. I still do not like these type of fermenters, and they are usually only used when horizontal space comes at a premium.

Can someone tell me if there is any difference between the gelatin finings sold in homebrew stores and the plain unflavored gelatin you can buy at the supermarket. I have a supply of the supermarket variety and was considering using some on my latest batch.

I've been wondering about this for a while. Just how does high alcohol induce mutation? I'm assuming it's just natural selection for more attenuative individual yeast cells. If so, is this necessarily a problem? Can strange esters / by-products / flavors be created by this kind of random mutation due to high-alcohol storage media (ie slurry)? If adverse mutations occur, can't they be detected in the starter? Is there something I'm missing?

Have another beer,  
Jake.

Subject: 2 Stage Fermentation

In response to Mark Elliott's questions about adding priming sugar to secondary:

The method I was taught, which works great, is siphoning the secondary ferment into another vessel -- to which you have already added the priming sugar -- just prior to bottling (to get it off the secondary trub/sediment). Since the priming sugar is added to the new vessel first, it is thoroughly mixed during the transfer. You really wouldn't want to mix up the sediment into your beer just before bottling, I should think!

If this is clear as mud, and others don't explain more clearly, feel free to e-mail me directly, and I'll explain step-by-step the method I use.

Subject: Re: 2 stage fermentation and bottling

In HBD # 1080, Markham R. Elliott asks:  
2.) How important is it not to aerate the wort during the transfer from primary to secondary.  
3.) By leaving behind the sediment, won't there be a tremendous (significant) amount of viable yeast left behind?

...  
1.) What am I missing here? Do I accept putting all the precipitate back into suspension and into the bottles, or,  
2.) Is there a method of mixing the priming sugar/equivalent without disturbing the junk in the secondary?

This is my bottling procedure:

- 1) Make up the priming solution by boiling a mixture of about 3 cups of the beer in the secondary and 3/4 cup corn sugar or 1 cup of malt extract.
- 2) Carefully pour (avoid splashing/oxidation) the priming solution into a clean tertiary (originally the primary).
- 3) Rack the beer from the secondary onto the priming solution.
- 4) Immediately bottle the primed beer.

This procedure leaves behind the sediment and achieves uniform mixing of the priming solution with the beer. Although most of the yeast has been separated out at this point, I don't worry about it. There is still plenty of viable yeast in suspension as long as you're bottling within 3 weeks of brewing.

As for oxidation, your biggest concern should be with hot wort. At fermentation temperatures the effect is reduced by orders of magnitude. But as long as you are using a racking tube to siphon the beer off the sediment, why not avoid a little splashing and make the best beer you can?

Eric

Subject: The real reason we brew

Steven Tollefsrud writes in HBD #1080:

>While it was refreshing to see a few all-grain brewers come to  
>the defense of the extract brewer, I have yet to see one come  
>out in favor of extract brewing over all-grain brewing.  
>...  
>If I were an all-grain brewer  
>who had made all the investment in equipment and time, I too would  
>find it difficult to admit, afterward, that it wasn't worth it.

In my post to HBD #1078, I stated that I brew both extract and all-grain.

Although I didn't explicitly say "I am in favor of extract brewing over all-grain brewing," I hope I implied that extract brewing is perfectly acceptable. It simply comes down to what your goals are and how you choose to meet them. If there are snobs (whether a'g'ers or EXTRACTERS) who criticize the choice of others, all I can say is, \*\*\* Give people information, but let them choose their own goals and means \*\*\*.

>One of the most common reasons given by all-grain advocates for  
>taking the plunge is for greater control over what goes into the beer.  
>But .. inconsistency ... make me shy away from having such "control"

Greater control in all-grain brewing isn't the same thing as having a process that is "in control". A'g'ers have more control available to them because they can choose the mashing procedures and temperatures, sparging temperatures and times, and many other variables. Having more control (read: choices, parameters, variables, tweak points, etc.) means it DOES take more work to stay in control. I think everybody's FIRST goal is to have fun with a hobby that interests you. If you want good beer, use good extract. If you want to play with these other controls, then play.

The  
>cap hissed a very little on opening, but the beer tastes REALLY flat,  
>subjectively only marginally, if any, more than there was when it was  
bottled.

I usually wait at least a week to 10 days before expecting carbonation.  
That a beer appears clear (not clouded with yeast) only means that the  
yeast count has dropped below 10,000 cells/ml (I THINK -- I don't  
remember  
if this is the right number -- perhaps someone can verify/correct?).  
There's  
still lots of yeast in suspension and should be plenty to carbonate your  
beer unless you gave the yeast a temperature shock, in which case it may  
take a bit longer.

\*\*\*\*\*

Markham writes:

>This past weekend I finally aquired a second 5 gallon glass  
>carboy. After three successful single-stage extract brewings, I

>brewing ladder: Doing a two-stage fermentation. Additionally,  
>this will be my first go at using no sugar in the process, except  
>for what appears to be the standard use of 3/4 cup for priming.

The sugar-freeness will improve your beer a lot more than the secondary.

>As I understand the procedure, after the respiration phase has  
>completed, and the blow-off tube has cleared, I am to siphon the  
>fermenting brew into the secondary fermentation vessel (with as  
>little aeration of the liquid as possible), leaving behind whatever  
>sediment is on the bottom of the primary vessel.

You can, if you wish. Many a prize-winning ale has been done with  
single-  
stage fermentation. I personally feel, that a secondary is only needed  
for long ferments like lagers and thus I only use a secondary for lagers.  
Note that respiration occurs before any activity can be seen. Perhaps  
what you mean is "after blowoff ends" which is perhaps 1/2 to 1/3 of the  
way through the fermentation phase.

>1.) Must the transfer to the secondary be done immediately, or  
>is there a safe window of a day or two?

To gain the maximum benefit (which is to get the beer off the trub)  
you want to go to the secondary right after blowoff ends, but if the  
whole ferment is going to last only a week, I feel that the added  
risk of infection and aeration are not outweighed by the benefits

of using a secondary. Personally, I feel you're better off using the second carboy to make another (concurrent) batch.

>2.) How important is it not to aerate the wort during the >transfer from primary to secondary.

If active fermentation is still ongoing, then it's less (but not much less) important. The CO2 escaping from the beer will scrub out much of any oxygen you add. If fermentation is over, then I feel it's more important. Just do your best and don't worry too much.

>3.) By leaving behind the sediment, won't there be a >tremendous (significant) amount of viable yeast left behind? My >observations of the fermentation process show that the CO2 rises >from the precipitate at the bottom of the carboy, not from the >material in suspension.

There's still plenty of yeast in suspension and although I don't have a clear answer to why you see the majority of the CO2 coming from the sediment, I'm quite certain that the yeast in suspension does most of the work. Note that when by beer is actively fermenting, there so much yeast in suspension that the beer looks like chocolate milk and I can't see much more than 1/2 inch into the fermenter.

>Now, all my primings to this point have been by adding a >measured amount of corn sugar to each bottle, then filling the >bottle, capping, conditioning ... enjoying (er, sort of). Hey, >what can I say, I followed the directions that came with the >extract, and those supplied with the microbrewery kit ... how was >I to know. Beat me, whip me, make me write bad checks! I'm trying >to reform myself.

Don't be so hard on yourself. If you like the way your beer has been turning out... great! However, we all have room for improvement and the difference between a great brewer and a good one is one that is constantly trying something new, whether it be a new procedure or a new ingredient or a new style. I feel that you'll get better consistency and less chance for infection if you bulk prime (what you are suggesting in the next paragraph).

>If I understand the literature, about 3/4 cup of sugar/sugar >equivalent should be boiled in water or sterile wort, then added to >the contents of the secondary, cooled to the temperature of the >remaining 5 gal liquid (is it still called wort at this stage?), >bottled and conditioned as usual.

Boil the priming sugar in water, not sterile wort. Sterile wort has fermentables in it too and you want to use just the 1/2 to 3/4 cup of corn sugar (dextrose) for priming OR a measured amount of sterile wort... not both. It's called green beer at this point -- fermentation is over, so it's not wort anymore.

>

>It would seem that if I add anything to the remaining 5 gal >liquid in the secondary, and mix, all the precipitate will go back >into suspension and consequently be bottled. If I don't mix, what >will be bottled will not be consistently primed. I was under the >impression that one of the advantages of doing a two-stage >fermentation was to eliminate as much particulate from the bottled >product as possible.

>

>Questions:

>1.) What am I missing here? Do I accept putting all the >precipitate back into suspension and into the bottles, or,

You're missing the priming vessel (aka bottling bucket). No, don't do that -- siphon the beer onto the priming solution in another sanitized container, stir very gently and then bottle from that vessel. I use another carboy since the narrow neck is a smaller opening for nasties through which to float in via the wind.

>2.) Is there a method of mixing the priming sugar/equivalent  
>without disturbing the junk in the secondary?

Yes. See above.

>3.) Noting that the 3/4 cup is not carved in stone, if I  
>substitute dry malt extract for corn sugar, do I use the same 3/4  
>cup? What if I substitute liquid extract?

I've never used liquid since dry extract is easier to store partially opened. Dry malt extract is only about 80% fermentable, so if you use it in place of corn sugar, increase weight used by 20% or so. Malt extract syrup is about 20% water, so increase the weight used by another 20% over dry malt extract.

>4.) Lastly, if I use (for conversation sake) a 3 pound can of  
>a hopped liquid extract, and want to use dry malt extract (instead  
>of a second un-hopped can of liquid or [gasp!] sugar) to finish  
>off the ingredient list, what would be a reasonable amount of DME  
>to use as a baseline starting point for future experimentation?

As I mentioned above, the liquid is partly water, so if you substitute dry for liquid extract, cut back by about 20% by weight. NOTE THAT LAAGLANDER DRY MALT EXTRACT IS LESS FERMENTABLE THAN MUNTON & FISON, SO EXPECT A HIGH FINISHING GRAVITY AND A SWEETER BEER. I use Laaglander intentionally to make my Young's Special London Ale clone. It would be good for other high FG styles like Scotch Ale or Sweet Stout.

Subject: sadistic bestial necrophilia

I think all we all grainers should get down on our knees and pray to Steve Tollefsrud for showing us the light by telling us we are all inferior to the extract brewmeisters, but are afraid to admit it because we are embarrassed about the expense in equipment and time we spend to produce beer when the mighty extract brewers produce award winning brew in a couple of hours.

The error of our ways, spending less than half what the mighty extract brewers spend on malt superbly extracted by professionals, controlling mashes so poorly that the quality must be less consistent than the sugary, corn syrupy, overdark extracts. And we never know what extract we'll get like the extract brewers, given the superb consistency of syrup (Alexanders?), or TG from attenuative dried extracts (Laaglander) on the market. Thank you for pointing this out to us. We can now plant plants in our lauter tuns, donate our mills to charity, and get most of our Saturday afternoons back again to spend \$20 for 6.6lb of malt extract that isn't for pale wussy inferior beers we make now with grain.

A repentant all grainer,  
Ulick Stafford

Subject: queries

Hello everybody from a new reader, but brewer for 6-7 years, in near-total isolation. Hence discovering the HBD was a mind-blower. I'll resist the temptation to comment on recent flare-ups between extracters and all-grainers. How's that for self-restraint? A few questions please.

- 1) hydrometer reading: at the highest level the wort climbs up the instrument, or at the bottom of the curve? I've been reading at the highest part. Crude experiments with plain tapwater at 60 degrees suggest I'm right.
- 2) I've counted on Papazian's book for ages. Must I buy the new revised version? What do I get that's new (besides an index)?
- 3) Since Charlie mis-defined krausening (and I thought I'd been krausening all this time and I've only been wort-priming! with great success too), please someone give the real definition.
- 4) Go ahead-convince me that Wyeast is worth the extra investment. I'm all ears.
- 5) Anyone tried the Brew Werk 'Abby Beer' kit? How was it?

>that are Reinheitsgebot?

Personally, I dryhop virtually all my beers, but then again most of them  
are pale ales. I have never had problems clearing my dryhopped beers --  
they all turn out crystal clear without *\*any\** finings. Perhaps you  
should  
look elsewhere (besides dryhopping) for your clarity problem. For the  
record, I use whole hops for dryhopping because they float and I just  
siphon  
the beer out from under them. I dryhop when fermentation has gotten down  
to the 1 bubble/minute range and let the beer sit with the hops for  
exactly  
seven days (more or less appears to reduce bouquet).  
>  
>Norm Pyle considers Miller to be a lager book. I dispute that. It is a

>with corn sugar. What is Miller's Continental Pilsener book like?

I feel that there are errors in Miller's "Complete Handbook of  
Homebrewing"  
albeit not as many as in Noonan's "Brewing Lager Beer." I feel Charlie's  
NCJoHB is the most error-free, although I have a few sticking points with  
that too (like not recommending a strain of yeast -- I feel the yeast has  
more to do with the flavor than virtually anything else -- certainly more  
than which brand of extract!). Miller's "Continental Pilsener" is a good  
book with relatively few errors (IMO), but not as *\*great\** as Guinard's  
"Lambic" or the Fix's "Vienna."

Sure, but taste it before you bottle. If it has gone bad and you hate  
the  
taste, then don't bother.

>I used Wyeast American Ale and it was a slow starter, and even slower  
>finisher, but the FG is around 1009. Due to lack of time it has been

>basically ignored. I don't want to say exactly how long it has sat, but  
The slow finisher scares me a bit. I've found 1056 to finish quite  
quickly  
and suddenly. Now don't get worried, but the slow finish may be related  
to  
the slow start, namely, that during the slow start, something else got in  
there. But fear not. Taste it and trust your tastebuds -- they won't  
steer you wrong.

these  
>two causes the higher bottle conditioning? (I am still not convinced  
that  
>some bacteria, or more likely wild yeast, are not carried in on the  
hops).

I haven't had this kind of effect and have brewed perhaps 40 dryhopped  
beers in the last two years. It took me a long time to convince myself  
to  
dryhop (I was afraid of contamination) and eventually two things (both  
suggested by the HBD):

1. when you dryhop, the beer already has very little sugar left, quite  
a bit of alcohol and the antibiotic effects of the boiling and flavoring  
hops, and
2. what self-respecting yeast or bacteria would live on hops!?! It's not  
like it's a grape skin or a cup of raspberry puree... I think that hops  
would tend to carry no more microbiota than the area that they have been  
stored in contains (i.e. the dust in the area is just as likely to infect  
your beer during bottle filling as the dryhops).

From: Andy Kurtz <ak35+@andrew.cmu.edu>  
Subject: I heart the listermann sparger

I know there have been some postings in the past about the LS, but it worked out so well for me that I thought I would plug it once again. The LS (for those of you who don't know) is merely two 5 gal. plastic tubs. One is for holding sparging water; the other is a lauter tun (it has a neat false bottom insert). Both are drilled near the bottom and have lengths of plastic tubing inserted in them. The tube coming out of the water container is terminated with a couple of lengths of pvc pipe fitted perpendicular to each other so that they sit atop the lauter tun.

Water is sprayed onto the mash via a small brass pipe connected to the pvc (and the plastic tubing, of course). As water flows through the tube, the brass pipe whirls around fan-like, spraying water slowly and evenly across the grain. The grain bed is never disturbed and the water level is easy to regulate by keeping an eye on how fast the water shoots through the "fan" and out of the lauter tun.

My extracts have gone from a dismal 1.035 (for 8-10 lbs of grain!!) to over 1.060! It cost me about 40 bucks, but IMHO was well worth it (I'm sure y'all who are handy would be able to make something like this for much less -- but hey, I'm into convenience).

From: richer@desi.HQ.Ileaf.COM (Al Richer)  
Subject: Malt question

I am a bit confused as to the differences between 2-row British and 2-row American malts. I have a homebrew supplier that is happy to sell me Klages as suitable for British styles (bitters, pale ales, stouts...) and tells me that the major difference is that the American 2-row will convert faster.

Well.... I dunno.

I have traditionally used British malts in my ales and stouts, and will likely continue to do so for the specialty grains. At \$40 for a 55-pound bag (as opposed to \$56 for Brit 2-row), it's awfully tempting...

On a related note...

Anybody got any good suggestions as to where to buy bulk grain malt in the Boston area? This price is from Barleymalt and Vine in Framingham. Beer and Wine Hobby in Woburn is a bit lower, but not much. Mailorder would be fine only with a BIIIGGG price differential, considering the shipping ( I prefer dealing over the counter and shipping by Mazda pickup...<grin>).

Opinions, speculation (labeled as such), and other input welcome.

From: Garland O Burton <gburton@magnus.acs.ohio-state.edu>  
Subject: no more syrup

i am at the stage of omitting the 4lb can of syrup in my recipes and using all dry malt extract and hop pellets for the first time.

the recipe was:

4lb stout syrup (w/hop and roast barley extracts) i have heard that this does not ferment efficiently

3lb dry malt extract  
1/2lb dark roast barley (steeped)  
and most recently the addition of 1/2lb flaked barley. first i steeped at end of boil with dark roast, then on next batch boiled 10 min and strained  
milky soup into wort.

at first i was using dry yeast.  
the last 2 batches used yeast from local brewpub yeast harvest.

the boil was 15 min. primary less than a week. secondary more than a week.  
i can tell (luck?) when it's time to act.

i just got a hydrometer and the og was 1.042 on the last batch. it is still  
in the secondary.

my (5) batches have all tasted ok, (great compared to store bought) but i want to use all dry malt extract and hop pellets. i do stout, and am thinking of moving to pale ale (bitter) next.

what is the proper amount of dme to use. 6lb? dark dme is all i have ever used. i was told that i could use 7lb light malt extract and 2 lb "black patent." is that unmalted stuff to steep like i do the dark roast?

i think the action of the brewpub yeast has spoiled me as far as ever using  
dry yeast again so i will probably use liquid irish ale yeast in future.

i haven't tasted the brewpub yeast batches yet, but i think i will be pleasantly surprised.

what kind of hop pellets, and what kind of boil times will i want for my new, unknown recipe? i don't know what flavor hops are good for which brews, but i am sure there is the obvious hop and procedure for the stout/porter i am trying to brew.

can i grow decent hops in mid ohio?

sorry for all the ?s but i have been reading dozens of hbd's and this is my first post. thanks for replies and all of your posts to peruse in the last couple of months.

cheers!

gob!

Subject: Good chocolate beer, but...

My first batch with chocolate malt matured yesterday, so I had some friends over and generally it's a yummy beer. However, I still have that slight, annoying cidery taste. I did add about 150g of sugar beet molasses besides the malt extract and coarsely ground chocolate malt. Is it perhaps too refined of a sugar and adds mostly alcohol and not much flavor? Other suggestions?

I liked the dark ale too, and I thought the color was very nice. Nice malty flavor.

and BB says:

>
>On the subject of staleness, try comparing a bottle of 1992 Thomas
>Hardy's to a 1991 version...
>

Sure wish we could get Thomas Hardy's here in the WasteLand (read beer envy here!).

On the subject of maple beers: I was cooking up a favorite ham steak with maple syrup/mustard sauce in January. While in the kitchen, I happened to be quaffing a few bottles of the Winter Warmer. All of a sudden I had maple syrup in one hand and empty beer glass in the other: seeking, as always, oral gratification I poured a tablespoon or two of syrup into the glass and then poured a fresh Winter Warmer on top: the result was fantastic! Great maple flavor and the sweetness really seemed to complement the spicy flavor. I've tried maple syrup in pale ales, other ales, and porter now but liked it best in the Winter Warmer and pretty good in the porter.

Just another date point.

Subject: request for extract information

In regards to the `dead horse' thread started by Steve Tollefsrud, how about providing extract brewers with information and characteristics of malt extract?

In my college days, my friends and I were extract brewers. Being major geeks (RPI), we didn't bat an eye at massaging variables like hops (plugs, pellets, whole, centennial, saaz, boiling, finishing), adjuncts (crystal, black patent, brown sugar, molasses, cocoa, ginger, spruce, oats) and yeast (dry, liquid, ale, lager). But when it came to malt, we didn't get much beyond the questions of amber/dark? and syrup/dry? We stayed away from hopped extracts, preferring even as novices to control this.

One of the reasons all grain brewing is extolled is for the ability to get your hands on more of the variables in the brewing process and tweaking them to your satisfaction. Similarly, one of the reasons extract brewing gets panned is due to the lack of control of the extract. Well, let's put the collective wisdom of the HBD to work and give extract brewers the ability to have this control.

What I suggest is that people submit entries to me with the following information:

BRAND:
FORM: (syrup/dry)
- the percentage fermentable would be helpful for syrup
COLOR: (light, amber, dark)
- perhaps an equivalent to the lovibond scale?
HOPS: (hopped/unhopped)
- the name of the hops and the IBUs
SUGAR PROFILE: (percent of sugar from malt, percent of sugar from other sources such as wheat, corn or cane)
UNFERMENTABLES: (are there proteins, starches or other unfermentables present that may affect body, mouthfeel or head retention)
OTHER: (distinguishing characteristics such as roast barley, which would be appropriate for stouts, noticable tannin astringency, or perhaps the oxidized funk of wet cardboard)

Being a longtime reader (since #4xx, yet infrequent poster), I vaguely remember a mention of a comparative study of malts conducted by a Saskatchewan (yea, my home province) university. I also vaguely remember some difficulty in obtaining the results of that study. This seems like it would be an excellent place to start. Does anyone remember the details better? Does anyone know where this post is in the archives?

Subject: Great Englis Pub

When we got the chance to fly Virgin Atlantic for \$93 ea. way, we jumped. Don't let the weather in the UK in Jan. scare you - just keep close to your CAMRA Good Beer Guide!

It was our 4th of 7 days in England and we were heading south from the county of Norfolk in East Anglia towards Oxford. As it was getting late, we detoured off the A47 to the town of Wisbech. We couldn't see any B&B signs but we did find a Real Ale pub from the Good Beer Guide and thought that would be a good place to ask. Thus we entered The Rose Tavern freehouse in Wisbech.

They had just opened @ 5:30 and there were already 3 or so gents at the 12 seat bar. We ordered Woodford's Wherry Best Bitter (OG 1.039 ABV 4%) and asked about places to stay in the area. Graham appeared from the back room and set about to helping us find a room. A call to the Marmin Hotel, his first choice, proved them full. So he asks 'Who's driving?'. I answered that I was and he say's 'Come on. We'll go get you a room at a good rate'. So I left my wife at the bar and headed out to explore Wisbech with the local publican. At his direction, I drove around the town stopping at two hotels that he declared 'too expensive', the Marmin again 'Just to check', and ended up at the Orchard Hotel (which came complete with Basil and Sybil - but that's another story). He also gave me an impromptu historical tour and showed me the Elgoods Brewery in town telling me to go in and 'tell 'em you came from America for a tour!'.

We returned to the Rose. As I sat down one gent asks 'So you work with computers?' and a second chimes in 'And make your own beer?!' Patty had been having quite a chat! Over pints of Butterknowle's Conciliation Ale (1.042, 4.2%) I got to know the folks who seemed to know me so well. Graham was starting us collecting bar coasters (of which he has quite a collection) by the time we tried Morrells Varsity (1.041, 4.3%).

All made us feel as welcome as we've ever been! Sensing my curiosity about Real Ale, Graham gave us a cellar tour (his cellar trousers are the butt of the locals jokes), showed us where he has his beer festival in the summer complete with live music and dancing, and gave us a copy of all the Real Ale literature he could find.

We returned after dinner for the Everards Tiger Best Bitter (1.041, 4.2%) and the best beer of the trip, Cains Formidable Ale (1.048, 5.1%) - smooth, tasty and sneaky!

We consider ourselves fortunate to be adopted by Graham and the Rose Tavern folks. If you're ever anywhere near England, GO! Best, freshest and most diverse Real Ales (and conversation!) on our trip!

A local micro [Niagra Falls Brewing] makes a maple
syrup beer. It is very maple like. It's also fairly
expensive. Most of this brewery's products are on
the high side in terms of alcohol. This is no
exception. I think 7+% volume. There is no doubt that
there is maple in this beer. I'd hate to guess how
much syrup is in there.

BTW the stout they produce is also very nice.

Subject: re: Rolling Rocks #33

There are 33 words on the back of a Rolling Rock bottle.
Count 'em.

I know this is the reason for the "33" because on the back
of a bottle of Rolling Rock Light, it doesn't say "Rolling
Rock Light" (that'd be 34 words), but "Rock Light." The
back of the bottles said "Premium Light" when the light beer
was first released (also 33 words).

>does anyone know what the 33 on the Rolling Rock label REALLY stands
for?

Well, the story I heard is that it's the number of *words* on the label,
including their cute little slogan that's printed on the back of the
label and read through the glass. Either that or the number of words
just in the cute little slogan, I can't remember...

Anyway, this is just as unlikely to be the real reason as any other
you'll hear, but it does happen to be true. That is, there ARE 33 words.

The general consensus, I believe, is that you should let your nose and
tastebuds be the judge. Fermented beer can last quite a long time in
the secondary if kept from contact with air. If it still tastes and
smells good, then it's good, and you can bottle it without worry.

In fact, I brewed a cherry wheat beer recently that I left in the
secondary (or perhaps it was even tertiary) for three months, on
purpose. It turned out wonderfully, and four months later it continues
to get better. My general experience with fruit beers is that they are
extremely complex and take a lot of aging to reach their peak, so 7
months may have improved it!

From: atl@kpc.com
Subject: Starch Conversion Weirdness

About three nights ago, I purchased a 5 gallon igloo cooler to try single step infusion mashes in. I have been doing all my mashes in my brewpot, using my kooker to add heat when necessary. The temperature fluctuations were quite difficult to control.

Anyway, I put 12.25 lbs of grain into the cooler, and added 12.25 qts of 172F water, stirred, and the temperature settled at exactly 155F, the desired temperature for this batch. I closed the lid, and let it sit for an hour. At this time, I sampled a bit of liquid from the surface and performed the iodine test for starch conversion. There was no color change, indicating complete conversion. Then, on a whim, I sampled some liquid from the spigot at the bottom of the cooler, and performed the iodine test on this as well. The test instantly turned jet black, indicating incomplete conversion. I thought this might be a result of fluid in the spigot itself, so I ran about a quart of liquid through, and tested again with the same (incomplete conversion) results.

Note: I had placed a stopper, short piece of plastic tubing, and a "Mr. Tuffy" sink scrubber into the spigot so I could drain liquid from the spigot cleanly.

At this point, the temperature had dropped to about 152F, so I drained about 1.5qts of liquid from the spigot, boiled it, and stirred it back into the mash. I then stirred the mash well, thinking that maybe I had been sampling from a portion of the mash local to the Cara Pils malt I had added. This brought the temperature back up to about 154F, and I let it sit for another hour. I repeated the pair of tests again with the same results.

Now frustrated, and up past my bedtime on a weekday, I drained out about 2 qts of liquid, boiled it, and stirred it back into the mash, bringing the temperature up to about 158F. I put the lid on, and went to bed. In the morning, the temperature had dropped to 144F, and the test from both top and bottom indicated complete conversion. I sparged with my "PVC manifold in the bottom of a bucket" system, and brewed as usual. My extraction rate was 26.9.

Now, the questions:

- 1) How is it possible to have different conversion rates in different portions of the mash?
- 2) I regularly get extraction rates from 24-28. What can I do to approach the magic 30 that I hear commonly in this forum. My sparges usually take 1-1.5 hours, and the temperature in the lauter tun stays between 150F and 170F.
- 3) The method used above to reheat the mash seems similar to decoction mashing. With regards to decoction mashing:
 - a) is it usual to drain and boil just liquid, or liquid and grain?
 - b) doesn't this process denature the enzymes needed for conversion?
 - c) is there some formula for how much of the liquid or liquid and grain to reboil to make a desired temperature change?
- 4) Are the enzymes converting the starches dissolved in the liquid, or bound into the starch itself?

p5) Unrelated question: Is boiling 2oz of hops for an hour the same as boiling 4oz for 30 minutes? In other words, in the equation for IBU's can you trade off boil time against total hop weight and acheive the same results?

Thanks,
Drew

-

Lastly: Shut the f**k up about all grain versus extract! Brew what you like, how you like, when you like! If you must argue the point further into the ground, take it OFFLINE! Phew, sorry, just had to get that off my chest.

From: Lee Menegon <necis!lmenegon@transfer.stratus.com>
Subject: Yeast type and beer style

I plan on developing and refining an Oktoberfest recipe. My goal is to try to produce a Spaten Ur Marzen clone. I realize Jackson considers this one of the world's finest beers so I guess I am aiming high. I am an all grain non fart snob and would appreciate input on this project.
What Wyeast strain is appropriate to this style:
Bohemian, Bavarian or Munich?

At a recent club meeting a fellow brewer mentioned using the Bohemian yeast in a Pilsner and finding his brew came out drier than a similar brew using the Bavarian strain. This inspite of the published attenuation for the Bavarian being the greater of the two. Any data points on this issue?

The Munich yeast is some times refered to as "unstable" what does this mean? What effect does instability have with regards to culturing this strain?

PS: I have yet to get an injunction for using the same letters in Boston in the name of my Brown Ale so this project will yield:
not so Bavarian Fest Beer.

Brian writes:

>The Imperial stout comes in a clear bottle and 50% of the time I
>buy it, it is light-struck (skunky). I don't drink much of the taddy
>porter.

I read somewhere that keeping beer at around 50F (in the dark) for a few days will cause some chemical reactions that make the light-struck (skunky)

aromas go away. I tried it on a sixpack of severly light-struck Newcastle

Brown Ale (clear bottles) and it worked! Perhaps some of the rest of you could try it and see if I just lucked out or was influenced by wishful thinking? I'd say a bottle of Pilsner Urquell after a week or three under fluorescent lights would be the ultimate challenge.

BTW: All the Samuel Smith's beers that we get here are in clear bottles. Frankly, I can wait till I open to look at the color.

Rob writes:

>Ironically, Guy McDonnell mentioned one in the article immediately
>below AL's post! I posted here in January about the Chicago Brewing
>Company's Legacy Irish Ale. I find it a very tasty brew. It is both

>you must have tried it. The blurb on the bottle says Irish immigrant
>brewers brewed in this style in 19th century Chicago. It's certainly a
>plausible tale.

Someone (was it Tony? sorry) recently speculated that perhaps Irish Ale (in Ireland) tends towards a malty version of a Pale Ale. This may be true, but my recollection of CBC's Legacy Red Ale is that the balance was definately towards bitterness as opposed to maltiness. Perhaps it's the Chinook they use and the Chinook bitterness "stands out" more than an equivalent IBU of a milder hop? So maybe all ties of Irish-American

Red Ales with Irish-Irish Ales have been long severed and the two styles (if indeed they are styles) have diverged or perhaps have never been related?

Matt writes:

>Recently, I found a raspberry wheat beer in a fermenter that I forgot about.

Sure, I've done it, but mine was 9 months old and I initially pitched not only Saccharomyces, but also Brettanomyces Lambicus yeast and Pediococcus Cerevisiae bacteria. It was my pseudo-lambik-kriek! The pseudo-lambik-framboise is still in the fermenter (10 months and counting...). I liked the p-kriek but felt it needed more sourness and Brett character. If you

taste yours and feel that it has developed a lactic infection which you don't like, well then send them to me... I'll drink them!

Al.

Subject: A Modest Proposal/Irish Ales/Snobs

<<A Modest Proposal>>

Recently, the Homebrew Digest has had what seems to be an increasing number of contributions (some very long) about people's tours through commercial beer land. I hasten to say that I have no problem with people writing about the microbrews they've discovered, or how much they loved the Pacific Northwest -- in fact I think articles like this can be quite interesting, and I've even written a few myself.

I'm not convinced, however, that the Homebrew Digest is the right place for such articles. Frankly, I have a tough time plowing through the Digest every day and wouldn't mind if it was a little shorter. I've also noticed that the lag time is getting pretty long, and that articles seem to need several days now to be posted; I think this hurts the utility of the Digest, and the flavor of almost-instant electronic response that makes the Digest so useful for those with questions (especially panicky questions about why "nothing's happening!").

In Usenet, there is a distinct difference between alt.beer and rec.crafts.brewing. People who post questions (usually beginner's) about how to make beer on alt.beer, quickly get shuffled off to rcb. Why do we not have a similar division here -- and soon?

No, I don't have the means nor the knowledge to run a Beer Digest myself. But I suspect someone else could, and that Rob wouldn't mind offering some advice.

<<Irish Ales>>

I have a reference somewhere, not to hand, given to me by my father, a retired food technologist. In a book on the economic and political impact of various seed grains there was some attention given to the economic boycott imposed on the Irish by the British in (I believe) the 18th century in order to bring Ireland to a colonial status. One of the restrictions was on the importation of hops; according to the author this resulted in the Irish switching to "porter". The Irish have succeeded over the years in becoming dandy smugglers, but it still appears that not very many hops made it in to the country.

Any "authentic" ales, then, are likely to have very low hopping rates, and especially be lacking in the finest of finishing hops.

<<All-Grain Snobbery>>

Being primarily an all-grain brewer myself, I've watched the bickering here with a certain alarm. Recent converts to all-grain brewing tend to sound much like those who just quit smoking -- there is an appalling air of self-righteousness (except for you, of course, Jack). A number of people have pointed out that a good many award-winning beers are brewed from an extract base; I have long since gotten over being surprised by this phenomenon. In my own experience, assuming the same quality yeast and hops, and quality malt extract and additional grains, the real difference comes from using a full boil. I teach a beginning homebrew class and brew using the "Papazian" method, more or less, having pre-boiled the water in the carboy; I also occasionally brew an extract

batch at home. No matter how hard I try, the batch brewed in class is NEVER as good as the one I brew using a large kettle and a wort chiller.

But, hell, what do I know? I don't care what method a brewer uses; if the beer is good and they're willing to let me drink it, what possible difference can their process make?

Subject: mash vs extract

I'd like to add my opinion to the mash vs. extract discussion. I made my first extract beer in several years last Sunday and I enjoyed it thoroughly. (I did add some home toasted malt for color/flavor.) It was definitely easier, and the wort was clearer than any mash I've ever made. I racked it last night to the secondary - it looks and tastes wonderful.

My general rule of thumb is to mash for pale beers, and use extract for dark beers. Because I do believe pale beers simply come out better when mashed. Although I made some good pale beers using Alexander's extract. It seems like a waste to me to take a good home mashed wort and cover it up with dark malts, that's why I say use extract for dark beers.

As for having better control over the brewing process, not in my case. Sometimes I hit the mash temperature I want, sometimes I have to adjust it. I never mash or boil for exactly the same amount of time each time. I never have exactly the same yield in gallons or points per gallon. And fermentation temperature control? whatever room temp is for ales, and basement temp for lagers.

I took the plunge into mashing over ten years ago, after twelve years of extract brewing, and made the switch to Wyeast two years ago. I'd say that liquid yeast is more important in making excellent, consistent beer than mashing. In fact, using extract would be a better choice for getting consistent beer than mashing.

Now I mash because I like pale beers, and since I've made the investment in equipment, it's cheaper. Otherwise, I'd use Alexander's malt, specialty malts, Freshhops, and Wyeast. And keep the stinking brown sugar out of my beer.

Subject: Micah's PS Starters
Full-Name: "John Cotterill"

I have also tried to duplicate Micah's procedure for using powdered sugar starters. My results are similar to Bob's and I DID use a yeast nutrient in the starter. I did not do any side by side like Bob, just a normal batch of beer with the PS starter. My initial starter was 500ml of 1.020 powdered sugar with a pinch of yeast nutrient. After two days I fed the starter 200ml of 1.030 PS solution with additional nutrient. A day later I brewed. I was impressed with the quantity of slurry at the bottom of the starter. It was about 300ml of fairly dense/cloudy material. The yeast also flocculated very well (BTW it was 1056 yeast). I poured off the clear liquid on top, pitched the 70F starter into 70F wort and fermented at 70F. The OG of the wort was 1.061. My lag time was the almost the longest that I have recorded...almost 2 days! I think a single package of 1056 would have started faster. And indeed, just like Bob, the fermentation was slow and the FG was high. I eventually repitched with a standard 1056 DME starter and the beer fermented out fine.

I am going to stick with the standard DME starters. I don't think the yeast pitch rate is as high with similar volumes of DME and PS, but the PS yeast must get severely shocked going into the beer environment from the PS env. A bunch of the beasties must die, and those that survive must take a while to adjust.

refrigerator that can hold a carboy with airlock. I'll buy
new if necessary, as I am desperate.

"Are any of you familiar with refrigerator models that are
currently available, or were available not long ago, that
fit this bill?"

I have a small refrigerator which is just tall enough, if one takes out
all of the internal racks. The freezer is too low to allow a vapor lock,
but I can think of a couple of workarounds, including a flexible piece of
hose (which could also lead out of the refrigerator, so that you can see
it percolating), a hole in the freezer / refrigerator barrier, or the
removal of the freezer compartment altogether (leaving behind the coils
on the sides and top of the refrigerator, of course).

It's called a Welbilt, model W 555 AX. Says Welbilt is a US corporation
on the back, but it also says the refrigerator was built in Yugoslavia.
I'd guess it was made in the Seventies, but refrigeration technology is
pretty stable, few or no differences between apartment refrigerators made
in the Seventies, and those made now.

It's just the right size and height to hold a small microwave oven, or
a collection of cookbooks, or a spice rack and associated materials.

Subject: yeast

Dear Brewers

Just a quick question here: I recently brewed up a batch of leftovers to make a total of 1 gal. of beer... just simply for the hell of it. I threw in approximately 1# dry wheat malt and 1# dry light malt (though I suspect both were less than a full pound, and therefore total at maybe 1.67#?). Plus, I tossed in 1/2 oz. Tett. and another 1/2 oz Cascade hops, though I think I left the Tett. for the finishing stages. (For all of you exacting and technical brewers out there, I appologize for my rather cavalier recounting of my proceedures; I assure you, my brewing is seldom so relaxed! Usually, my gilrfriend leaves the house for her own sanity when I brew!!). I cooled the wort while also rehydrating some ale yeast - but now here's the rub: Such yeast is seldom available in quantities less that what is needed for the traditional 5 gal. batch. But I tossed it all in anyway.

The fermentation was obviously through within a day and within two I bottled the brew. At that time, the taste and smell reminded me of a beach-side men's room in the summer time, without air conditioning! (Pfew-ee!). I'm hopeful, though. Maybe it'll age out? So the question is: could the large quantity of yeast (or the fact that it was dry) lend off flavors and/or aromas to the beer? I'm not too concerned about it over all, as this is a batch of left-overs, but I am interested in the learning experience.

Cheers,

John

From: Richard_Ahrens@vos.stratus.com
Subject: Rolling Rock #33

Michael T. Lobo asked for the real meaning of the "33" on the Rolling Rock label. Cecil Adams, who writes "The Straight Dope" column in numerous papers, researched this some time ago. His answer is included in the second collection of extracts from those columns, "More of The Straight Dope." The book is a gas - check your bookstore. Where else would you find all 32 of the variations of the spelling of Muammar Qaddafi's name recognized by the Library of Congress?

Anyway, Adams says that the number "officially" represents two things: the year Prohibition ended and the number of words in the slogan on the bottle. That slogan is "Rolling Rock from glass lined tanks in the Laurel Highlands. We tender this premium beer for your enjoyment as a tribute to your good taste. It comes from the mountain springs to you."

He adds, "Now this is a touching sentiment, and there is no question that there are 33 words in it, but from the point of view of being intellectually satisfying, it sucks." So he interviewed James L. Tito, former CEO of Latrobe Brewing. Tito's family owned the company from Prohibition until 1985. His answer was based on notes and discussions with now dead family members. In other words, it probably can't be substantiated either, so take it with a grain of salt.

Apparently when the Titos were preparing to introduce Rolling Rock in the late thirties, there was much argument about what slogan to put on the back of the bottle. Long and short ones were debated. When the one eventually used was written, someone wrote a big "33" on it to indicate its length. When the original copy went to the bottle maker, they did not realize that the number was not part of the text and it made its way onto the first run of bottles. Rather than throw out perfectly good bottles, they then made up a story about it representing the end of Prohibition.

Adams seems a bit skeptical of this version, too, but he seems to have gotten as close as one can get to a real source of any folklore.

End of HOMEBREW Digest #1083, 02/23/93

Date: Sat, 20 Feb 93 13:02:21 MST
From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
Subject: Why does my beer smell like bubble gum?

A few questions for those with more homebrewing experience:

- 1) Why does my homebrew smell like bubblegum? This is my third batch; I used the following ingredients:

- 7 lb. container of Steinbart's Light liquid malt extract
- 0.5 lb. dried light malt extract
- 1 lb. crushed crystal malt
- 1.5 oz cascade pellet hops (60 min)
- 0.5 oz cascade hop pellets (10 min)
- 1.2 oz cascade hop flowers (1 min)
- 2 tsp gypsum
- 0.5 tsp salt
- 1 qt. Wyeast 1056 starter

I put 1.5 gallons distilled water in a stainless pot. I steeped the crystal malt about 30 min as the water was heating up, then removed before full boil. Added extracts, salt, gypsum, boiling hops, then aroma hops as indicated. Placed boiling pot into sink full of ice cubes and chilled to ~80 degrees F. Poured into carboy, without attempting to strain out pellet hop residue. Topped with presumably sterile bottled water. Pitched yeast solution when I felt that the wort had cooled to room temp.

The next morning, about 12 hours after pitching, there was noticeable activity. 36 hours after pitching, the fermentation was furious, and had actually churned up the trub into suspension. BTW, I used a blow-off tube.

After 10 days, I bottled with 0.75 C corn sugar. 7 days after bottling, I tried one. Carbonation was OK, but the beer smelled of bubblegum. My wife thinks it smells like licorice, but to me it smells like a fresh package of Bazooka Joe.

Does anyone know why this happened? I realize that I haven't given it very long in the bottle. I seem to remember reading about this phenomenon somewhere before, but I haven't been able to find it.

- 2) I would really like to replicate Sierra Nevada Pale Ale. I really like its hoppy aroma. My second batch of homebrew (recipe almost exactly that given for batch #3, above) had good hop aroma, but it disappeared after about 1 - 2 weeks. The above batch has almost no hop aroma; maybe it is masked by the bubble gum scent.

Why can't I get this nice hop aroma? I have a few ideas:

- a) My hops are not fresh enough.
- b) boiling bag reduces hop aroma extraction
- c) I need to dry hop the beer
- d) Hop aroma carried off during blow-off

If anyone can help me out here, I would appreciate it.

Thanks a lot for your help.

From: J. Michael Diehl <mdiehl@triton.unm.edu>
Subject: Carbonation w/ Dry Ice?

I think this was rehashed some time ago, but I missed the discussion. Anyway, a friend and I have decided to try homebrewing and would like to brew a bier that we could share with our friends. Unfortunately, most of our friends would be turned off by a bier with "bugs" floating around in it. So we were wondering if we could carbonate our bier with dry ice. We were thinking of putting some in the bier at bottling time. The dry ice should sublimate directly into solution with the bier. Might take some experimentation to find the dosage, but what do you think?

Thanx in advance.

> some pubs and/or breweries to visit.

When in London the best beers are Fullers and Youngs. Fullers is brewed
in
Chiswick and is common in West London, Youngs is brewed in Wandsworth
and common in south west London. The (once) good chain of "Firkin" (as in
a
Firkin good pint) brewpubs eg Phoenix & Firkin, Frog & Firkin etc are
also
worth trying.

Try the following pubs:

Anglesea Arms, South Kensington
County Arms, Wandsworth
Dove, Hammersmith
Hand in Hand, Wimbledon
Orange Tree, Pimlico (brewpub)
Princess Louise, Holborn
Spotted Cow, Putney
Thatched House, Hammersmith
White Cross, Richmond
Windmill, Clapam Common

Get copies of CAMRA publications:
Good Beer Guide (national coverage, available in bookshops)
various local guides (available from CAMRA and some local bookshops)
London Drinker Magazine (available in some pubs, eg Dove and Anglesea)

Also Good Pub Guide (available in bookshops), as good beers and good pubs
don't necessarily go together. CAMRA often recommends good beer in grotty
pubs. Only if both guides recommend it can the place be a certain hit.

From: mgx@ornl.gov (Michael D. Galloway)
Subject: Sierra Nevada Bock?

Well I did the dirty deed this weekend: My first all grain batch (batch number 25). The recipe was supposed to be SNPA:

10 lb British Pale Ale Malt
0.5 lb British Crystal Malt (50 L)
1oz Perle (8.1%)
1/2 oz Cascade Whole Hops - Flavor
1oz Cascade Whole Hops - To Be Dry Hopped Next Week
500 ml Starter of WYeast 1056

Mashed the pale ale malt and crystal in 13 quarts treated (i.e. boiled) water at 150 F for 1.5 hr in a 10 gal Gott with a Phils Phalse Bottem.

Sparged with 4+ gal acidified (1/8 tsp "acid blend") to pH = 5.5 water at 170 F. Sparged to 6.5 gal. The gravity at 6.5 gal was 1053. This implies:

$(53 \text{ pts}) \times (6.5 \text{ gal}) / 10.5 \text{ lbs} = 32.8 \text{ pts/lb/gal} !$

When boiled to 5.5 gal and racked to primary that yields an OG of 62.6. What should I call this stuff? Sierra Nevada Potent Ale?

Anyway, the mash went very well. The temperature drop was only two degrees over the 1.5 hrs (I preheated the Gott). Now sparging, that is another story. I was somewhat overwhelmed by the sparging: I kept drawing off wort and recirculating it but it never seemed to clear the way I expected it. I finally said to hell with it and ran off the initial wort and proceded to sparge with water to 6.5 gal. There was still good sugar in the sparge at this point. What is the lowdown on sparging? How much do YOU recirculate? Am I needlessly worrying?

All in all, an interesting adventure and it went much easier than I expected. Maybe Sierra Nevada Helles Bock?

I located some 3/4" round labels that are designed for use on
a laser printer; unfortunately they seemed EXTREMELY expensive
at \$15 a box but I don't recall how many labels were in a box.

I've used this size label before by writing on them and then
sticking them on the caps; no mess on the bottle! It seems
that with the proper font you could get beer name and possibly
bottling date or other info.

Author:

Subject: removing foam scum

Hello all. Most of my previous brews have been fermented in five gallon glass carboys used as primary fermenters followed by secondary fermentation in another glass carboy. Since I have always been somewhat bothered about the quart or two loss of beer from the blowoff of the primary fermenter, I recently invested in a 6.5 gallon glass carboy.

Since my new primary has a larger headspace, I do not get any lost due to blowoff. The beer that I have subsequently produced have been good, but now I find that it has a tad more of a bitter "bite" than before (but this only means a slightly longer aging time before consuming the brew). Any suggestions as to how to remove the scummy resinous brown globs that float on the foam in a sanitary fashion? (Yes, I do believe that the blowoffs from my previous setup remove the "nasties" and hence yield a smoother beer.)

Eagerly awaiting your suggestions,

Dan "Sven" Yee

Subject: Beer Labels for laser printers

In HBD 1082 Andy Rowan asks about beer labels for laser printers.

3M (No I don't own stock in them), makes at least one kind of 8 1/2 X 11 laser printer label. Its adhesive is the post-it note kind, i.e., removeable. They may also make one with stronger adhesive, since I've found that the post-it note kind, tends to peel off when the bottle is put into the refrigerator.

The main deal here though is that you can print up 9 labels on a single page, and then cut them up. There are 3 score lines across the backing so that you can peel the backing paper off once the labels are printed.

Subject: Phenolic flavours (long) part I

Hi. I was recently asked by some colleagues to write a few notes on the problems of phenolic off-flavours in beers. The following summarises my views of what I have read on the subject. I thought you might be interested. What I would like is comments and suggestions on where I might be in error, or where I should make changes to improve clarity.

It (just) exceeds the 8K limit so the end is in another message.

Many thanks in advance.

Geoff
-o-o-o-o-o-o-o-o-o-o-o-o-

TCP

TCP is a term used by amateur beermakers in the UK to refer to a particular group of off-flavours and odours reminiscent of a commercially available antiseptic. These taints, although not necessarily just trichlorophenols, are caused by phenolic compounds. Beer will, typically, contain 100-200 parts per million (ppm) of tannins ("tannin" being a term referring to a large group of polyphenolic compounds) which come predominantly from the barley, although there is some contribution from the hops. Whilst in this form the flavour threshold is quite high, when combined with chlorine their contribution to flavour is quite out of proportion to their concentration. The flavour thresholds for chlorinated phenols is around 2-3 parts per billion (ppb).

The common causes of this taint are summarised along with suggestions of how the taint might be avoided.

Water Supply

Chlorination is the almost universal method of sterilising domestic water supplies. In the distribution system, chlorine gas can be dissolved directly in the water, a hypochlorite (e.g. sodium hypochlorite) can be added to the water, or a chloramine process may be used. Whilst the first two methods perform in fundamentally the same way, chloramines, which are produced by combining chlorine with ammonia, persist many times longer than free residual chlorine. Chloramines are particularly useful on long transmission lines and where reliable penetration into stagnant areas of the distribution system is needed.

Although the level of chlorine in the water should be less than 1 ppm, it is necessary for it to be removed before using the water to make beer. To be safe, chlorine must not come in contact with the phenols naturally occurring in wort and beer so all added water must be treated wherever it is used in the beermaking process, including water used in diluting a beer to produce a beer of lower gravity.

If the supply is also contaminated with phenols then reactions

will occur resulting in unavoidable phenolic flavours. Fortunately this is rare, the World Health Organisation and European regulations specify a permissible limit of 1 ppb of phenolic substances, but water authorities endeavour to remove all of the phenols as a matter of course, so as to avoid undesirable flavours. If it does occur then beverages other than beer, e.g. tea or homemade wine, will also be affected, and the only practical solution is for the water to be passed through an active carbon filter. This method is extremely effective and reliable; it removes all the free chlorine and, if flow rates are not too great, the phenolic compounds also.

In the majority of cases, where the supply is not contaminated with phenols, other methods for the removal of chlorine may be employed.

Commercially, a common recommendation is the addition of sulphur dioxide, followed by rousing. The sulphur dioxide almost instantaneously reacts with the free chlorine and also removes any chloramines in just a few minutes. It is normal for sodium (or potassium) metabisulphite to be used at the rate of 1-2 mg per litre. The addition of one campden tablet to five gallons of water will supply in excess of ten times the required dose. It should be noted that this method affects the levels of salts in the water, which might be undesirable, but which should be allowed for in any subsequent water treatment.

It is more normal, however, for the amateur simply to boil the water to drive off the chlorine. A boil of 20 minutes is usually sufficient and this is no imposition because most water treatments prior to brewing involve boiling the water.

Sterilisers

Chlorine from sterilising agents such as domestic bleach or commercial cleansing agents, inadvertently left in fermenting bins, on cooling coils or other equipment could be responsible for the taint. All equipment, if sterilised initially with chlorine containing agents should be thoroughly rinsed, preferably with a dilute metabisulphite solution, prior to use.

Wort Bacteria

Very few breweries, especially home breweries, are free from contamination with enterobacteria which, if their growth proceeds to any great extent, can impart very noticeable odours and flavours to the beer. In particular, contamination with *Hafnia protea* (formerly *Obesumbacterium proteus*) or the coliform bacteria *Escherichia coli* and those of genus *Klebsiella* (*Aerobacter*), can be the cause of phenolic or medicinal taints. They can also be responsible for other off-flavours including a parsnip odour and the production of celery-like flavours, and can influence the development of high levels of diacetyl.

The action of these bacteria is severely inhibited during the progress of fermentation, as the pH drops and the alcohol rises, but they multiply quite rapidly during the early stages and, if allowed a sufficiently strong foothold, will leave behind significant levels of their metabolic products. The *H. protea* bacterium is also quite capable of surviving fermentation and appears to be able to influence yeast metabolism in a way that encourages a high final pH and final

gravity of the beer, and thus assists the survival of both it and other enterobacteria.

These bacteria, being present in soil and vegetation and also possibly present in very small numbers in the water supply, are readily introduced into a brewery. Once established, they can be persistent and difficult to remove, and are frequently transferred, in the pitching yeast or by contaminated equipment, onto successive brews.

Beer is at its most vulnerable between the cooling of the wort and the time that a strong and active ferment is underway, so this period must be kept to as short as possible. The normally low pH of wines means that these bacteria are usually inhibited and their presence is unlikely to cause phenolic flavours in home made wines. Also, the naturally high acidity of roasted grains means that dark beers are less susceptible to these problems and, conversely, the higher pH of lagers makes them more vulnerable.

The concluding part of the phenolic flavours article

Geoff

-o-o-o-o-o-o-o-o-o-o-o-o-

Wild Yeasts

Wild yeast can be the cause of a number of problems in beer. In addition to off-flavours the most common are surface films, turbidity and gushing.

Phenolic flavours are known to be produced by certain wild yeasts, including some strains of *Saccharomyces cerevisiae*, and *S. carlsbergensis*. Also certain strains have developed the ability to kill other sensitive yeasts and, under appropriate conditions, can begin to dominate fermentation. A number of these strains, otherwise suitable for brewing, are characterised by the unacceptable production of medicinal flavours.

It may be worth noting the, perhaps extreme, case where one of the strains of yeast used to ferment Bavarian wheat beers produces 4-vinyl guaiacol. This gives the beer its characteristic "clovelike" phenolic flavour.

Avoiding problems with wild yeasts is essentially a matter of pitching yeasts free of infection and keeping equipment clean. Continued reuse of a yeasts from previous brews can, over time, contribute to a build up of contamination.

Avoiding Phenolic Off-flavours

- 1.The quality of domestic water supplies clearly varies greatly throughout the country, and within a single district is subject to seasonal fluctuation. All added water should be boiled prior to use and in extreme cases it might be necessary to filter the water through an active carbon filter prior to this boiling. As an alternative chlorine may be removed by the addition of metabisulphite but the added salts may make this undesirable.
- 2.Any equipment that might come in contact with the wort or beer, if sterilised initially with chlorine containing agents must be thoroughly rinsed, preferably with a dilute metabisulphite solution before use.
- 3.Microbial infections should be avoided by rapidly cooling the boiled and strained wort and getting the fermentation off to a good start by the addition of a sufficient quantity of an active yeast starter. If yeasts are being re-used from previous batches, fresh cultures should be obtained at regular intervals.

Subject: Hot Tip on dry hopping!

Ok boys and girls here is the hot tip of the month...

During the Calif. Allstate Competition I judged Barley wines with Steve Harrison from Sierra Nevada. I mentioned to Steve how much better this years Celebration Ale was than last years. It was more like it used to be about 8 years ago. He said it was the same exact recipe as last year! The ONLY thing they did different was seal the fermentor after dry hopping to reduce scrubbing the aromatics out with CO2 release.

Ok, I went home and tried this technique on a batch. What I did was rack to a 5 gallon keg and place the dry hops in a nylon bag with a big brass ball in it to help sink the bag and hops. I then sealed the keg and applied a small pressure. Everyday as a passed by the kegs I gave it a sort of rocking motion. After 1 week I opened the keg and fished out the hop bag with a coat hanger that had been staightened. I resealed keg, cooled and artificially carbonated. The results are really amazing! I have dry hopped many times and NEVER had the results this technique provides. The resultant beer is like taking a hand full of hops and rubbing them in your face with ever glass. The beers head and clarity are amazing at two weeks. I did use 1 oz per 5 gallons and they were Centenials and very fresh. I will cut back on the next dry hopped batch. You keggers must give this a try.

I'm already thinking about the next batch, a Pilsener with 100% Saaz and dry hopped with Saaz.

Subject: Curious about Copper

Just a question out of idle curiosity that one of you chemists or historians out there may be able to answer.

This weekend my father-in-law cycled over for a visit and we got on the subject of brewing. He is an ex-FBI agent, and was retelling a story about an investigation of an employee of the Pabst Brewery in (Milwaukee ?) back in the late 40's. At any rate, we started talking about the machinery and processes etc (I have been known to be a gadget freak). We both started wondering about why copper is the traditional material of choice in most parts of the brewing process. We never figured it out, so I told him I'd ask the Digest.

Is copper's use a carry over from the days before stainless or is there some quality about the metal that makes it the most desirable.

Although I minored in Chemistry years ago, it wasn't/isn't my strong suite, so any answers in semi-technical/laymans terms would be appreciated and understood better. (Grammar wasn't my either favorite).

I purchased a package of 25 pre-gummed, water-based adhesive sheets of 8 1/2" X 11" paper specifically designed for making labels. They come off the bottle easily with warm water.

The package states that it is photocopier safe (although they do not guarantee compatibility with all brands of photocopiers).

I bought mine for \$3.99 from:

I just got one of these also, and did some experimentation to test for
this. I did NOT see any variation with temp. Maybe there is something
in
your water that is changing as when it heats up. Have you gone back and
forth in temp a couple of times with the same water to see if this is
repeatable? The instructions imply that the readings should be good over
a
temp range of 0 to 50 deg C (32 to 122 deg F). I see some seeming random
variations with mine of about .1 units, but I see no obvious correlation
to
temperature.

The local Brew pub that I frequent (Callahan's) uses pure O2 (at least it
comes from a green bottle). His beer comes out good. Next time I see the
brewer I will ask him what grade of O2 he uses.

That's because "diver's O2" is actually compressed *air*, not O2 at
all.
The air that goes into a SCUBA cylinder has to be dry and oil-free,
though it
is not any more "sterile" than the air it is made from. An aquarium pump
with
an in-line filter works well for this purpose.

Subject: Farewell wherever you fare

Well, since I posted two articles this morning and the automagical reply said that there are 51 articles ahead of mine in the queue, I'd better post this today as well if it is to be seen before Friday.

Friday, February 26th will be my last day here at Intergraph. I am leaving and going to work in Orlando for another company. My access to the net (and therefore email and the HBD) will cease with my leaving, at least until I buy a PC for home.

I have thoroughly enjoyed reading the HBD since 1990 when I subscribed. Access to the Digest, as well as Charlie's book (recommended overwhelmingly by the digest contributors) have made my brewing experiences most pleasant. I read for several months before I jumped in and I have yet to make a single batch that was "bad". At times in the past, as well as of late, the Digest degenerates into a forum for "one-upmanship" and the usually high signal to noise ratio goes the other way. It gets carried out to the ridiculous and none of the participants seem willing to let it drop. It eventually returns to normal, though not without casualty. Witness the formation another brewing forum because of this very thing not so long ago. If I might make a gentle suggestion, think before you post. As someone suggested long ago, if you see a post to which you are considering an inflammatory response, have a homebrew first, sleep on it, and then, if you still must respond in that manner, do it by email. The Digest is constipated now from those wanting to get the last word in on the all-grain vs extract snob issue. Email it! If you simply must post to show your rapier wit or superior knowledge, do it on rec.crafts. since that type of thing is the norm on usenet. You will dazzle many more by doing so, if that is your aim. If it is not, then email was more appropriate anyway. Think about it. My hope is that, by the time I get a connection again, things will be back to normal. In the meantime I raise a glass to you all and I look forward to when our paths cross again.

Subject: hbd1081 re: semi-beginner question

Chris,

I would never boil ANY grains. What I would do is get a grain bag and seep it in your wort until apx 180 deg F. This allows some of the flavor and the nice unfermentables to enhance you beer. Mashing allows you to convert starch to sugar for more fermentables. I always seep something when I am doing and extract batch and sometimes even when doing a full mash.

Subject: Refractometers and Hydrometers
Full-Name: "John Cotterill"

Brew Dudes and Dudettes,

I have been using a refractometer for a few months now. This past weekend

I decided to do an experiment to see how the refractometer readings match up to hydrometer readings on beer. I filled my test jar with an IPA and put my hydrometer in and it read 1.015. I took a drop of the IPA and put it on my refractometer and it read 8.2% Brix. Converting this number to points S.G., its about 1.032!! What gives here? BTW, both numbers are temperature corrected.

From: Doug Cripe <doug@crevasse.ATMOS.ColoState.EDU>
Subject: WYeast

I've got a few questions regarding the use of WYeast. I'm fairly new to the joys of homebrewing, and up till now have only pitched dry yeast. However, over the weekend I decided to hoist myself off the bottom rung of the ladder and try the recipe for an Irish Red Ale that appeared in HBD a few weeks back, which called for the WYeast. My questions are these:

1) The instructions state that a period of incubation is needed (1-3) days before pitching. Why is that? I assume that when you break the inner seal, some sort of ****cose is mixed with the yeast to wake them up from hibernation and thus this is some sort of proofing period to see if they're viable.

2) The rule of thumb is that 1 day is needed for each month beyond the manufacturing date on the foil pouch at the time of purchase. Well, the date stamped on mine was Feb 17, and I bought it on Feb 20, so I concluded that even less incubation time than a day would be necessary - was this a safe conclusion? This suspicion was confirmed by what comes next...

3) Another instruction is that the foil pouch should expand to at least an inch diameter before pitching. I broke the seal, kneaded the pouch well, and set it on top of my water heater which I guessed to be about the recommended 80F degrees for the incubation. I checked on it three hours later, and the pouch had expanded to the point that it was very taut, and I thought it would burst if I waited much longer, so I went ahead and pitched it. The instructions led me to believe that the fact of expansion was more important than the actual length of time of incubation - was that a correct interpretation?

4) My roommate brewed at the same time I did, and he used dry yeast. The next morning his carboy was bubbling merrily (as we've found to be a normal time span for dry yeast), but there wasn't even a hiccup in mine. The following morning, however, mine was also bubbling, though with a tad more melancholy than my roommate's had the morning before. The temperature in the pantry where the fermentation takes place is about 67-70F degrees. Is this slow start normal? Should I expect the total fermentation time to be longer than the usual two weeks?

Thanks in advance,

From: Lee Menegon <necis!lmenegon@transfer.stratus.com>
Subject: us vs Brit malt/ Fruit in beer

Some comments on recent posts:

US vs British Malt

According to the data provided by a grain vendors, NorthEast Brewers Supply, they list the degree of modification for grains from 1 least modified to 4

most modified. They indicate that the British grain they stock is "4" while the US Klages + Harrington, as 3. I have been led to believe that the less modified a malt the longer it takes to protein rest and mash. Taking this further, that the highly modified, British, malts often do not require a protein rest hence their single step infusion mash.

I have just brewed a cream ale using all US grains, my extraction rate was

essentially the same as the British malt I usually use. The mash time was essentially the same since I always do a 15-30 minute protein rest. The color was the palest I have ever brewed a very light yellow/ gold I could never get a beer this pale using British malt.

-Fruit in Beer

I brewed a strawberry Ale this summer. What I learned is add fruit to the

secondary, like dry hopping, or all the aromatic properties will be lost out

the air lock during active fermentation. Lightly hop the brew or the subtle

fruit flavor will be over powered. If the fruit has pectin in it add pectic

enzyme or the beer will never clear, it breaks down the pectin. Remember that

yeast metabolizes sugar, that sweet fruit juice will become alcohol and fruit

essence.

- Apple Beer? I don't know if this is a good combination, fermented apple

juice is cider, and I find cidery tasting beer unenjoyable. I have had wonderful raspberry, strawberry and cranberry beers.

Brewing books:

As a beginner I found the Miller "Complete handbook of Home Brewing" more informative than the original Papazian book. I have not looked at the new

versions. I would recommend some of the Zymurgy special issues to someone

wanting to improve their knowledge. The Hops issue has useful information

on more accurately determining the level of bitterness in a beer. The Yeast issue has information on yeast reuse which make liquid yeast less costly per batch. The Trouble shooting issue cover many floor faults.

Subject: Fermenting on trub

Hello Everyone,

A few months ago there was discussion in this digest about fermenting on the trub. There was some argument whether to rack your cooled wort off of the trub as soon as it settles or to forget about it and pitch.

Well I did a little experiment with my last 2 batches of Scotch Ale.

Batch 1: After chilling I let the trub settle for 45min and then racked the beer into a glass carboy and pitched the yeast [wyeast 1098].

Batch 2: After chilling I did not let the trub settle but I pitched right away with wyeast 1098.

Observations:

Batch 1 had a fast fermentation and cleared quickly. It was ready to keg in 2 weeks. Single stage fermentation.

Batch 2 started in about the same time as Batch 1 but the fermentation took longer and it never really cleared up. It was ready to keg in 3 weeks. Single stage fermentation.

Flavour:

Batch 1 had a nice clean taste with the usual flavours associated with a dark ale, the specialty grains seemed to really come through in the beer.

It was really good and did not last too long.

Batch 2 is not very good at all. It's flavour and smell is musty, yeasty, and somewhat astringent. I am having a hard time giving this stuff away.

Well you can say I learned my lesson and will from now on always let the trub settle and rack the beer off the trub before pitching.

From: elser@NADC.NADC.NAVY.MIL (S. Elser)
Subject: Alcohol content of Homebrew

Being a relatively novice brewer, I enjoy gathering new information from this digest. I have seen several references to alcohol content in homebrew recently.

One dealt with siphoning trub into the secondary fermentor (creating more fusel alcohols), the other I dug up touched upon the relationship between the body of the brew and the alcohol content.

My questions: When using partial mask method (following instructions from a recipe for holding grains at specific temps for specified lengths of time, then adding the resulting liquid to more water containing extract or DME)

is the temperature/time relationship the determinant factor in alcohol content of the finished beer? Some people tell me my beer seems to have higher alcohol than they're used to (this would be commercial American or Canadian brews). I have never tried to calculate the alcohol content, but I would imagine that with mashing variations, an accurate estimate might be way off. What are the rules of thumb for starch conversion vs. temperature?

I suppose the "trub" reference is a different factor in alcohol? And how does a blow-off tube affect alcohol?

Thanks!
Sheila Elser

Please substitute "mash" for "mask" in second paragraph.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: oxidation in the bottle

I've been wondering about beer oxidising when in the bottle, due to excessive splashing in the syphoning/bottling process. Given that yeast are present in the bottle also (or else bottle conditioning wouldn't happen) why don't they simply use any introduced oxygen to multiply before fermenting the priming sugar?

A reasonable answer would be that oxidation takes place more quickly than the yeast can remove the oxygen, but does anyone know the real answer?

Peter

From: KLIGERMAN@herlvx.rtpnc.epa.gov

Subject: yeast mutation

Jacob Galley posted a question dealing with yeast mutation. Alcohol when metabolized can produce acetaldehyde which is mutagenic, but my guess is that since there are always spontaneous mutations occurring, if you use one yeast batch for too long a time, you wind up selecting strains that will out compete your original strains as the environment (wort) changes.

Subject: Re: labels for laser printer

I used to use adhesive labels, and you're right, they're hell to get off. I've read on the digest here that plain paper, dipped in milk (that's right!) will hold labels on well, once dry. When re-wetted, they supposedly slip right off. I haven't tried it, as I've just plain given up labelling (too paranoid, lazy, and ill-informed, you know ;-).

Subject: Saving Yeast

Hallo thar homebrewers!

My brewing partner and I recently started using liquid yeast and are quite pleased with the results - the cost, however, is making us wonder about whether or not we should buy a new packet every time when a strain could be reused...I guess our question is this: How have the experiences of other digesters been regarding saving the sludge? Do you seal it up with some malt extract? Do you put it into a container that would allow stoppering/airlocking? Just curious..

.
we saw a couple of possible containers the other day, but I thought I'd beter write first...How about "Grolsch-type" bottles?

Thanks in advance for any input

>bucket.

I'd like to advise against this last suggestion, especially if you used a
different liquid yeast for the primary fermentation. If the yeast you
add at bottling is more attenuative than the fermentation yeast you could
get exploding bottles. Also, if you are using dry yeast in the primary
ferment and are bottling with the same yeast, I strongly suggest
rehydrating
the yeast in both cases. In a sort of newsletter from Lallemand (the
yeast manufacturer), they say that dry yeast rehydrated in wort (as
opposed
to rehydrating in 104-115F sterile water) is more likely to produce
off-flavors. I've found that the lag time was quite a bit longer when
I didn't rehydrate in water in recent tests with Coopers and Lallemand
yeasts.

On a related note, I have written in the past warning about the use of
the yeast that comes with Munton & Fison Kits (it use to be called
Muntona, but now I think it just says "yeast"). I said that it gave
very, very high levels of phenolic/clove aromas and flavors and that
I suggested it not be used. I'd like to point out that I had not
rehydrated this yeast in water (since it was not mentioned by M&F in the
instructions). Perhaps if the yeast is rehydrated in water, it may be
more
acceptable in terms of the phenolic/clove flavors? Note that this still
does not address the issue of bacterial infection of the dry yeast
which was a problem years ago with the Muntona yeast (eventually the
beers would become gushers... when I switched to Wyeast, I could keep
the beers for years without them becoming gushers, so it was NOT my
sanitation methods).

From: rcd@raven.eklektix.com (Dick Dunn)
Subject: extract barleywine

A while back, amidst all the extract/all-grain ego-excreta, there was a comment about "tang" of extract brews with a lot of malt. The recent "found beer" note (I like it!) reminded me of an extract barleywine we've had for some years, with a fair stash turning up recently (in bottle). It was strong enough to start (1.095 OG) that we'd have been able to pick up any off-flavors or especially any tang, but nobody who's tasted it has had any complaint...either when it was young, or now, several years later. (In its youth, we did some comparisons against Old Foghorn. It came out in a dead heat. I loved it, and spent some considerable effort comparing the two:-)

There was also a suggestion somewhere along the way that dry malt might be better than canned. This old barleywine was made with M&F spraymalt, so FWIW there's a possible datapoint in favor of dry. Anyone else made any comparisons, or even have any good/bad single datapoints? Most of my brewing isn't beer these days, but barleywine is the one exception I'd make, so if I brew extract I'd like to aim carefully.

I'm also intrigued by the processes. I think I'd heard that the dried malt was essentially "sprayed" and evaporated by dry air and low pressure, as opposed to boiling off water. If so, this would make a good case for why dry malt would survive processing better than canned (less heat). True?

UPSTATE NEW YORK HOMEBREWERS ASSOCIATION

15th Annual Contest & 4th Empire State Open
Saturday, April 24, 1993

at
McGinnity's Restaurant and Party House
534 West Ridge Road, Rochester, New York

Donation \$5
Doors open at 6:00 p.m.

Public judging starts at 7:00 p.m.

COME AND JOIN THE FUN AT NEW YORK STATE'S OLDEST HOMEBREW CONTEST!

*** FREE SAMPLES OF HOMEBREW ***

--

THERE WILL BE 11 CATEGORIES:

- 1) British Ale
- 2) North American Ale
- 3) Brown Ale
- 4) Belgian Ale
- 5) Light Lager
- 6) Amber Lager
- 7) Dark Lager
- 8) Looks Like SARANAC
- 9) Porter
- 10) Stout
- 11) Specialty

No entries will be accepted after April 14 (see details below).
Beers can be entered at shops in: Buffalo, Rochester, Syracuse, and Ithaca,
or they can be shipped.

CONTEST SANCTIONED BY THE AMERICAN HOMEBREWERS ASSOCIATION

--

CONTEST PRIZES:

- BEST OF SHOW: A complete home kegging system
- 1st Runner Up: \$50 gift certificate for homebrew supplies
- 2nd Runner Up: \$25 gift certificate for homebrew supplies
- Prizes in each category: malt extract or other homebrewing supplies
- Prizes in Looks Like SARANAC: items awarded by F.X. Matt Brewery

>qts of 172F water, stirred, and the temperature settled at exactly
>155F, the desired temperature for this batch. I closed the lid, and

How well did you stir? How long before you checked
the temp? Personally I add the water first. The
cooler will suck up a fair bit of temp. With my
larger cooler I count on losing close to 10F to the
cooler itself. I also stir quite a bit during mashin
to make sure no hot spots develop. I also tend to
wait 1min at least before mashing in. I'm sure hot
spots mean cold spots.

>let it sit for an hour. At this time, I sampled a bit of liquid from
>the surface and performed the iodine test for starch conversion.

>(incomplete conversion) results.

Did you do any stirring during the mash? I usually
stir a little bit every 15-20mins. Also I think most
people will tell you that iodine results aren't
perfect.

> At this point, the temperature had dropped to about 152F, so I

I don't lose this much temp during 1-2hours usually.
I wonder if the temps weren't evened out during
mashin.

>Now, the questions:

>1) How is it possible to have different conversion rates in different
> portions of the mash?

I think that if you didn't stir at all it could. I
personally don't do an iodine test. I just mash for
a certain time. 1.5hours pale beers 2hours for
stouts/porters. If you are worried I'd guess pulling
off a sample and testing it's gravity would be
better than an iodine test.

> can be quite interesting, and I've even written a few myself.
>
> I'm not convinced, however, that the Homebrew Digest is the right place
> for such articles.

Since I'm the author of the most recent of these brewery reviews, I
have
to disagree. From the heading of this most useful forum:

"FORUM ON BEER, HOMEBREWING, AND RELATED ISSUES"

I think that brewery tour reports certainly belong. Mine was long so
I
broke it into three parts. It probably doesn't matter much to those who
now
take for granted accessible microbreweries and their products but we,
here in
Alabama, have had no such luxury until the opening of the micro in
Birmingham.
Some of the most enjoyable and informative articles in this forum have
been
about brewery tours. They give clues to those wishing to approximate a
favorite beer on the brewing process and ingredients used in that beer as
well
as interesting insight on the microbrewing industry which most of us
support
whenever possible.

Far more damaging and digest-clogging are the continued ramblings on
such
banal subjects as the "all-grain snobbery" thread that is *still*
continuing
and is even treated in some length at the end of this article containing
a
"modest proposal" to shorten the digest. We hear about which groups are
"snobs"
(are not! are too!) and why and then we are treated to lengthy articles
from
people in each group explaining why they, at least, do not fit this
description
("I have *friends* who are all-grain/extract brewers - I can't be a snob!
").

> In Usenet, there is a distinct difference between alt.beer and rec.
> crafts.brewing. People who post questions (usually beginner's) about
> how to make beer on alt.beer, quickly get shuffled off to rcb. Why

> do we not have a similar division here -- and soon?

How about let's just drop all the namecalling and criticizing articles?
I'll bet that those have taken up far more space than any brewery tour articles combined. Also, there *is* another brewing list which is always short. I get both but guess which one I've found most useful thus far, warts and all.

From: Robert Pulliam <pulliam@monty.rand.org>
Subject: Yeast and Malt

Greetings Brewmiesters,

Just a couple of quick questions for the collective wisdom of the HBD crowd.

1. I have just put a small amount of wyeast European Ale #1338 in a sterile Fisher bottle with some lightly hopped weak wort (around SG 1020) and attached an air lock. I would like to keep this as a starter base in my refridgerator. When do I place it in the fridge, and when, with what and how often do I feed it?
2. Is it possible to make our own specialty malts (i.e. roasted, chocolate, black patent, etc.) from a regular 2 row? How about crystals etc.? This would certainly help cut down the costs.

Any and all help would be greatly appreciated.

Robert Pulliam

>and using all dry malt extract and hop pellets for the first time.
>
>the recipe was:
>
>4lb stout syrup (w/hop and roast barley extracts) i have heard that
>this does not ferment effciently

The efficiency of the fermentation is dependent on a lot of things, one of them being the amount of yeast nutrients in the wort, another being the amount of glucose/fructose/sucrose in the wort (recall Bob Jones' et al. reports of high FGs with sucrose starters). A lot depends on the quality of the extract you use (see later in this post).

>3lb dry malt extract
>1/2lb dark roast barley (steeped)
>and most recently the addition of 1/2lb flaked barley. first i steeped
>at end of boil with dark roast, then on next batch boiled 10 min and strained
>milky soup into wort.

I suggest that you steep all the specialty grains before the boil (as the water is coming up to 170F -- pull them out at 170F) since you would like to coagulate any of the large proteins that you may have introduced from the grains -- which will take the whole 60 min boil.

>what is the proper amount of dme to use. 6lb? dark dme is all i have
>ever used. i was told that i could use 7lb light malt extract and 2 lb
>"black patent." is that unmalted stuff to steep like i do the dark
roast?

2 lbs is quite a bit of black patent for a 5 gallon batch. I used 1/2 lb roasted barley and 1/2 lb black patent in a recently tasted batch with two cans (6.6#) of John Bull Dark syrup and it fermented out just fine with Wyeast #1084. I'd say a pound of black patent should be enough if you are using light malt extract.

>what kind of hop pellets, and what kind of boil times will i want for
>my new, unknown recipe? i don't know what flavor hops are good for
>which brews, but i am sure there is the obvious hop and procedure for
>the stout/porter i am trying to brew.

I used 3 ounces of Clusters for the boil and a half-ounce of Cascades in the fermenter (after the kraeusen fell), but I would recommend adding another 1 ounce of Fuggles or Goldings for the last 15 minutes of the boil (for flavor).

>can i grow decent hops in mid ohio?

Sure. Give them plenty of sun, plenty of string to climb (15-20 feet!) and lots of water (6-7 gallons per plant, per day).

Karl writes:

>My first batch with chocolate malt matured yesterday, so I had some friends
>over and generally it's a yummy beer. However, I still have that slight,
>annoying cidery taste. I did add about 150g of sugar beet molasses besides
>the malt extract and coarsely ground chocolate malt. Is it perhaps too
>refined of a sugar and adds mostly alcohol and not much flavor? Other
>suggestions?

It's not the level of the refinement, it's the type of sugar. Too much sucrose (cane or beet sugar), dextrose, glucose or fructose will give you cidery flavors. It may not be all your fault -- it could be the fault of your extract (see below).

Dan `Stout' Wiesen writes:

>how about providing extract brewers with information and
>characteristics of malt extract?

Pick up the Zymurgy special issue on Extract Brewing. It has a listing of virtually every extract brand that was available at the time (1986?). One popular extract that was not available at the time is Northwestern. I've spoken to the manufacturer and it is made from 100% barley malt (except the Bavarian Weizen which is 65% wheat malt 35% barley malt) and contains no other sugars, flavors or colorings. The hopped extracts contain the equivalent of 10 IBU of pre-isomerized hop extract (from unlisted hop varieties, alas) for a 5 gallon batch in one 3.3 lb box. (Therefore two 3.3# boxes in a 5 gallon batch will give you 20 IBU).

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)
Subject: Call a spade a spade

What with the over-abundance of interesting and informative braying about extract vs all-grain brewing, I have taken the liberty of compiling a list which, I feel, best summarizes the characteristics of the two types of brewers:

Extract: Scum of the earth, lazy, ignorant, obtuse, oppressed, white bread with no crust, born-out-of-wedlock complainers.

All-grain: Scum of the earth, pompous, swaggering, self-righteous, ill-tempered, intolerant, vain, incestuous braggarts.

Naturally I've left out the more colorful descriptors so as not to offend the under-aged (or humor-impaired).

So it seems that no matter which brewing technique you employ, you fall into one of the two categories. Now I don't know about the rest of you, but this is one scum-of-the-earth who would like to put this topic to bed. And if we don't do it toot sweet, I'll be forced to post about other beer-related topics even more vulgar than farting. And let me tell you, there are a few.

You have been warned.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>
Subject: Sugared Extracts

A discussion of the adulteration of malt extracts with corn sugars has been going on over in the newsgroup rec.food.drink, and Paul Chisholm of Bell Labs asked me to let HBD in on the secret. I started the whole fracas by making a cryptic reference to recent research that cast the purity of extracts in doubt, and Doug DeMers of Amdahl immediately asked for sources, and more information. So the following day I posted this:

The flap all began in Zymurgy, Vol. 13 #5, Winter 1990. On page 15, in Dan Fink's "Brew News" column, was an item describing a report presented by Professor Michael Ingledew of the University of Saskatchewan to the 1990 meeting of the American Society of Brewing Chemists, on research he and his colleagues were doing on the composition of malt extracts. This research, a combination of High Performance Liquid Chromatography and fermentation studies, disclosed the substantial unlabeled presence of glucose syrup, invert syrup/liquid sucrose, and high fructose corn syrup in the extracts tested. They also discovered poor fermentation from some extracts, due to a deficiency in the free amino nitrogen content normally provided by barley malt (had any stuck fermentations lately?). In the presentation, they did not identify the extracts tested.

I don't have to tell you what a storm that raised! The AHA followed up on it, and in Dan Fink's column (page 14) in the Summer 1991 issue of Zymurgy (Vol. 14 #2) they published a letter from Professor Ingledew in which he said that they indeed were NOT planning to release the names of the extracts tested. They felt they couldn't be sure whether the adulteration was done by the manufacturers, or by the distributors. They also felt their sample might not be representative, as they had only tested 44 "lager" extracts, and no "ale" extracts (their terms). They didn't feel they had the time or money to handle either additional testing or possible legal action. They also felt that the burden of following up on the problem they'd identified rested with the brewing industry, through the marketplace. Then Professor Ingledew closed with this paragraph:

In spite of my comments above, I have complete

confidence in the results obtained in my lab by my colleagues. There is no doubt that some manufacturers are profiting from the addition of lower cost corn sugars to malt extract.

Well! Where does that leave us? Neither of the articles made it clear what percentage of the extracts tested had been "juiced", or to what degree. And, of course, we have no idea what they were testing.

I hope you're not too terribly depressed.

>Brew Dudes and Dudettes,

>I have been using a refractometer for a few months now. This past weekend

>I decided to do an experiment to see how the refractometer readings match

>up to hydrometer readings on beer. I filled my test jar with an IPA and
>put my hydrometer in and it read 1.015. I took a drop of the IPA and
put

>it on my refractometer and it read 8.2% Brix. Converting this number to
>points S.G., its about 1.032!! What gives here? BTW, both numbers are
>temperature corrected.

Sounds ok:

I did a simple experiment once with a bit of unfermented wort,
adding (96%) alcohol volumes to see the effect on measured
density:

F.G.= density of wort without the alcohol.

Numbers in the table are the measured values (with a hydrometer)
after adding the percentage of alcohol given in the columns
(All values +/- my accuracy; your mileage had better vary....)

%AbV->
F.G. |12468

1020 | 1019 1018 1014 1011 1009
1030 | 1029 1028 1025 1021 1017
1040 | 1038 1036 1032 1029 1026

So, I would guess that your beer, with 32 gravity points of
sugars, contains a little over 8% alcohol by volume,
which produces a 1015 hydrometer reading....

Subject: Laser Labels Adhesive/tale of "33"

Last HBD someone asked how to apply the labels they make on the laser printer.
Stolen directly from an old HBD-- MILK!!!! I have used this technique. I used skim milk, dipped the label in and smoothed out the bubbles. It held extremely well. Non-toxic too!
On another note, the story I heard regarding the 33 on the Rolling Rock label, which by the way is not stuck on with milk :) When the designs for the RR labels were submitted, they were numbered. The one chosen was (you guessed it) #33. As the tale goes, when it went into production someone neglected to take the 33 off and it has been on the label ever since.

>From: lawson@acuson.com (Drew Lawson)

>I would like to point out that there is a great difference between CompuServe and the Digest. That is that most CIS users do not read all the message threads.... Also, of course, the Digest has developed ARF antibodies and will likely react to even borderline messages if they are from you.

Good points, both. But perhaps the former is a symptom of the latter.

Just a point of reference, I have lost interest in CIS for exactly that reason. It would cost a fortune to read all the articles and there is no way to sort out what is worth reading. People have no qualms about posting messages such as "Good idea, Bob." and the board is loaded with them, probably even the majority. Even a thread with one's own name in the subject can lead to endless drivel but you keep reading it so as not to miss anything that might be appropriate. I think the dicipline forced on people by knowing that everyone has to at least download what one writes is a tremendous house cleaner.

Subject: Beer Crawls

Re: Jeff Frane on Beer Crawls

I have posted an article in response to many postings several times over the past two weeks and it has yet to get into the digest. I try to minimize bandwidth by combing many responses into a single posting. Obviously, the Digest software is sorting out long messages and "clensing" them. In order to fool the system, I have broken it down into many short ones and eliminated the ones that no longer have relevance.

Whether people agree with what I say or not, I suggest that responses to current discussions are more relevant and in line with the objectives of this forum than long feature articles on commercial beer and establishments. I won't go so far as to say they do not belong here but perhaps they could be saved till the Digest gets the "slows" again.

>From: hopduvel!john@linac.fnal.gov (John Isenhour)
>Subject: galvanized hardware cloth ok for sparging?

>I've been wanting to build a mash/sparge cooler with a mesh filter as the rigid manifold arrangement sits a little too high off the bottom of my cooler. I havent been able to locate brass or stainless mesh locally but I found some 1/8" galvanized hardware cloth. I haven't heard of anyone using this - is there a problem?

I used galvanized hardware cloth on the original EASYMASHER (tm) for several dozen batches and soo no problem with it. Zinc is a common mineral supplement in vitimin pills so I see no reason not to use it. Not sure why you want to use 1/8" mesh. I use 30 mesh (30 wires/inch) in the EM and it works very well. The original used widow screen, whatever that is and it also worked well.

The only source I have found for SS screen is McMaster Carr but I have to buy about \$50 worth. Not too practical if you are only making one.

> Also, what is a reasonable minimum length of mesh if its rolled into a tube?

Don't quite understand what you are doing but the tube in the EM is 6 inches long and 3/8" in diameter. It is pinched off at one end and slips over 3/8" copper tubing on the other. The tubing is bent so the screen rests on the bottom. This handles the entire task of the false bottom, slotted tube and other such devices.

From: Jim Grady <jimg@hpwarga.wal.hp.com>
Subject: Gluten in beer

I believe that this was discussed before, or at least something similar, but I do not know how it was resolved.

We will be having company over for dinner in a couple weeks and one of the people coming cannot have any gluten in his diet. The question naturally is, would homebrew be a problem?

The discussion earlier was along the lines of how much wheat is in the beer but "The Cook's Companion" says that barley has some gluten too (albeit, not as much as wheat). Furthermore, it says that gluten is a protein. This makes me ask a couple questions:

1. Is it some of the protein that settles out in the hot or cold break?
2. Is it one of the proteins responsible for aiding head retention (if indeed proteins are responsible)? After all, wheat is high in gluten and wheat malt is often recommended to aid head retention.
3. Is it a protein that is broken down in the protein rest or in the malting process?

e-mail or posting is fine. I will summarize any e-mail responses I get.

Thanks for your help.

calibrated with
>;the 7 and 4 solutions minutes before....and soaked in a conditioning
solution
>;for 30 mins as recomended.... does any one have the temp diffs for pH?

>pH, much like specific gravity, is dependent on temperature. I would
think
>there would be a temperature correction table that came with your meter.

The Hanna does not come with a calibration table, however you can get a
accurate reading by measuring the wort pH at the SAME temperature as the
electrode was calibrated. You must calibrate fairly often (at least
each
day), so if you calibrate at 60F and cool wort to 60F you should be ok.
Even
if you are off by 0.5 unit you are still far more accurate than pH papers
INMH(color blind)O. I love mine.

The operational definition of pH is: $pH = pH(s) + E/k$. Where $pH(s)$ is the pH
of a
known standard, E is the emf of the cell, $k = 2.302RT/F$ where R is the gas
constant, **T is temperature** and F is the value of the Faraday. As you
can
see, since temperature is a variable, the measure of pH is definitely
temperature dependant. From Handbook of Chem/Phys.

[end of chemistry digression]

On the hydrometer topic, Irecently discovered (when brewing with a
friend who
uses his religiously) that mine is horribly and uselessly inaccurate, so
I have
gone back to not using the thing. The old OG estimates of STRONG, NORMAL
and
WEAK always worked for me before, but occasionally I'd like to check my
efficiency. Thermometers can be very different from one to another and
so can
hydrometers. Short of purchasing a refractometer are there any mail
order
shops that sell a reasonably priced (\$15-20 ...??) CALIBRATED hydrometer?

Thanks, DanMcC

Jeff J. Miller writes:

> I located some 3/4" round labels that are designed for use on
> a laser printer; unfortunately they seemed EXTREMELY expensive
> at \$15 a box but I don't recall how many labels were in a box.

Well, let's see. If they're packed tightly on the page, you've got maybe 150 on a page. If the box has 50 pages, then there would be 7500 of them in the box. So they're .2 cents each. Not really expensive, except up front. Even if there were only 10 pages, they'd still be 1c each. That's less than you pay for bottle caps.

From: Timothy J. Dalton <dalton@mtl.mit.edu>
Subject: pH Meter Temperature Compensation

To answer some ongoing problems with pH meters and temperature dependence:

pH measurements ARE temperature dependent.
Some pH meters come with built in temperature compensation (a separate temp. probe is used in this case) and some pH meters allow for manual compensation.

With pH meters, we use the Nernst Equation

$$E = E_x + 2.3 \cdot R \cdot T_k / n \cdot F \cdot \log(a_i)$$

Plugging in all the constants,

$$\text{we get } E = E_x - 1.98 \cdot T_k \cdot \text{pH}$$

E_x is a constant depending on your reference electrode and E is the potential measured by the pH electrode.

As you can see, a change in T_k (Temperature, in Kelvin) will change the slope of your E/pH curve.

Important notes, pH will always read 7.0 at 0 mV output (Temp. compensation is not important near pH 7)

At pH 3 or 11, a temp difference of 15C leads to a pH difference of 0.2

pH error can be approximated as 0.03 pH error/pH unit/10C

Subject: Chill haze help, copper

When I chill my lagers I get a chill haze, and with this at the back of my mind I read George Fix's Brewing Science book and he wrote of phenol-protein interactions that cause chill haze. There seemed to be 3 solutions 1) remove proteins with Irish moss or gelatin, 2) remove the tannins with polyclar, or 3) lager for 5-7 week at 0C. I would love to use the latter method, but until I get a chest freezer it is impractical. Other things that help are sparging less, and boiling for the right time.

My question is how do people use polyclar? I don't really want to, but it seems like a better option than gelatin or Irish moss that may remove head proteins. Should I add it to the beer when I rack to lager and lager with it there, or would it be sufficient to add it when I chill the wort, let that sit at 0C till fairly clear and then rack onto the yeast. Is this last idea ridiculous?

Re. Copper about which Mark Elliot asks. The reason are mainly traditional. Copper is a metal that has been known forever nearly. At beer making pH's it doesn't corrode, and the main advantage is that it has the second highest heat transfer coefficient of all metals. This was more important when fire brewing was the only heating method. Since this method is still used by us homebrewers, I would like nothing better than a big copper jam pot. But I have not seen any for sale.

Subject: Hops in Ohio

Garland Burton asks if you can grow decent hops in Ohio.

Answer: YES!

You can definitely grow decent hops in Ohio.

I've been growing them for a couple of years in Cincinnati, and I have a friend in Dayton who has been growing them for over 5 years.

Very successfully, I might add!

Cascades do best in this area, but try Hallertauer as well (Hersbrucker)

.

Order the rhizomes from a good source like Freshops in Oregon, and plant them as soon as the danger of frost is over.

You won't have any way of knowing exactly what the alpha acid percentage is, but you can guess, based on the average for the variety. You can also do what I do, which is ignore the issue and just use them for dry hopping. Works great!

Lots of sun seems to be the most critical factor.

From: cook@uars.DNET.NASA.GOV (Chris Cook)
Subject: Decoction Mash Questions

In HBD 1083, while talking about starch conversion during infusion mashing,
Drew asked (about drawing off some of the mash for reheating):

> 3) The method used above to reheat the mash seems similar to decoction
> mashing. With regards to decoction mashing:
> a) is it usual to drain and boil just liquid, or liquid and grain?
> b) doesn't this process denature the enzymes needed for conversion?
> c) is there some formula for how much of the liquid or liquid and
> grain to reboil to make a desired temperature change?

Good questions. Like Drew, I'm looking to use some simple use of a
decoction
in infusion mashing, either to raise the temperature of the infusion, for
a
rudimentary step mash or for a mash-out. Plus, I'd like to try full
decoction mashing, just to see for myself.

A few weeks ago I asked what Noonan meant in his reference to removing
"...the thickest third..." of the mash. There were several answers
posted,
but they reinforced my impression that people were interpreting Noonan's
directions in different ways.

One person said that the thickest part was at the bottom of the mash-tun
after letting the grains settle. Another said that 'thickest part'
description was misleading, referring to a decoction consisting mostly of
grains. He recommended that the mash be gently stirred before scooping
off
the decoction.

Logically, I can believe that the mash will settle into heavier and
lighter
layers, but we're talking about pretty uniformly-sized grains. Is it
important to scoop from the bottom, or is it more that we should avoid
using
the top layer. Do the husks migrate to the surface or some such?

How much liquid should be drawn off with the decoction? I got three
general
answers in the Digest:

- 1) With a small pot, scoop up a bunch of grain and pour off the liquid
until the grains are barely covered, something like a stew.
- 2) With a small pot, scoop a bunch of grain against the side wall of
the
mash-tun and slide the pot up the wall, letting most of the liquid
drain back. It wasn't clear how much liquid should remain in the pot,
but the writer implied that only a little liquid should be in the
decoction.
- 3) Scoop the decoction with a sieve or colander. I assume this leaves
almost no liquid in the decoction. Barley stir-fry?

Several people emphasized the problems with grain sticking in the pot
while
heating the decoction. I don't know whether the drier decoctions were
significantly worse, but it seems they should be.

Book references and logic are only good to a point. Anybody have
experience
using a decoction to heat up a cool infusion mash, for a simple step
mash,
or for a mash-out? How large are the decoctions, how much liquid should
be
left in the decoction, and how bad is the sticking?

Subject: Answers about bottle labels

I got lots of mail in response to my question about making bottle labels on a laser printer, so I thought I'd summarize them for others. I guess longer-time readers of HBD or r.c.b. will have seen these already...

Lots of people suggested printing on regular paper and then sticking it to the bottle by wetting it with milk (yes, milk). All said it sticks perfectly well as long as the bottle stays dry, and comes off easily with a soak.

As far as glues, I got the following suggestions:

1 part white glue (like Elmers) to 2 parts water. Water soak to remove.

Glue sticks for kids, which are soluble in water.

Dennison "Tack a Note" glue stick, with sticking power of a post-it note.

Rubber cement. Remove label (and cement) by peeling it off.

As far as self-adhesive (mailing) labels, most are VERY difficult to remove, but Don Howard wrote that Z-LABEL brand laser printer labels come off easily after a short soak, and cost about 2 cents each.

Subject: Cat's Meow Evaluation

The Cat's Meow (for those who don't know) is a compilation of recipes posted on the Internet and in HBD. It is available via anonymous ftp from sierra.stanford.edu in /pub/homebrew/recipes.

I have already posted this to the internet, but realized that I forgot to post to home brew digest. So please excuse the duplicate posting.

Looking through the Cat's Meow recipe book, there seems to be no indication of whether the recipe has been tried by others and found to be reasonable and/or whether it gives the same results.

I have been talking with Mark Stevens (one of the compilers of the recipe book) and we agreed that a survey of this kind would be most useful.

Therefore I am asking you all to reply to me (jwsb@netcom.com) with details as follows:

- . chapter containing recipe (beer style)
- . name of recipe
- . number of times brewed
- . changes to any ingredients (if any)
- . changes to the procedure (if any)
- . SG/OG
- . overall quality of the beer
- . if problems were experienced what you think the reasons for the problems were
- . would you brew it again?
- . if you would what would you change.

Please send only recipes which you did not significantly change.

To the originators of the recipe - if you have repeated the recipe since feel free to send me your comments as well.

Results will be forthcoming. I will probably not post them since this might cause ruffled feathers, but will mail to anyone requesting them.

Thank you in advance for all your time.

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>
Subject: pH

Just a quick point. It is perfectly normal for pH to vary with temperature. Thus, your pH meter should give a different reading for hot and cold solutions. Good laboratory pH meters have a temperature adjustment, and the really nice ones automatically compensate for temperature. If you want to you can find how to correct pH meter readings for the temp. effect, but it is probably easier to just adjust your sample to the right temp. before making the reading.

Subject: Re: fermenter geometry

"Date: Mon, 22 Feb 93 07:49:20 PST
From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: Fermenter geometry

"During my discussion with Pierre Celis, the subject of fermenter geometry came up. He mentioned that the head or foam cap in a shallow open fermenter was much more dense and stable than one in a closed smaller fermenter. He said he don't understand it either. I know when I visit Anchor and see their fermentations at high krausen I am only getting a snap shot of the fermentation. Say Russ, when you've walked by that room several nites in a row, have you EVER seen that foam fall? I don't know how any of this would apply to us, it is just an interesting observation and may explain how open fermentation can be safe in some cases."

My intuition is that there is a connection between the fermentation and the surface-to-volume ratio. In the book On Aggression (author's name escapes me, alas) it discusses the difficulty of maintaining enough oxygen in the aquariums (this was before World War II, no pumps, little electricity) and notes that, even with the inclusion of a large portion of the closed ecology of proximate ponds into the tanks, including moving creatures which stirred up the water ... a very large surface-to-volume ratio was a prerequisite. (The author was researching the aggressive instincts of cichlids ...)

Others have noted that readings for mash efficiency, as well as temperature, vary from top to bottom in mash geometries which emphasize height. This is optimal for conservation of heat, but not so for circulation of mash solution, such that this too bears some additional examination.

Summary : I'd guess there is a lot of garnered experience which has guided some isolated brewers down this path, and that this bears further examination in both the mash and the fermentation sequences.

I haven't done a mash yet myself (ObDisc: I have used grains as adjuncts), but when I do, I expect I'll stir things to keep a temperature gradient from forming and to evenly expose everything to walls and atmosphere. I don't do

open fermentation and, lacking a controlled environment, I'd hesitate to,
as
this would also provide a larger target for drifting spores and bacteria

Subject: Proposed North Bay Bike Ride & Pub Crawl

I just purchased a lovely new mountain bicycle, and have been riding all over San Francisco, having a blast. It didn't take me long to conceive of other possibilities ... such as taking the ferry boat to Angel Island, in the middle of San Francisco Bay ... or beyond, to Larkspur or San Rafael.

I mentioned this to a few bicycle-riding beer buddies, and they told me of a brewery that's apparently just a stone's throw from the San Rafael ferry landing. This is apparently a well-known ride amongst many locals. I don't know its name but I'm sure many others do. (-:

So, I'm proposing a Bay Area HBD Ride, from San Francisco - probably the south end of the Golden Gate Bridge - across the Bridge, through Sausalito, along the edge of the Bay, northwards to San Rafael, using existing bike trails already established, stopping at pre-established points for those wishing to join en route.

Once at the brewery, we disassemble for excellent (I've been told) food and beer, departing as convenient to ride back to our vehicles along the route, if appropriate, or taking the ferry back to San Francisco, and then riding back from whence we came within San Francisco. (Those doubting that this might be possible might prefer to park along the Embarcadero and ride their bikes to the Golden Gate Bridge in the morning, so that their cars are only a few blocks away when they get off the ferry.) Naturally, some people might prefer to remain together all the way back to the Toronado .
..
or we could even meet there in the first place, instead of the Bridge.

Naturally, mountain bikes (18 speed or above) are recommended, as this is not a short ride (although every effort has been made to plan it so that it is not necessary to ride uphill and that the majority of the trip will be downhill or level bayshore), but I leave the final decision to the discretion of the individuals, and promise to assist anyone who has problems en route, as the person responsible for this proposal.

I think this would be a great opportunity to match names with faces, and get a few of the lurkers to emerge into the light and let us introduce ourselves and sweep them into the mileau. As well as establish that one can be physically competent while drinking copiously, and still brewing.

Proposed date : Sunday, 07 March 1993.

What say ye ? Email me at pascal@netcom.com, please.

Subject: Yeast Starter Temperature

I have 3 Lagers fermenting now, 2 at 42 degrees F and 1 at 48F. All of these are fermenting (what I would consider) rather slowly. All 3 batches started at 1.052 and after a month in the Primary are between 1.032 and 1.040. Fermentation does not appear stuck as they all have a good krausen still and are generating a fair amount of co2 (1 bubble every 10-15 seconds).

I'm using 2035, 2308 and 2007, 2 cultured from my slants and one straight out of the Wyeast pack. My question is: these yeasts were built up to pitching volume (about 2/3 quart of slurry) in 2 steps, the first in 1/2 pint of wort and then into 1.5 quarts, over 5 days. The starters were fermented on top of the fridge and with the heat from the back of the fridge I would guess it was about 80-85F. The starters were chilled to match the wort at pitching time and all started to ferment actively within 15 hours.

Is there a correlation between yeast performance and starter fermentation temperature with S.uvarum? I'm concerned that I've promoted mutated cell growth, generating an active starter that performs well only at warmer temperatures.

Gravity has slowly declined over the last month, the beer tastes fine so I suspect patience will be the solution to my problem. Any other comments or suggestions?.....

>Subject: George Fix's Address
> I'm trying to send mail to George Fix, and his address as it shows-up in the digest is not sufficiently complete to accomplish this (gjfix@utamam).....

Sure glad someone else is having this problem. Virtually all my mail bounces to George but it seems to get through often enough to prove that it is a good address. The last two letters I have sent about 10 times and specifically asked him to acknowledge receipt. It is particularly frustrating because it contains an apology to his wife which I hereby extend to anyone else who may have been offended by my use of an old boy's term referring to things that happen to men in the night.

This is the way the bounce appears in my mail and I get the response within seconds so it is not happening at his location.....

Subject: Re: galvanized screen & Zinc

I would caution against giving an unqualified 'yes' to using galvanized screen in the mash. I seem to recall that Zinc can be highly toxic in too high a concentration, though it is a 'vitamin' at lower concentrations.

If I am remembering wrongly, someone please correct me, but I do believe that as far as Zinc goes, there can be 'too much of a good thing'.

This aint necessarily so. I use about 3.5 gal of mash water to 12 lbs
of
grain and when it settles down after mashing, I end up with one inch of
liquid above the grain. This level is maintained through the entire
sparge
so the ratio of grain to liquid does not change till I turn off the
sparge
water source at the end.

>A thought: If unconverted starch, originating from dry sections of malt, might be released during the sparge; would it not be prudent to forgo the mash-out so that the enzymes, which are also in suspension (I assume), can do their bit on the newly released starch?

Two problems here... As most people claim to be sparging at 170F, the enzymes would be deactivated by the heat. Of course some of us realize that the real temp in the grain is closer to mash temp so you are probably right. Therefore, what you are effectively doing is increasing the mash time without increasing the time it takes to mash. Not a bad idea, probably.

The real problem with forgoing the mash out is that the real temp in the grain bed drops even lower and could create all sorts of other problems.

>On a related note, I have written in the past warning about the use of the yeast that comes with Munton & Fison Kits (it use to be called Muntona, but now I think it just says "yeast"). I said that it gave very, very high levels of phenolic/clove aromas and flavors and that I suggested it not be used.

This sounds dangerously reminiscent of my experiences with Red Star and all its repackaged clones. When I thought I was trying different yeasts, I later learned that it was all repackaged Red Star.

Do you know who makes the yeast? I personally, would never use a yeast that did not identify the actual lab that makes it.

I suspect that 90% of the love affair (mine included) with liquid yeast results not from switching to liquid but from getting away from Red Star and its stealth progeny.

> what point does the heat buildup become high enough
> to affect the ferment? Also are the Wyeast preferred
> temps for the ferment or ambient? So does a
> 40-50litre ferment create enough heat to alter an
> ale ferment? How about lagers?

well Nick, I would guess that you would like to keep the primary ferment temp as close to the recommended temps as possible (65F for ales, 55F for lager). I would say that depending on the flavour profile you want anything more than +/- 10F is too much. Smaller batches, from my limited playing with them don't seem to change very much from ambient +/- 5F in the middle of the vessel. I would venture that the 10 or so gallon batches could produce enough heat to require attemperation. I dont have a 10 gallon fermenter, but my 2BBL fermenter will generate quite alot. If I pitch at 70F, ambient temp being in the low 60'sF, the next morning at the peak of fermentation - temps will be approaching 80F. This only happened once - thankfully. I now cool the fermetner down to 62F after I see signs of fermentation - this usually takes a few hours.

As an aside here - I would like to use a sankey keg for a fermenter. I have heard of George Fix using a pony (1/4BBL) which I assume has no internal/external plate or coil. Anyone using any 1/2BBL ekgs with attemperation devices, other than sticking in a drum of water???

SRIRACHA <radavfs@ube.ub.umd.edu> asks:

..
>we saw a couple of possible containers the other day, but I thought I'd
>beter write first...How about "Grolsch-type" bottles?

You can store it in a sanitized (or as close to sterilized as you can get) vessel (jug, - i use a pop keg). If you are not going to repitch within a day or so (guessing here -- anyone know how long?), put the vessel in a refrig (40F). It should last a week or so (again how long??). I would repitch within a week or dump it myself. Grolsch bottles should work fine for smaller (5-10 gallons ferments). When you do take it out of the refrig (as Mike Sharp recomends warming the slurry up well in advance). I assume that when Mike does this it is done fairly slowly not to shock

the beasts into mutation. My process is to remove from the refrig 2 days in advance, on the first day store it at 10F higher than refrig temp. The second day store at a 10F higher than the previous. As I cool the wort some of the wort is diverted to the keg with the slurry. I allow this to sit at temps as close to pitching for an hour or so. The fermenter is then aerated for 45 min with sterile air. At the half way point in aeration the slurry is pitched. Since doing it this way (past 4 times) the fermentation is underway in 2 hrs (no lag here) and the final gravity is reached within 3 days (usually 2).

>From the general reading in HBD and other pubs - if your clean you can bet on repitch of 5-6 times. If your really clean and do the lab work - you should be able to repitch forever(???). I will be stopping at 5 times - until I can afford the time do it, a scope, chemies and the lab space.

good luck and stay clean!

Subject: Sugared Extracts

A subject thread about the quality of malt extracts led Richard Stueven to re-post Martin Lodahl's article about the report from Professor Ingledew's of the University of Saskatchewan about sugar in malt extracts. Since Prof. Ingledew seems so afraid of lawsuits, let me point out that I am not asserting in the following that any company, foreign or domestic, is adulterating its malt extract with sugar. I merely note these observations; draw your own conclusions.

I recently bought some American Eagle light dry malt extract. It seems peculiar in a number of ways:

- 1) It is not a uniform powder like other DME that I've bought (M&F, Laaglander). Rather, it is a mixture of a light brown powder and white crystals.
- 2) It doesn't clump into hard blobs like other DME when mixed with water. It just dissolves more like, say, sugar.
- 3) It doesn't have a strong malt taste like other DME. It tastes more like slightly malty very sweet wall paper paste.
- 4) When used in a yeast starter, the starter tastes, well, cidery.

Keep in mind Prof. Ingledew's point that any adulteration can be done by a distributor as well as the supplier.

We all know about the high FG's from using Laaglander, presumably from a high dextrin content. Any experiences with American Eagle (the DME, not the canned extract)?

Subject: Labels: Affixing & Removing

Since I make my own paper labels, I affix them with regular gluestick; they stay on fine, and come right off in hot water -- this hot tip brought to you from my homebrewer tutor, Mark Antush... Hi, Mark! :-)

For removing labels from used commercial beer bottles, I recently purchased a brush-scraper combination designed for cleaning bbq grills. After soaking the bottles in hot water, the scraper makes short work of removing the paper, and the brush takes off the glue. Although it is a metal-bristle brush, I haven't noticed any problem with scratched bottles.

Subject: re: iodophor, rinse/reuse

JS relates further experiments with iodophor sanitizer:

Hmmmm. How much headspace in each testtube? (headspace vs solution ratio could be fairly high in a testtube)
Did you open either tube (thus releasing iodine vapour in headspace) during the test? Both stoppers sealed tightly? Possible leak?
Ideally, the test should be carried out with several tubes in each group, and outliers discarded.
I've used my solution several times since my previous posting (without augmenting the iodophor) and though the amber colour may have faded a little (hard to remember what the original shade was - could mix up more I guess), it is still definitely amber. I guess there's no real way to know the sanitizing power vs colour relationship.
Ya pays yer money and ya takes yer chances.
Check the label on your iodophor - mine says the iodine is supplied in the form of a complex. This might make it less volatile.
Cheers,
Rick C.

Subject: Wyeast reuse/stretching

There's been some renewed interest in making the most of Wyeast packages lately. Although I think I've posted this before, it sounds like there's at least a few people who might find a repost useful. Here's the method for stretching the Wyeast that I have been using successfully. It should be noted that storing the yeast in the form of sediment may be suboptimal (someone else posted a simple yeast washing technique some time ago - haven't tried it). All I can say is that this method has worked for me with 4 different Wyeast ale strains (Whitbread, Irish, German, European)

.
It's simple, and requires no special equipment. Alternatively, it allows several brewers to swap yeasts with each brewer propagating one strain.

Briefly, my suggestion consists of converting the original Wyeast package into a number of 'copies' stored in beer bottles.
ie. it is a parallel propagation rather than a serial propagation

Step 1:

Prepare some starter wort (S.G. = 1.020), see Miller's book for recipe. Basically, you need about 1/2 gallon, but if you make more and can it in mason jars (using standard canning procedures), you will not have to prepare more at a later date.

Step 2:

Place 1/2 gallon or so of starter wort in a suitable container (1 gallon glass jug), pitch (inflated) Wyeast package at correct temp. and fit air lock. This is the 'master' starter.

Step 3:

Allow to ferment to completion. When fermentation has ceased, agitate the 'beer' to suspend all sediment, and very carefully bottle it.

You will now have about 6 bottles of very thin beer with a good deal of viable yeast sediment in each bottle. Use each bottle as you would use a package of Wyeast - ie. prepare a starter culture a couple days before brewing. This is facilitated by canning wort when you prepare the master starter. All you need to in that case is pop open a mason jar of wort, dump it into a sanitized bottle/jug of appropriate size, pop open one of your bottle cultures, add it, agitate vigorously, and fit an air lock.

All yeast starters are of the same 'generation', ie. 'twice removed' from the original Wyeast package (as opposed to the usual 'once removed'). This helps avoid the accumulated contamination over multiple generations that may occur with serial propagation.

I've had the bottled cultures remain viable for more than 6 months (so far).

Observe proper sanitation and wort aeration procedures throughout.

Equipment: 1 gallon jug (for 'master' starter)
1.5 litre wine bottle (for subsequent starters)
air lock
6 beer bottles, caps and capper

Optional equipment: mason jars and canning pot.

Later,
Rick C.

From: MAXWELLS@axe.humboldt.edu
Subject: ? lagel ?

I have a question about a lager (?) beer I brewed about six weeks ago.

To start with I'm an intermediate brewer who uses both extract and grains I find, that the combination of the two usually yields a great flavor. I don't quite go to the extent of mashing (still not quite sure on the procedure) - what I do is boil the grains for about 45min at 150deg, then I strain the resulting "extract" into my brewpot and combine it with the canned extract. I usually use either one can or bag of extract and about 5 lbs. of grain (although how much extract I end up with is a mystery to me).

Anyway, for this recipe I used 1lb of Munich Malt, 1lb Malted Wheat, 4 cups pale malted barley, 1/2lb corn sugar, and a 3.3lb can of John Bull unhopped light malt extract. I also used Saaz hops for primary and Mt. Hood for aromatic. And to start with I used Wyeast European Lager liquid yeast.

The problem is this - after the brewing process, when the beer was cool enough to add the yeast I realized the package was about 3 months old, and had not yet risen (I gave it two days, and assumed it would be done... usually when I use the liquid ale yeast it is newer) Not really thinking I added the yeast anyway and put the fermentor outside (Humboldt temp is about 45-50 deg this time of year) After two days, there still was no sign of fermentation so I panicked and went out and bought two packages of dry ale yeast (couldn't find dry lager yeast). After adding that and moving the fermentor back inside, fermentation showed up within twelve hours...So I left the primary inside for 12 days and then put it into the secondary and put the carboy back outside. I left it out there for about 3 weeks (hoping the lager yeast would kick back in).

So I guess my question is this, now that I've bottled I can't decide to let it age at room temp or in the refrig...I put half of the batch in the fridge and half at room temp...there is sediment building at the bottom of the bottles in both cases and both still have a very light color...I just hope it is not oxidized...Any ideas if this beer is an ale, lager, or maybe its a lagel?>
anyway any suggestions would be appreciated...

thanks...the Humboldt Hophead

From: atl@kpc.com
Subject: Yeast Ranching

I have recently seen and contributed to threads on the various ways to save yeast from one batch to another. Especially after realizing the per batch cost savings of all grain brewing, the price of a Wyeast packet was a large percentage (20%) of the total cost of each batch. I decided to try to maintain my own yeast stock.

My first method was to simply place a portion of the trub from primary or secondary fermenter into a glass milk bottle and attach a fermentation lock. To reuse this yeast, I either simply pitched the whole thing into the next batch, or "re-started" it with some fresh wort. This worked fine as long as the yeast was reused very quickly. This was a particular problem for me, as I like to use different yeast strains for different brews, and rarely use the same yeast twice in a row. If you don't brew weekly, this problem would worsen. Another potential problem here is that successively reusing the yeast does increment the generation count, and many of the yeasts we use, Wyeast American Ale for example, are known to mutate rapidly with successive generations.

After a few tries at the "saving the trub" method with various results, I went out and bought the Zymurgy special issue on yeast. Most of what follows is my experience using the information from that volume. If you decide to try what I've tried, I highly recommend it's purchase.

My local BrewShop, Fermentation Frenzy in Los Altos, Ca, carries assorted yeast cultures on agar slants. These slants may be used in two ways. One is to wash all the yeast from the slant into a small (500ml) starter, and when it is just past high kraeusen, pitch it into you cooled wort. This will net you a small savings over Wyeast, as the slants are \$2.50 each. The most economical method is to use an inoculation loop (a small wire at the end of a stick) that has been flame sanitized to pick up a minute portion of the yeast from the slant, and rinse it (yeast) off into a very small (50-100ml) starter. When this is at high krauesen, pitch this starter into a 500ml starter, and use as above. I now perform one more step and pitch this 500ml starter into a 1l starter and pitch that into my wort after high krauesen. I have found that each "step" takes one to two days. This method has the additional benefit of keeping the master culture at the same generation. For my starter vessels, I use 500ml and 1000ml ehrlemeyer flasks, with matching stoppers and fermentation locks.

I home can wort for use as starters and for priming my beer. I purchased a case of Ball 1 pint canning jars (\$7.50), filled them with highly hopped 1.040 extract based wort, attached the lids loosely, and set them in a boiling water bath for about 30 minutes. If you have a large enough pressure cooker, that's better than the boiling water bath, but resist the temptation to "speed cool" the cooker or remove the pressure lock as it will cause the jars of wort to come to a boil again and spew their contents into the pressure cooker. As the jars cool, the lids suck down and seal the jars tightly. It is a good idea to let the wort cool and trub settle before pouring it into the canning jars, otherwise, you will loose several ounces of wort when you use them. The wort does come to a second boil in the boiling water bath, so don't worry about infection. Quality control is as easy as making sure the lids are difficult to remove when using the canned

wort. This may sound like a lot of work, but it sure beats boiling up small starters when you need them, and is easier than reserving gyle from each batch.

While attending the Brewers Luncheon at Gordon Biersch in Palo Alto (thanks for the info gak!) the head brewer, Mike Ferguson, was generous enough to trade me a liter of yeast straight from the secondary fermenter for a few of my best brews! I decided at this time that I needed to try making my own slants to preserve yeast that I collected from other sources such as breweries or purchased Wyeast packets.

Sterile slants can be purchased through the brewshop for \$1.50, and saving the acquired yeast can be as easy as using your inoculation loop to streak a tiny (read invisible) portion of yeast onto the surface of the slant. Store this at room temperature for a few days, *LOOSELY CAPPED*. Soon you will see a bit of milky white growth on the slant. It can then be used as described in the previous paragraph, and stored in the refridgerator for up to 6 months. BE WARNED: It is active, and if the cap is screwed on all the way it CAN explode!!

At this point, after collecting a number of empty slant bottles, I decided to try making my own slants and plates for yeast culturing. Plates are nice because you can grow a larger culture and check for discoloration (infection). They are not a good choice for long term storage of yeast, as they are not really sealed, and will eventually become infected. I purchased a assortment of bottles, a couple of petri dishes and a bottle of powdered agar from our local chemist's supply, LabPro in Sunnyvale, Ca. The agar was quite expensive, \$24.50 for 100g. This agar does not contain any nutrients or sugars to feed the yeast. It can be compared to gelatin, as it's purpose is to set wort into a semi solid mass for culutring yeast. I place a rounded tablespoon of agar into 1 cup of boiling wort. This is then poured into the slant bottles, which are then run through a process similar to home canning. Before they cool, they are set on an angle so when the agar hardens, it forms an elliptical surface larger than the diameter of the slant bottle itself. Be careful when choosing bottles for slants, avoid soft plastic seal inserts as they will melt in the pressure cooker/boiling water bath. The wort/agar mixture is also poured into the sanitized petri dishes and allowed to harden. Set these aside for a week, and re-pour any that show *any* signs of growth. (Note: I occasionally ignore the last safety tip, and haven't been caught by it yet...) You can also preserve unused wort/agar by canning in a larger jar.

The next step I suppose, is to get a microscope, and learn all about what I am looking at through it. We'll see...

Hope this answers some questions,
Drew

I agree 100%.

>fruit flavor will be over powered. If the fruit has pectin in it add
pectic
>enzyme or the beer will never clear, it breaks down the pectin.
Remember that

I did not use pectinase and the beer cleared wonderfully. I did not,
however,
boil the fruit to sanitize (this will definately set the pectins), rather
I froze it and then blanched it in 212F water.

Steve writes:

>I'm an extract brewer with a single stage fermentation setup. Is there
>any way to make a lager without a secondary fermenter. I will be moving

You can, but the long ferment on the trub and dead yeast is why you need
a secondary (if you did an ale that took 8 weeks to ferment out a
secondary
would be recommended), not that fact that it's a lager. You can go ahead
and do it in just a primary, but the resulting beer *may* have yeasty and
sulfury flavors. I'd go with the steam until you get a secondary.

Carlo writes:

>Well you can say I learned my lesson and will from now on always let the
>trub settle and rack the beer off the trub before pitching.

I've done similar tests and for ales, I don't really worry about the
trub,
use the blowoff method (do you?) and my single-stage ales have beer
turning
out quite well. I have do say that I have many data points contrary to
yours. Maybe the blowoff is the difference?

Sheila writes:

alcohol

>than they're used to (this would be commercial American or Canadian brews). I

Yes. Lower mash temperatures, i.e. around 148F, will give you a more fermentable wort and thus the final result will be a higher alcohol beer.

>have never tried to calculate the alcohol content, but I would imagine that with
>mashing variations, an accurate estimate might be way off. What are the rules
>of thumb for starch conversion vs. temperature?

Low temps (~148F) will give you a more fermentable wort and higher mash temps (~158F) will give you a less fermentable wort (higher FG, lower alcohol).

> I suppose the "trub" reference is a different factor in alcohol? And how
>does a blow-off tube affect alcohol?

Fermenting on trub reportedly increases fusel (higher) alcohol production. These higher alcohols can indeed have more "alcohol flavor" which may give the impression of a stronger drink. Some higher alcohols give your beer a "solventlike" flavor/aroma, like paint thinner or model airplane glue.

The majority of the alcohol in your beer is ethanol and this can be calculated from your specific gravity. It's not difficult, thanks to an HBD post by Tom Kuhn in August of 1989:

> OK, for all of you who hate algebra but can plug numbers into a
>formula (or formulas into a program), here is the relationship between
>initial specific gravity (SG1) and the temperature at which it was
>measured (T1), final specific gravity (SG2) and the temperature at which

>why don't they simply use any introduced oxygen to multiply before
>fermenting the priming sugar?

Because the yeast multiply and respire due to the concentrations of oxygen *AND YEAST* in the "wort" not just oxygen. When you introduce yeast into your oxygenated wort, they first respire *not* until they run out of oxygen, but rather until they reach a certain concentration. They then shift into the fermentation phase and the rest of the oxygen in the wort (if there's any left) is scrubbed out by the CO2 produced.

At cellar or fridge temperatures, the oxidation takes some time, but I would suspect that the yeast aren't interested in it at bottling time, only in the sugar.

)

That's correct, it's the 1986 Special Issue (vol. 9, no. 4). The article is "AHA Definitive Guide - The Lowdown on Malt Extracts" by Jill Singleton.

I happen to have it at my desk because I've been thinking about writing to someone about getting updated information (e.g., AHA, HBD). The article says "This Guide will be updated periodically." (I wonder what the period is.) It's the best information I've seen, but it is incomplete.

The table includes information such as Dry or Syrup, Package Size, Yeast Included?, Hop Flavored?, Barley Type, BU per can, BU per pound, and Ingredients. Quite a lot of the bittering information is left blank, as is a good deal of the Barley Type and Ingredients. Other information that would be useful might be hops type (not given in the ingredients), more detail concerning Barley Type and Ingredients, and possibly some sort of color expectations.

I think Dan `Stout' Wiesen is asking for more complete information. (I'd send some to him, but unfortunately I don't have any. I've looked around Compu\$erve a little, but haven't found anything there, either.) Hopefully, there is information that can be sent to Dan. I look forward to seeing an updated report.

Subject: O2'ing your wort

As I promised, I checked with the brewmaster at my local hang-out (Callahan's) about what type of oxygen he uses to oxygenate his wort. He confirmed that oxygen is often sold with a fungicide in it. He said that most companies also have it available without the fungicide. So, you just have to make sure when you order it, that you specify the non-fungicide version.

Subject: Decoction

>From: cook@uars.DNET.NASA.GOV (Chris Cook)

>A few weeks ago I asked what Noonan meant in his reference to removing "...the thickest third..." of the mash. There were several answers posted, but they reinforced my impression that people were interpreting Noonan's directions in different ways.

I hate to sound pompous but Noonan's book is replete with such incongruities.

In many cases he seems to be simply repeating information someone else gave

him and he does not have the background to sort out the contradictions. In

others, he doesn't seem to be able to put himself into the readers shoes and

try to understand what he is saying. I would also like to point out that his

book is loaded with useful facts and details and they are only spoiled by not

knowing which ones to believe.

Having said that, here is the procedure I have developed to incorporate decoction into my Easymash process.

I bring the mash to the low end of saccharification temp using the gas flame.

I then scoop several quarts of mash and heat this to boiling in a separate

kettle. I just dip in and take what I get. I add this to the mash and after through mixing I do it again. I find that I can do this three

times during an hour mash and keep the temp within the proper range. The fourth

time takes me toward mashout and I then turn the fire back on to complete it.

This provides about a 60% decoction. I make no claims for the results aside

from giving me something to do while mashing as I ponder all the virtues

Noonan claims for decoction.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Review of a new RIMS system - Part 1

The following review will appear in a future issue of Zymurgy. I have posted it on HBD to get pre-publication comments.

DISCLAIMER> I am not involved financially or otherwise with the company producing this product. BRD, a company for whom I consult, does not do systems less than 7 bbls. They are not involved, nor have any interest in, the product discussed below. Finally, I am also doing consulting work for Crosby and Baker, and they too will not be involved with the system reviewed below.

A New RIMS System

RIMS stands for recirculating infusion mashing system. The fundamental ideas were developed by Rodney Morris, a noted brewer and microbiologist. His overall concept, described in several publications, is truly remarkable. First of all, his concept addressed in a direct way many problems found in conventional homebrew mashing systems such chronic low yields, poor grain mixing, and turbid runoffs. Moreover, his system addressed these problems in a highly original way. The reviewer is not aware of anyone, commercial or amateur, who considered a continuously circulating mash during the saccharification rest. That, of course, is the heart of Rodney's concept.

Shortly after the early articles on RIMS appeared, many people started to build versions in the 1/2 to 1 barrel range, volumes which are finding wide spread favor by equipment oriented homebrewers. The reviewer did not get the opportunity to taste beer made by all of these systems, but the ones tasted were very disappointing. Rodney's prototype did make good beer, but it was much smaller. It hard to characterize the various defects encountered, but the overall malt character of each was less than ideal, and often had an upfront grain astringent tones. Also in each case the brewers told me that they got better results with their stove top mashing systems. Micah Millspaw, a noted homebrewer, told me that he had given up on the idea of a large RIMS system, and that he could do better going in different directions. Micah's system, by the way, is quite impressive, but is based on a no circulation philosophy, and therefore is quite different from the one discussed in this review.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Review of a new RIMS system - Part 2

It was in this context that I met Conrad Keys of Houston, Texas. At the 1991 Dixie Cup he informed me that he had designed a new and improved RIMS system. I was very skeptical, and tried to talk him out of it. The main reason for doing this review is to "eat corn" in public, for he was able to do what I thought was impossible. This became clear on Saturday, August 29, 1992. On that date both Rodney and I were invited to Houston to witness a full 1/2 bbl. brew on his new system. We were simply astonished.

The first thing noted was the controllers on the system. Electronics is one of Conrad's strong suits, particularly in dealing with the nonlinear effects inherent in the circuits in these types of controllers. The result is a totally automated system, with which the brewer can exert precise control. The mash was started at 125F, and this was held for 30 mins. This was followed by a transition to 154F at the classic monotone rate of 1F per min. The circulation was started at this point, and much to my surprise, not only was there no frothing or foaming, there were even no air bubbles present. Later analysis of the finished beer indicated that there was no hot side aeration during the recirculation. In fact, the beer was exceptionally smooth with a mellow malt flavor. Rodney brought a refractometer so the increase in SG was monitored throughout the duration of the mash. It had peaked by 10 mins. into the rest at 154F, and conversion as determined by the iodine test was obtained after 15-20 mins. The ultimate yield was a whopping 72%, or 34.5 pts./lb./gal.

The system was designed so that at the end of the mash the hot sparge water is pumped through the entire system ahead of the mash tun creating a self cleaning effect. This was followed by a brilliantly clear runoff. The clarity of runoffs has always been a strong point of all the RIMS built. At the end of the day Rodney told me before leaving that this indeed was the best realization of his ideas.

I have not had the opportunity to talk with Conrad about prices and related issues. Apparently, he wants to produce a variety of different variations of his basic design, including 1/2, 1, and 2 barrel systems, each likely being in a different price range. All of these systems will be fabricated from 304 stainless. The workmanship on the current prototype is first rate. The system itself has a highly attractive and professional appearance. Interested readers should contact Conrad at 713-666-9735.

Subject: Tried a few commercial brews, Seeking Alt recipe and local beer judge

Sorry about stuffing this all into one post, Okay maybe not that sorry :
-)

1) Tried a few commercial brews:

a) Emerald City Ale, from Emerald City Brewing Company and it says "where it rains it pours" on the bottle. I found it to be a somewhat lifeless boring beer (glad I only bought 1 bottle :-). I think the snappy saying should be "where it rains its poor"

b) Altbairisch Dunkel from Ayinger. I liked this one. Is this a good commercial example of an Alt? If not where can I find one?

2) I am looking for an Alt recipe. All grain is preferred but not necessary.

Is it a lager/or / ale? I looked in my copy of winners circle last night and saw that some people lagered and some didn't. The type of yeast didn't provide me a clue either. Mark me down as confused. Also I wouldnt mind a recipe for your favorite red/amber ale that isnt too strong. I need to brew up a storm for my wedding reception (end of July) and it was suggested that I might want to bring beer for 200 or so. You can probably guess what I am doing with my weeekends for awhile :-)

3) I really want to become a better judge of beer and would like to get some inputs from some local (in and about Seattle) judges. I have a "brown ale" that is very dark, and I am pretty sure it is not to style and am wondering what I have (other than a beer that seems to be evaporating with at alarming rate). I was hoping somebody could come over have a taste and let me know what it is that I have and how to converge more closly with the desired style.

Thanks for your time and patience.

From: Darryl Richman <darrylri@microsoft.com>
Subject: Irish "Red" Ales

As a further note on this style, the February issue of "What's Brewing," the newspaper of CAMRA, contains an article by Michael Jackson about the state of brewing in Ireland. Here are a few notes from the article that relate to the discussion:

On Irish Ales: All ale producers in Ireland are owned by Guinness. These include Cherry's (in Waterford), Smithwick's (in Kilkenny), and Macardle's (in Dundalk). Jackson describes them as all using some roasted barley, which would tend towards giving them all a common color. He says "Of the Irish ales that I have tasted over the years, most have tended toward a buttery, malty sweetness, rather than a hoppy dryness. If we accept that hops were first used in Bohemia or Bavaria, and came via Northern France and Flanders to Britain, it is reasonable to assume that their use arrived rather late in Ireland."

On George Killian Lett's Red Ale, he notes that he has tasted the varieties brewed under license in France and Colorado. "The Lett's brewery had a Ruby Ale before it closed in the 1950s, so I cannot wholly accept the popular story that the Irish brewers were inspired by the success in the 1960s of Younger's Tartan."

On Irish Red Ales in general: "Why Irish ales tend towards a reddish colour, I am not sure. Malting techniques do vary from one country to another, and that may have had something to do with it in the past."

Subject: unfermentables/email size/ferment temps

Chris writes:

>Hi, I was wondering what grains have significant amounts of
>unfermentables etc.... i.e.

>I like my beers to have a heavy malty taste.. just like when you put
>loads of 'malted milk' in your milkshake... I beleive that is a barley
>malt.

It sure is. I suggest Laaglander Light Dried Malt extract for the most
unfermentables available to homebrewers in an extract. Crystal malts
have quite a bit of unfermentables also.

>Question remains what type of unfermentables are we talking about here?

Complex carbohydrates. The carbohydrates in our worts range from the
simplest (glucose) to the most complex (starch). Of course we would like
to minimize the amount of unconverted starch in our worts. These
carbohydrates are a continuum of complexity, glucose, fructose, sucrose,
maltose, maltotriose... etc. The simplest carbohydrates are fermentable
by virtually all strains of yeast. As the complexity of the
carbohydrates

increases, less and less strains are able to ferment them (that's why
some strains of yeast are said to be more attenuative -- they are able to
ferment the more complex types of carbohydrates, the ones some less
attenuative strains cannot). Some carbohydrates are not fermentable by
any beer yeast, for example lactose. Lactose is thus used by some
brewers to make sweet stouts. [I'm no biologist, but I'll bet money that
Lactobacillus *is* able to ferment lactose, by the way.]

I'm not sure where melanoidins fit into this puzzle -- I'm sure they are
responsible at least in part for malty flavors (consider the difference
in flavor between sucrose and caramel made from sucrose). Perhaps others
who know can take over here and explain?

Jack writes:

>Figured out how to beat the system. I posted 7 articles yesterday and

one
>acknowledged was 33 lines. Here is the "long" one in two parts...

I don't think it's the length in lines, rather the size in bytes. I know
that the HBD rejects any post longer than 8K. I also know that if I post
a long and a short post around the same time, the short one always gets
in
faster than the long. I think the routing algoritms in the machines that
route from my machine to the HBD server have a tendency to delay longer
posts (perhaps till the evening when phone rates are lower?). Finally,
you
may have restrictions on mail length on your own machine -- ask your
administrator.

>
>well Nick, I would guess that you would like to keep
>the primary ferment temp as close to the recommended temps
>as possible (65F for ales, 55F for lager). I would say that
>depending on the flavour profile you want anything more than
>+/- 10F is too much. Smaller batches, from my limited playing

I agree with everything Joe wrote, except the recommended temperatures. In my opinion, the recommended fermentation temperatures for ales are between 60F and 75F (but you can go a little higher if your yeast is very neutral, i.e. does not make too many esters/higher alcohols/phenolics). For lagers, depending on the yeast, the recommended fermentation temperatures are between 40F and 55F. Some will ferment a bit lower, but I wouldn't push it too much.

Get to know your yeast. I stick to relatively few yeasts that I've gotten to know over the years and I can tell when things are going well or when the yeast is not happy. Occasionally, I add another yeast to my stable and at first everything it does is a mystery. I've had some trouble getting a handle on Wyeast Belgian Ale, I think I'll stick to 1 gallon batches till I figure these beasts out.

Subject: Laaglander high FG/poetry

1. I'm new to the list and to home brewing and have seen a couple of mentions of the fact that Laaglander DME does not ferment as completely as some others. So I have a question about this: In my current batch I was using the specs. from Papazian's chart for "special red bitter"--6 lb. amber DME (I used Laag-ed lander) and 1/8 lb. roasted unmalted barley (which I brought to a boil and then strained out). The OG was 1050; fermentation seems to have stopped and the FG is 1030. This seems too high. has something gone wrong--incomplete fermentation--or would this be a reasonable FG? (Sorry--forgot to note that I am brewing 5 gal.) The beer seems a bit too sweet for my taste.

2. I sometimes quote the lines from Housman ("malt does more than Milton can" etc.) but I know them not from "The Welsh Marches" but from "Terence This Is Stupid Stuff" (from the collection A SHROPSHIRE LAD)--and for this reason I quote them with a certain self-conscious irony. The next lines of the poem read:
Ale, man, ale's the stuff to drink
For fellows whom it hurts to think:
Look into the pewter pot
To see the world as the world's not.
Read the whole poem, rather than the snippet from the Oxford book of quotations and you will get a new view of the famous lines.

Subject: BOOK REVIEW & A PROPOSAL

Since there are often requests for information about locations of brewpubs and microbreweries in HBD, I thought I would pass on some information in the form of a book review, and a proposal.

BOOK REVIEW

Johnson, Steve. ON TAP: The Guide to U.S. Brewpubs. Clemson, SC: WBR Publications. paperback, 314 pp. \$15.95.

I just received my copy of this publication yesterday. As it purports to be in the subtitle, it is a complete directory of U.S. brewpubs, "including brewery restaurants and microbrewery taprooms and tasting rooms," so the definition of "brewpub" has been extended slightly. I would agree with Mr. Johnson, however, that his extension is the most useful for this sort of directory. (He is even polite enough to provide an appendix of establishments, listed by state, that were not included because they did not fit his admittedly liberal definition of "brewpub.")

The entries are listed by state, with each establishment listed in alphabetical order for each state. Every state's section starts with a map to provide a general orientation of where they are. Each entry distinguishes between brewpub and microbrewery, provides complete address, phone number, hours, styles (and names!) of the beers brewed/sold, types of food, entertainment, or special events, whether they have their own parking, smoking policy -- and just about anything else he could find out. For its directory listings alone this book is a treasure trove. But he also provides interesting introductory material about the recent history of microbreweries in this country (short!), the brewing process, and a glossary of beer-related terminology. It is also illustrated throughout with cartoons, microbrew beer labels, and beer quotes.

As regards the Washington section, I am sorry to relate that you can cross out page 283, for the Noggins Westlake Brewpub is no more. (Heavy sigh!)

ON TAP is priced at \$15.95 and is available from WBR Publications, PO Box 71, Clemson, SC 29633. Don't be silly, of course I have no monetary connection with WBR Publications!

PROPOSAL

I would strongly urge anyone who might be traveling the country to get a copy of this book. I'll keep my copy handy and when I see the occasional request for such info, I'll e-mail said party with relevant data and remind them of the existence of this book. However, my proposal is this: if you will e-mail me the authors names, titles, publishers, and price of books that are guides to your local (state or city), I will compile them and share it with this forum. For example, we have a book for Seattle entitled SEATTLE BREWS which is a complete guide to the pubs, micros, and taverns of this great beer city. Whaddya say?

Subject: Korean malt extract (I kid you not)

I saw something new and different yesterday.

I was browsing through a local Oriental food store. First I located some semi-polished unenriched rice for a sake project. Above that I saw some wheat starch. Then some potato starch. Then some mung bean starch. "Hmm," I says to myself, "This might be fun to try in a beer one of these days."

Then, of course, right next to it I see the "malt powder" and several other things (wheat & rice flour, etc.) with labels on them saying "It is illegal to make wine at home for sale."

The "malt powder" I saw was Korean and came in reasonably priced bags of about 1 lb.

Now, of COURSE I am not even beginning to suggest that this stuff might be of any particular quality or use in brewing beer, but I suppose I will have to at least look into it! More than anything else I just think it's amusing

Subject: dry-hopping vs. hop nose

From: roy.rudebusch@travel.com

DH:>that the way to
DH:>retain good hop aroma is to dry hop in a *sealed* secondary, so the
goodies
DH:>aren't lost thru the air lock. Is that safe in plastic/glass?

Hop nose is achieved by boiling pellet hops for two min. and
loose hops for 5 min.

Dry-hopping seems to contribute mostly to palate flavor.

The best way to achieve maximum hop nose would be to utilize a
"hop cage". Run hot wort through these hops on the way to
a counterflow chiller. This would be "distillation" of the volatile hop
compounds.

Here is Pale Ale I just brewed:

11 Gal 1060
14# U.S. 2-row
4# Munich, Ireks
4# CaraVienne
2# Aromatic

30 HBUs Centennial
finished with 1 1/2 oz Centennial loose hops (boiled 5 min.)
Chilled with immersion chiller
W-1028 repitch.

OBTW, I have also discovered that filtering tends to *improve* the hop
flavor and hop nose of a beer. The beer flavors are cleaned up thus
allowing the hop goodness to shine through.

Brew on.

* OLX 2.2 * If your mind goes blank, remember to turn off the sound.

In HBD 1087 Peter Maxwell asks:

> So if I measure the FG with a hydrometer to be 1.018, how do I know if
it's

> really 1.030 with 8% or 1.020 with 2%?
You don't know (from F.G. alone)

> Or does this matter?

The two mentioned cases will taste very differently, so in that sense
it matters.

> How, then, do I calculate what the % alcohol of my beer really is?
> From the difference between O.G and F.G., for example with one of
the formulas cited by Al Korz in HBD 1087.

Just to make things clear: The table is a definite 'don't worry' item
if you use normal methods for measuring the density. It is intended
for refractometers, which determine the extract concentration
not the gravity.

I only use the real extract value, corrected for alcohol, to get
some insight in the yeast and mash characteristics across
very different batches

Subject: Pitching Idea

I was thinking...

pitch your ale yeast around 60 F... let it ferment at this temp for a day or two to discourage bacteria growth and to let the yeast make alcohol, the stuff that kills some bacteria... then jack the temp up to 65 F to finish...

how valid is this statement? I mean, it almost sounds like making a steam beer etc. but I was just wondering...

> I home can wort for use as starters and for priming my beer. I purchased a case of Ball 1 pint canning jars (\$7.50), filled them with highly hopped 1.040 extract based wort.....

I'm with you up to this point but why not just eliminate this whole step by saving a pint of wort from the previous batch. A further bonus (for all-grain brewers) is that the starter is more like your actual brews than one made with extract.

> This may sound like a lot of work, but it sure beats boiling up small starters when you need them, and is easier than reserving gyle from each batch.

Not sure what you mean by "gyle", I would call it bitter wort but anyway, how can your process possibly be simpler than setting aside a pint of wort before pitching?

You did not mention what kind of air lock you are using on the flask but if you use a glass one, simply putting it on at the end of boiling will sterilize it and fill it with sterile water as the steam condenses. Nothing could be simpler.

> The agar was quite expensive, \$24.50 for 100g.

A suitable agar can be had from oriental food shops for far less. It is sold in stick form and you need about 6 inches to a cup of wort.

Nice article. I don't want to start another snob thread but I put yeast culture right up there with all-grain as one of the more rewarding aspects of homebrewing.

>is this right, 1 oz to 1 gal.?? That is 10 times the amount recommended for usage. If this is indeed correct does this test really tell us anything since the concentrations are an order of magnitude above what people normally use??

>hoping that was a typo....

No typo. I also used bleach neat or at least 2:1 when I used it. It is all relative and I find the long contact times discomfoting. For example, unless one uses 5 gallons of sanitizer in a 5 gallon keg, how can one ever be sure of a one minute contact time? If used at higher concentrations, one can simply slosh a small amount around for a minute and get a more effective sanitization than doing the same with a small amount at the recommended concentration.

As rinse water is not a problem around here, I don't mind more thorough rinsing and it is still far less than I had to do with bleach.

From: Dave Whitman <rsndww@rohmmaas.com>
Subject: Ginger beer problem

To homebrew@hpfcmi.fc.hp.co
X-Mailer: LeeMail 1.2.4

This is my first post to hbd, although I've been reading for a while now. I've been extract brewing for about 2 years.

I'm in the middle of a batch of ginger beer, using a recipe which is a hodge-podge of Cat's Meow recipes and my own warped ideas. What I'm shooting for is something with a pronounced ginger flavor and aroma, good body, but a very light color. I think I'm going to hit all the goals except the ginger flavor, which is a problem given that this is supposed to be a ginger beer.

Here's the fine print for a 5 gallon batch:

2 cans Munton & Fison extra light extract (for light color)
0.5 lb. maltodextrin powder (for body w/o color)
2 oz Hallertauer leaf hop (4.6% alpha)
3 oz sliced ginger root (peeled for lighter color)
4 each juice from fresh lemons
1 pkt Whitbread ale yeast

The ginger and hops were boiled in the wort for 45 minutes, then lemon juice was added along with my immersion chiller. After an additional 10 minute boil, the batch was chilled to 65F. ph: 5.3 before lemon juice, 4.0 afterwards.

To my chagrin, the resulting wort had very little ginger flavor.

1. Did I steam distill off all the good stuff by boiling the ginger too long?
2. Can I "dry ginger" the batch by adding shredded ginger to my secondary fermenter? Any suggestions on how much to try?

Dave Whitman/rsndww@rohmmaas.com "I had a homebrew, but I'm *still* worried."

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Mashout

If we are going to go off on a discussion of mashout and whether one should or should not, and the temperatures in the grain bed during the sparge and so on, perhaps we should state the reason for a mashout at all.

I may be completely off track here, but the only reason I can see for a mashout at enzyme-deactivating temperatures is consistency. When brewing

a sweet ale, for example, you don't want to convert all your polysaccharides down to glucose, so you kill off the enzymes before they can completely chop them up. You like the beer, you want to reproduce it as closely as possible (especially if you're a commercial brewer) so you control the mash precisely, and then you deactivate the enzymes. If, on the other hand, you are a homebrewer trying to squeeze out an extra extraction point or so in a "Swilling Beer" (please note this term refers to an individual's standard recipe that keeps the fridge full, allowing slightly longer interludes between experimental batches), you might just let the enzymes play a little longer.

Jack suggested that the mashout also increases the grain bed temperature to allow for an easier sparge. This may well be true, but

I suspect that this would be more important for commercial breweries. A friend and I compared the extraction rates for two brews, one sparged with

cold water, the other with hot. The hot sparge was done very slowly (3 hrs

or so) while the cold sparge was fairly quick (1 hr). The end result: the

long sparge produced a much clearer wort, but the extraction rates were virtually identical. Unfortunately these rates were on the low side, around 25-26, but at least the sparge can be ruled out as the cause of poor

extraction. Prime suspects for low extraction rate are the malt itself (canadian 2-row pale) and the crush (gotta get a MaltMill one of these days).

In summary: If you have a brew you like and would like to brew consistently, mashout (of course, you have to be consistent with the malt and the mash protocol too). If you want to squeeze out an extra 1/2 point of

extraction, and don't care about consistency, don't bother with mashout. If

you want to avoid HSA during the sparge, chill the mash and use cold water.

(Jack, you seem to get good results, would you mind trying a cold sparge through the EM and let us know how it turns out?)

Subject: RIMS system

George,

I'm posting this RIMS discussion to the digest, because I think this is of general interest to a lot of brewers.

I too have tried the RIMS setup, and spent a lot of time trying to make it work. I finally came to the conclusion that it only works with a specific geometry and only with small batch sizes. My attempts at a 10 gallon size RIMS was a bust. I refocused all my attention to convincing others that wanted to try the system not to waste their time. Your post wasn't very specific on details that describes the recirculating mechanics. This IS the problem area. You got mother nature to deal with here, and she is tuff to change. I found the grain compression at any speed was too much in a 10 gallon sanke keg mash tun. Again I came to the conclusion that it MIGHT work IF the mash/grain area was large compared to the depth. How does this new system overcome these obvious problems? I must have discussed this problem with 10 scientists and engineers around here with no good fool proof ideas. I would sure like to know what makes this new system work. My present system has a gas fired mash tun that I must stir continuously while heating. This is the only WORK in my system, and I dislike it. Micah's system of underleting has its problems too. The management of water volumes can be tricky. I have tried it and it too did not work as Micah would have us all believe. I think he just makes it work because, that is the only way he had to add additional heat to his mash tun. I'm sure if Micah was around to defend his approach he would.

> 60 F. (All temperatures are F.):

>
>
> $[0.0190 \times (T1 - T2)] + [131.25 \times (SG1 - SG2)] = A$
>

What I'd like to know is SG2 the value obtained with a hydrometer, which therefore includes the effect of the alcohol present? Or does SG2 represent the "real" SG, in terms of residual sugars?

Subject: filter questions

I am considering filtering my beer for the first time and I thought I would consult the HBD for any tips. My primary reason to filter is merely to remove any residual yeast. I am aware of a filter sold by the Filter Store, which is merely a wholehouse cartridge type filter. The filter cartridge is some kind of polypropelyne substance that retails for about \$33. Now, my local Hechingers has a woven type sediment filter for use in just such a house filter and it is only \$5. Anyone have experiences using either of these filters? Any tips on cleaning or sanitizing? I have heard that chlorine will break down this filter, but the people at the Filter Store specifically said to backflush at low pressure and use 1TBls chlorox per 1 gallon! Seems like if anything will breakdown this polypro, this would. Any thoughts about iodophor and or caustics (weak)??

Thanks,

Jim Busch

>fermentation--or would this be a reasonable FG? (Sorry--forgot to note
that
>I am brewing 5 gal.) The beer seems a bit too sweet for my taste.

I brewed a version of Papazian's Palalia Ale to make an IPA using a dried
malt
extract from Holland with similar results to yours. OG was around 1053.
FG
was around 1029 even after being in secondary for 2 weeks. It's been in
bottles for a few weeks now and I haven't had any gushers or beer bombs
so it
looks like it did ferment out. It doesn't seem as sweet as a previous
batch
of ale I made from 2 cans of dark extract syrup. That may be due to my
use of
oak chips in the IPA. The tannins in the oak may be hiding some of the
residual sweetness.

>
>Dry-hopping seems to contribute mostly to palate flavor.

I must disagree. I have about 40 datapoints to the contrary. I agree that *some* hop bouquet can be gained from finishing hops (last 1 to 5 minutes of the boil), but not *nearly* as much as from dryhopping. Please note that I've found that in my setup (5 gallon glass carboy with blowoff; switch to airlock after krausen falls; dryhop with whole hops or plugs for exactly 7 days after the airlock rate falls to 1 bubble/minute) any more or less than 7 days of dryhopping gives me less hop bouquet and an order of magnitude more than finishing hops. Perhaps in your previous dryhopping attempts, you waited too long or not long enough. You also *must* wait for the fermentation to subside or the CO2 will scrub the hop aromatics out of the beer.

Subject: Re: Korean Malt extract (digest #1087)

A few months ago, while shopping in an oriental supermarket in Rockville, MD, I came across the same assortment of flours (bean, rice etc.), including the mysterious Malt Powder Joseph Hall seems to have come across. Since it seemed significantly cheaper than the stuff I get at the brew supply store, I thought I'd give it a try.

I bought 2 1-lb bags, and tried a small batch of ale, with no other malts or sugars, as if it were out of a can of malt extract. Much to my disappointment, nothing happened. The stuff never fermented. No bubbles, not beer aroma. The only transformation which did eventually occur was the film of greenish-brown slime which grew on the surface after about 2 months, and the pungent and noxious odor which emanated when I opened the fermenter to look in.

I then decided to taste the malt powder. Oddly, it didn't taste anything like the powdered malt extracts I usually buy. It tasted more like flour--no sweetness to it. It seemed starchy.

Now, the closest I have come to brewing all-grain beers is partial fermentation. Could it be, perhaps, that this malt powder has to be heated slowly to a given temperature, and then be allowed to rest for a starch conversion? Should, perhaps other sources of malt/sugar be added to help/activate the conversion?

I had given up on this idea, but would be happy to continue experimenting with the stuff if you or others could share your thoughts about what might have gone wrong.

Cheers,

From: Mike Deliman <miked@wrs.com>
Subject: Test Driving Mills

Hello all in Home Brew Land,

Recently one of our fellow homebrewers and I decided that when I received my maltmill, we'd try to do an honest side-by-side comparison of the crush produced by a Corona and a MaltMill. I had intended to pick-nits with the analyses; even to the point of weighing the flour produced from one pound of milled malt, etc.

Unfortunately, the testing may need to be delayed. Although I've received the maltmill, and assembly was trivial, there is one large problem with the maltmill as it stands.

As delivered, I'm sure that the maltmill wouldn't pass the simplest of FDA inspections for food preparation machinery. Probably not even in <insert third world nation here>.

The construction of the mill itself is acceptable.

The problem lies in the accumulated detritus lodged into the rollers. While assembling the mill, I brushed my hand on the surface of the rollers. I was aghast to see zebra stripes on my hand. Stripes of lubricant mixed with metal particles, dirt, grunge.

The rollers have a nice design - they are grooved, which could facilitate the uptake of grain. It is also a poor design, as it's nearly impossible to remove the accumulated detritus from the grooves.

I spent about an hour trying to clean the rollers last night, and at this point, I'd still pronounce it unusable. It would seem that in order to properly clean the things, I'll need to disassemble the mill completely, and break out innumerable amounts of soaps, degreasers, solvents, etc. Something I'd rather not do. Certainly not in the Rheinheitsgebot.

To be honest, I'm appalled that someone would ship food processing machinery in such a state; especially priced at \$130.

In the interest of being fair, I've written to the producer and asked for a clean set of rollers to replace these. I'll post the results of this inquiry.

- -----

I have a question for the chem types out there. Does anyone know which would

contain more energy per given volume: LNG (natural gas) or LPG (propane)
?

I ask as I recently purchased a nice burner, which I thought was designed
for
LPG. When I run int off of a propane tank, however, it burns far too
rich.
(it coats the boiler with soot, and the flames never do adjust down to
that
nice, blue, clean burn!)

- - - - -

Brew question: does anybody out there have a recipe (pref all grain) for
Samuel Smith's Pale? Please!! Send to me!!

Thanks all! (grain mill results will be posted)

-mike

I'm very curious what Al's comments were on the different yeasts.
Al, if you've had a chance to taste the above beers you've
referred to, please comment. I'd also be very interested in
hearing from others who have experimented with various dry
yeasts.

Subject: pH

With respect to the recent thread on pH vs. temperature...I assume that when adjusting the pH of sparge water that the calibration of the meter using the calibration solution should be done at sparge temperature and that the desired pH be set at that temperature, not room or 60 deg. I found that the boiling (conditioning) of my sparge water went from an initial room temp reading of 7.0 to 8.3 at 170. I used citric acid to make adjustment to 5.8 at the sparge temperature. The first time I tried this, I too used gypsum initially but after 2 Tbs. changed only a couple of tenths, I went to the acid and overshot to 5.0. I salvaged the sparge with bicarb and all seemed to go well.

Subject: re: powdered sugar

In HBD #1083 John Freeman asks:

>Isn't powdered sugar just sugar? I don't understand the insistence on
>using the powdered form versus the crystalline form.

Powdered sugar is a mix of finely ground table sugar and cornstarch
(about
60%/40%). This is why powdered sugar doesn't cake or clump, and why you
don't substitute powdered sugar for regular sugar when baking (the doughs
become impossibly stiff).

Subject: RE: Decoction Mash Questions

In HBD 1086, Chris Cook asks about decoction mashing.

I have brewed 10+ decoction mashed beers of varying quality: some were horrible (got dumped), some were outstanding.

When I first started out, I attempted to get the decoctions as thick as possible. The result was caramelization in the decoction no matter how much I stirred, and the more I stirred, the more HSA became a factor. My solution to this dilemma was to ensure that the decoction was dilute enough not to require stirring, either by adding boiling water after dextrinization, or by including some of the mash liquid in the decoction.

I also tried several different (and messy!) means of removing the decoction. In the end, I found the quickest, cleanest, and easiest to be siphoning: I use a 1"ID soft-pvc tube about 5 feet long. Another advantage to siphoning is that it eliminates a source of HSA.

It is not important to pull only the 'thickest' or the 'thinnest' portion for a particular decoction. If a fairly representative sample of the entire mash is taken, all works well. I have found that the most important thing to be aware of is the quantity: beware of taking too little. Perhaps if one is using a malt of low diastatic strength, such as Munich, one may need to be careful not to boil too much of the mash liquid, but with domestic 2-row, I have not had a problem. Noonan recommends that the lauter decoction be thinnest portion, so as to deactivate the enzymes and as not to gelatinize unconverted starch. Neither of these is really an issue. When the decoction is remixed, the temperature should be at mash-out which will denature the enzymes anyway. Any starch that is released should be trapped by a proper lauter: only clear run-off goes to the boiler. Hence, his two points are non-issues.

Noonan makes a big deal of slowly and evenly mixing the decoction back into the mash to avoid hot spots. For larger brewing operations this may be important, but I have never found it so, where a dozen strokes with a spoon will completely mix my mere 5-gallon mashes. To return the decoction to the cold settlement, I use the siphon hose to return the entire decoction at once. I mix thoroughly and stabilize the temperature with boiling or cold water. Siphoning here further reduces sources of HSA.

I have been experimenting with a modified decoction mash wherein the enzyme-rich liquor of the dough-in is lautered off and reserved prior to the first decoction, enabling the _entire_ grain mass to be boiled at once. The initial trial of this method was promising: extraction was high; the beer is good. If it yields worthwhile technique, I'll post.

Subject: Open Fermentors

Owing to the encouragement of seeing someone (Jim Busch?) advocate open fermentation, I gave it a try. It is one of my best beers to date, much better than many that I have made in carboys.

The fermentor used was a 6-gallon crock that my Dad used to brew his beer in. I sterilized it with boiling water before siphoning in the cooled wort and pitching the yeast. I used a culture from the bottom of the secondary of a beer fermented with Nottingham ale yeast. The yeast had been acid-washed and fed with several 1.020 sucrose solutions. At pitching time there was about 5 oz. of healthy yeast in the starter. Lag time was about 12 hours, and fermentation was finished within 60 hours of pitching. Fermentation temperature was 68degF at the peak, finishing at 65degF when I racked to a secondary and dry-hopped.

I found it much easier to monitor the ferment with an open fermentor: just sterilize the hydrometer or thermometer and drop it in; want a taste? -- just dip in a (sterilized) spoon. I have been used to just pitching the yeast and waiting until the fermentation visibly subsided before racking to secondary; there was nothing to do during primary except check on it every 12 hours or so. With open fermentation and no blow-off, I had to keep an eye on it and skim the foam every 6 hours, lest it push off the kettle lid that I had on it. (This may be because the crock was just barely big enough to hold 5 gallons of beer and the foam of high-kraeusen; if the fermentor were larger, then perhaps I would not have been concerned.)

I had expected to be able to harvest clumps of new yeast from the top of the primary, but they never appeared. This may be because the yeast is highly flocculant. (The beer does have a slight diacetyl component.) I had thought that perhaps the yeast did not reproduce much, due to the high pitching rate, but I did collect about a pint of yeast slurry from the bottom of the fermentor, so that obviously wasn't the case. Any ideas? Does the flocculant nature of Nottingham yeast make it a bottom cropping strain?

Recent discussions have centered on fermentor geometry. The crock has roughly

the same proportions as a carboy, or a little more squat. Judging from recent posts, this is not the 'ideal' geometry, having too small of a surface-to-volume ratio. Would this have had an effect on yeast cropping?

>procedure) - what I do is boil the grains for about 45min at 150deg,
then

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
This is mashing.

>I strain the resulting "extract" into my brewpot and combine it with the
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

This is sparging.

>canned extract. I usually use either one can or bag of extract and
about
>5 lbs. of grain (although how much extract I end up with is a mystery to
>me).

I hate to tell you this HH, but you do know the procedure for mashing.
You
are just doing it on a smaller scale. My first mash was done this way,
called a partial mash, adding the extract from the grains to the extract
from
the can. To go all-grain, all you have to do is increase the amount of
grains and skip the extract. Of course, that assumes you would ever want
to
go all-grain, etc. etc. (ACKK! do I have to be PC here, too? - I hate
this.)

Roy sez:

>Hop nose is achieved by boiling pellet hops for two min. and
>loose hops for 5 min.
>
>Dry-hopping seems to contribute mostly to palate flavor.

I tend to slightly disagree with this statement. My experience tells me
that
dry-hopping contributes greatly to the nose and the flavor. Also, and
this
may be bunk, it seems to accentuate bitter hops as well. I mean that,
although it doesn't actually add bittering, the bittering hops seem more
assertive when boosted with a large dose of dry hops. This may only be
true
when the two hops are the same or similar varieties (i.e. I haven't done
any
real scientific research to prove/disprove my theories).

Cheers,
Norm

In HBD 1088, Eric said that "Powdered sugar is a mix of finely ground table sugar and cornstarch (about 60%/40%). This is why powdered sugar doesn't cake or clump, and why you don't substitute powdered sugar for regular sugar when baking (the doughs become impossibly stiff)."

Welllll, at my local grocery, that stuff is called confectioners' sugar and is intended for making cake icing and such. 100 percent powdered sugar is available as well. Some places might call it bartenders' sugar. it mixes well in drinks, without leaving undissolved grit.

Both types are clearly labelled as to contents.

That said, I only use dry malt for my yeast starters, canning 7 or 8 qts at a time in a pressure canner.

Return-Path: <miked@wrs.com>
Subject: Re: MaltMill

>The rollers are filthy, coated fariley well with oil residue, metal particles, and ground in grime. The easiest way to clean it would be to dissassemble it and soak the rollers in solvent.

>If you would be willing to ship me a set of clean rollers I'd be gald to ship back the currently unusable rollers. I'm not exactly thrilled about the thought of dissassembling/reassembling the thing, but if it'll save me from the thought of injesting unknown contaminants with my beer, it'd be worthwhile. (not to mention probably a lot easier than spending hours with cleaning rags, solvents, boiling water, degreasers, etc...)

>Let me know your thoughts,

I don't think we could remain friends if you knew my thoughts at the moment :)

However, here are the facts:

The only thing on the rollers is a thin coating of rust-proofing oil. This is applied after they are knurled so they do not rust in inventory. At the time they are assembled, the rollers are wiped vigorously with a clean rag to remove as much as possible. The easiest way to get the rest of it off is to mill a few pounds of malt with it and feed it to the birds.

Our QC procedure here is to mill a pound with one mill out of every batch of 10 to make sure there are no systemic problems. We simply blow it off with an air hose after testing and you may have gotten one of these which would have some dust or debris on the rollers. However, it would be the same as if you had run a pound through it.

Unless something happened to yours from the time it left here till you received it, it should look just like the 600 others we have shipped and no one has previously even commented on what you find unacceptable.

Unless you want to pay \$75 for the ss roller option, oil is a necessary evil

on a steel product. Once it is in regular use, it will stay clean without any special attention but I can not inventory hundreds of expensive rollers and take the chance of them getting rusty nor getting rusty before the customer has a chance to use it.

You can clean them with a wire brush and cooking oil and then wipe them down thoroughly. Other than that, I do not know what to tell you. If I send you another set of rollers, they will look exactly like the ones you have.

Your money will, of course, be cheerfully refunded if you choose to return the mill.

Sorry for the trouble,

js

Apology accepted, but how's this work?

" The only thing on the rollers is a thin coating of rust-proofing oil."

"The easiest way to get the rest of it off is to mill a few pounds of malt with it and feed it to the birds."

okay, I see. take my home brew supplies, coat them with machine oil, and give it to the birds. Well, I never DID like pigeons.

I guess either the other 600 users did the above, cleaned with a wire brush, et all, or were just too embarrassed to complain. Or they don't mind machine oil lager.

nuff said.

Thanks much to all who responded to the LPG vs LNG question. I suspected what seems to be true: the burner is probably jetted for LNG, and needs re-jetted for LPG. The LPG supplies more energy per given volume and thus requires more O₂; since there is no way to increase flow of air into the venturi, I gotta decrease the fuel flow. Thanks guys!

>pffft< have a homebrew,

-mike

P.S. After I clean the MM properly, the crush analysis will be posted.

Subject: RIMS

I want to thank the many people who sent comments on my RIMS review.
The typos noted were the following:

1. Replace "It hard" with "It is hard" in the second paragraph.
2. Replace "eat corn" with "eat crow" in the third paragraph.

I have been very critical of the AHA for these sort of typos. I seem to remember from my youth a story about glass houses and stones. Does anyone remember how that one goes?

Bob Jones in HBD#1088 raises some very interesting points. As such things pertain to the specific case of Conrad's system, I would feel a good deal more comfortable if they were addressed directly to Conrad. Those who saw pictures of my own 1/2 bbl. system in Milwaukee know it is quite different from Conrad's. It is also different from Bob's, who in turn differs from Micah. I look on all of this with a good deal of favor. What a boring world it would be if total uniformity reigned!

Because of length restrictions, reviews differ from technical articles.
What

I look for in a review is a clear statement of the product claims made by the producer, and a good faith effort on the part of the reviewer to check them. Interested readers can then contact the producer for details. The following are what I understand to be the claims Conrad is making for his system. My observation of an actual brew being done with his system leads me to believe that they are all valid.

1. Total temperature control through uniquely designed controllers and heating elements. Any reasonable type of infusion mashing schedule can be used with the system.
2. Recirculation without HSA.
3. High yields and brilliantly clear run offs.
4. A system that is trivial to clean.

Would someone be so kind and post a list of Rodney's articles about RIMS? I have kept only the one that appeared in the Maltose Falcon newsletter, since it appeared to be the most complete and detailed.

Subject: Re: Korean Malt extract (digest #1087)

I expected to see plenty of responses on this, but since they don't seem to be coming, here goes:

I bought some of that stuff before, too. It was from the local alternative food co-op, and it was not Korean, but I bet it was the same. What it is is ground-up malt (grains that have been sprouted, dried again, and ground into flour). It is not dried malt extract, which you (and I) were hoping to get.

Theoretically, the enzymes should still be in there, so you might be able to convert it to sugar, but you would have a really hard time getting it filtered.

I think I tried using it in bread, but it didn't work as flour, either. It was too sticky because it does contain some sugars. I am not sure what it is supposed to be good for.

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject:how come you taste so good?

I have advocated the use of brown sugar in pale ales in this forum on at least two occasions. The first was in HBD#528 in a recipe which appears in Cat's Meow (p.1-12 in the postscript version). The second was a little over a month ago in the post where I coined the phrase "all-grain snob" (mea culpa). This practice recently took a slam:

In HBD#1083 John Freeman sez:

>And keep the stinking brown sugar out of my beer.

Do I detect an all-malt attitude? (I'll avoid the "s" word :-)

Many of us began brewing from kits, using enormous amounts of sugar, and eventually learned that cutting back on the sugar meant getting rid of the cidery flavors. This doesn't necessarily imply that all sugar must be cut out in all circumstances. Belgian beer homebrewing seems to have become vastly more popular during my three years on the HBD, and homebrewers are willing to follow Belgian practice when it comes to sugar. Why should we treat UK brewers differently?

Looking back in my log book, I notice that my first two bitters contained small amounts of brown sugar - under 15%. Both were served on draft at parties and both were overwhelming successes. Having lived in England for two years, I can also assure you that the flavor was quite authentic. As well, there were occasional pale ales and brown ales which had brown sugar additions. In all, something like 4-5% of my 200+ batches. No particular problems noted, and some raves received.

I notice that I haven't used brown sugar myself since since posting my Cat's Meow recipe. I think I'll try a brown and/or pale ale with 10-15% sugar in the near future. I'd also appreciate e-mail from people who've tried my Cat's Meow recipe, with their opinions on using brown sugar in a Bass-alike.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: Brown sugar.....

Some beers, especially British ones, are brewed with small amounts of brown sugar. I believe that reputable UK brewers keep the total amount of extract from adjuncts and sugars at or below 15% (see Foster's Pale Ale). I also understand that when brown sugar is used, it is more likely to be a "raw" brown sugar, like demerara, than the stuff one finds in a North American supermarket. The latter is likely to be ordinary white cane sugar doctored with molasses.

My palate tells me that there is brown sugar in Newcastle Brown Ale, and an English friend who is quite a good judge of beer agrees. On a more cautious claim, I believe I have tasted subtle brown sugar tones in bottled Bass. After a recent experience, though, I'm reluctant to state definitively that the tones actually come from brown sugar.

Last Friday I had a bottle of Pike's Place Pale Ale, from White River Junction, VT. This is a really fine brew: on the dark side of pale ale color, with good body and substantial hop bitterness :-)
On the nose, though, I picked up an unmistakable brown sugar aroma. A pleasant one, I might add. However, the label states only malt, hops, yeast and water, and I have no reason to doubt them. So my conclusion is that a brown sugar aroma can develop without the addition of brown sugar in the wort. Any comments?

There has been recent interest in Housman's poetry and the towns where we live:

I had considered using all-grain to make the canned wort, but went
with extract for simplicity. (I had a batch to mash and three to
bottle at this point) Also, I brew widely divergent beers weekly, so
reserving a pint of stout might not be appropriate for starting a
batch of light lager. My canned wort is "least common denominator"
pale type.

I called it gyle from Papazian's description of reserving bitter
wort for later priming purposes. You may have a point on simplicity,
but I had more faith in the "canned" wort keeping for a long period of
time at room temperature. Also, since I had been reserving gyle for
priming purposes (usually 3 22oz bottles per batch), and frequently
have 2-5 batches fermenting simultaneously, my refridgerator just
isn't big enough.

Nothing

> could be simpler.

I'm not sure which flask you are referring to. I use flasks for
growing my starters, but I don't boil at that point. I pour sterile,
canned wort into the sanitized flask, stir in a small sample of yeast,
and affix a sanitized plastic airlock. At appropriate times, I add
more sterile wort to enlarge the starter, and move to larger flasks
when appropriate.

Subject: Ginger beer summary

To homebrew@hpfcmi.fc.hp.co
X-Mailer: LeeMail 1.2.4

I was astonished at the number of responses to my post about low ginger flavor in my ginger beer wort. Thanks everyone!

Many people pointed out that the sweetness of the wort may be masking the ginger flavor. The message is that 1) lots of recipes use about 3 oz of ginger and use 1 hour boil times, and 2) a little ginger goes a long way. Before panicking, I'll taste the beer during racking into my secondary.

Jim Grady suggests grating the ginger rather than slicing it. For what it's worth, I tasted the ginger slices after boiling, and they were pretty flavorless, suggesting that the flavor was successfully extracted.

Spenser Thomas warns that he tried adding pieces of ginger to each bottle, which gave good flavor, but also caused gushing. He suggests making a ginger tea by steeping ginger in hot water, and adding that to the secondary. Would steeping sanitize the ginger enough to avoid the infection suggested by gushing?
How hot / how much time do I need to sanitize an ingredient?

Dan Butler-Ehle says that he uses ginger a lot, but has never been really happy with the flavor - the pepperiness is missing. He thinks the ginger oils boil off early. He has added ginger to his secondary, and that doesn't seem to help, and sometimes leads to off-flavors. He speculates the pulp rots, and suggests I try dried, ground ginger.

I looked up ginger and oil of ginger in the Merck Index, and got some insight into just what's there. The major flavor component is a fairly high molecular weight phenol called gingerol. It doesn't look very volatile. However, there are a number of other constituents which DO look volatile: camphene, phellandrene, borneol, citral and cineol. I suspect at least some of these are lost during an extended boil, explaining my and other's reports of disappointing flavor.

Subject: Propane Cooker Problems.

Mike Deliman writes about problems with his propane cooker...

I believe that propane (LPG) has more heat per volume. As for the soot from your burner, it may be that the air/fuel ratio is not set correctly. Look at the inlet and there should be a rotatable shutter that you can adjust the air/fuel mixture with. Mine was a fairly cheap unit from Sears and it had one.

The other problem I noted with mine was that the gas/flame distribution was uneven with the far side of the burner having a much longer flame than the near side. A little surgery with a drill grinding bit and I was able to change the configuration of the casting to allow a more even gas flow. See crude graphics below.

Original Improved

Although it's a bit crude, the two X's in the right hand drawing show where the carving was done. The left hand carved out area opened up the gas flow to the inlet side of the burner, and the right hand X carving made a "bounceback" kind of effect with the gas so that the jet of gas (later flame) didn't simply flow straight out the opposite side of the burner from the gase inlet. It's still not perfect, but the flame distribution is a lot more even than it was as the unit was shipped to me.

Despite the appearance of the drawing above however, the actual grinding does not (should not) go anywhere near the edge of the casting.

Kip Damrow asks about color copier labels. They don't run when wet. The toner powder used in photocopying is a plastic powder that is melted (fused) to the paper. If flexed however, you may see flaking of the material off the paper.

Subject: hop aroma

It seems that every couple of months there is another discussion about hop nose or aroma and flavor and methods of achieving it in the beer. It's the general lack of good info in the homebrewing literature and even texts on brewing science like Biotechnology of Brewing and Malting and even Malting and Brewing Science on this topic that leads to repeated queries. That's what led Mark Garetz to put together a nice article for zymurgy, appearing in the summer issue, about dry-hopping. Mark has done a really professional job putting the article together with interviews with Fritz Maytag (several hours), Jim Koch (the beloved one in this forum) and many other people in the hop industry. The article discusses several methods using finishing hops such as dry-hopping, hop backs, finishing hops at the end of the boil, hop tea, etc.

It's interesting that all of these approaches contribute to hop flavor and aroma of the beer, but the hop flavor and aroma can be very different for each technique. This is due to the fact that hop oil which is the stuff which contributes the hop flavor and aroma is really many different oils. Some are more volative than others and some are more chemically reactive than others and all are more reactive and volatile at higher temperatures.

Thus the type and amount of oils and secondary oil products in the beer depends on the variety of hop, amount, temperature, time and many other factors, including, as Bob Jones pointed out, opened or sealed vessel. Bob's advice is right on the mark. You will get more hop aroma by dryhopping in the keg. The reason for this is that volatile hop oils are not soluble in beer but rather are in suspension. The volatile suspended oils would really prefer to float away. Take Bob's advice, don't give them a chance; keep the lid on.

Rather than say that one method of using finishing hops is 'better' than another, I prefer to say that they are all wonderful but different. If you have any doubt about the incredibly vast difference of hop aroma and flavor betwenn using the same type of hop in (I believe) nearly equal amounts in two different ways, just compare Sierra Nevada Pale Ale and Anchor Liberty Ale. Both use Cascade finishing hops. One is dry-hopped and the other uses a hop back.

I am a proponent of the idea of including more information in a recipe with regard to finishing hops. it's really not enough to say "dryhopped with 1 oz cascades." if I want to really match the beer I need to know how long the hops were in the fermenter or keg and the temperature. similarly, if you use finishing hops at the end of the boil, i not only need to know how much for how long, i need to know the rate at which the hot wort was cooled because the hop flavor and character are altered significantly during a slow cooling.

afterwards.
>To my chagin, the resulting wort had very little ginger flavor.

>1. Did I steam distill off all the good stuff by boiling the ginger too
long?

I don't think so. I made a batch about 6 mo. ago with 1.5 oz of ginger
boiled for an hour and it had a very good ginger flavor. I think that I
might have grated my ginger as opposed to slicing it. Ginger is
powerfull
stuff and 3 oz seems like a lot. Maybe it is like hops in that there can
be a lot of variation of "the good stuff" season to season etc.

>2. Can I "dry ginger" the batch by adding shredded ginger to my
secondary
> fermenter? Any suggestions on how much to try?

This sounds like a cool idea, but I think that I would finish this batch
without it. Then, if in the end, if there is not enough ginger flavor,
you
can brew another batch and "dry ginger" it. This way, you will have a
better idea where the ginger flavor came from.

BTW... How well do your yeasties like that low pH wort?

metal
> particles, dirt, grunge.

I found the machine-oil smell of the device a bit worrisome, but after passing a few pounds of grain through as a trial I decided it was in fact not a problem. The odor has largely gone away now that I've run a batch through. The odor is not evident in the grain passed through.

> The rollers have a nice design - they are grooved, which could facilitate the
> uptake of grain. It is also a poor design, as it's nearly impossible to
> remove the accumulated detritus from the grooves.

So? Over the long haul this doesn't make a bit of difference. Over the short term, yes, it would be nice if Jack brushed the rollers clean in something like hexane and then with a mild detergent.

> I spent about an hour trying to clean the rollers last night, and at
this
> point, I'd still pronounce it unusable. It would seem that in order to
> properly clean the things, I'll need to disassemble the mill
completely, and
> break out innumerable amounts of soaps, degreasers, solvents, etc.
> Something I'd rather not do. Certainly not in the Rheinheitsgebot.

I wish Jack had shipped mine smelling like Ivory soap, but I'm not sure what if any difference it makes. Certainly I have no problem with the particles of grain that tend to lodge in the grooved rollers.

> To be honest, I'm appalled that someone would ship food processing
machinery
> in such a state; especially priced at \$130.

Calling it "food processing machinery" is a bit loose. After all, you are going to thoroughly filter and boil the output. You aren't really going to "eat" the output of the mill at all. The chance of, say, a chip of steel making it through to a bottled beer is zero, considering all the settling and sedimentation that goes on.

Finally, casual experimentation (just now) reveals that a dry toothbrush suffices to clean the rollers down to the shine on the portion (about 2/3) of the rollers where the grain gets crushed. Why don't you just run 5-10 lbs of cheap malt through and get on with things ... ?

The effect of the maltmill on fat British 2-row malt is most impressive. The husks are left almost completely in one piece, and the kernel

is squished perfectly into coarse chunks. The results on less modified American 2-row and particularly 6-row are a little less remarkable, but I gather that these grains are harder to crush anyway.

I will print a detailed review when I have some data points. I am looking for a reduction in astringency (vs. grain from Corona) and an improvement in extraction rates. So far, at least the latter seems likely.

>alcohol, the stuff that kills some bacteria... then jack the temp up
>to 65 F to finish...

>

>how valid is this statement? I mean, it almost sounds like making a
>steam beer etc. but I was just wondering...

Well, it's sort of valid... but you're making ale. Ale temperatures are between, say, 60F and say, 75F. I don't understand why you suggest that you should first ferment at 60F to "let the yeast make alcohol, the stuff that kills some bacteria" and then raise the temperature. It's sort

of backwards from one common way to make lagers: to start the batch at around 65F and then once the yeast get going, (slowly) lower the temp to 40F or 45F. If you have good sanitation techniques and are pitching clean yeast, you can ferment the whole batch at 65F or the whole hatch at 60F. The Steam(tm) beer you suggest this might be (it's not) would be made with lager yeast (Wyeast #2112 might be a good choice ;^) fermented

at the cool end of ale temperatures (say 60-65F).

Jack writes:

> No typo. I also used bleach neat or at least 2:1 when I used it. It is all
> relative and I find the long contact times discomforting. For example,

I'm no biologist, but I think that contact times are much more important than concentrations, i.e. 10 min at 200ppm is more lethal to nasties than 1 min at 10000ppm, no? Biologists?

Personally, I'm trying to move away from Chlorine as a sanitizer from an environmental point of view. Moving to Iodine may not be much better for the environment either. I'm looking for a source of Peracetic Acid (Acetic acid and Hydrogen Peroxide). The H2O2 quickly becomes water and acetic acid is plentiful in the world. Also, a few stray ppm of acetic acid

won't affect my brew as much as a few ppm of Sodium Hypochlorite will.

Dave writes:

>3 oz sliced ginger root (peeled for lighter color)

>

>The ginger and hops were boiled in the wort for 45 minutes, then lemon juice

>was added along with my immersion chiller. After an additional 10 minute boil,

If you had grated the ginger and added it only for the last 2-3 minutes of the boil, you would have had a lot of ginger flavor and aroma. I used 2 ounces

like this and the beer took 4 months to be drinkable -- but very good eventually.

>1. Did I steam distill off all the good stuff by boiling the ginger too long?

Yes.

>2. Can I "dry ginger" the batch by adding shredded ginger to my secondary fermenter? Any suggestions on how much to try?

Yes, but just to be on the safe side, after you peel the ginger (I did) but before you grate it (coursey) on your sanitized grater, I suggest blanching it (dip it in boiling water for 10 seconds).

I wrote:

>
> BREWER'S OF SOUTH SUBURBIA
> (south-suburban Chicagoland)
>AHA Sanctioned
> Regional Homebrew Competition

That should be BREWERS OF SOUTH SUBURBIA (no apostrophe). I don't know why I've lately been randomly putting apostrophes in front of trailing s's.

Deb writes:

>I brewed a batch of Wit last weekend, which is bubbling nicely in the primary.
>The recipe (Miller) calls for the addition of 1 ounce of coriander seed to the secondary. Do I have to boil the coriander before adding it or will there be enough alcohol present to ward off any nasties? Any help would be very much appreciated. Thanks in advance.

Boiling would definately reduce the aromatics you have available. I would just blanch them (dip them in boiling water for 10 seconds) and then crush them in your sanitized coriander mill (I guess you could use a sanitized spoon in a sanitized cup if you don't have a true coriander mill ;^).

C. Lyons writes;

>> yeasts (Coopers, Nottingham and Windsor) to choose from in addition to >> the yeasts from Wyeast.
>
>I'm very curious what Al's comments were on the different yeasts.
>Al, if you've had a chance to taste the above beers you've referred to, please comment. I'd also be very interested in hearing from others who have experimented with various dry yeasts.

I've tasted two batches now made with the Nottingham. One was split between bottles and a keg. It's very clean and only very slightly fruity in the keg, but tastes/smells nutty (peanutty, like Grant's IPA [sic] or Grant's Scottish [sic] Ale) in the bottled version. Although I've only tried it on two batches, so I don't quite have a handle on this yeast, but the Nottingham appears to be relatively attenuative (more so than the Coopers, I'd say). I haven't had a chance to taste the Windsor --

I only made a 1 gallon batch to try it out and then sort of forgot about it. I've been told that the Windsor tends to be even more attenuative and less flocculent (these two factors are related) than the Nottingham. The Nottingham batches were fermented at 65F.

The Coopers is quite fruity fermented at 65F and probably the best dry ale yeast I've ever tried. It's not phenolic at all and all the flavor is a very clean fruitiness.

For those of you who made it to the Mainstreet beer tasting, the American Light Ale and English Pale Ale were made with Coopers and the Medium-dry Stout was made with Nottingham. The *DRY* stout was made with Wyeast #1084 (two years ago!). How about that -- the driest beer of the bunch was made not with dry yeast, but with liquid!

From: THOMAS VODACEK <87749194@ucs.uwplatt.edu>
Subject: Old "Potato Beer" recepie

To: Homebrew Digest
Fm: 87749194@uwplatt.eduThomas Vodacek

A friend gave me an old recepie from his uncle that was for potato beer. The idea is a little odd, but I would like to try it to see the result.

It calls for cutting each potato into just larger than matchstick size pieces and mashing them seperately from the grain portion and then filtering with cloth and -then- mixing the worts for the boil.

I was wondering where the enzymes for the potato starch conversion come from? It seems to me that if there were enzymes present they would be converting the starches right away in the field and in the store. Or does the tuber have a way to control the enzymes in the living tissue? I would guess that when a potato is stored a long time and then gets soft before it begins to grow eyes (like mine usually do) this is like the point in grain malting where the grain is dried in a kiln. If this is true:

1. Do I have to let all of the potatos get to this stage, or
2. Are there enough enzymes in just one or two that can do all of the work, or
3. Are the potato starches in such a state that they are (very) quickly converted by the grain enzymes after mixing, or
4. Should I hold the wort at mashing temps for a time as comversion takes place?

The recepie doesn't say to wait for conversion, but then it doesn't say to test for it either.

Has anyone used potatos in a "beer" that can lend assistance?

Thanks.

Thomas Vodacek

From: James Thompson <sirjames@u.washington.edu>
Subject: Proposal (Repeat) & Review (New)

PROPOSAL

To repeat my proposal in HBD #1087: if you will e-mail me the authors names, titles, publishers, and prices of books that are pub/brewpub/microbrewery guides to your local (state or city), I will compile them and share the results with this forum. (You could also send me oneliners such as "homebrewing is illegal in Georgia" or "there are no brewpubs in Texas." (These sad facts we learned in recent postings.) The book which is the object of the following book review is an example of the sort of guidebook I have in mind. Is doable, yes/no?

BOOK REVIEW

Becker, Bart. SEATTLE BREWS: The Insider's Guide to Neighborhood Alehouses, Brewpubs, & Bars. Anchorage & Seattle: Alaska Northwest Books, 1992. 176 pp., paperback. \$9.95. ISBN: 0-88240-425-3.

Bart Becker has saved me the task of writing such a book -- and deprived me the fun of the research! He also did a better job than I might have done. Besides listing all the pubs, brewpubs and microbreweries in the Seattle area, he includes some basic introductory material on the history of beer, how beer is made, and beer terminology; he also provides a few recipes for food using beer as an ingredient, a list of brewpubs & microbreweries in Oregon, Idaho, Alaska, British Columbia and California, and an appendix giving information on organizations, publications and events. The actual directory listings are given by neighborhood -- which makes it easy for planning pubcrawls!

One feature that makes this guide slightly confusing is that the directory information itself is divided into two separate categories, one part listing brewpubs and microbreweries, and another listing "Alehouses and Bars." However, the book is well indexed, so it is easy to find the entry for a place whose name you already know. For all your folks heading for Portland for the AHA convention, you might consider a side trip to Seattle, truly "The Best Place In America to Drink Beer!" And if you do so, you will find this book the perfect companion to make your way around like a native.

Don't be silly; of course I do not have any monetary interest in the sale of this book. I just wish I had written it. :-)

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Mashout, RIMS

>From: Ed Hitchcock <ECH@ac.dal.ca>
> Jack suggested that the mashout also increases the grain
bed temperature to allow for an easier sparge. This may well be true,
but
I suspect that this would be more important for commercial breweries. A
friend and I compared the extraction rates for two brews, one sparged
with
cold water, the other with hot..

Just for the record, I never made claims that mashout improves yield.
Only
that it would tend to prevent stuck mashes in cases where this could be
a
problem. I tend to agree that, assuming a working system, the yield
depends
primarily on the malt. My last batch was 34/pts/lb/gal and the only
thing I
changed was the malt. I used Belgian Munich.

> (Jack, you seem to get good results, would you mind trying a cold
sparge through the EM and let us know how it turns out?)

Hmmm... That's a bit like asking my wife if she would mind if I brought
another women home. I think I know the answer and am not sure what the
exercise would prove.

I am sure it would work and with the EM, you can stir it anytime and
eliminate set mashes but there is just something about sugar and hot
water
that seems right.

>From: "Bob Jones" <bjones@novax.llnl.gov> on RIMS...

Reading the article in Zymurgy on RIMS put me to sleep and the question
of
"why" kept haunting my dreams. Now that someone seems to have made it
work,
I still ask, "why"? It seems a bit like a computer controlled, laser
guided
nail clipper. Would someone please tell me what the benefits are
supposed to
be?

Subject: Belgium

I've been wanting to find an excuse to check out the Belgian brews real close up, and recently someone told me there was some kind of brewfest that occurs once every five years called the Leeven Festival (his spelling) and that it was about 10 Km out of Brussels. I can find a town called Leuven northeast of Brussels and am hoping this is the right place. Anyway, if anyone has any info on this (its supposed to be in late May) I would really like to hear about it.

And as long as I'm there:-) I might as well see as much of the brewscape as I can, so any hints on good places to go or routes or whatever will be greatly appreciated. How do you go about dragging back beers? Should I consider renting a car (or a truck and a driver?).

Subject: cooker conversion summary available...

Greetings All,

Last month I groveled in the following manner...

```
> I have a question about cajun cookers. I have put an addition
> on the ol' homestead, and moved the laundry room into the addition.
> I now want to turn the old laundry room into my brewery :-[>
>
> I have a double sink, a floor drain, and the gas line and vent from
> the dryer. What I want to do is convert my cajun cooker from a propane
> unit into a natural gas unit. Can I do this?? If so, does anyone
> know what is involved? How much it might cost?? Where to get parts??
>
> Any help would be very welcome!!!
>
> Thanks,
```

Well, I recieved many responses...many more than I expected :-D
I would like to thank everyone personally, but, there are too many!!!
So, you know who you are....THANKS, THANKS, and more THANKS!!!
I am in the process of preparing a summary and will send it to whoever
wants it. I guess this thread was covered over the summer (before I
started reading HBD) so I won't waste any more bandwidth posting the
whole
summary. So if you want it, send email to the address below, with a
subject
of "cooker summary", and I will forward it to you.

See all you CBS/BOSS members at the Goose tonight.

Again...many thanks to all!!

```

I didn't boil or anything, and had no trouble. But I was careful about
handling
the seeds. I didn't roll `em around in my hands or anything. I cracked
`em
open with my coffee grinder -- you could crush with a heavy glass on a
cutting
board, rolling-pin style. I think some people microwave their dry-herbs
to try
to kill nasties. I can't comment on the effectiveness of this. I
counted on
careful handling and the alcohol. Its probably nothing to worry about.

Subject: Fastest Homebrewer/dry beer

Subject: Time:9:51 AM

OFFICE MEMO Fastest Homebrewer/dry beer Date:3/3/93
I have just discovered the ultimate in quick homebrewed beer. I can, with this product make beer in 30 seconds, thus I think I deserve the title of World's Ultra-Fastest Homebrewer. The product is South Hills BEER flavored Dry Beverage. All you do is add water and presto....beer! You can make it any alcoholic strength you want by adding alcohol. You can make it alcohol free and be socially acceptable. This is the ultimate in dry beer. Just pour the powder on your tongue (anyone else ever eat a Fizzie?).

Other marketing claims tell us this product has "micro-brewery taste". Hummm, I wonder which micro? "This refreshing drink will help revitalize the weary by providing carbohydrates necessary to lift the spirit and move the body" (move over George Clinton). "You may enjoy this beverage with or without alcohol. If adding alcohol, please do not drive or undertake activities requiring sharp, mental acuity." What, we need warnings on products that contain no alcohol, but can have alcohol added? Next I expect warnings on orange juice, coffee, Kool-aid.....

Ingredients: Maltodextrine, natural and artificial beer and malt flavors, dried beer, and corn syrup solids.

This is made for the backpacking and mountaineering set in mind. Cost is \$1.59 for 8oz which comes to a whopping \$127.20 for 5 gallons.

Now for the product review. I prepared it according to package instructions, adding the package (less the small amount that I ate dry) to 1 cup of cold water (the colder, the better), and waited for the "head" to go down. I also waited for the large floating blobs to dissolve. The batch was divided in half and the recommended 1/2 tablespoon of grain alcohol was added to one.

Dry: Slightly sweet, sour and effervescent. Fun and pleasant.

Non-alcohol: Slightly cloudy. Aroma is that of licorice, no hops, no malt. Low carbonation. Taste is thin, sour with some lemon notes. Not at all beer-like. Drain food.

Alcohol: Same appearance as NA version. Alcohol present in nose with licorice. Low carbonation. Flavor is flat, the alcohol predominates over the sour, lemon flavor. Drain food.

Overall impression: a waste of perfectly good water.

I'm glad I didn't make a 5 gal batch! I guess that I will go back to more time consuming methods:-)

DanMcC

Subject: Starting that siphon!!

What I usually do is use a sanitized turkey baster to start my siphon... it's kinda hard to explain, but I usually wind up with the turkey baster full of beer and the hose too (wich is good)...

I usually suck, then let it sit for a second, then squeeze to purge the air, then suck again, let it settle, then squeeze...

now, if you keep your mind out of the gutter, we should be all set :)

it helps if the baster is at the level you are going to siphon to...

this should get the hose full of beer, then rip the baster out and away you go... and of course, empty the baster full of beer into the carboy.

From: Jim Busch <busch@daacdev1.stx.com>
Subject: efficient propane burners

Since this burner thread has started up, I thought I would share my experience with building a propane fed direct fired burner unit. My problem was to find a efficient variable output burner to both heat the mash tun through various steps without carmelizing the mash, and also be used to quickly heat large volumes of water or wort. I was aware of the Solarflo corporation from a comment in Bill Owens pamphlet on building a brewery. I got the brochure from solarflo (22901 Aurora Rd, Bedford Heights, OH, 44146, 216-439-1680) and discovered a large selection of slotted cap and impinged burners. These units are made of cast iron and feature air venting that ensures even burning and optimum combustion. The burners are very impressive units, incorporating numerous geometries and numbers of jets available. This kind of product is not cheap, the unit I selected has 24 slotted cap jets on a 10.5 inch disk. This unit ran approx \$160. I do believe it is worth the cost for larger applications. All you need other than the burner is a propane ball valve, regulator, tank and a connection means, I used 1/2 inch refridge copper tubing flared onto 1/2 inch black iron pipe. The real nice thing about this design is that it is flexible, I can lower or raise the burner height or I can adjust the flame BTUs using the Ball valve. During mashing, the distributed flame front from 24 jets allows me to rapidly raise temp without carmelization. It will also boil over my wort kettle if I let it.

Thanks to the people who responded to my filtering question, I am gathering the necessary elements and will post a synopsis when complete.

Good Brewing,

Subject: Alcohol Free -- Can It Be Done?

Dear Homebrewers,
Here's a challenge for you. I'm an avid beer lover who has been told that I may not consume alcohol anymore for medical reasons. The current cast of non-alcoholic brews pales (no relation to ales) in comparison with the variety and quality of microbrew and macrobrew available for consumption. To date I have found only one non-alcoholic brew which has any hops flavor at all and this is Freeport USA made by the FX Matt Brewing Co of Utica, NY. My question then is twofold: 1) Do you know of any other non-alcoholic brews of any quality? 2) Can one homebrew a non-alcoholic beer? (short of brewing, distilling, and recarbonating) Are there solutions which do not involve huge capital expenditures? Are there yeasts which produce CO2 but not EtOH? Any info you have will help.
Thanks In Advance,
Jim Lando

From: haney@soul.ampex.com (Kenneth Haney)
Subject: First all grain

Hi all,

Well I finally took the plunge and tried an all-grain beer. I am so excited I just had to post it. Everything seemed to go amazingly smooth without any real hic-ups. I think I need to make a bigger lauter-tun, the one I've been using for partial mashes just isn't big enough, the grain comes to the top of the bucket. Anyway here is my first attempt.

9 lbs. Munton & Fison Lager (purchased precrushed, don't have a mill)
1/2 lbs. same grain toasted for 10 min at 350 in oven
1/2 lbs. Munton & Fison Crystal Malt (No idea about L. rating)
1 oz. Kent Goldings 60 min boil
1/2 oz. Hershbacher Hallertau (sp??) 30 min boil
1/2 oz. Hersh. Hall. 10 min boil
pinch Irish Moss 10 min boil
1 pk Edme dry yeast

I used a step mash ala THCOHB. Lauter-tun got filled up to the top with grain so there was no way to keep sparge water above the grain bed, still seemed to go smooth. I only have small pots so I had to use 4 of them to hold and boil all of the wort. I also split up the hops between the pots so they all got some. I chilled with my new immersion chiller thanks to a none brewer friend that found a copper coil in his travels and gave it to me. Boy it sure beats the cold bath tub bit. It is now fermenting as we speak.

I am going to have to get a big boiling pot some day. I do have a cooler to convert to a mash/lauter-tun. Does anyone have any suggestions about what to do to convert it?????

I sure hope this batch turns out OK, because it sure was fun and not as hard as I had always thought it would be.

Subject: Brewcap, Korea Malt, Chinook

Mike gildner asks about brewcaps. They are cheap and very useful for starting siphons. My preferred method is sucking on the brewcap when racking to a carboy with the cap on the receiving part of the siphon. Other than that just suck. Starting siphons is not all that likely to infect a batch. I am convinced all the handling while filling the siphone with water is more risky. Swill your mouth with hard liquor before starting it, if you are concerned.

It is interesting about the Korean malt as I noticed it in an oriental food store around the same time as the original mention here. It was very pale and cheap so flour seems like the likely explanation. I used to use a cheap dried malt extract that I got at a health food store for brewing. It was dark and relatively cheap. However, my girlfriend had a reaction to beer made with it, and it made Laaglander seem fermentable. I still have some for straters, but since I started canning boil dregs I haven't used it.

I have been using Chinook hops as bittering hops, and have been a little disturbed by a slightly unpleasent aftertaste from beers brewed with them. I have heard some criticism of this hop variety. Am I seeing the effect of it? If so can someone recommend a palatable high alpha bittering hop.

Subject: INDEX, BS, Ranching

I noticed in yesterday's index that I had sent two messages to the Digest, subject Maltmill, which I did not. Fortunately, they did not appear in the body and I gather that Rob's Automagical software can sort out cc's from email but somehow they stick in the index.

>From: bradley@adx.adelphi.edu (Rob Bradley)
>Subject: Brown sugar.....

>Some beers, especially British ones, are brewed with small amounts of brown sugar.

If brown sugar gives you the taste you are looking for, then Reinheightsgbot be damned. However, you should know that "brown sugar" in the U.S. (thanks to the good old FDA again) is nothing but refined white sugar with molasses added. If you don't believe it, try it. I made some when I first heard this and have not bought brown sugar since.

The point is, if you only want the flavor contributed by brown sugar you might consider just using molasses and leaving out the sugar. You also have a much wider range of flavors in molasses than you do in brown sugar.

>From: atl@kpc.com
>Subject: Re: Yeast Ranching

I dealt with most of this in email but here are a few comments that may be of interest to others...

> You may have a point on simplicity, but I had more faith in the "canned" wort keeping for a long period of time at room temperature.

You run the risk of the neck and mouth of the jar contaminating the wort as you pour it out. I put my pint in the fridge and PC just before use if I need to use it directly.

> I'm not sure which flask you are referring to. I use flasks for growing my starters, but I don't boil at that point. I pour sterile, canned wort into the sanitized flask, stir in a small sample of yeast, and affix a sanitized plastic airlock.

If you use a glass airlock, you can sterilize the wort, flask and airlock all at the same time. When the wort comes to a boil, put on the lock and the

steam sterilizes and fills the lock with sterile water.

I am not trying to be hard to get along with, just hate to see people re-inventing the wheel.

> Can you give me the asian name(s) for this? I can just imagine going into my local asian grocery and trying to describe agar. :-)

Strangely enough, they call it agar agar. If you just say agar, you get a blank stare.

From: SCHREMPP_MIKE/HP4200_42@pollux.svale.hp.com
Subject: siphon starting

Here's the best siphon starting techniques I've found:

1. Put a racking tube on both ends of the siphon hose. It makes it a lot easier to handle, and helps with step 2.
2. Put a short piece (6") of siphon tube on the out-end of the thing.
3. Sterilize the whole mess.
4. Put the input end into the wort (or whatever). Hold the output end racking tube up so the siphon hose is in the air as high as possible.
5. Suck on the out-end to draw liquid up to the top of the upraised siphon.
6. Bring the siphon tube down, but keep the out end of the tube above the level of the liquid (the rest is below the liquid level).
7. Pull off the 6" piece off the end so your mouth-nasties are not going into your beer.
8. Put the out end where you want the wort to go and then lower it below the level of the liquid.

This really works. My spilled wort coefficient has dropped dramatically with this procedure. Finding a 6" piece of tubing with a slightly bigger diameter than typical tubing makes it easier to take off when the time comes.

Subject: Opaline phytoliths and hop rash

Spring is coming and all of us hop growers are getting excited. I just got an answer to a question about hops that had been puzzling me since last harvest. Some of us hop pickers get a red rash and irritation on the backs of hands and inside of forearms when picking hops. There was some speculation last fall about the cause of this: plant juices, resins, the sticky things on the bines, etc.

Last week I had a visit from my friend Ryan Drum, the second homebrewer after my Uncle Charlie that I knew. In addition to brewing, Ryan is also a botanist and skilled in electron microscopy. His explanation of the hop rash is that the stems are covered with tiny needle-like mineral bodies called opaline phytoliths (sp?) These are broken off and get lodged in the skin, just like fiber-glass insulation. The little cuts in the skin are raw and open to further irritation from sweat or other nasties.

Ryan says that nettles have a similar phytolith and this is how the nasty oil gets into our skin when we brush against them. He mentioned hops, nettles and cannabis as all having this kind of needle-like phytoliths. A long time ago he classified plants by their phytoliths and used this to examine coprolites (fossil stools) to determine diets....

Paul.

Subject: brown sugar or caramel malt?

In yesterday's digest Rob Bradley stated he found the "brown sugar aroma" in a beer made with malt only, no brown sugar. For several years I was under the impression that you needed brown sugar or molasses (Treacle) to get that flavor and aroma and assumed that the English ales which have that aroma do indeed use these adjuncts. like Rob, i now wonder if I haven't been mistaken. what tipped me off was my first sniff of crushed Special B malt, a belgian crystal (caramel) malt of about 200 degrees lovibond. i've used this malt is several ales now and it does indeed impart something very similar to the 'brown sugar aroma' that Rob refers to.

so my question is, does anyone have DIRECT knowledge as to which English ales use adjuncts such as brown sugar or treacle? i wonder if some of the ones which we think use these are actually using very dark crystal malts similar to special B. does anyone know if there are very dark english crystal malts which are unavailable in the U.S.

From: Daniel Butler-Ehle <DWBUTLER@MTUS5.cts.mtu.edu>
Subject: BrewCap

To Mike Gildner <gildner@mml.mmc.com> who asked about the BrewCap:

BrewCap doesn't really make it easier to take samples. You have two tubes: one reaches up to the bottom of the inverted carboy to allow CO2 and kraeusen to escape, and the other collects yeast. In order to get a sample of the beer, you have two choices:

1) Empty all the yeast out of the yeast collection tube and let it drain until you have clear beer coming out. But the instructions say never to remove ALL the yeast from the tube. If you do this, you may cause the water trap liquid in the tube to get sucked up into the carboy.

or

2) Drain the water from the larger tube (the blowoff tube), cap it, and shake the carboy until enough beer splashes up into the end of the rigid tube inside the carboy. This gives a clearer sample than (1).

I've only used my BrewCap once. It works well, but it'll take a little getting used to. Maybe I'll use it on one of my beers next week. It should be great for repitching yeast when batches overlap because of the yeast collection tube; it's easy to remove a large sample of freshly-settled yeast.

It took me two years to get around to using BrewCap after I bought it. The main reason is that it requires that I have some way to hold a carboy upsidedown without resting it on its neck. I took a bunch of backpack straps and sewed them together in such a way that they can hold an inverted carboy by the shoulders. I then hung this setup in an upsidedown steel kitchen stool.

From: tony@spss.com (Tony Babinec)
Subject: sugar in English beers/other thoughts

A perusal of Roger Protz's "Real Ale Drinker's Almanac" indicates that a substantial fraction of English ale recipes employ adjuncts and additives such as sugar, molasses, treacle, caramel, flaked maize, and occasionally flaked wheat. Somewhere -- it may be in Terry Foster's "Porter" -- I read that in the 19th century English producers were encouraged by the Government to use sugar. Was this an effort by the Government to encourage the home island to patronize the colonial sources of sugar? In any event, the smoothness and lightness of body contributed by the adjuncts might make the preferred "session beers" less filling to the palate, thereby encouraging the quaffing of another pint. While I don't know the relative prices, it could be (and might have been) that the cost of ingredients for such a beer might be less than if it were an all-malt beer. And, the unfermentables in the less-refined sugars would contribute to aroma and flavor.

I agree with Rob Bradley that as novices we learn to stay away from sugar, but that it nonetheless has its place. So, by all means, experiment with sugars in your ales.

On Bass Ale, they are quite secretive about their process and ingredients. None of the publications I've seen, such as the Roger Protz books, say anything about ingredients such as the hops used, because the brewer isn't telling.

It also seems that an important contributor to flavor, aroma, and palate is the yeast used, and also the fermentation temperature. John The Hop Devil ("More malt, More hops"), I'd love to take some of that Fuller's yeast off your hands!

Subject: hop aroma / real ale

Donald O'Connor's comments about dry hopping made me think about what the Brit's call "Real Ale". I believe this term is intended to describe ale that has been dry hopped, and that has finished fermentation/conditioning in the keg. Since this is done under pressure, this may explain the English folks' love of real ale. Actually, it probably doesn't imply dry-hopping as much as leaving hops in the keg (perhaps left from the boil), but in either case, more hop aroma would be retained in this situation.

Cheers,
Norm

Before I switched to Wyeast I used Nottingham Ale yeast quite a lot. Generally I had very good results except for two successive batches that produced a very strange flavor strongly reminiscent of that found in German wheat beers. In fact, one person who tasted it said that brewers strive to get this flavor. Well, in a pale ale it's rather out of character. I don't know why this happened. It could have been higher than normal brew temperatures (done in summer) or a contaminated batch. At any rate, I switched to Wyeast after that and haven't had any more problems. Reusing slurry from the secondary cuts down the extra cast involved.

As an aside, 1056 is REALLY attenuative! My latest was fermented with slurry from the previous (which used 1056 from the packet, via a starter)

.
In 3 days the SG went from 1.042 to 1.008. I've heard it becomes even more attenuative with successive mutations, too.

Peter

Subject: more info on British pubs

Hi all

I too would like to appeal to all you worldly people and locals out there. Someone posted a request for recommended English pubs and brewpubs of London some time ago. I will also be in London in the next couple of weeks. But I will also be elsewhere on the island. I plan to visit all type of places in the south of England concentrating on the Portsmouth and Bournemouth areas. I have plans to go to Bristol and Exeter. Just about anywhere in the southern half of the country is fare game.

So, if any of you have any experiences you would like to share, I would like to hear them. So far the only brewery I plan to visit/tour is the Eldridge Pope brewery. Hope they have a tasting room somewhere :). You can post privately to me, or send it to the digest. There is bound to be someone out there besides me that would find any info useful.

thanks
scott

Subject: Finings / Starter Wort

A recent post asked about the use of Polyclar as finings when to add and how much. I would warn against using Polyclar immediately after racking to the secondary. Both my self and a fellow brewer were experiencing high levels of diacetyl in our beers. One of the causes was the addition of Polyclar immediately into the secondary. This caused the yeast to fall out of suspension before it worked on reducing the diacetyl caused by pitching at too high a temp. 1 to 1.5 tsp is plenty to add to the secondary after a couple days of "diacetyl rest".

Starter Wort: I use the following technique for producing starter wort. After racking off the trub I add a gallon of very cold water to the trub. I let the trub, wort, hop particles settle and siphon the clear liquid in to clean bottles which I immerse in boiling water for 30 minutes. I cap these and refridgerate. This produces a starter of about 20 to 25 sg points. I was led to believe that starters should not be high gravity since yeast mutation could occur as the alchol level rises. Is this a valid assumption?

Subject: Pectate enzyme

I have a very short question regarding the use of pectate enzyme. As I understand it, this enzyme can be used to break down the pectate that will set as a result of boiling a fruit, preventing the set pectate from clouding beer.

My question(s) are these: Is that statement above correct? At what point in the process is this enzyme added to the wort? (Before, after boil, in secondary...) How much is necessary?

I'm planning to use this in a cherry beer that I am making. Actually, the beer is already fermenting, and I'm planning to add the crushed cherries in a couple of days. To avoid nasties, I'd like to boil the fruit before it's added to the fermentation.

Thanks for any help,
Chuck

Subject: Yeast Starter Questions

Greetings all...

I have a couple quick questions about yeast starters and survivability. First, can yeast survive being frozen for long periods of time? Does it depend on the type of yeast used? If so, does anyone have info on what type work and what types don't? Second, and health-store type Brewer's Yeast be used as a yeast nutrient? It would seem reasonable to me, since brewers yeast is killed yeast, so it should have all the things yeast wants, in all the right quantities. Now, here is what I want to do... I want to get good yeast, and make a large patch of starter which is then frozen. Then, whenever I go to add yeast to my wort or must, I just 'chip' some yeast off of my starter ice block, re-start it in a glass or jar, and add that to the wort or must. This would decrease my expense for yeast a good bit, and would be easier than trying to keep active growth going for-bloody-ever (not to mention that this would avoid all the problems with mutation). So, what do people think? If no one has an answer, I will try it out myself...

Also, to all the people I promised a review of my medieval brewing techniques to, sorry that it's taking so long, but I'm writing it up, and I'm currently bogged down at school, so...

Subject: Attention Grain-Brewing, Would Be Control Freaks

My feelings concerning the ridiculous running debate over AG vs. ME brewing (I can resist no longer):

You cretins have got it all wrong! The beauty of grain brewing lies not in gaining control, but in relinquishing control! Once I brewed extract beers, and they were good, but they all tasted more or less the same. Any changes in character (body, bitterness, color, strength, aroma, etc.) were totally predictable, based on my simple alterations in the recipe. There was absolutely no surprise (read adventure) in cracking a new batch. Now I grain brew exclusively, because every batch is a totally new experience. Burners, brewpots, lauter tuns, thermostatically controlled immersion heaters, circulators, chillers, every new piece of paraphenalia I employ only adds another variable and source of unpredictable complexity to my brews. Call it the Heidelberg Uncertainty Principle of brewing. My beers just get better and better, no two taste the same (regardless of using the same recipe), and, best of all, none of them tastes remotely like a commercial product. If my objective was to gradually perfect some imitation of a "classic style" by trial and error repetition, I'd buy a case of Pilsner Urquell or Guinness Extra Stout, scrape off the labels, and spend all my weekends fishing! What do you people consider to be fine art, paint by the numbers? Grain brewing allows you to unleash the infinite variability of grain combinations, complex carbohydrates, protein interactions, acid-base and redox biochemistry. The result is like ice sculpture: You can marvel at it, savor it, and enjoy it in different lights, but you can't put it in a museum. If you think grain brewing gives you more control over the finished product, you're seriously deluded. If that is what you're after, you are also missing the point.

From: roman@tix.timeplex.com (Daniel Roman)
Subject: Clear beer

Apparently Miller and some others are trying to go after a "younger" market as well as trying to go after women. They define "younger" as 21-25 ;-). Anyway, following on the coattails of the light beer wave and then the dry beer wave and now Crystal Pepsi, clear beer had to be next.

Think of it as marketing genius for the big boys to make even more money with an even more tasteless product. They won't have to spend much money on malt, just more rice and corn (remember the Bud commercial "It's the rice"). They'll charge the same price and end up with something that tastes more like Perrier than Coors light does now but has as much alcohol as a light beer.

Hopefully the FDA (or whoever is in charge of this kind of thing) won't allow them to call it beer anymore. It's really gonna give beer a bad name (or at least "WATER" down the definition of "beer"). My suggestion for a name would be "Alcoholized Seltzer". I don't know why they just don't go ahead and make seltzer by artificially carbonating it and then just add some grain alcohol, that's gotta be cheaper than going through the trouble of brewing it.

I certainly don't expect anyone to get into homebrewing to make "clear beer".

Subject: Sugar and real ale

Speaking as a Brit familiar with local brews and breweries:

Many, but by no means all, UK breweries use small amounts of caramel or brown sugar to colour their beers. I've never heard of it being used for flavour. Other breweries use none at all and would be insulted if you suggested they did, so be careful how you ask. They use larger quantities of crystal malt instead. I can only obtain one type of crystal malt for homebrewing and it adds a lot of colour and flavour. Darker types don't seem at all common. I have a vague notion cara pils is a pale crystal malt. It is certainly not commonly used in British beers.

The excessive use of sugar in brewing is generally regarded in the UK with the same contempt and disgust as elsewhere. Only mega marketing muck makers do it, to cut costs and to hell with quality.

Real Ale in the UK is beer which has not been filtered, pasteurised or pressurised, and which is allowed to condition in the barrel. Air is drawn in as it is served, so its shelf life is 4 days max. If any hops are present they will be fresh hops added to the barrel when the beer is racked, they would NEVER be spent hops from the boil.

Some UK pubs pressurise the beer with CO2 to force it to the bar. Others keep it under a CO2 blanket to extend shelf life. The former is called "top pressure" and the latter "blanket pressure". Purists condemn both methods and say beers kept in this way are not real. CO2 adds an unpleasant prickle to real ale, though this is usually only evedent when top pressure is used. Normally real ale is handpumped. If the beer is served through a tap (or switch) or if the handpump is pulled back and left while the beer runs out, ask if they are using an electric pump or top pressure. The former is OK, the latter often is not.

PS please don't refer to England or English when you mean Britain or British. It upsets the natives no end.

From: eisen@kopf.HQ.Ileaf.COM (Carl West)
Subject: Beer on a stick (was BrewCap)

Dan sez:

It took me two years to get around to using BrewCap after I bought it.
The main reason is that it requires that I have some way to hold a
carboy upsidedown without resting it on its neck.

Took me a little while too.

My suggestion:

- Stand a 5' or 6' 2x4 on end,
- Drill a hole through the top end,
- Drill another hole through it about a foot down from the first hole,
- Run each of 2 lengths of rope through the holes,
- Tie a loop in the lower rope that will hold the neck of your inverted carboy (experiment with an empty carboy),
- Tie the upper rope around the erstwhile base of the carboy, make sure that it won't slip off, if it can, re-drill one of the holes so that the ropes will be closer together,

At Brewing Time:

- Set your full carboy on the floor,
- Invert the 2x4,
- Hook the neck-loop on the neck of the carboy (watch the hoses),
- Tie the base-rope really tight,
- Holding onto the carboy, pick up the whole operation, turn it over, and rest the 2x4 on the floor (keep it balanced),
- Lean it in a corner, make sure the 2x4 won't slip, and put a bag over it.

The hoses will hang down as straight as you please and the rotary shaking to move the yeast into the neck is easy.
I hung a gallon jug further down the 2x4 to serve as the blowoff/airlock, tie this on after it's all set up.

Carl West
Waltham, Mass.

When I stop learning, bury me.

[Kinney, if you like this enough to include it in future instruction sheets, feel free to do so. I'll happily trade good illustrations for another BrewCap or two ;)]

Subject: Dry Hopping, English Beers, Just a Thought

Recent talk of dry hopping has really peaked my curiosity. I would really like to brew an ale with a strong hop nose. I have tried the standard "add at the end of the boil" method but I haven't gotten the results I would like. It seems that dry hopping is the answer, but I don't really know how to do it. The literature I have found has little or no mention of dry hopping, and the only place I have gotten any substantial information has been on HBD. From what I understand all that is really necessary is to add a quality hop plug to the secondary and let sit for a week. Is there something I'm missing? Can you use pellets? Is sanitation a problem? What type of hops are best? Any details would be greatly appreciated.

Recently someone was asking about British beers and pubs (I'm sorry, I don't recall the name). I hope you haven't left yet, you lucky @\$%! My advice is to go to as many different pubs, and try as many different beers as possible. Not only will you expand your beer horizons, but you will probably meet some very interesting people.

A couple of pubs that might be of interest are The Queen's Larder, and the Salisbury, both in London. The Queen's Larder is a small neighborhood pub, simply decorated, with a friendly atmosphere. In addition to the beer, the stilton was very nice also. The Queen's Larder is located in the Bloomsbury section of London, not far from The British Museum. The Salisbury is a much larger and more elegant pub, but they let me in anyway. In addition to the ales they had on tap, they also have some good bottled beer.

In addition to the beers available in England that have already been mentioned, one of my favorites is Flowers Strong Ale. They also make an IPA which is quite good, but IMHO the strong ale is really something special. It is available on tap, at The Sherlock Holmes Pub, located near Trafalgar Square. It's a little touristy, but at this time of year you'll probably meet some of the local chaps. If anyone knows anything more about Flowers Strong Ale, I would appreciate any information.

Finally, if there is something that you read in HBD that you find stupid, useless, inappropriate, ridiculous, etc., why don't you just be an adult and *ignore it* instead of helping to propagate useless threads.

Have Fun!

Subject: Assorted Questions.

I have a DoppleBock fermenting right now that has 'been at it' for about 5 weeks. I used 12 lbs extract, and 1.5 lbs grains in this brew. I also have used a starter culture (With extract, and it works GREAT!). Well, the brew started in about 8 hours after pitching and has been kept at 40 F +/- 7 F for the past 4 weeks and 5 days (two days to ensure fermentation was going well enough, actually just a day and a half). Anyway, I was wondering if anyone would have an idea when this thing will end? I know I should have taken hydrometer readings, but I hate to 'waste' this brew in anyway shape or form. I am using an 's' type air lock and the solution levels are not level and there are still bubbles on the surface of the brew...

My next question pretains to homebrew clubs in the Laramie WY area. My wife has applied to a Ph.D. program there and we would move if she is accepted. So, does anyone know of the 'brew scene' in Laramie?

Much thanks for your efforts to help me out!

Gene in Duluth

From: Jeffers.Wbst129@xerox.com
Subject: Starting that siphon/bottle brushing

I have a very simple method of starting siphons. I use a plastic bottle filler tube with the little spring loaded valve in the bottom. After sterilizing the hose and tubes I rinse them with with very hot tap water. Then I put the bottle filler tube on the end of the siphon hose and rinse the assembly by opening the valve while running hot water through. I then release the valve and have a siphon hose and tube full of water. I attach the pickup tube empty and put it into the carboy. I start the siphon by pushing the bottle filler tube against the bottom of an empty bowl until the beer strts to come out. I then use one of these large black paper clamps to hold it against the bottom of my bottling bucket so my hand doesn't get tired. The flow through the bottle filler is slower but it is ever so easy to control.

Whenever I was brushing away at my bottles my mind would be dreaming of automatic bottle washers and automated spinning brushes and stuff of that sort.

I was also a little paranoid that my little bottle brush has to be coaxed to hit all the inside surfaces of the bottle. Well one day a simple idea struck me. I got a wine bottle brush, cut the loop off the end and chucked it up in my battery powered drill. The bigger diameter brush is a little harder to push in but it seems to have a better chance of hitting all of the corners. Now I power brush my bottles right in the sanitizing solution. I just have to hold the bottle to keep it from spinning, cram the brush in, pull the trigger, wobble it around as I run it down and up. I have used this on 8 or 9 batches and it is much easier. Please note that 110v drills could be dangerous if they were used in this manner.

From: Jeff Frane <70670.2067@compuserve.com>
Subject: Sugar

Jack is right* about American brown sugar, one of the reasons I find it inappropriate for ales. Much closer, I believe, is something called Turbinado sugar, which I pick up at the health food store -- this is a raw brown sugar, with a very different consistency than "brown sugar" from the supermarket.

Incidentally, H L Hind's brewing text, written in Britain in the 1930s, gives representative grists for a variety of beers. He offers grain bills for pale ales with and without sugar (more with, I recall, than without). Relying on memory at the moment, it seems that there is a good deal of discussion about various forms of sugar and that "invert" sugar is preferred.

====

In reference to the production of "continental" aroma characteristics, I've found in a recent brew that a small amount of fresh Mt Hood pellets, added at the end of the boil gave the beer an astonishing Hallertau nose -- exactly like a good German lager. In larger quantities Mt Hood has its own distinctive aroma, but at this level, about 1/2 oz/5 gallons, it is easy to see why it was developed as a replacement for German Hallertau mittelfreuh.

> OK. I couldnt believe it, but, alas, it was on NPR. Miller will soon
> be offering a clear beer! Anyone got any details?

lencell@unmc.edu (Lance Encell) writes:
> anybody hear about Miller coming out with a "clear" beer?
> Can you believe it?

I have in front of me the Food section from the March 3, 1993 Boston
Globe.
It has an article on colorless drinks and how well they are selling. It
mentions that Miller is working on one and that Coors "is test marketing
a new product called Zima ClearMalt, which looks like a barbershop tonic,
is meant to be drunk like beer, but tastes of gin." Yuch, I think I'll
give
them a pass.

The article (which is primarily about clear soft drinks) goes on to
state:
"It's the biggest marketing fad since the 'lite' craze of the '80s." And
we all know the 'lite craze' improved American beers.

>
>-- End of excerpt from Norm Pyle

Well, not really. Real Ale doesn't have to be dry hopped and solids from
the boil usually won't find their way into the barrel. Real Ale means
the
beer undergoes a secondary fermentation in the barrel (or bottle) and is
served without the use of external pressure. The word "keg" is frowned
upon by Real Ale aficionados because it means a closed system effectively
preventing any secondary fermentation. To an Englishman, "keg beer"
equates
to dead beer, pasteurized and pumped full of CO2 at the brewery/factory,
as popularized by beers like Watneys' Red Barrel in the 60s.

"Cask conditioned" ale requires the skill of the cellarman in overseeing
the fermentation after the barrel is delivered to the pub. This involves
the use of soft (porous) and hard (non-permeable) wooden plugs, called
"spiles" to "vent" the barrel to control the fermentation, the level of
carbonation and the contact with oxygen from the air. Real Ales are
usually pumped from the barrel because there is insufficient pressure in
it to propel the beer from inside. Hence, the beautiful sight of a set
of ornamental handpumps sprouting from the bar of many British pubs.
Electric pumps are fine too, as long as they draw the beer from the cask.
"Gravity dispense" involves placing the glass under the tap on the barrel
itself - the most natural way of serving a pint!

Of course, many British Real Ales are dry-hopped. This usually involves
adding a handful of fresh hops at the brewery, just before the barrel is
sent to the pub.

Subject: Isn't Chinook an Army helicopter?

In HOMEBREW Digest #1090 Ulick Stafford writes:

> I have been using Chinook hops as bittering hops, and have been a
little
> disturbed by a slightly unpleasent aftertaste from beers brewed with
> them. I have heard some criticism of this hop variety. Am I seeing
the
> effect of it? If so can someone recommend a palatable high alpha
bittering
> hop.

A few weeks back I solicited opinions of Chinook hops for flavor/aroma.
Summary of responses: Joseph Nall said that they were disdained for
their flavor/aroma, and recommends Centennial instead. Jack Schmidling
uses them extensively for bittering and flavor, and finds them excellent
for both uses. Scott Barrett (earlier private communication) had seen
them described as "spicy." A couple of months ago, Al Korzonis posted
Alpha and Beta acid information from Hopunion for many hop varieties.
[Enter fallible memory mode] Somewhere, the argument was made that high
Alpha bittering hops can leave harsh overtones because the Alpha/Beta
ratio is much higher than it is for the noble hops (about 1.0). By this
meric, Galena would be a better choice, though not as good as sticking
to noble varieties.

My interest in Chinooks originated with a first year harvest of almost
12 ounces. I brewed a pale ale hopped solely with home grown Chinook
hops to educate my palate. It was a generic 1.060 SG pale wort with:
(full 5 gal. boil) 3/4oz. at 60 min, 1/2oz. at 30 min, 1/2oz. at 2 min
and 1/2oz. for dryhopping in the secondary. I found the flavor to be
unusual, but not unpleasant - pretty mild hop character considering
the IBU that I had calculated (about 55, assuming Alpha=12). This
was such a popular brew that the second part of the experiment (the
effect of aging) had to be abandoned. What would be nice would be a
reference to a commercial brew X, where, say,
brew X : ChinookasAnchor Liberty Ale : Cascades.

Ah, well, back to experiments.

I'm no biologist either, but how's this: if you have the means to
generate and manage it, wouldn't live steam make a reasonable and
"green" sanitizing agent? Of course, it's just as nasty to, say, human
skin as it is to nasty-bugs, but like I said, you'd need some way to
manage it.

Biologists? Environmental Engineers? Plumbers? Rank amateurs?

Actually, the peracetic acid idea doesn't sound too bad. Wonder what
the Aldrich catalog has to say... (Yes, Mike, I'll be giving it back
to you any day now.)

have fun

Subject: My Current RIMS setup

I have been a RIMS nut/experimenter since I first read Rodney's article in Zymurgy. I've used coolers, kegs, and any other container I could find to experiment.

My batch size has always been 10 gallons, and I have occasionally run into the grain bed compaction problem described by others.

I have done two things over the last few months which have helped considerably:

- (1) I started using a roller mill (yes, the infamous MM - if you put aside all the arm-waving and frothing at the mouth, it is a very good mill for the money).

My corona always seemed to produce some amount of flour, depending on how good my adjustment was. Sometimes, this flour would make a paste and clog my screen at the bottom of the mash/lauter tun.

This problem went away when I started using the roller mill.

- (2) My current mash/lauter tun is a 1/2 barrel keg with the top cut off and a drain pipe in the bottom, with a SS screen false bottom. When I start a batch, I place a "tube" formed by rolling up some SS screen in the center of the keg, resting on top of the false bottom. The diameter of the tube is about 3-4 inches. The mash is placed around the outside of the screen tube, so from a top view, it looks like a donut.

The recirculating wort now flows through the screen in the middle as well as through the bottom. Since the primary goal during the mash phase is to control temperature, it really doesn't matter that the flow is not uniform through the grain bed any more. The temperature seems to be reasonably uniform through the mash, and no compaction occurs.

Also, by having the return flow from the pump exit below the surface of the wort, I no longer have any foaming. That hopefully reduces HSE.

At sparge time, I simply reduce the flow way down, pull the tube out, and give the mash a gentle stir. After about 5-10 minutes, the wort is running clear again. I then turn the pump off, start the pre-heated sparge water flowing in at about the same rate as the wort drains out the bottom.

I have about 5 batches under my belt (figuratively and literally) using this setup, and it seems to work well.

I hope this helps give someone more ideas to keep improving the RIMS technology. More personal equipment experiences would really help the s/n ratio on the digest. One does not have to agree or approve of someone else's methods to gain benefit (food for thought) from them.

I would be very interested in hearing about what type of temperature controls anyone is using with a RIMS setup.

Subject: Re: siphon starting/Edme... yikes!

My method for sanitizing my racking setup and siphoning:

1. Fill the priming vessel (usually a carboy) with sanitizing solution.
2. Fill the racking tube/hose with tapwater and close the plastic hose clamp
3. Dip the racking tube into the priming vessel, put the out-end of the setup into a small bowl or pitcher, place this lower than the level of the top of the sanitizing solution, open the clamp and siphon some of the sanitizing solution till you get the small bowl 3/4 full. Close the hose clamp.
4. Let this sit for 10-15 minutes to sanitize the inside of the tubes, the outside of the racking cane and the last foot or two of the out-end of the hose.
5. Remove the setup from the priming vessel and the bowl and rinse off the outside in hot water.
6. Hand it to your brew-partner to hold by the "safe-to-touch" areas (the areas that will not be in touch with the beer) or place it down on a previously sanitized place (I hang mine from the ceiling by a loop of string -- touching only at the "safe-to-touch" areas).
7. Dump the sanitizing solution into a large bucket (I ususally use my old plastic fermenter for this) just in case you need to re-sanitize. Rinse the priming vessel and add your priming solution to it.
8. Pour some hot water (or boiled water if your water has bacterial problems) into a vessel and place the in-end of the racking tube (the racking cane, in my case) into this water. Lower the out-end below the level of the water and run the siphon for a few minutes to rinse out the sanitizing solution. Make sure stop the siphon (close the hose clamp) before you run out of water.
9. Move the in-end of the setup into the beer you wish to siphon and the out-end into a slop bucket. Open the hose clamp and run the siphon till it's full of beer. Shut the clamp, move the out-end into the priming vessel and re-open the clamp.
10. By the way, I don't let the siphon run dry at this stage either. When I've finished siphoning the green beer into the priming vessel, I shut off the clamp, raise the priming vessel, move the in-end of the setup into the priming vessel, attach a sanitized bottling wand and siphon a few seconds into the slop bucket to purge the un-primed beer out of the setup.

Once I got to be good at this method, I only have to start my siphon once and just use the previous liquid to start the siphon of the liquid I want to siphon. It may sound complicated, but it's not.

I would like to recommend **against** starting a siphon with one's mouth

in the strongest possible way (even if you rinse your mouth out with hard liquor, etc.)... it's an invitation for trouble. I used to use a turkey baster, but it did not have enough volume to start the siphon in one draw, so inevitably, I would blow a bunch of air through my beer -- not good.

Kenneth writes:

>Subject: First all grain

> 9 lbs. Munton & Fison Lager (purchased precrushed, don't have a mill)

> 1/2 lbs. Munton & Fison Crystal Malt (No idea about L. rating)
> 1 oz. Kent Goldings 60 min boil
> 1/2 oz. Hallertauer Hersbrucher 30 min boil
> 1/2 oz. Hall. Hers. 10 min boil
> pinch Irish Moss 10 min boil
> 1 pk Edme dry yeast

I humbly would like to suggest that your beer would improve much more if you switched away from Edme dry yeast. I cringed when at the end of your wonderful ingredient list, I read "Edme dry yeast." If you want to stay with dry yeast, try Lallemand Nottingham, or even better, try Coopers dry yeast.

Subject: Lager starting

In a recent post, I described *one* method that is used to start a lager fermentation, in which the ferment is started at a warmer temperature and then cooled for the main ferment. Jim Busch, in private email pointed out:

><stuff that kills some bacteria" and then raise the temperature. It's sort
><of backwards from one common way to make lagers: to start the batch at
><around 65F and then once the yeast get going, (slowly) lower the temp
>to
><40F or 45F.
>
>I personally believe this is bad advice to those wishing to brew
authentic
>lagers. Yes, starting the ferment at 65F will go a long way toward
>getting the ferment going, but it will adversely affect the flavor
>profile of the finished product.

What Jim means is that esters will be produced and you'll get the fruity flavors of an ale which you would like to avoid in a lager.

>Once the ferment gets going at 65F, the
>thermal energy will push the average internal temp up as much as 10F!
>Unless the brewer has a amazingly efficient attemperation device, the
>"lager ferment" stage would be at high kraeusen around 65-70F until the
>chiller could kick in. It can take as much as three days at 49F to
>reduce the temp into the acceptable range and by this time most of the
>primary ferment will be complete. Also, one does not want to reduce the
>temp below 48F until 90+% of the primary is complete. At this time,
>a two day rest at 42F will be adequate to reduce diacetyl levels, prior
to
>reduction to 31F for lagering. This is another personal nit of mine
that
>I frequently hear homebrewers refer to a 70F diacetyl rest. This is
indeed
>an effective way to "rush ferment" lagers as Professor Narziss has
documented
>very well. But this technique is intended to produce lagers in less
than 21
>days, total time! Even in this method, the primary is carried out at
55-58F
>and not into the 60s.
>
>This is not intended to be a flame, and I think you are doing a good job
>of informing the public of various techniques. I believe the attitude
to
>push the temperature is a result of grossly inadequate pitching
quantities,
>and is a poor substitute for healthy yeast.

He's right. I should probably mentioned the preferred method in which the starter is slowly (to avoid temp shock) cooled to, say, 50F and pitched into 50F wort. Then you can slowly bring the temp down to the 40s if you want. Note that this will give you a much slower start than the method I suggested in my original post and therefore will require much better sanitation, but if it's lager you're after, I recommend (as Jim does)

that you follow the German methods as opposed to the "rush ferments" that the American industrial giants use. Note that fruitiness is also tied to the strain and some are less fruity at warmer temps than others.

Thanks Jim.
Al.

Al says:

>The Coopers is quite fruity fermented at 65F and probably the
>best dry ale yeast I've ever tried. It's not phenolic at all
>and all the flavor is a very clean fruitiness.

My experience with Cooper's is that it has a distinct "bready" character.
I generally use Sierra Nevada cultured from a few Pale Ale bottles. I have substituted Cooper's at times when my starter didn't make the grade. I make a house ale regularly with no modifications to the recipe unless I pitch the Cooper's rather than the SNPA. The Cooper's is much less fruity with more yeast taste or, as I said, "bready". Attenuation seems to be about the same between the two. My house ale has an OG of 1.060 and finishes around 1.018 with both yeasts.

From: "Joe Stone" <JSTONE@SJEVM5.VNET.IBM.COM>
Subject: All-Grain Help/BrewCap

I completed my first all-grain batch about three weeks ago. Two-and-a-half gallons are now bottled. The other two-and-a-half gallons were filtered (0.5-micron "Filter Store" filter) and are now carbonating in a keg in my fridge. I sampled the beer in between the primary and secondary and it had a pronounced "grainy" taste (grainy as in grain husk). Being my first all-grain batch, I severely underestimated the heat-retention capabilities of a Vollrath pot. I combined nine pounds of grain (one pound at a time) with a steady stream of 170oF water. The initial mash temperature was 150oF. In my haste, I immediately applied heat to the mash with a 35K BTU cooker. The Vollrath pot has a SS tooled screen in the bottom. Upon applying heat, the temperature of the water/grain-dust solution below the screen increases rapidly. By the time I could thoroughly stir the mash, the temperature was at 190oF. Oops! Not only did the temperature hit 190oF, but it took a good 45 minutes for the temperature to return to the target range. I was hoping that someone could confirm my seemingly-obvious diagnosis of the "grainy" taste.

I also have a question regarding sparging. I often read of two and three hour sparges. I use an elevated cooker/pot arrangement to bring heated water to the grain bed via a sparge ring. I have good control over the drip-rate. My question involves what is considered appropriate in terms of a sparge rate. With my first all-grain batch mentioned above, I "throttled-back" the flow rate using the spigot in the bottom of the pot. My objective was to sparge for one hour and collect about six-and-a-half gallons of wort. After about 45 minutes, the flow rate had reduced to a trickle (with the spigot now wide open). I would estimate that I collected about four gallons of wort. Does this seem appropriate? Should I be calculating my extraction rate?

I can't imagine a better siphon-starter than a BrewCap. I took a very sharp 0.5" drill bit and drilled out the main stem of the BrewCap. There is a significant amount of excess material between the I.D. and the O.D. of the main stem. I soaked the BrewCap in hot water for a few minutes and inserted my 0.5" O.D. hooked racking tube into this enlarged stem. I slid an 8" piece of tubing over the auxiliary stem into which I simply blow. The siphon starts

every time and your mouth doesn't come anywhere near your beer.

Subject: re: Ginger beer summary

Dave Whitman <rsndww@rohmmaas.com> writes about ginger...

> Many people pointed out that the sweetness of the wort may be masking
the
> ginger flavor...

This is backwards from my experience (and some cooking experience as
well)
- a bit of sweetness usually tends to bring out spices, ginger in
particular.

>...The message is that 1) lots of recipes use about 3 oz of ginger

FWIW, we've used a lot more than that, and had good results. We used
about
9 oz in an amber ale that turned out nicely, and about twice that in a
mead. (these were 5 gal recipes) The amber ale was a prize-winner some
years ago. The mead is still young, hence a bit assertive, and you need
to
calibrate the difference in alcohol content (meads generally being a lot
stronger), but it's not excessive. Don't be too bashful! I'd say you
can
put half a pound of ginger in a serious ale, and a pound in a good mead.

> Jim Grady suggests grating the ginger rather than slicing it. For what
it's
> worth, I tasted the ginger slices after boiling, and they were pretty
> flavorless, suggesting that the flavor was successfully extracted.

That's a good test, but I wonder if you may not have boiled off some part
of the essence? (conjecture only) We have added ginger to the hot wort
or must, then transferred it to the primary and let it stay for at least
the first week or so.

> Spenser Thomas warns that he tried adding pieces of ginger to each
bottle,
> which gave good flavor, but also caused gushing...

Definitely a problem...nucleation points. Anything rough will cause CO2
to
come out of solution rapidly. (It could be a sanitation problem as you
suggested later, but I think not. It's just a matter of providing the
kind
of surface that makes CO2 bubble out.)

> (another) He has added ginger to his secondary, and that doesn't seem
to
> help, and sometimes leads to off-flavors. He speculates the pulp rots,
and
> suggests I try dried, ground ginger.

No, stay with fresh ginger. You lose too much otherwise. I'd suggest
trying to treat it more gently--get it hot enough to sterilize, but don't
boil it.

From: pascal@netcom.com (Richard Childers)
Subject: bikePUBcrawl

Despite suggestions to the contrary, I have decided to go ahead and carry out this bicycle-based pub crawl, as scheduled, this Sunday, 07 March 1993.

I realize that the weather may not prove suitable but my intuition is that it will be a glorious day. Early March in San Francisco usually is.

If anyone cares to skip this bicycle ride, it may happen again, if it proves at all to be successful or reasonably well-attended, in a month or so. It's also possible some other bikePUBcrawls might be scheduled, elsewhere in the Bay Area ...

Those of you without the inclination to bicycle (Russ Wigglesworth, to be precise, but surely others as well) are welcome to meet us at the brewery, within the time range we estimate we'll be arriving within - see below for the approximate schedule.

The destination is the Marin Brewing Company, 'in Larkspur, at 1809 Larkspur Landing Circle(ph# 415.461.4677)', to quote a helpful soul. (Thanks, PDK.)
The route is described below, although it is also reachable by car as well as by ferry. (This route is also summarized below, but I include other directions for purposes of redundancy of informedness - thanks, Paul J.)

I encourage everyone to invite a friend or three. Safety in numbers ...

Here's the schedule :

Sunday 1130 arrive at south end of Golden Gate Bridge, via bicycle from Fisherman's Wharf (where car is optionally parked), or, park on ocean side of bridge, by old WWII artillery bunkers and ride bicycle over to meeting point (short stroll).

1200 depart from south end of Golden Gate Bridge, meeting on the west side of the bridge (bicycle side) between 1130 - 1200. bring a windbreaker, a backpack, and water, of course, as well as ancillary items - tools, spare tire, pump, headlight if you plan to ride at night, etc.

Over bridge, loop around to road underneath, follow around to Sausalito, through Sausalito, through Mill Valley, under 101 overpass, across marshes, to stop light @ Blythedale.

1300 Depart intersection of Blythedale, negotiate neighborhood via bike path, towards and parallel to 101, over hill and into Corte Madera, to Tamal Vista Street.

Follow Tamal Vista to end, turn right, cross 101, turn left,
follow bike path parallel to 101, into Larkspur.

1400 Arrive Larkspur, check ferry schedules, converge on pub for
cold ale and hot food.

1600 Head back to San Francisco via ferry. Windbreakers useful.

1800 Possible sunset gathering at the infamous Toronado.

Caveats :

- There won't be any good way to deal with dead bicycles en
route, so I ask everyone to

- (a) determine that their vehicles are in good shape, and

- (b) determine how they will cope with problems if they
occur (I suggest Golden Gate Transit).

I'll have a pump but I'm not a professional bike mechanic.

- Bring spare change in case you need to make calls or take a bus,
as well as bicycle locks and the like.

- Bring tools if you have them, between us we may be able to fix
any small problems that crop up.

- Mountain bikes are advised simply because they are more able to
resist flat tires through their architecture, and flats
are the single greatest nemesis of bicyclists.

- Bring some snacks, we'll be working up an appetite ...

Here's a longer but more precise explanation provided by Paul Jasper.

- -- richard

Subject: Siphoning, clear bear

Call me primitive, but I siphon beer the way we learned to siphon gas as kids.....So far I've had only one lousy batch (for totally different reasons), and a couple of award winning brews. I sterilize the tubes while doing the rest of the equipment, so my hands are pretty clean. If worried about contaminating the batch I sometimes hold the end of the tube in my hand and suck through my hand. I've done this much more often than we did gas as kids, and brew tastes much better.

Daniel Roman,,,,,You don't think that clear beer appeals to "women's taste", do you???? I was a little insulted to be put into a category of people who like that kind of thing. Perhaps you (and Miller) should find someother words to use for people who like clear beer. Women I know who drink beer (most of us brew our own) prefer strong ales and stouts.

In HBD # 1091, Dan Roman says: "I certainly don't expect anyone to get into homebrewing to make "clear beer"."

Dan, haven't you seen the advanced copy of the 1994 AHA style definitions?:

CLASSIC EGREGIOUS BEER-TYPE BEVERAGES

29. CLEAR BEER

Category award sponsored by CMB, the consortium of mega brewers (current membership: coors, miller, bud, though a wannabe in Boston(tm) has applied).

a) American standard clear beer--effervescent, no color, no head, no malt flavor or aroma, no fruitiness, diacetyl, or esters, imperceptible hop bitterness, flavor and aroma.

Geographic subcategories:

1) Milwaukee style--low levels of PCB's acceptable, must be in a clear bottle.

2) Colorado style--should be indistinguishable from pure Rocky Mountain spring water (except for alcohol content).

Not to be confused with Colorado Clear Bastardized Malt Beverage.

3) St. Louis style--should bear a striking resemblance to filtered Mississippi river water, but with lighter body and crisper flavor.

b) American premium clear beer--a generally "bigger" version of American standard clear beer. Geographic subcategories still applicable.

Also, look for Clear Beer Light and Clear Beer Dry for the 1995 competition.

And, for 1996, or '97 should anticipated legal hassles arise, expect to see a

Boston Clear Beer category, details relating to trademark restrictions and the

numbers of marketing weenies and lawyers required to assist in the brewing

process are yet to be worked out.

Ooogy wawa,

John

Subject: RIMS Questions

Message:

I am submitting this for Jeff, a fellow homebrewer who is experimenting with RIMS. His statement is:
We use the standard RIMS revisited (from Zymurgy gadget issue) and the temp control works fine. Temp readout is not working well because it is subject to some EMI (electro magnetic interference) caused by all the equipment (pump, heater etc). Our real problem is the motor control which due to its open loop nature is unsatisfactory. We are looking to implement a closed loop control using a Motorola chip TDA1185A or some other integrated solution. How does your motor control work? Has anyone implemented a closed loop control?

The recirculating wort now flows through the screen in the middle as well as through the bottom. Since the primary goal during the mash phase is to control temperature, it really doesn't matter that the flow is not uniform through the grain bed any more. The temperature seems to be reasonably uniform through the mash, and no compaction occurs.

Also, by having the return flow from the pump exit below the surface of the wort, I no longer have any foaming. That hopefully reduces HSE.

At sparge time, I simply reduce the flow way down, pull the tube out, and give the mash a gentle stir. After about 5-10 minutes, the wort is running clear again. I then turn the pump off, start the pre-heated sparge water flowing in at about the same rate as the wort drains out the bottom."

I've been thinking about RIMS designs for a year or so myself, and while I'm hardly a mechanical engineer, it seems to me that it would be possible and efficient to agitate the grain bed and maintain circulation, not with a pump, but with a few sources of vibration around the container, which would massage the grain and distribute the heat very nicely, without the problem of aerating the solution.

Subject: Boiling on electric stove

From: Steve Slade <sslade@ucsd.edu>
Date sent: 5-MAR-1993 09:11:29 PT

Joe Thomas asks about boiling his brew water in an 8 gallon ceramic on steel kettle on an electric stove.

I've been doing this for several years now. It takes a few hours with the lid on the pot, but the water does eventually come to a boil, and maintains the boil for as long as needed. I use the one large burner on our stove, on HIGH. This tends to heat the stove top from heat reflected off the bottom of the kettle. I've found that placing aluminum foil on the stove top around the big burner prior to brewing helps the stove to survive. Before I did this I had several pieces of the stove top flake off after brewing, so beware!

Now a question I've been meaning to ask: How do I make a beer that is, for lack of a better term, thick? The best beers I have tasted have all seemed like they have more body, or greater viscosity, than the ones I brew using a partial mash. I don't want to brew a sweet beer, so using less attenuative yeast is out. Do dextrans add body without a sweet taste? I've tried using 1/4 cup flaked barley in a 5 gallon batch without much luck. Is carapils or one of the Belgian malts a better choice?

Thanks,

Steve Slade

Subject: Miller Clear "ZIMA"

Yes folks, you have heard right. Miller has produced a clear liquid they are touting as a clear malt named "ZIMA". We've tried it and I suppose it will soon become a fad for the politically correct. Like Corona and a squeeze of lime. Yuk! Anyway, IMHO it tastes like 7-Up and alcohol and, again, IHMO is not very pleasant. It reminds me of my younger days in the service when we used to mix "Everclear" (198 proof alcohol) with 7-Up for that quick buzz. In ZIMA, the alcohol tast/aroma is very pronounced as is the citrus taste. I've had one and will never (yes, I mean NEVER) have another.

My son will probably like it and buy it. You know, he's the one who drinks Coors Light and calls himself a beer drinker. Viva le difference!

>added to the fermentation.

I've never used pectic enzymes, but I have a suggestion. This worked
for me on a recent beer and in 6 months, no gushers, therefore, no
infection. I surmised that any nasties would be on the OUTSIDE of the
fruit, therefore, I simply dipped the frozen cherries in very hot (212F)
water, for 15 seconds. I figured that the coldness of the frozen centers
would keep the pectins from setting. Well, they did a little bit, but
most of the cloudyness settled out and the beer is quite clear for a
fruit
beer. Perhaps you might want to consider freezing and blanching like I
did and then also using a bit of pectic enzyme? I'm also eager to learn
about pectic enzymes, so I hope someone out there tells us more about
them.
I'll bet there's something in the Fruit and Beer issue of Zymurgy (sorry,
don't recall which issue it is) on pectic enzymes, but I haven't had the
time to read all of it.

Can't answer any of your questions regarding beer but...

My last batch of cider was made from apples just about too far gone to use.

The juice looked more like watery apple sauce than juice. Nothing settled out in the overnight settle and after fermenting it still looked like apple sauce. It sat for months with no change even though I racked it several times.

Several weeks ago I racked again and added pectic enzyme and was astounded to find it crystal clear in the morning with two inches of apple sauce on the bottom. This stuff is like magic.

Before I starting using a propane burner I never had any real problems with using my electric stove. Just set the kettle up so it sits on two elements. It takes awhile to come to a boil and you have to leave the lid on to get a good boil but it works. Usually when the water is heating up I have other things to do.[i.e crushing grain]

Subject: Boiling on an electric stove

Joe Thomas asked about boiling an 8 gallon pot on an electric stove. What yo need is a HotRod (tm). Get a 220v electric hot water heater element of the type that screws into the tank. Get a 1 or 2 litre plastic juice bottle, and cut the bottom off of it. Hook a 110v cord to the element, and screw the element into the neck of the juice bottle so the element sticks out. See graphic below. Float this sucker in you pot to give the stove a help. Also useful for raisnin temperature of cooler type mash tuns. Note at 110v the element will be approx 1/4 the power rating for 220v. We have 3000 element that yields about 750w.

Bill Crick

> SO, HOW LONG DOES IT TAKE AND CAN YOU SUGGEST ANY TIPS TO SPEED THE
> PROCESS WITH MY 8 GAL. CERAMIC ON STEEL POT.

Before I got my outdoors propane burner set up, I used to boil my wort on a standard GE electric kitchen stove burner. I, too, was using a ceramic on steel pot. I found the burner to be most inadequate.

I also found several methods to improve the situation.

- To get the wort hot initially, I used two smaller stainless pots which has aluminum-clad bottoms. When the stuff was boiling, I moved it to the big ceramic on steel pot.

(BTW, I still use the same pot, and am still unhappy with it. I have yet to find a place to buy a 6 gal and up stainless pot of decent construction with an aluminum-clad bottom [the aluminum transfers the heat better]).

- Before I hit on the use two burners with the smaller pots idea, I would heat up the large pot faster by putting on the lid, then first placing pot holders all over the top, then secondly draping kitchen towels over that, with the towels hanging down the sides to help hold the heat in.

You can tell by the sound when you need to take the lid off to avoid boil-over. It is risky until you know though, and I did create one heck of a mess before I got the system down!

- If the burner does not put out enough heat to sustain a full boil with the lid off, then put the lid on between stirs after it hits the full boil. When you hear it going real good, take the lid off and stir it around for a bit. The full boil will continue with the lid off for a while, then die back down. Time for the lid again.

That is all the advice I can offer you on that one. Best of luck!

From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>
Subject: Sparge efficiency

When people indicate the degree of extraction they get for all grain batches what technique do they use? I do the following:
After sparging I stir the contents of the brew pot and take a sample of the well mixed liquid. I measure and temp adjust the specific gravity.

I multiply this value times the volume in the brew pot and divide the total by the number of pound of grain.

eg. an sg of 40 in 7 gallons of liquid = 280 total sg points
divided by the 10 lbs of grain = 28 pts per lb.

I have acidified my sparge water, verified my grain bed temp was over 150 made sure that the Corona cracked grain was not under milled and verified complete conversion using iodine tests of the stirred mash. I have not had

haze or clarity problems with my beer. Sparge time is about 1.5 hours using

a zappap lauter tun with a 1" false bottom. What am I doing wrong that prevents me me from getting to the next level of all grain snobbery the thirtysomething level of extraction all grain snob??

Subject: Re: Dallas Carboys

Roddy McColl asks, in HBD #1090, where a homebrewer can find a carboy for under \$15. Several suggestions:

1. Work a deal with a local homebrew shop on a used 5 gal carboy. there's an excellent shop in the area.
2. Mail order a 6 or 7 gal carboy - it's a bit more expensive, but I think Miller and Papazian recommend this size over a 5 gal. I've seen a 7 gal Italian carboy (real homebrewer's art...) for ~\$25. (I use a 5 gal secondary, but a 7 gal bucket as primary)
3. Call one of the bottled water suppliers and ask for an empty glass carboy (there are a lot of plastic ones around), for which you'll be asked to pay the deposit (~\$8).
4. Go to Whole Foods, or some other quality supplier, and buy a 5 gal w/water (~\$15 including deposit) and use the water in your first batch (makes great SNPA if not distilled water) and the carboy is yours.

Cheers.

From: BELLAGIO_DAVID@Tandem.COM
Subject: RE: Boiling Water on Electric Burner

Joe Thomas wonders about boiling water on an electric stove. I have an electric stove that I use for my brewing and have learned some lessons. The first lesson is that if you are doing a full 5-6 gallon boil it takes a long time to boil (about 40 minutes). The second lesson is that if you do a full boil for an hour, your element will last about 3 batches before becoming extremely warped (thus decreasing contact surface and increasing boiling time and heat directed elsewhere). This warped element eventually leads to a melted connector (this actually happens after batch #7 since I was alternating between both my big burners). So, then I went to the appliance part store and had to buy a connector plug, two reflector shields, a regular large burner, and an extra heavy duty canning burner. The canning burner cost \$35.00 and I highly recommend it! It has extra support and is raised higher than the stove top. It also has a higher heat output. Now, I boil my wort and don't have to worry about the heat and weight warping my burner. I would think a way to decrease the boiling time would be to start boiling a gallon of water on both burners, once they are close to boiling, put one in the other and refill the empty one with a gallon and bring it to near boil. Keep doing this until you have the desired amount in your big boiling kettle and it should all be near boiling then. I have not done this since I am lazy. Have fun.

Subject: survey results

I posted in 1089 about brown sugar. I asked HBD readers who had experience using brown sugar to write with me. The results are mixed but generally positive.

In HBD1090, Russ Gelinias said:

> Re. brown sugar: In my book, it's virtually *required* in an English
> style ale. Yes, I actually add brown sugar to all-grain batches,
usually
> 1 lb (10-15%). Purist, I'm not. Beer drinker, I am.

In HBD1091, Rick Zydenbos said:

> I'm an all-grain freak in search of a caramel taste in my ale.
> I've tried using brown sugar but with little or no success.

I had four people e-mail me about their experiences brewing with modest amounts of brown sugar:

Respondent #1 brewed with:

2 packages Northwestern Gold Malt Extract
1/2 # 80 L crystal
2 c. North American dark brown sugar (about .8 #)

The result:

> ...[it] was a big hit with my friends, and a number even remarked that
it
> was quite similar to BA but with more carbonation and hop aroma. There
was
> no 'cidery' flavor, but a nice caramel/molasses note in the beer which I
> thought was appropriate.

Respondent 2:

80% all-grain
20% US domestic brown sugar

The result:

> ...Well the beer was well received by
> some and not liked by others. I now know the flavor and I personally
> don't like it. As said, others do. I can now taste it in some
> draught English bitters

BEWARE:

> .. When I brewed the 20%
> batch it smelled like H2S--sulfury rotten eggs during the ferment.
> It tasted fine, but the basement stunk during primary. This is the
> only time I've ever had sulfur smell in primary and it was the only
> time I used brown sugar, so the two might be related...

Respondent 3 says he took my recipe for

> Bass Ale from Cat's Meow and cranked it up.

10# 2-row Klages Malt
.5# Cara Pils Malt
.5# Crystal Malt, 90L
1# brown sugar, added to boil

The result:

>First Place in Classic Pale Ale category in an AHA competition

Respondent 4 brewed:

> ...a Bass-ale type beer, the recipe compiled from 3-4 others
>in the CM and elsewhere, and I did use 1 lb. brown sugar

The result:

> I think it tastes great.

Other notes:

Arf sez:

> you might consider just using molasses and leaving out the sugar.

I've experimented with molasses in the past. It never gave me the
caramel flavor I sought. Just a heavy molasses-ey flavor.

Donald O'Connor suggests Belgian Special B. I'm going to give that
a try. A good solution for the purists, too.

Cheers,

Rob (bradley@adx.adelphi.edu)

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: demerara & turbinado

"Turbinado" and "Demerara" are the "real" brown sugars. They are both partially refined cane sugars. I've heard it said that they are, respectively, the American and British names for the same thing. However, turbinado is very pale, lighter than a brown paper bag. Demerara is about as dark as a brown beer bottle.

Demerara is readily available in the UK. Can UK readers confirm whether turbinado is the same thing called "Trinidad" sugar by Dave Line?

As Jeff Frane said, turbinado is available in North America in health food stores. When I lived in Toronto, I could buy demerara, imported from the UK, in homebrew shops. My respondent #2 tells me it can be bought from Great Fermentations in Santa Rosa, CA, but in the form of sugar cubes!!!!

North American supermarket brown sugars are refined cane sugar with molasses added. (HBDers must be getting sick of hearing this: I said it in HBD1089. Arf repeated it in 1090, as though it was news. In 1091 Jeff Frane said "Jack is right". Is it a fact yet?) Some questions: since molasses is a by-product of the refining process, what's the difference between a solution of turbinado and a solution of refined white sugar with the appropriate amount of molasses? Could a chemist tell the difference? Could a yeast cell? Are there nasty trace chemicals in the supermarket brown sugar because of the refining process? Did respondent #2's H2S smell arise because his brown sugar was doctored with sulfurized molasses?

Cheers,

Rob (bradley@adx.adelphi.edu)

From: pyle@intellistor.com (Norm Pyle)
Subject: Older, but not sweeter / Cloudy

I seem to have two problems with my homebrews, which I will discuss separately.

The first problem I've had from my very first brews. It involves sweetness, or a lack thereof. As my beers age, they seem to lose the sweetness they had when they were younger. I'm comparing the flavor profile from a 1-month old brew to a 3-month old brew (since bottling). This has happened with extract brews, partial mashes, and all-grain'ers. I really like my beers when they are young, but as they age, I like them less and less. The hop bitterness starts to overpower them, as the sweetness fades. Others have reported hoppiness fading with time, but with this problem, it seems to gain prominence. Anyway, I suspect the hop-fade reports really refer to aroma, less so than bittering. So, this sounds like an infection problem, right? Bacteria/wild yeasts eating up the "unfermentables", etc. etc. Well, none of my brews have ever experienced gushing. The worst its ever gotten is some bottles having more carbonation than others, which I attributed to poor mixing of the priming sugar (this hasn't happened in quite a while). Of late, I can't discern a difference in carbonation between the "young" beer and the "old" beer. Of course, comparing a 3-month old beer to the memory of a 1-month old beer is difficult at best. Help? Comments? I'll discuss my sanitation procedures in another post if that seems to be the tack to take.

Second problem: my all-grain brews (3 to date) are, without exception, cloudy. I do a simple single-stage infusion at 150-158F. I've used American and British 2-row. I try to do a mash-out, but I know the temperature isn't 165F+ like it should be (I don't think mash-out would have anything to do with this anyway). Do I need to a protein rest? At what temp? I mash in a cooler, so upward infusion is doable, but I'd only like to do it if necessary. BTW, the cloudiness doesn't make them any less tasty, but a friend says he likes all-grain because he can get his beers much clearer than with extracts (probably among other reasons as well). What gives? Thanks for your (collective) advice. It will be appreciated.

Cheers,
Norm

JS:>pass between the two plates. You must have a gauge on both sides at
JS:>the same time to do this.

Well said! But I would like to elaborate:

First, disassemble and wash with dishsoap.

Remove and do not replace the inner snap ring. The only purpose for this
ring was to prevent from losing the steel ball when it is disassembled!

To remove the snap ring just turn in the adjustment screw till the
ring is pushed out.

Remove the cotter key from the shaft and adjust the plate so it is more
perpendicular to the shaft. The mobile plate needs to run a parallel
course to the fixed plate. The hub may give some options for refitting.
Also the cotter key may need to be replaced.

File the end of shaft so it smooth and flat.

Crush on!

From: hpfcla.fc.hp.com!melkor!rick (Rick Larson)
Subject: Alan's RIMS Implementation, Part 1

Here is part 1 of some text I received from Alan Gerhardt about his RIMS implementation.

- -----Alan's-Text-----

Hi Rick,

I built my mash tun by getting a 15.5 gal keg, using a metal cutting blade in a circular saw to cut the top off at the top seam where the handle ring is welded on. As it turns out, the groove at that weld tends to guide the blade, so it is easy to get a straight cut. Be sure and use safety glasses, however, because sparks and metal bits will be flying. Make sure you follow all the normal safety tips for working with kegs as well.

I then drilled a drain hole in the bottom, and used a brass "cooler drain" fitting. The fitting has a nut and a gasket, which gives a good seal, and is threaded on the inside as well. I then attached the required pipe/fittings to connect the drain to my RIMS unit.

I used a water heater jacket as insulation by cutting it in approx thirds, and wrapping three layers around the keg and securing it with duct tape.

For a false bottom, used a piece of 3/8" copper tubing formed in a circle to fit the bottom of the keg, and soldered a straight piece as an extra support across the center. Picture an international "NO xxx" symbol and thats what it looks like. A piece of stainless screen rests on top. I also soldered a 1/2" copper coupling to one side of the inside of the copper ring into which I stick a vertical piece of copper tube as a vent stack which sticks above the grain bed. This limits the compaction of the grain bed by the suction from the RIMS pump. If you're not using a RIMS, then you don't need the vent stack, and you have a conventional mash/lauter tun.

My plumbing is set up as follows:

x

drain
w/valve

On the next installment, I will describe the construction of my
RIMS unit, which is patterned after the original Rodney Morris unit.

Cheers,
Alan

Subject: Alan's RIMS Implementation, Part 2

Below is the remaining text I received from Alan.
- -----

outside of the cap (with hole drilled in it), and the element just screws into the end of the pipe. The supplied gasket makes a water tight seal. The element is easily removed for inspection/cleaning, although cleaning is seldom required if a clean water rinse and recirculation is performed after use.

I put the thermistor inside of a .125" copper tube, and sealed it in epoxy, being careful not to short it out. The tube is inserted through the stopper so that it sticks into the fluid flow.

The Radio Shack thermometer Rodney used is no longer available, so I didn't put that through the stopper too. I use an external digital thermometer instead.

I put the whole thing into a wood case, with the inlet and outlet tubes sticking out through drilled holes. I connect to the unit using plastic tubing and band clamps.

I built a pump speed control per Rodney's design and it works fine.

I have not been able to get his temperature controller to work yet, and am currently using a toggle switch instead.

As he recommended, I used a GFI outlet inside my box, from which I get all power. That is in my opinion, a very wise investment.

I set the whole system up on two Workmates, one for the RIMS unit, and the other for the mash tun. The whole thing disassembles and stores so I have my garage back when done.

Observations:

- (1) At full flow, the outlet stream will sometimes generate a LOT of foam in the mash tun if not properly directed.
- (2) Sparging is a snap now. I just add as much water as my mash tun will hold, raise to 165-170 degrees, and recirculate for about 30 minutes. My efficiency is typically 30-31/lb/gal, for 6 row malt (Stew's Brew malt), just short of Miller's numbers. For larger quantities of malt (not as much room for more water), I plan to drain/replace the sparge water as required.
- (3) A proper grain grind is just as important as always.
- (4) The wort runs incredibly clear by the time you are sparging, and no husks or other particles make it into the boiling kettle.
- (5) If you are contemplating building a RIMS, don't scrimp on the pump or the heating element.
- (6) You have to be crazy or an obsessive tinkerer to go to this much trouble.

I hope this helps somebody !

Cheers,
Alan

Subject: Thicker Beer Body

To homebrew@hpfcmi.fc.hp.co
X-Mailer: LeeMail 1.2.4

In HBD #1092, Steve Slade asks:

>How do I make a beer that is, for
>lack of a better term, thick? The best beers I have tasted have all
seemed
>like they have more body, or greater viscosity, than the ones I brew
using
>a partial mash. I don't want to brew a sweet beer, so useing less
>attenuative yeast is out. Do dextrans add body without a sweet taste?
I've
>tried using 1/4 cup flaked barley in a 5 gallon batch without much luck.
Is
>carapils or one of the Belgian malts a better choice?

I'm using 0.5 lb maltodextrin powder in my latest batch in an attempt to
improve body. I added it in the hopes of improving body without
increasing
color, but I tasted the powder prior to addition, and it had very little
taste.
As such, you might give it a try to increase body w/o sweetness.

I'm also interested in cara-pils malt. Could someone post a nano-
tutorial on
its use? From reading, I thought I could treat cara-pils as a very low
color
replacement for crystal malt, just steep it in my brew water while
heating to a
boil, then filter off before adding my extract. However, the guy at my
local
brew store told me that it needs to be mashed to allow conversion. I
don't
want to let enzymes chew the nice dextrans down too much, since the whole
point
is to get some viscosity. What's the story?

Subject: some comments on sugar

HBD is in one of its cyclical sugar threads. Here are a few thoughts on sugars.

Sugars such as American cane sugar (American table sugar) are highly refined sugars that, from the standpoint of brewing and your yeast, are fully fermentable. Molasses is a thick syrup produced when sugar is refined. American light brown sugar and dark brown sugar are highly refined sugar with some of the molasses added back in. From this, it does not follow that you cannot or should not use them in your brewing. As I understand it, brown sugar has some unfermentables that will impart flavor to the finished beer.

Demerara sugar is a light-colored, partially refined sugar. Did you know that there is a Demerara River in Guyana? This must have been (still is?) a sugar-producing area. Turbinado sugar is a less-refined, darker, sticky sugar. You might be able to find these in health food stores.

"Sugar in the Raw" is a light amber fine-crystal sugar available in commercial supermarkets (in the Chicago area, anyway) in 2-pound boxes. "Raw Hawaiian Sugar" is an amberish rock-candy sugar available in 2-pound bags.

If you cannot find demerara or turbinado sugar, permit me to suggest that in recipes calling for demerara sugar, use Sugar in the Raw or Raw Hawaiian Sugar if you can find them, or use light brown sugar, and that in recipes calling for turbinado sugar use dark brown sugar.

Molasses is available in at least two forms -- as mild molasses or as a stronger blackstrap molasses. I've avoided the blackstrap molasses but have used mild molasses in a few recipes. I didn't have a good idea how much to add, but I started with small additions on the order of 1/4 - 1/2 cup, as I didn't want the flavor to dominate.

Finally, Rajotte's "Belgian Ales" suggests that Belgian brewers use sugar for coloring. The grain bills of Rajotte's homebrew recipes typically feature only small amounts of crystal malt or highly roasted malts, if any. Instead, he suggests that for pale beers use pilsner malt and refined sugar (or consider a light honey such as clover honey or alfalfa honey), and for color use small amounts of crystal malt or brown malt and use darker candi sugar. I think it's a great suggestion, though I don't know how to calculate the color contribution of darker sugars to the finished beer!

Subject: Clear beer...

There is a recipe in Cat's Meow called "Sima" that calls for brown sugar and priming sugar bittered with lemons. It sounds like this new "Zima" is priming sugar with lemons (or something similar).

Here's my recipe for dull clear beer:

5 gallons water
1 lb rice
1 lb corn sugar
4 lbs priming sugar
1 oz cheap hops

Boil hops alone for 1 hour (there's nothing to be added to the water/wort)

Add priming sugar

Ferment

Result: A clear beer with no body (what a great marketing strategy)!

Subject: Recurring infections

I started homebrewing two months ago and have had two out of three batches go sour. The first batch was the only not to bad. For all batches I used a plastic bucket primary and a glass carboy secondary. I sanitized all surfaces with bleach solution for each batch (I was especially careful for the last batch). I preboiled all the water for the last two batches. The first batch used dry yeast, the last two used liquid.

Any ideas on what I am doing wrong? I'm getting very frustrated! Should I throw out my plastic primary and get another glass carboy?

All advice is appreciated.

From: pascal@netcom.com (Richard Childers)
Subject: Marin, Bicycles, and the Marin Brewery

"Date: Thu, 4 Mar 93 22:23:57 -0800
From: pascal@netcom.com (Richard Childers)
Subject: bikePUBcrawl

"Despite suggestions to the contrary, I have decided to go ahead and carry out this bicycle-based pub crawl, as scheduled, this Sunday, 07 March 1993."

For those interested, the day was great, and so was the ride. A bit of fog while crossing the Golden Gate, but this also was an indicator of the wind's minimal presence. Across in Marin, the fog evaporated and was not seen until we crossed the Bay via ferry that evening.

The route is pretty straightforward ... down to Sausalito, along the bike path, under 101, across Blithedale in Mill Valley, right at the school, then along Lomita to 101, right, onto the bike path paralleling 101, over the hill and down into Corte Madera. Cross at the light, onto Madera, which becomes Tamal Vista. Go to the end, turn right, cross the freeway at the pedestrian bridge, then continue along, parallel to 101, back onto the bike path, along 101, down the off ramp, bearing right with the road, into the parking complex of the Larkspur Golden Gate ferry landing.

It all sounds very complex but the secret is that everyone uses this path all of the time and it is well established, as well as quite intuitive. In every case but one - at the school, where the right turn is unobtrusive - choices were either obvious, IE, straight ahead, or intuitive, IE, in order to cross the freeway I needed to zig-zag a bit but the goal was obvious.

We checked the schedule, then crossed the pedestrian bridge to the shopping complex Marin Brewery was within. We sat outside, on the patio, at a small table. (There were only three of us - both, friends, neither HBD readers but both interested in brewing.) The beer was good, but it was not noteworthy ... although my tiredness may have had something to do with this perception. The food, also, was good but not noteworthy, and the fish & chips, a touch oily.

However, the clam chowder was excellent, and next time I'll have a bowl of that and skip the fish & chips. Their hamburgers may be much better, I'll have to see another time.

Afterwards, we returned to the ferry building and boarded ... returning, we put two bikes in my truck and drove up to meet the third person, at the Toro-nado ... thence, homeward.

Overall, one of the best benefits of this ride is seeing just how easy it is to cover 20-plus miles in under two hours. (We did it in 2:08 and loafed a lot.) Another thirty minutes of riding and I could have been up in San Rafael, picking up brewing supplies at Great Fermentations ... and, of course, there are many other nice rides in Marin, as well as some nice picnic spots we passed en route. Although the brewery was not as rewarding as I thought it should be, the ride amply compensated for this lack ... and I will return to the brewery again.

One problem is the meeting place - where we met was not immediately obvious, although it is the southmost end of the bridge, and it is on the west side, and it is the beginning of the bike path, as clearly denoted by the very large sign at the beginning of the crossing, which directs bike riders to go down the ramp and under the bridge, to the other side ... I hope this did not cause anyone any inconvenience.

Subject: False Bottoms, Efficiency

From: "Joe Stone" <JSTONE@SJEVM5.VNET.IBM.COM>

>In my haste, I immediately applied heat to the mash with a 35K BTU
cooker.
The Vollrath pot has a SS tooled screen in the bottom. Upon applying
heat,
the temperature of the water/grain-dust solution below the screen
increases
rapidly. By the time I could thoroughly stir the mash, the temperature
was
at 190oF. Oops!

Welcome to the ranks of us drones who have blindly built the "standard"
version of the scaled down commercial mash tun only to find it poorly
suited
for home brewing. The following is the relevant section from my soon to
be
published article on Kettle Mashing.....
.....

The key to the system is the screening device and the spigot for the
kettle.
The first one I made was to be used in conjunction with an overlaying
false
bottom. The false bottom was a stainless steel plate the size of the
kettle
bottom with a zillion holes laboriously punched into it. It created no
end
of problems on the very first batch. Mash got under it and scorching
was
just about impossible to control. So in disgust, I pulled it out,
continued
the mash and assumed a disaster was at hand.

Much to my incredulous delight, when I opened the spigot, the wort ran
clear
after less than a cup of turbid runoff. I have since made about 50
batches
using only the screen device and get very consistent and respectable
extract
yields.

.....

If anyone would like a copy of the entire article, drop me mail.

>From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>
>Subject: Sparge efficiency

>What am I doing wrong that prevents me from getting to the next level
of all
grain snobbery the thirtysomething level of extraction all grain snob??

Probably just telling the truth and not fudging the numbers :)

We have been through this a zillion times and my opinion is that

instrumentation error and measurement technique can easily account for +
/- 5
points of uncertainty. 28 is well within the range of nominal. On my
last
batch I got 33 and the only thing I changed from the previous batch (30)
was
the malt.

The most important thing is that, once you are in the ballpark, with
what is
expected, you should worry less about what others get and more about
establishing a meaningful measurement technique that will give you
consistent
and meaningful results. If you change a process or ingredient, you want
to
know that any change in yield results from that and not from sloppy
measuring.

It is perfectly legitimate for example, to include the liquid in the
trub you
throw out in your volume determination but you must keep this in mind
when
you compare results with others and you must do it all the time. The
same
applies to reading the hydrometer. If you fudge to the top of the
meniscus
or the bottom, you must do it consistently and keep in mind that it has
about
a 4 point effect on the bottom line when comparing with others.

Subject: Nalgene bottles

Nalgene makes 20 litre (about 7 gallons) PLASTIC bottles that have the following features:

- 1) Large mouth
- 2) Screw top cap
- 3) Large handles to carry it
- 4) Best of all, a spigot about 3/4 inch above the bottom of the bottle

The biggest problem would obviously be sanitation, but these bottles are designed for laboratories, and the large mouth would make cleaning easier than a narrow mouthed carboy. Punch a hole in the cap for the fermentation lock, and I think it would make one hell of a closed fermenter. They cost about \$23.

Anyone use these before, and if so, how did it work?

Subject: questions from a new snob :')

Well, I finally did it. Yesterday I brewed my very first all-grain batch. Back in December I asked for some tips and got them, so a very belated thanks to Jay Hersh and Tim Norris (lauter tun designs), Rob Thomas (strike heat/mash temp formula), Jeff Benjamin and Spencer Thomas (general all-round advice), and Jack (quick delivery of a MALTMILL--for the record, mine had no debris and only a very light coating of oil which I took care of with a toothbrush and some really crummy roasted barley I had laying around).

Some observations and questions:

First, things went pretty well. Temperature control in my picnic cooler was harder than I expected and sparging was easier than I expected. I got about 28 points a pound. The runoff cleared *very* quickly, like within a quart or two. (I suspect Jack's mill is the reason why.) And about this business of the iodine showing conversion at the top of the cooler but not with the wort from the spigot: I didn't experience this phenomenon. At the beginning of the mash, both top and bottom turned black; at the end of the mash, neither did. So, who knows....

In terms of time, I would say that I only spent about 2 hours longer than my extract batches, and much of that was due to fumbling on my part since I don't have my technique down yet. Naturally, it took me longer to crush the malt than the pound or so of specialty grains I was used to using, but the sparge took place while the rest of the runoff was heating up on the stove, so that didn't really add much extra time (I've been doing full-volume boils). As far as I could see, only the hour or so mash represented any significant time over and above an extract batch.

Now the questions. First, in yesterday's digest, Joe Stone asks how long the sparge should take. I've got the same question. Miller, people in my club, and lots of other folks talk about the sparge slowing to a trickle. Mine didn't. It did slow a little, but never to a trickle. If I'd've wanted to, I could have run it out like gangbusters. Again, my guess is that Jack's mill

is why, and for me the length of the sparge seems to be strictly under my control. So, how long should I make it? The most convenient is to finish the sparge right as the wort on the stove is coming to a boil. Is this reasonable? Is longer better (more sugars?), or is shorter better (fewer tannins?)?

Second, what's the deal on acidifying the mash? Miller says to get the pH to 5.0 to 5.5. I checked right after doughing in, and it was like maybe 6.3. I thought to myself, "Man, this is my first all-grain batch. I've got a lot more important stuff to worry about than acidifying the mash." Also, I remembered Miller saying something about not fighting the "natural inclinations of the malt." So I remembered not to worry, decided to let the malt naturally inclinate, and opened the day's first homebrew. What should I do in the future?

Finally, should I acidify the sparge water? Charlie P.'s silent on the matter, Miller says to acidify to a pH of 5.7, and Noonan spouts of a typically let's-make-it-harder-than-it-needs-to-be Noonanism, something like acidify if the pH rises .7 during sparge but never more than .2 unless the azimuth of the moon corresponds to the declination of blah, blah, blah..
..
What should I do and how important is it?
Thanks a bunch, folks,
- --frank

End of HOMEBREW Digest #1093, 03/09/93

Date: Mon, 8 Mar 93 19:54:56 GMT
From: u4imdmre@cpc41.cpc.usace.army.mil (Markham R. Elliott)
Subject: Sanitizing Chemicals

To all you technicals out there (and laymen like me), If I could get some clarification on sanitation please.

In my last post to the HBD, I asked about the techniques of using a secondary fermentation vessel, and a consensus on the amount of different priming agents that could be used. Many replies suggested I get a plastic bucket and mix the priming agent with the beer in the bucket, then bottle from it.

Well I made the batch using a secondary and bottled it before getting a bucket, we will see how it turns out. I am a bit concerned about the tremendous amount of fermentation activity for 3 days, then nothing. But, that is another matter.

This weekend I acquired a 5 gal pail (Carl West was right, check out Chinese Food places [HBD #1041], not only do they get oil in them, but soy sauce as well). I took it home to clean it up (yuch! :-b), using massive amounts of Tide laundry soap, mass quantities of water and an old sponge. I got to thinking while in the midst of this mess, how should I really be cleaning and sanitizing this thing.

A discussion was held in HBD issues 1030 through 1055 about cleansing agents, disinfectants, food vs. lab grade plastics and the like. What bothers me is that nothing was really definitively stated about cleaning plastic pails.

It was noted that Iodine and Iodophor shouldn't be used because they stain, and the plastic absorbs/leeches back the chemicals. Detergents shouldn't be used because they leave surfacants which are detrimental to the brew. If peracetic acid (acetic acid+H2O2) will dissolve an un-jacketed bullet, I'm not going to use it on my equipment. Finally, a lot was said about using chlorine bleach, but no one seems to agree about how to use it (concentration vs contact time etc.), or if it should really be used, again because of the absorption/leeching problem(s).

I know, I know, RDWHAHB. Really though, is there an accepted method and or chemical to use, and what is it? The bucket originally had soy sauce in it, then apparently was used as a frying oil/grease repository. Pretty gross stuff before "cleaning". I realize that the beer will be in the bucket for only a short time, but I would hate to ruin a good batch of beer during the bottling process just because I didn't clean the plastic right.

Suggestions are welcome, but again, is there a DEFINITIVE answer with regard to HDPE plastic?

Noch einmal, bitte!! Mark

Subject: Texas Brewpub Legalization

Folks, Texas Brewpub Legislation is in committee. Please write & call the following legislators this week. All the major changes that would make the proposed bad legislation into good legislation will be considered as you read this. If you have any questions please email me. I didn't know if this was the correct forum for BPub legalization issues but I figured a brewpub is a perfect place for homebrew clubs to meet! Please forward to all Texans who like beer. Thanks Joe Barfield, Publisher, SWBN

- - - -

Southwest Brewing News Brewpub Legalization Guide. 3/8/93. Please forward to interested friends.

Brewpub n. A brewery that sells its own beer on premise. Or a Restaurant that brews its own beer. Legal in 42 states. Something Texas needs to legalize to join the rest of the civilized nation.

Folks, we can legalize brewpubs this year. All you have to do is call and write to the following legislators and voice a few simple requests.

What to tell the legislators: Key consideration: BE BRIEF!

These folks are busy. If as many folks call in as we hope, we could possibly end up alienating some V.I.P.'s if we drone on. It really won't hurt if you limit your calls to the following three statements.

1. "I support brewpub legalization in the TABC Sunset Bill"

The bill considered is referred to as the T.A.B Sunset Bill. There are identical bills introduced in the Senate and the House.

2. "I want brewpubs to have the right to sell for on and off-premise consumption."

Currently, the legislation disallows sales for off-premise consumption. Most states allow people to purchase a refillable container with which to carry beer purchased at the brewpub home for consumption. Currently many bars in Texas enjoy this right. Why should this privilege be denied to brewpubs in Texas?

3. "I want brewpubs to have the right to limited self-distribution."

Brewpubs generally start small. So small that it's not worth a large distributor's effort to distribute a brewpub's products to local venues.

In

order to supply a local area with fresh products, a brewpub has to initially be able to distribute its own products. This may be as few as a couple of kegs per week to a nearby bar. As the brewpub grows, it becomes more rewarding to each party if a distributor handles a brewpubs contracts.

In fact, in California, brewpubs can distribute their beer, yet over 95% of

California's brewpub beer is distributed by beer wholesalers.

Who to contact:

Write to and call the following important people: (and communicate the 3 phrases listed above)

1. Sponsors of Senate Bill #622: Senator Carriker (512) 463-0130, Speak with Mark Moran, Legislative Aide.

Senator Ike Harris, Co-author (512) 463-0108, Speak with Tiffany Wehner, Staff Assistant.

Senator Carl Parker, Co-author (512) 463-0104, Speak with David Gonzales, Legislative Aide.

2. Sponsors of House TABC Sunset Bill: Representative David Cain (512) 463-0476, Speak with the receptionist.

Representative Ron Wilson (512) 463-0744

3. Members of Committees reviewing the bill

Senate State Affairs Committee

O. H. (Ike) Harris, Chair 463-0108

Peggy Rosson, Vice Chair 463-0129

Steve Carriker 463-0130

Don Henderson 463-0107

John Leedom 463-0116

Eddie Lucio 463-0127

Gregory Luna 463-0119

Jane Nelson 463-0122

Jerry Patterson 463-0111

Dan Shelley 463-0106

John Whitmire 463-011 House Licensing and Administrative Procedures Committee

Ron Wilson, Chair 463-0744

Dan Kubiak, Vice Chair 463-0600

David Cain 463-0476

Ben Campbell 463-0478

Bill G. Carter 463-0482

Mario Gallegos 463-0614

Tony Goolsby 463-0454

Paul Hilbert 463-0572

Delwin Jones 463-0542

Garfield Thompson 463-0716

Ken Yarbrough 463-0648

4. Your local Senator and House Representative a. Call them at the phone numbers listed on back page

b. Write to them at the following addresses:

The Honorable [Representative] The Honorable [Senator]

The House of Representatives The Senate of Texas

P.O. Box 2910 P.O. 12068

Austin, TX 78768-2910 Austin, TX 78711-2068

If you aren't sure who your legislator is, call your county voter registration office and ask for the names of your House Representative and

Senator. Your county's voter registration telephone number should be on your voter registration card or in the county section of your telephone book's blue pages. If you can't find the number call 1-800-253-9693. They may be able to tell you your senator & representatives' names.

Attend the Public Hearings:

Call the bill tracking service at 1-800-253-9693. You can follow the progress of the bills as they are reviewed by committees. Remember, the bills in question are referred to as the "TABC Sunset Bill". HB335 is NOT

the Brewpub bill. By all means, attend the public hearing! Sign up in support of Brewpub Legalization. When your turn to testify is announced say

"I support brewpub legalization. I defer my comments to (the designated spokespeople)." We will be at the hearing in advance and will let you know

who will speak on Brewpub Legalization's behalf. Of course you have the right to speak on your own behalf, but exasperating the committee members by droning on will hinder rather than help us. Remember, please BE BRIEF. Questions can be referred to Joe Barfield, Publisher, Southwest Brewing News at ifby546@ccwf.cc.utexas.edu

Address mail to 406 W. 35th, Austin, TX 78705. (512) 467-2225.

OK, yeast are fungi. But, have you ever heard of a mushroom ranch? I
think not. Most fungi grow from the soil. I brew beer and raise yeast
on my 5 acre farm. Therefore, yeast must be "farmed"...

Subject: White beer: let's talk turkey

The arrival of Celis has spurred an interest in brewing white beers, and in addition some HBDers have expressed a desire for more recipes on the net. The following recipe and comments should provide a good start for people who want to get ready for their summer white beer drinking.

CITADELLE WHITE (5 gals.)

5 lbs. 2-row pale malt
3 lbs. Belgian wheat malt
.75 lb. hard red winter wheat
.5 oz Styrian Goldings (6.8% AA), boiled for 60 minutes

10 grams ground coriander (boiled 10 minutes)
zest of 4 oranges and one lime (added after end of boil)
12.5 ml 88% lactic acid (added at bottling)
110 grams corn sugar in 4.75 gallons for priming

Hoegaarden white yeast cultured from brewery sample

OG: 1.042
FG: 1.012

Procedure:

Strike with 8 quarts @ 135F for 20 minute protein rest at 122-124F; Add 1 gallon boiling water to raise to 145F, then heat to 158F for 30 minute sacchrification; add 2 gallons boiling water for 10-minute mashout at 170F; transfer to lauter tun and let sit 20 mins, then sparge with 6 gallons water @ 180F. I stopped sparging at 1.008, collecting 6.25 gallons at 1.037. Boiled for 90 minutes and cooled with immersion chiller.

Tasting notes:

Lemon/gold color with a substantial haze and white head. Slightly orangey aroma. Light to medium body with full, almost moussy carbonation. Light to moderate tartness with subtle but pleasant coriander flavor, some orange present but faint. Aftertaste mostly tart and coriander-ish. I wouldn't go head to head with Celis White, but this is unmistakably a white beer and will make for excellent hot-weather drinking.

Specifics:

Grain bill--The basic bill is 60% barley malt, 30% wheat malt, and 10% raw wheat. The latter was purchased at my local food coop for \$0.55/lb. I would increase the gravity to 1.046 next time but think these proportions provide good results with little trouble. The raw wheat was absolute hell to grind, but there were no problems with the mash and sparge. Thanks to Jim Busch, the sultan of wheat beer, for help with the grain proportions.

Hops: Anything will do as long as it's not too caustic or spicy. Go for something noble-ish. My target was 14 IBU.

Yeast: A local brewer brought back yeast from the Hoegaarden brewery, but I don't think the yeast choice is critical. This yeast has less character than the Celis, so anything that

ferments reasonably thoroughly and has some character should do.

Coriander: 10 grams (about 2 teaspoons) gave good but not strong flavor, to my palate a bit more than the Celis white but not anywhere near excessive.

Orange: I purchased some dried orange peel at my coop, and boiled 2 grams in one gallon of water as a test. The result had a very unpleasant, ham-like flavor and aroma. The same applied when I used dried McCormick peel, and even fresh peel (though a little less so). I did NOT want this flavor in my beer (if you don't believe me, try it!). For this reason I used the Papazian fruit method, adding the peel just after the boil for sanitation reasons. This worked pretty well, though most of the aromatics were scrubbed during the fermentation; I used a 6.7 gallon carboy for a single-stage fermentation, and for the first 3 days it smelled like orange juice. If you want more orange aroma, add some peel to your secondary. Since Sunkist oranges aren't curacao oranges, I added the peel of one lime for some tartness and character. Can't tell if it helped, but it sure didn't hurt.

Lactic acid: At time of bottling the beer was 4.7 pH, and not tart. I added lactic acid (available from the Malt Shop in Wisconsin) to taste, starting with 10 ml. 2.5 additional ml brought it to about where I wanted it, and the pH at that point was +/- 4.3. However, I dosed it according to taste, not numbers. The result was right on target, taste-wise, and I'm thoroughly sold on the use of this stuff.

Thanks to the many HBDers who provided information on their experiments with this ingredient.

Please note that this recipe will not make you two cases of Celis or Hoegaarden, but I think you'll do fine with it. Some tweaking to bring it in line with your own tastes, and I hope the notes will save you some time, effort, and experimentation.

Subject: Peracetic acid; sodium hydroxide

Darrell said:

) A recent thread concerning the possible use of peracetic as a sanitizer
) prompted me to search for some information on this compound. The Merck
) Index lists peracetic as "a powerful oxidizer, strongly corrosive to
) tissue, explodes violently upon heating to 110 deg. C." Coupled with
) the fact that one liter costs \$90, this information left me wondering
) if any significant benefit could be realized by using this compound.
) Anyone have any practical experience with this substance?

I myself have wondered why a couple of the hbd luminaries have announced their intentions to use this stuff for sanitation purposes. In any event, I think you can roll your own by mixing strong acetic acid and strong hydrogen peroxide. Now, the glacial acetic is cheap, and so is 30% h2o2. (Stay away from the 50% stuff.)

BUT: Not having tried this, I can't tell you whether or not it blows up in your face.

- - - - -

In a similar vein, I just tried using sodium hydroxide (lye; caustic soda) to clean some hoses. All I can say is, WOW.

I added about 1 oz of a saturated, filtered solution of sodium hydroxide (about 1 part NaOH to 2 parts water) to 3-4 inches of warm water in my sink and dropped in the offending hoses, which included one blowoff tube coated inside with hop and protein scudge. (Needless to say, I was wearing a nice, thick pair of rubber gloves.) The stuff *immediately* came off the tube into the water, much as water soluble ink might have. A few minutes soak and a little swish, followed by a thorough rinse, and, voila, squeaky clean tubes.

Although the handling precautions are considerable, I would recommend this to anyone who has a tough cleaning problem. (But obviously you should keep lye away from your aluminum utensils unless you want to dissolve them.) I may begin using it to clean my carboys after messy primary fermentations.

Subject: Re: English/British

> >PS please don't refer to England or English when you mean Britain or
> >British. It upsets the natives no end.

My somewhat flippant remark provoked so many inquiries by mail I felt a post to clarify was in order, despite having nothing to do with homebrew. I'll keep it short and suggest follow-ups to soc.culture.british or by mail.

Britain / British Isles / UK mean practically the same thing. England does not. Britain comprises England, Wales, Scotland, Northern Ireland, the Isle of Man and the Channel Islands. The English are of predominantly Northern European extraction: Saxon and Dane. All the others are predominantly Celtic and were there before the Romans came. They all have their own languages and culture. (If you visit England take a trip into Wales and you'll see bilingual road signs).

Owing to political and economic domination by England, a fierce nationalistic pride is possessed by the Welsh, Scots and Irish, who do not wish to see their national identity submerged and dominated by the English. So they don't like it when they are referred to as "English". British is OK but if you know the person's origin, Welsh, Scot/Scottish, or Irish is better.

Only Northern Ireland is in the UK. Eire is not. They are Irish, period. "Brit" is a common term of abuse there.

Is this recognisable to some of you? Funny lot humans...

Greetings,

A new home brewing store opened in Cranford NJ a few days ago.
They don't have a credit card machine yet, but have mostly
everything else that Teaneck & Red Bank have.

The Brewmeister
115 N. Union Ave
Cranford, NJ 07016
(908) 709-9295

GSP south to Cranford Exit (just past Union tolls)
This puts you on North Avenue (going towards Cranford)
At first light (gas station) make a right (Elizabeth St.)
At blinking light (next light) make a left (North Union Ave)
You follow this road going over a small bridge and past a church.
It is in the center of town on the right side next to a
Hallmark-type store.

Mon, Tues, Wed: 12:30 - 8:00pm
Thurs: 12:30 - 9:00pm
Fri: 12:30 - 8:00pm
Sat: 10:00 - 6:00pm
Sun: 12:00 - 3:00pm

As you can see, mighty convinent hours.
The proprier is the secratry of a local home brewing club
(They meet at Sandy Hook every month).
He plans on keeping a fresh rotating grain stock with
specials from different countries every month.

PROST !

From: CHUCKM@PBN73.Prime.COM
Subject: weisse bier

Hi BrewFolk,

I'm interested in peoples experiences brewing Bavarian Weisse Bier. I have read Warner's book and still have some questions.

Re: Weisse beer yeast

Wyeast 3056 is the only commercial weisse yeast I know of. Warner indicated in his book that some German brewers prime their Weisse biers with lager yeast and some do not. Does this mean that some are primed with the same yeast that they are fermented with? If yes, are any of these biers available in the US and is their yeast re-culturable. In the Gadgets issue of Zymurgy, Warner was written up in the winner's circle section for Weisse Bier. His recipe said he used yeast cultured from a bottle of German Moy Weisse Bier. -- Has anyone ever seen this in the US?

Re: Mashing

Warner maintains that decoction is the only way to go and barely had two or three sentences about infusion. Any comments?

Your replies will be greatly appreciated,
Chuckm@pbn73.prime.com

Subject: Newbie Questions

Guys and Gals of the brewing world,

I starting brewing about six months and six batches ago, and I have several questions that I am sure will make me look foolish but I would like to have answers.

For the record I have Charlie P's book and just purchased Dave Miller's The Complete Handbook of Home Brewing so if you could point me towards chapters or sections (that answer my questions) that I might have missed or not fully understood at the time I read them, that would probably save bandwidth and make everyone very happy. :)

I have been adding specialty grains (crystal, chocolate, etc.) to my brews and IMHO they are turning out great!! My question pertains to the purpose of the specialty grains. Do they simply impart a flavor to the beer? I realize they have little or no enzymes so 'no' conversion of the starches can take place like in a real mash. Right?

My second question is about using flaked maize as an adjunct. My wife likes Miller Genuine Draft. I know, I know, I can see the flames coming already. I am slowly converting her over to 'real' beer, but I aldo told her I would attempt an American Lager with some corn in it. Can I simply boil these little devils, strain and add to the wort or do the starches provided by the maize also have be coverted through a mash with malts containing enzymes?

If anyone has any extract recipes for this type of beer I would greatly appreciate seeing them.

Thanks to all who have taken the time to read all of this and reply.

I have learned a lot from the collective wisdom of the net and wish you all great beers.

Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu>

>So, how long should I make it? The most convenient is to finish the
>sparge right as the wort on the stove is coming to a boil. Is this
>reasonable?

Whether its reasonable depends, of course, on how long it takes your
stove to
raise the wort to a boil 8-) One of the brewers in my club starts
heating the
boiling kettle after its about 1/3 full, and by the time the last of the
sparge
is running into the kettle, it been boiling for 10-15 minutes. His beers
are
consistently among the very best in the club. This technique saves him
maybe 45
minutes per brewing session. Not bad, eh?

>Is longer better (more sugars?),

Yes

>or is shorter better (fewer tannins)?

Yes

My favorite authority (Miller) says the sparge should take 45 minutes to
an
hour. He says this gives a good balance between extraction and avoiding
tannins. It has worked well for me. My wheat ale took about 1:15 -- my
other
beers work like yours -- I have to close the spigot to make the sparge
take more
time. I insulate my lauter tun and keep a lid on it to keep it hot. I'm
using
a grain bag in my bottling bucket, which I fitted with a false bottom
made from
the lid of the bottling bucket. Keeping the grain bed hot makes
controlling the
runoff rate much easier --it becomes a matter of throttling the thing
down.
I've changed my technique a bit since I made the wheat ale, so I'm
expecting it
to go better next time.

I have been acidifying my sparge water, but I'm not convinced it makes a
difference, at least in higher-gravity, dark beers. In the lighter beers
(1040
or less) I'm sure the effect would be more pronounced because there's
less stuff
in there to mask the tannins. Your comments on Noonan's book gave me a
big
grin, but in his defense, he's writing mainly for commercial brewers
(small
scale and pilot plant operators), and the key in that game is batch-to-
batch

consistency, in the extreme. What should you do? HMMMMMM. If you notice any kind of astringency in your beer, try acidifying your sparge water. Astringency leaves a kind of dry, chalky feeling in your mouth. The other thing you might try is testing the pH of the last cup of your runoff. If the pH is above 5.5, try acidifying. The other thing to keep in mind is that all this depends on the grains you use. Dark, roasty malts tend to make the mash more acidic than light malts. If you want to experiment with your techniques, make measurements, and write down what you do, just as they taught you in chemistry lab 8-)

>So, this sounds like an infection problem, right?
>Bacteria/wild yeasts eating up the "unfermentables", etc. etc. Well,
>none of
>my brews have ever experienced gushing.

Well, *something* is reducing the complex sugars after bottling, and
since you are not getting gushers, it doesn't seem likely that it's
bacteria. My guess would be that you are using a highly attenuative
yeast.
What strain of yeast are you using? Also, if you are reusing yeast
across
several batches, the strain will become noticeably more attenuative after
a few batches.

>Second problem: my all-grain brews (3 to date) are, without exception,
>cloudy. I do a simple single-stage infusion at 150-158F. I've used
>American
>and British 2-row
>...
>Do I need to a protein rest?

Could you provide a little more detail, Norm? Is the beer cloudy at
room temperature, or does it become cloudy after the beer is chilled?
If it's cloudy at room temperature, the problem is probably not excess
protein, but a starch haze. A too-fine crush of the malt results in
excessive flour and pulverizing of the husks, which leads to poor
filtration during sparging. Check your crush, and make sure the husks
are
intact or nearly so.

If the beer is clear at room temperature but becomes cloudy when
chilled,
you have chill haze (don't worry, it's not contagious :-)). Chill haze
is
a reaction between long chain proteins and tannins in the beer. There
are
many ways to treat this problem. A protein rest of 115F-120F for 30
minutes
will reduce the long chain proteins that cause chill haze, however, this

is generally not necessary with highly modified British 2-row malt. Fining with 1 teaspoon of Irish moss 30 minutes before the end of the boil will help settle out the proteins. You could also fine with polyclar at the end of secondary fermentation, just before bottling. Polyclar helps to settle out the tannins that react with proteins to cause chill haze.

Also in HBD#1093, Steve Zabarnick writes:

>I started homebrewing two months ago and have had two out of
>three batches go sour. The first batch was the only not to
>bad. For all batches I used a plastic bucket primary

This suggests to me that you may have scratched the primary while cleaning it after your first batch. Once a plastic fermenter is scratched, it becomes very difficult to sanitize properly. Check your primary carefully for scratches, and if there are some, replace it.

Frank Tutzauer writes about his first all grain batch:

First, let me congratulate you on joining the ranks of the snobbish elite :-) :-) (smileys included for the humor impaired)

>First, in yesterday's digest, Joe Stone asks how long the
>sparge should take. I've got the same question. Miller, people in my club,
>and lots of other folks talk about the sparge slowing to a trickle. Mine
>didn't. It did slow a little, but never to a trickle. If I'd've wanted to, I
>could have run it out like gangbusters.

If your runoff slows to a trickle when the tap is wide open and the tun full of water, this is a problem, the mash is starting to set.

I experimented with runoff rates for a while trying to determine the optimal rate. I started running off about 1 gal/15 minutes, or 90 minutes for 6 gallons, and carefully measured and recorded my extraction rate. Gradually, I sped this up until I got to 1 gal/8 minutes, or just over 45 minutes for 6 gallons. At rates higher than this, my extraction began to drop. Of course, this is based on my brewing environment (geometry of my tun, my procedures, etc.), your mileage may and probably will vary. Don't be afraid to experiment.

>Is longer better (more sugars?), or is shorter better (fewer
>tannins?)?

I think tannin extraction is more a function of pH and the amount of sparge water used, rather than the runoff rate. As sparge water is added, sugars are extracted, and the pH of the mash becomes more alkaline.

Eventually, you get to the point where more tannin than sugar is being extracted, you want to stop before this occurs. So, sparge at the fastest rate possible without extraction dropping off, and use both your hydrometer and your palate to determine when to stop. I start tasting the runoff and monitoring the gravity as I get close to 6 gallons collected. For my setup, when the gravity gets to ~1.010 the taste of tannin first becomes

noticeable, and this is when I stop sparging.

>Second, what's the deal on acidifying the mash? Miller says to get the pH to
>5.0 to 5.5. I checked right after doughing in, and it was like maybe 6.
3.
>...What should I do in the future?

The amylase enzyme works well at the pH range Miller recommends.
Adding
a small amount of gypsum to the mash should do the trick.

>Finally, should I acidify the sparge water?

This question should be a FAQ, if it isn't already. Unless you have an extreme water situation, this should not be necessary. In my case, I have a private well with extremely hard water. I had an astrigency problem with my beers because the pH of the mash was getting too alkaline during sparging. Acidifying the sparge water helped me, but I'd guess it's not necessary in your case, judging by the pH of your mash after doughing in.

Now that I've answered your questions, could you answer one for me?

>I got about 28 points a pound.

>but the sparge
>took place while the rest of the runoff was heating up on the stove

How are you measuring your extraction rating with part of the wort on the stove, and part of it still coming out of the tun?

Cheers,
Jim

"I started homebrewing two months ago and have had two out of three batches go sour. The first batch was the only not to bad. For all batches I used a plastic bucket primary and a glass carboy secondary."

It is a truism, I have been told, that plastic is hard to sanitize, especially inside any scratches in the inside surface. It has been a major effort, after every brewing session, to not place all of my paraphernalia inside my plastic mega-container, which naturally would hold everything very nicely. But I've resisted the temptation.

Despite this, I still don't use the plastic vat for anything but short periods of exposure, and often leave a powerful bleach solution within it with the lid on tight, for weeks, when not in use. I use it as a temporary container for inducing hot breaks before racking, as well as an intermediate holding place while adding corn sugar before bottling, but never for long periods of time (IE, over an hour).

"Any ideas on what I am doing wrong? I'm getting very frustrated! Should I throw out my plastic primary and get another glass carboy?"

Don't throw it out but do invest in a second glass carboy, it's not a waste of money, IMHO.

Subject: Celis Substitute?

Michael Howe reports that he hasn't seen Celis White in Colorado. Sorry, Michael but I haven't seen it here yet, nor have I even tasted it, but I have a suggestion. Try Sunshine Wheat by the New Belgium Brewery in Fort Collins.

This is the first wheat beer I've ever truthfully enjoyed. It is spiced in the Belgian tradition with coriander and orange peel, as CW is reported to be. It is just a wonderful, full bodied wheat beer with some very interesting flavor components. I'd like to try CW as a comparison, but until I find in our neck of the woods, SW will do just fine.

Cheers,
Norm

That was established in the first sentence.

> Some questions: since molasses is a by-product of the refining
process,
what's the difference between a solution of turbinado and a solution
of refined white sugar with the appropriate amount of molasses?

Not much.

>Could a chemist tell the difference? Could a yeast cell?

Not likely.

Let me caution you that the terms used in the industry are a lot like
those
in any other, i.e. they mean different things to different people. I am
not
an expert on sugar but while shooting "Orchids vs Hamburgers", we spent
a day
filming at a sugar refinery in Costa Rica and everything coming out of
the
centrifuge (turbine?) was called turbinado. Raw sugar usually means
the
evaporated and crystalized juice from the cane crusher. It can also
mean the
output of the centrifuge after most of the molasses has been removed or
even
a fairly light colored sugar with all the molasses removed. It is also
the
trade name for a Yuppie product that has nothing to do with anything.

What this refinery called raw sugar were kilo sized blocks in the shape
of
truncated cones about 5 in in diameter at the bottom. These are
available
everywhere in Central America and used in a popular drink called agua
dulce.
One drops the block in boiling water and pulls it out when the water is
appropriately sweet and it is served like tea, but of course in a glass.

We brought one of these home in 1985 and needless to say, have most of
it
still intact. As a result of this thread, I bashed it up with a hammer
and
ran it through a MM and can now use it in tea.

Now if Jeff will give us the nod, we can move on and wind up laser
lables.

>From: pyle@intellistor.com (Norm Pyle)

>Second problem: my all-grain brews (3 to date) are, without exception,

cloudy.

Your process description leaves out any information about fermenting procedure. Given time, I have never made a beer that would not clear. I do

however, always use secondary fermentation and highly recommend it as SOP for high quality beer.

How long is your primary?

How long is your secondary?

What kind of yeast are you using?

>Is the likely problem a stuck sparge or simply poor conversion of
>the adjuncts?

It won't make the sparge stick any more than usual (no problems since I switched to a copper-pipe manifold), though you could get poor conversion of the adjuncts.

If you're aiming for gainness, you want to increase the protein content of the finished product. By all means go ahead and eliminate the protein rest, even if you use lager malt. The result is excellent head retention, creamy mouthfeel, and additional haze, which is no problem in a stout.

Frank Tutzauer <COMFRANK@ubvmsb.cc.buffalo.edu> writes:

>First, things went pretty well. Temperature control in my picnic cooler was
was
>harder than I expected and sparging was easier than I expected. I got
about
>28 points a pound. The runoff cleared *very* quickly, like within a
quart or
>two. (I suspect Jack's mill is the reason why.)

I assume you used a slotted copper pipe manifold which will not stick. I cut too many holes in mine, and the runoff is actually too fast for great extraction. I was always having stuck sparges with a Zapap lauter tun. Crushing the grain with a Maltmill only made a minor difference. Shorter mash times helped the most - I think the husk material begins to decompose after about 90 minutes and tends to clog a false bottom.

Anyway, now my technique is as follows: 1) crush all the grain and place in cooler, stir (dry) to mix. 2) hook a siphon hose up to the outlet, and gently upward-infuse with 163F water, to avoid oxidation. when the water is well above the level of the grain, you can (gently) stir the (thin) mash without any additional oxidation. 3) To mash out, drain a gallon or two, heat to 170F, and return to the mash. This can all be done (gently) through the siphon hose, simply by lowering or raising the kettle. 4) drain completely, possibly recirculating .5-1 gal. 5) siphon in 170F acidified sparge water. Again, backwards, through the copper pipe manifold. 6) repeats step 4, then 5 and 4 again if you wish.

>From an oxidation standpoint, it would be preferable to be able to sparge with water running just under the surface of the mash, while it is being drained from below. The copper pipe manifold drains so quickly that the sparge water does not run evenly through the grain bed, leading to poor extraction when this is done. Perhaps this would work if there were fewer slots in the manifold (mine

currently is 7 ft long, with ~100 slots in it, 1 slot per inch), and if the slots were closer together farther away from the outlet.

>Now the questions. First, in yesterday's digest, Joe Stone asks how long the
>sparge should take. I've got the same question. Miller, people in my club,
>and lots of other folks talk about the sparge slowing to a trickle. Mine
>didn't. It did slow a little, but never to a trickle. If I'd wanted to, I
>could have run it out like gangbusters.

One of the advantages (disadvantages) of a copper pipe manifold. The disadvantage is that if it runs too fast, you get poor extraction. If you try to slow it down, you're only draining wort through the slots nearest the outlet.

>The most convenient is to finish the sparge right as the wort on the stove
>is coming to a boil. Is this reasonable?

The first running from my setup are around SG 1.100, which will caramelize easily if I heat it too vigorously. I usually wait until I collect a full 7 gallons before I start heating towards a boil. If you do heat the first runnings earlier, so it gently to avoid caramelization, and do not splash the hot wort when you add the second runnings later, to avoid oxidation.

>Second, what's the deal on acidifying the mash? Miller says to get the pH to
>5.0 to 5.5. I checked right after doughing in, and it was like maybe 6.3.

If I preboil my mash water, mine always comes out 5.3-5.5, so I don't worry about it. (it's impossible to use pH papers accurately with dark malts anyway, due to the staining action). If you don't boil the mash water to drive off the chlorine, the buffering action will insure that the pH never gets low enough, unless you add massive amounts of acid (gypsum won't do it), which will adversely affect the flavor of the final product.

>Finally, should I acidify the sparge water? Charlie P.'s silent on the
>matter, Miller says to acidify to a pH of 5.7, and Noonan spouts of a
>typically let's-make-it-harder-than-it-needs-to-be Noonanism, something like
>acidify if the pH rises .7 during sparge but never more than .2 unless the
>azimuth of the moon corresponds to the declination of blah, blah, blah.
...
>What should I do and how important is it?

The consensus is to try to get it down below 5.8. For me, this works out to be about .5 tsp of acid blend in 5 gal water. If you add, say 1 tsp, then the pH of the sparge water will drop further (to 5.0 or below), but as soon as the sparge water mixes with the wort in the grain bed, the buffering action will raise the pH back to the 5.2-5.5 range. better to overdo it (slightly) than under do it.

Subject: Re: Cloudy, questions

Norm Pyle writes:

> Second problem: my all-grain brews (3 to date) are, without exception,
> cloudy.... What gives?

Eliminating the particles that can cause hazy beer happens at two points in the brewing process (and neither one is in the mash, although I suppose your mashing technique may have a small effect). The first is during the boil, where proteins coagulate. This is known as "hot break". I've heard a good hot break referred to as "egg drop soup", and sometimes you see 1-2 inch long strands of goo rolling around in your boil. The second is during cooling, where more protein particles coagulate. This is the "cold break". To make things confusing, both the process and the resulting sludge from the boil are called "hot break", but the result of the cold break process is called "trub". Go figure.

Here are some tips I've collected to help you maximize your breaks :-)
and maximize your chance at clear beer:

Hot Break:

1. Make sure you have a full, rolling boil (can't be stirred down).
2. Try adding Irish moss about 10-15 minutes before the end of the boil. This is supposed to provide nucleation sites for the protein strands so they settle out.
3. Leave the hot break in the kettle. I use a copper Chore Boy wrapped around a 4" piece of slotted copper tubing to siphon with, and that seems to filter nicely.

Cold Break:

1. Cool the wort as quickly as possible after the boil.
2. Cool to as low a temperature as possible. Noonan states that you don't get effective cold break until you cool to 50F or so. I think that's a little much, but if you can cool to 60F or so you'll get a much better cold break.

If your beer is still cloudy, you can try racking to a secondary and fining to get the remaining particles out of suspension. After racking, add a teaspoon of gelatine dissolved in water. As the gelatine settles, it should carry a lot of the particulates with it.

Frank Tutzauer has a few questions after his first all-grain batch.

> Joe Stone asks how long the sparge should take. I've got the same question.

I haven't really seen a consensus on this in the Digest. My experience is that a 20 min. sparge suffices to get me a 30-33 pts/lb/gal extract rate, but your mileage may vary. Others insist a 2 hour sparge with lots of recycling is the way to go. Try experimenting, and make sure you taste the runoff. Your tastebuds will be your biggest guide for avoiding tannin extraction.

> Second, what's the deal on acidifying the mash?
> Finally, should I acidify the sparge water?

It depends on your local water. Where I live, the water is naturally

soft and I haven't worried about it (in fact, I've never even checked the pH of my mash or sparge water). Regulating the pH seems to be a way of reducing tannin extraction, so if your beer doesn't come out overly astringent, you probably don't need to adjust anything.

Subject: Lager Starter?? General Comments

I will be brewing a lager soon. I use a refridgerator with Hunter Air stat for temp control. The controls on the fridge are broken so my choices are on / off. This limits my lagering temp to 40F. Given this constraint what is the promary fermentation temp I should use for Wyeast Bohemian yeast?

When producing a starter I plan to pop the bag at cellar temp 65F. What temp should the starter I pitch to be? Should I pich it at 65 and cool it to 60 let it reach full krausen, pitch this to a 2nd larger starter solution at 60 and cool to 55F and pitch this to the 55F wort? I plan to deal with the long lag time of cool initial wort temp by having a large amount 2-3oz of starter slurry. Am i corect in my assumption that pitching at to high a temp while reducing lag time can produce flavors and ester inappropriate for a pilsner?

Norm mentions having problems with his all grain brew remaining cloudy: did you iodine test the stirred mash? or just mash for x minutes? did you recirculate the first few gallons of sparge? did you rack off the trub? Taking the above steps I have not had a clarity problem with AG brews.

I protein rest all grains for 15 to 30 minutes even highly modifeied British grain. I find that the time to (mash only) == (mash + protein rest).

Beer loses sweetness in bottle. Attenutive yeast, like 1056, will continue to ferment complex sugars making for a less sweet beer over time. My sweet brown ale became a dry brown ale with 1056 yeast.

Acidified mash water reduces the amount of tannins that can be leached ot during the sparge. It helps reduce astringency and can improve yield.

Subject: Ginger beer update

To homebrew@hpfcmi.fc.hp.co
X-Mailer: LeeMail 1.2.4

I racked my ginger beer into the secondary last night. As in the wort, the beer had very little ginger flavor. This despite 3 oz of ginger added during boiling.

To attempt to correct this, I added 4 oz of shredded ginger root to the secondary. I dropped the whole root into a cup of boiling water for 10 minutes to sanitize. I figured that the short boil and low surface area of the uncut/ungrated root would minimize loss of volatiles while sanitizing at least the outside. After boiling, the root was grated in a sanitized food processor, and the grated material was added into the secondary (along with the boil water, which smelled strongly of ginger).

I'll taste again at bottling time, and post how it worked out.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: RIMS

We had the good fortune of having Conrad Keys at this years Bluebonnet, which was held last weekend. He was hoping to bring his first production RIMS model, but this unfortunately was not possible. He is wisely seeking insurance coverage for his system, and they have required that changes in the wiring be made before they extend coverage. He did come with a brochure on the system which contained a detailed picture of his prototype. Given the average homebrewer's skill at reverse engineering, this may provide a lot of grist for one's mill (so to speak). Conrad indicated he would sent copies free of charge to anyone who requests one.

I was reluctant to give out much detail in my review because I consider Conrad as a good friend, and I would have a hard time sleeping at night if I said something that was not in his best interest. However, he was very candid about things at the Bluebonnet, and the following is a summary of his ideas about RIMS:

1. There are three crucial design parameters. These are the following:
 - a. Type of crush used to mill the malt
 - b. Geometry of the mash tun
 - c. Diameter of the tubing used in the recirculationIt will come as no surprise that a corona is not appropriate, and any mill which gives too fine of crush will experience the problems described by Bob Jones in his post. The other two parameters are system dependent, and Conrad recommends that those who are designing RIMS cut themselves as much slack as possible in this area. For example, the optimal configuration in his 1/2 bbl. system is quite different than with the 2 bbl. system.
2. Top flight pumps are also crucial. Most pumps will eventually give a laminar flow. Some, however, will cause foaming at the start and at the end. These should be avoided.
3. Less than optimal yields will occur if there are temperature gradients in the system during the mash. This tends to be more important for the larger versions than the small one described in Rodney Morris' articles. I personally am not a "yield uber allen" type. My bottom line is the finished beer itself. If it is to my taste in the case of my beer, or to another's taste in the case of their beer, then whatever procedures used will not be faulted by me. In any case, those wishing to increase the yield of their RIMS may want to investigate the heating used with an eye to removing thermal gradients. Obviously this depends very sharply on the geometries involved.

George Fix

P.S. The Bluebonnet was a great success. I was really proud of the dignified and refined behavior of the participants. There were, at the very most, only 2 or 3 fistfights, a new record for Texas! Seriously, it was a lot of fun, and we were all grateful for the entries sent in from outside our region.

**** OPEN MSG TO JACK SCHMIDLING**** (did I spell that right?)

Hi Jack...

I've been reading the digest for a while now, and am considering the shift to all-grain. I have been slowly gearing-up, and recently lucked into a used 8 gal SS stock-pot with a spigot already attached. I remember reading a few posts about your Easymasher(tm) setup, and I'm curious to know how much trouble it would be to sort of "borrow" (brown-nose-mode on) your skill and experience. I was hoping you could see your way clear to sharing the basics of your design with me. Please please please please. I will- of course - understand, should you not wish to part with it.

Grovellingly yours, Mark

Subject: bottle conditioning takes a long time?

Recently I posted an item in which I expressed concern over my beer not conditioning. After regularly experiencing 3 day ferments, and reading about how conditioning occurs "rapidly" I was upset to find almost no pressure in the bottles after 4 days. I then tried experiments by modifying three bottles as follows:

- (a) add 1/4 teaspoon extra sugar directly
- (b) add 1/16 teaspoon (roughly measured) of dried yeast directly
- (c) put 1/4 teaspoon of dried yeast in 25 ml water to rehydrate and pour 5 ml of slurry into a bottle

This is to report the results of that experiment, since people have expressed interest.

The summary is that I was indeed too hasty. Two weeks later and the bottles had conditioned beautifully. In comparing each of bottles a,b and c above with an unmodified bottle, there is virtually no difference between b, c and the standard bottle, at least as far as carbonation is concerned. There seems to be a very subtle difference in flavor, but so subtle that it can be effectively ignored. In my case I suspect the M&F dried yeast I added is less attenuative than the WYEAST 1056. There may have been a difference if it was the other way around.

As far as bottle (a) goes, yes it's more carbonated, a bit too much so.

The bottom line is to not expect bottle carbonation within two weeks. TNCJHB suggests some beers are ready to drink in days, but this will be strongly dependent on the yeast used.

Thanks to everyone who replied to my original note.

Peter

Subject: American Black Malt

For those who are using American black malt in their beers, I thought the following might be interesting. It's from an article by Roger C. Briess, of the Briess Malting Co., in the October 1986 issue of Brewer's Digest, a professional publication. As far as I know, Briess is the only American malthouse producing black malt. This article was what convinced me to use only British black malt in my beer (since upgraded to include malts from Germany).

"Black malt is specifically produced for coloring value. Extract and enzyme activity are inconsequential.

"Historically, black malt imparted an astringent, harsh, smoky flavor to beer. Beers dating back several hundred years could tolerate such flavor profile due to high gravity worts. We have been successful in eliminating this undesirable characteristic to make the product compatible with the lowest gravity beers, such as 'light' beer.

"The proper application is in the mash tun; however, black malt flour may be added to the kettle for minor color adjustments.

"Coloring value has been empirically established at 0.08 lb/US Bbl to increase beer 14 degrees Lovibond. The value is linear. It was established in our pilot brewery in Chilton and corroborated by cooperative tests by select commercial breweries."

Briess black malt, in other words, is the brewing equivalent of decaffeinated coffee.

Subject: Cheap 5 Gallon Carboys

I don't know about 7 gallon carboys (I got my used one through mail order for \$10.00 plus \$8.00 shipping), but for brand new 5 gallon carboys, try your local Corning Glass outlet. They have them for \$8.99 brand new. I compared them to the ones for sale at the beer stores and they are exactly the same only \$7.00 cheaper! While you are there, pick up some foot, half yard, and yard classes in stands for magnitudes less than the beer store. The one I go to is in Gilroy Ca. I assume they are nation wide.

Subject: Real Root Beer and Cancer

While catching up on my cross-discipline reading on the train this morning, I came across a very interesting paper on natural vs. synthetic carcinogens in the diet (L. S. Gold, et.al., Science, vol. 258, pg 261, 9 Oct 92, "Rodent Carcinogens: Setting Priorities"). Since many of us long for the taste of REAL root beer, I thought it would be interesting to compare the banned chemical safrole (the primary carcinogen in sassafras) with other known carcinogens.

The paper ranked 80 natural and man-made chemicals shown to cause cancer in laboratory rats. First some definitions:

TD50 = the daily lifetime dose (milligrams of chemical per kilogram of body weight per day) which halves the proportion of rats which remain cancer-free at the end of a standard lifetime.

HEPR = (Human Exposure/Rat Potency) the percentage of TD50 received by a 70 kilogram human for the given lifetime intake rate, i.e.,

(mg chemical per day) / (70 kg)/(TD50 for that chemical).

HEPR (%)	HUMAN EXPOSURE (PER DAY)	RAT CARCINOGEN
4.7	Wine (250ml)	Ethanol (30 ml)
2.8	Beer (12 oz; 354 ml)	Ethanol (18 ml)
1.4	Mobile Home Air (14 hrs/day)	Formaldehyde (2.2 mg)
0.4	Regular Home Air (14 hrs/day)	Formaldehyde (598 ug)
0.3	Lettuce, 1/8 head (125 g)	Caffeic acid (66.3 mg)
0.2	Real Root Beer (12 oz; 354 ml)	Safrole (6.6 mg)
0.1	Apple, 1 whole (230 g)	Caffeic acid (24.4 mg)
0.1	Mushroom, 1 (15 g)	various hydrazines
0.1	Basil (1 g of dried leaf)	Estragole (3.8 mg)
0.07	Pear, 1 whole (200 g)	Caffeic acid (14.6 mg)
0.07	Brown Mustard (5 g)	Allyl isothiocyanate (4.6 mg)
0.06	Diet Cola (12 oz; 354 ml)	Saccharin (95 mg)
0.04	Coffee, 1 cup (from 4 g)	Caffeic acid (7.2 mg)
0.03	Celery, 1 stalk (50 g)	Caffeic acid (5.4 mg)
0.03	Carrot, 1 whole (100 g)	Caffeic acid (5.16 mg)
0.006	Bacon, cooked (100 g)	Diethylnitrosamine (0.1 ug)
0.002	White bread, 2 slices (45 g)	Furfural (333 ug)
0.002	DDT, daily avg before ban	DDT (13.8 ug) (before 1972)
0.001	Tap Water, US avg (1 liter)	Chloroform (83 ug)
0.00003	Approximate HEPR of upper-bound risk estimate used by US regulatory agencies to control exposure to man-made chemicals.	
0.00000006	Captan (synthetic pesticide), US daily avg residue intake	Captan (11.5 ng)

g = gram, m = milli-, u = micro-, n = nano-, l = liter

Please note that HEPR is NOT a direct estimate of the risk of a human getting cancer, but rather is an index of relative carcinogenicity. Thus, all it seems you can say is that drinking one bottle of real root beer entails about the same risk of cancer as eating two fresh, unsprayed, organically-grown apples.

Again, this is not my field, so I suggest anyone with an uncontrollable

urge to flame first read the whole paper and then refer their
professional
comments to the authors.

Subject: Re : British pubs

I came here to GB 3 years ago and was disappointed at the number of tied pubs which offer only one brewery's products. The best opportunity for beer education is to find a festival. These are advertised in the CAMRA mag "Whats Brewing", presumably available to non-subscribers from the London office. There is a festival somewhere in the southern regions about fortnightly. One tip: most brew is past its best after 2 days, so go early. Continental festivals are also starting to find their way in there, eg, Cantillon in Belgium seem to have regular beer breakfasts!

Subject: Peracetic Acid and Other Strong Cleaners!

With all of this talk about using peracetic acid, let me just give people a brief warning. Mixing peroxides and acids is not to be taken lightly.

We use a 3:1 mixture of a mineral acid (I will not name it) to 50 percent hydrogen peroxide as a method of removing photoresist from wafers. This mixture is called 'piranha etch' as it is very powerful. It will very strongly attack any organics, skin included.

Also, the cleaning power of such a mixture diminishes very rapidly. If allowed to stand for a while before use, its essentially just the same as using the acid by it self. The oxidizing power of the hydrogen peroxide is short lived.

Someone mentioned that the Merck Index talked about peracetic acid being explosive at 110C. Peroxides can be very unstable. A few years ago, the bomb squad had to remove hundreds of vials of peroxides from Thomas Edison's lab in NJ as he had lots of old peroxides sitting around for 50 to 75 years.

I have found that plain old unscented chlorine bleach is a very effective cleaner. Stuborn 'gunk' from a vigorous primary can easily be removed by just filling the carboy with water and adding a little bleach and letting it sit for a week. It is also safer than many of the more concentrated cleaners.

Similar warnings go for using strong caustics like sodium hydroxide. They are dangerous stuff, so please don't take they're use lightly. Its roughly equivalent to using draino as a cleanser.

Just some things to think about. Read up on these cleaners before you use them!

Subject: Non-Alcohol Brews

To The Gentleman Asking About Non-Alcohol Brewing,

To be a purist, non-alcoholic beer is a contradiction. For if it does not have alcohol it cannot be legally called beer. However, as long as we we're being picky the commercial versions of NA beers are not precisely NA beers. They contain something under 0.5% alcohol.

Recently, I saw an article written about such beverages and I just wanted to pass this information along to someone who really could use it. It was prepared by the Copley News Service.

Basically brewers employ either of two methods to achieve a non-alcoholic product:

1. The older technique takes beer that has been made in the usual way and evaporates the alcohol by heating the brew in a vacuum chamber, which allows a low boiling point. Kingsbury and Kaliber are made this way. The principal problem here is to avoid changing the taste of the brew by cooking it. In addition, this process would be very impractical for one of more modest means like most homebrewers.
2. A more modern method, used by most of the German brewers, uses intense cold and rapid extraction of the yeast to arrest the brewing process before too much alcohol forms. This technique seems to leave a lot of the sugar in the brew and therefore gives it a sweet taste.

The second option would seem to give homebrewers a chance to attempt a low-alcohol beverage. Assuming that you make ales, chilling the fermenting wort sufficiently would be practical in a refrigerator. In addition, the remaining yeast could be fined with your favorite fining (I would probably use polyclar since it would seem to be able to work with the high gravity liquid).

The resulting beer would not be the same, but much sweeter. It depends upon your taste. I have not read the HBD since you posted and I wonder whether you have heard similar words from others but I hope this helps. I hope you can drink beer in some way or other.

Good Luck.

Subject: help! nonstop fermentation

Dear Colleagues:

Words of consolation, anyone? My wife and I finally collaborated on a batch of HB and despite the initial excitement, we have a problem on our hands. Here's the dope:

1 can (4lbs.) Ironmaster "Special Lager" malt extract
packet of Isohop extract (included with above)
2 lbs. corn sugar
1/2 lb. maple syrup
2 oz. apricot wine flavoring ("Wines Inc.")
11.5 g sachet Edme dry yeast

It was a 50-minute boil with apricot extract only going in the last five. I rehydrated the yeast in warm water shortly before pitching. O.G. was 1.050 and when I racked to secondary three days later it was 1.018! Now here's the problem: *that was exactly four weeks ago and fermentation has not stopped.* Bubbles still rising, a cute layer of foam still on the surface. I've never encountered this before. I've always been a careful sanitizer, but should I assume something got by me this time? Temperature has been 58-62F for the duration. Don't pick on me for using corn sugar (it was the first time I've done so in years--my last few batches were nearly non-alcoholic and my checking account was low: MEA CULPA). And yes

I'll be going to liquid yeast for my next one. But what about now? Down the loo?

Thanks for you advice or condolences via e-mail.

Subject: Mashing Questions

Okay, I seem to be still confused about mashing...

-what is a protein (enzyme) rest and at what temperature?

-what is a good temperature to keep your mash so that the enzymes don't break down the complex sugars? I am more concerned about a heavy malty taste (not caramelly taste) than the alcohol content.

-what temperature converts starches over to sugars?

-what "normal" order or succession should each of temperature categories be in? does it matter?

any help would be most appreciated...
thanks,
-chris

From: William Boyle (CCAC-LAD) <wboyle@PICA.ARMY.MIL>
Subject: Crystal malt

I have a question about crystal malt. Crystal malt will add body, sweetness and color to a beer. These three contributions will vary depending on the lovibond of the malt. I feel that any crystal malt should add the same amount of unfermentables to the beer, this in-turn should add the same amount of body and sweetness to the beer. I think some of the sweetness may be masked by the flavor of darker crystal malt, but the increase in body will be the same for any crystal? Am I wrong for thinking like this?

On a side note in my dictionary beer is defined as a beverage made from malt, hops, yeast, and water. It does not say malted barley, so the clear beer can be called beer is it is made from malted rice or corn? I know it really does not matter but its a thought.

From: Jim Busch <busch@daacdev1.stx.com>
Subject: Filtration, pt 1 of 2

Filtration for homebrewers:

After brewing for several years, I finally had an occasion that called for me to consider filtering my beer. What happened is that in my quest to brew true to style beers, I used a different yeast strain, specifically a Weihenstephan Altbier strain (no, it is not from Wyeast). I calculated out a Alt bier recipe of 40 IBUs, 11% CaraMunich malt and 2 row grist to yield an OG of 12P (1.048). All went as planned, ferment was vigorous and a ton of yeast was skimmed off of my open fermenter. The beer was kegged and lagered at 31F for 3 weeks. After sampling this beer many times during the lager stage, it became apparent that the yeast was refusing to flocculate. I mean were talking milkshake looking stuff (kinda like Widmer "HefeWeizen" :-). So, I decided to do some research on home filtration. I had just won a copy of the AHA 92 conference transcripts and noticed that Steve Daniels wrote about filtering his beers. I was aware of The Filter Store and some of their products since a local brewer uses the standard kit to filter some of his beers. Steve also recommends using this basic kit. He claims to have tried all sorts of filters and found a "happy medium" using a .5 micron sterile filter. This is indeed the filter sold with the basic kit from the Filter Store. Now, I am quaffing a few ales with my local Brewmaster friend and we are discussing the merits of filtration and specifically the degree of filtration required. Old Dominion Brewing CO, where my brewmaster friend brews, filters using a plate filter and removing down to 5-7 microns. Another Baltimore brewpub does a similar level of yeast removal. The beers produced from these breweries have a fine degree of clarity to them. Not sparkling crystal clear, but certainly quite clear. I also feel the flavor from hops and malt and overall mouthfeel of these beers is very good and devoid of any "thinness" or lack of head retention. At this point, I decided to post a inquiry to the HBD on filtration methods. I got three responses, two of whom were using .5 micron sterile filters and one who said his was 2 microns. So, I was at a dilemma stage, where my professional brewer friends were claiming to not go below 5 microns to avoid

stripping the beer of important flavor elements, especially proteins, whereas people who actually used the home filter methods seemed happy with .5 micron sterile filtration. I decided to ask Dr. Fix, who provided the following:

>From gjfix@utam.uta.edu Wed Mar 3 14:22:15 1993
Jim:
Content-Length: 1736
X-Lines: 32
Status: RO

>A quick question, how many microns is a yeast cell? I need to
>buy a filter to clarify my Altbier that is real yeasty, despite
>being lagered at 31F for 3+ weeks. What I want is a real coarse
>filter, I am not interested in removing chill haze, I just want
>to remove yeast. Any ideas on the coarsest filter that will do
>the trick? All I read is about people using .5 micron filters
>and I believe this is smaller than I need.

Yeast cells vary from 5 to 10 microns. My own filter is a Zahm+Nagel cartridge which is precoated with DE. The cartridges come in 3, 1, and .45 micron sizes. I use the 3 micron version for my own homebrew. We also use this size for BRD brew pubs. Some yeast will make it through this type of filtration (don't ask me how!), but only at very low levels. >(apparently any very young cells can be smaller than 3 microns and thus >make it through the filter, JB)
Plating with SDA has indicated that the counts rarely go above 20-25 cells/100 ml, which is next to nothing considering we pitch at a rate of 10 million cells/ml. I have found that a 1 micron filtration will eliminate yeast, but will also start to compromise the beer's foam stand. Pedios, if present, will also make it through. They are only .8 microns in diameter. A filtration at .45 microns will remove everything, but it has a very negative effect on both beer foam and flavor. These defects in "sterile filtration" are well recognized. Nevertheless, many micros (as well as large breweries) are starting to filter at the submicron level. They claim their unpasteurized bottled beer tastes better after 3-4 weeks in the trade than it would if the sterile filtration were not used. They are likely correct, but I personally would do what ever it takes to keep the bugs out, and not go below a 1 micron filtration.
Take care.

George Fix

end part one.....

Date: Wed, 10 Mar 93 9:52:36 CST
From: tony@spss.com (Tony Babinec)
Subject: wit beer recipe and comments

Here's a wit beer recipe (for 5 gallons) and comments:

5 pounds pale malt
1 pound wheat malt
2.5 pounds flaked wheat
0.5 pounds flaked oats
hersbrucker hops to 18 IBUs
20 gms ground coriander seed
5 gms dried orange peel
2 gms ground cardamom
yeast: Wyeast Belgian

Process was an upward step infusion mash:

110 degrees F for 45 minutes
122 degrees F for 45 minutes
144 degrees F for 30 minutes
150 degrees F for 90 minutes
mash out

Spices were added in the last 10 minutes of the boil.

Flaked wheat is available from homebrew shops, but can also be found in health food stores or natural food sections of supermarkets. I MUCH prefer flaked wheat to raw wheat berries. The flaked wheat is already gelatinized. The raw wheat berries should be boiled and gelatinized, and that's a mess. Also, there are different wheats available, and it's not clear to me that what's available in the health food stores is the same wheat as the Belgians use. The wheat malt in the above grain bill was a hedge, and in retrospect could have been flaked wheat.

Flaked oats are available from homebrew shops, but rolled oats (such as Quaker oats) could be used.

Somewhere in Michael Jackson's writings, I'm pretty sure he says that Hoegaarden Wit has a grain bill as follows:

50 parts barley malt
45 parts wheat
5 parts oats

While my grain bill used a bit more barley malt than these proportions would suggest, I was nervous about conversion and my starting gravity. Not to worry -- the deliberate low temperature rests and long rest times did the trick, and I got about a 1.050 beer.

Ground coriander is a great spice, and I thought that 20 gms would not be too heavy-handed. Incidentally, there are different types of coriander seeds available. Instead of going to the spice rack of your favorite grocer, go to a spice specialty store to seek out the larger coriander seed that is more "noble" -- that is, aromatic and flavorful.

Ideally, the orange peel should be from the curacao orange. Here's a thought -- use a dash of orange curacao liquor in the beer. I

used McCormick dried orange peel to no apparent bad effect. If I were to do things again, I might up the amount a bit, or substitute something fresher.

Cardamom is a very elegant spice with a lemon-citrusy aroma and flavor. I use it lightly for background flavor and character.

Wyeast Belgian is a strong-gravity performer, but I used it here in a conventional-gravity beer. It did contribute a bit of its own flavor, though somewhat muted. I racked onto the yeast cake from a just-racked beer, and maybe that contributed a bit of pleasant dryness to the beer. I'd love to get my hands on Hoegaarden or Celis yeast, and failing that, might use Wyeast "London."

The suggestion in HBD to add a dash of lactic acid for some tartness sounds like something to try. As the acid is quite concentrated, it shouldn't take much.

End of HOMEBREW Digest #1095, 03/11/93

Date: Wed, 10 Mar 93 12:12:38 EST
From: Jim Busch <busch@daacdev1.stx.com>
Subject: Filtration, pt 2 of 2

Filter post, pt 2.....

So, armed with this information, I called The Filter Store and asked about coarse yeast filters. They informed me of a 5 micron and a 1 polypro 99.9% efficient filter. I ask about adaptability to my whole house filter and they agree that it is compatable. I order the 5 micron filter. I need to build the connectors.

The filter connects are 3/4" female NPT. So, I buy 2 3/4" male to 1/2" sweat copper connectors, and two 1/2" sweat to 1/4" thread bushings and two 1/4" threaded hose barbs. Soldering these together, and screwing in the hose barbs results in a solid 3/16" id hose to 3/4" filter union.

I buy a \$13 cheapo whole house filter from Hechingers, and my cartridge arrives. I filter the still beer through the 5 micron filter after sanitizing

the kegs with Iodophor and the filter with Vigilquat. I push lots of hot water through the filter to rinse prior to use.

The beer is noticably clear, with some haze remaining but no real detectable

yeast cloudiness. The beer vastly improved in flavor. The cartridge was quite

discolored, due to lots of yeast captured. I back flush with hot water and

soak overnight in a caustic solution. The filter is stored in a ziploc bag

containing water and a sanitizer of your choice. For my first filtering, I

only filtered 10 gallons, so I do not know the volume limitations of this filter. It is claimed to filter 150 -250 gallons of beer, but I suspect that with good cleaning it will last longer.

Conclusion:

I am quite satisfied with my 5 micron filter. It did what I wanted, removed the yeast, resulting in a polished product. I am quite sure that it would have been crystal clear with a .5 micron unit, but I suspect that flavor and head retention would have suffered. Note that a 5 micron filter is not a sterile filter and as such the brewer needs to have a good grasp on on proper sanitation techniques, but I suspect those of us using kegs and filters already have a good feel for sanitation.

Good brewing,

Jim Busch

PS: my Altbier was made using all Liberty hop pellets. The IBU was calculated to be around 40, but the bitterness perceptions to me are much less. This hop has an alpha of 4.0 and is the latest american attempt to produce domestically a hop with characteritics of Hallertau. I detect a grassy aroma from this hop, but at times it does appear to remind me of a hallertau essence.

Subject: Wort chiller using dryice

BREWERS,

The fellas and I were bottling a batch of winter Lager the other evening, and talk turned (as it will) to the Next Batch. We hit upon an idea that is simple, straightforward, and seemingly foolproof; why not cool a hot wort with dry ice? Think about it: No wort-chiller hardware, no sink full of icecubes, no floating the wort kettle in the cold swimming pool out in the back yard. Just cold wort, fast.

Has anyone tried this? Does it make sense? Seems to to me, but then we were relaxing and having a homebrew at the time.

In my lab at work, dry ice is available and free. (It can't be recycled...) I'm sure I could add enuf to the kettle to drop the wort temperature 75 degrees C in maybe two minutes. Follow this with vigorous stirring to re-oxygenate the wort, then pitch.

I invite comments and criticisms on this idea. Tell me now, before we burn \$20 worth of grain and yeast trying it.

If this works out, we plan to go to extremes and cool the next batch with liquid nitrogen...

Scott Knowles * I love beer. Is that such a crime? *

>This suggests to me that you may have scratched the primary while
cleaning it after your first batch. Once a plastic fermenter is
scratched, it becomes very difficult to sanitize properly. Check
your primary carefully for scratches, and if there are some,
replace it.

Far be it for me to question the wisdom of the ages but I have (had)
used the
same plastic primary since the early 70s and have not had an infected
beer

since a few months after I started to read the Digest. I attribute the record to one or both of two procedure changes.

Number one on the hit list was Red Star Yeast, contamination is built in at no extra cost. You also need to find out who actually produced the yeast you use to make sure it is not one of the many brands of re-packaged Red Star.

Number two was to ignore the usual instructions for making a sanitizing solution from bleach, i.e. 1 oz bleach to the gal or even 5 gallons of water.

After cleaning the fermenter with a sponge and Ivory, I rinse it and put in about a cup of bleach. I then put on the lid with a stopper in the hole for the air lock and slosh it around thoroughly and set it aside till the next use. Next time I need it, I slosh it around again, dump out the bleach and rinse it carefully. I guarantee, there is no scratch deep enough to evade this treatment.

If you use iodine, I would suggest the same procedure with maybe an oz of juice to a cup of water.

I now use my 10 gal mash kettle for primary and much prefer this because I can avoid all chemicals by simply boiling some water in it to sterilize it.

Subject: Re: Sanitizing Chemicals

I tried sending this directly to u4imdmre@cpc41.cpc.usace.army.mil, but I got a "Host unknown" bounce. So I post.

I have always used unsented Clorox bleach at 2 fl.oz./5gal to sanitize HDPE buckets. Contact times anywhere from 15min to 1 week. Then rinse with tap water. I often throw all of the equipment I need in the bucket for a while, then empty everything out and rinse. Then use th bucket for priming or fermenting. Never had any infections (knock on wood) or any damage to the plastic. The only problems I have had with bleach is leaving stainless steel (or most any other metal) in it for more than a half hour is can cause oxydation.

I don't know about using Tide though. I use Tide for a lot of things (including laundry, of all things), but not for my brew equipment. For that I use Cascade automatic dishwashing detergent. I have heard that that will not kill the head retention.

From: rich@bedford.progress.COM (Rich Lenihan)
Subject: Cleaning plastic buckets

One thing that will work for getting critters that are hiding in the cracks of plastic buckets is boiling water. I have an old plastic primary that has since been retired to bottling bucket. Before brewing I preboil 7+ gallons of water and transfer it to the plastic bucket. This makes the bucket very hot. Try this before you attack it with chemicals.

I then use a dilute bleach (1 tbsp/gal) for 15 minutes to sanitize before bottling. I do not recommend storing high concentrations of bleach in plastic for any length of time. The plastic will absorb the chlorine and even give off an odor of chlorine. Trust me. I *know*.

Subject: Re: Celis White Recipe

In HBD 1086, Alan Derr asked about a recipe for Celis White...

I've made three extract-based batches of Belgian ale over the last few months, refining the recipe towards my personal preferences. A few weeks ago, I finally got to taste Celis White, and (surprise!) my latest batch is very similar to Celis.

Basically, just use Papazian's "Who's In The Garden Grand Cru" recipe, reduce the malt and honey a bit, and slightly bump up the hops.

"Tamalpais Wit" ("tam-ul-PIE-us vit", or "der schlafen dame weiss" for you who don't speak coastal Miwok and Belgian)

4-3/4 lbs light dried malt extract (or 5-1/2 lbs light malt syrup)
2-1/4 lbs orange blossom (or other light) honey
1 oz Hallertauer (boiling), 6 HBU
1/2 oz Hallertauer (flavor)
1/2 oz Hallertauer (aroma)
1-1/2 oz freshly crushed coriander seeds
1/2 oz dried orange peel
Wyeast #1214 Belgian ale yeast

Papazian suggests a 1-1/2 gallon boil, but I've been doing full 5-gallon boils with great success. After 45 minutes, add the flavoring hops and half of the coriander; after 55 minutes add aroma hops, remaining coriander and orange peel for the last 5 minutes. Ferment at 72 degrees F.

I pitch the yeast (in a 1-qt starter) at about 78 degrees F to get the primary fermentation going quickly. This beer is ready to prime and bottle after about 10 days. The classic Belgian ale characteristics really come through when you ferment this ale at a slightly warm temperature, as others have pointed out in earlier digests.

Since Celis White is made with wheat malt, I'm going to start experimenting with replacing some of the malt extract with wheat extract...

>of "cooker summary", and I will forward it to you.

Well, guess what...I received over 40 requests. I guess that means
I should just go ahead and post it. However I am still compiling data.
I want to include info from a couple of vendors. The reason for speaking
with vendors is that the King Kooker company does not sell any burners
that they recommend for indoor use. (thanks Mike O'Brian at pico-
Brewing
Systems in Ypsilanti,MI). I guess the two major concerns are generation
of heat and exhaust gasses, and depletion of oxygen. I guess 100K+ BTU
might be a bit much for indoor use. Anyway the complete summary will
be posted next week. Sorry it's taking so long. (10 days were spent
visiting 18 of CA's finest brewpubs :-D hey gak, did you get that mug
yet?)

I will post the cooker summary ASAP....

Subject: Yeast Slant ?? / Mashed stout / Kegs

I have just been given a slant of
I have been given a slant of Weinstephan 3407 yeast. What information do
people have on this variety. What temp should I ferment / lager, what
are
its flavor charecteristics, is it stable for reculturing? Please post
responses to HBD or send to lmenegon@necis.ma.nec.com

Re infusion mashed stout:

I do not mash the dark grains with pale malt, it makes the iodine test
nearly impossible to read and the acidity of the highly kilned malts may
over acidify the mash. I steep the grains and add them to the mash
kettle
at mash out.

Re keg sanitation:

I fill my keg with water and add acouple Tbs of Bead Brite . I use a golf
tee or nail to depress the spring loaded valves of the liquid out and
tilt
the keg until a little of the sanitizer solution drips out. i repeat
this
for the gas in connection too. I then top off the keg close it shake it
ing water. Drain rinse with some more boiling water. Drain. Finally I
add
1 quart of boilning water apply CO2 and blow the water out thru your tap.
Your keg should now be sanitized , its liquid out tube clean and be
filled
with CO2 so oxidation should be minimized when you rack in the brew.

Just so someone isn't disappointed -- not all Sunshine Wheat is done in the White beer style. In fact, most is just an American pale ale-style wheat similar to that done by other micros. The White-spiced bottles of Sunshine Wheat were from a special batch that was one-time only, as far as I know. (Apologies to you non-Colorado folks who don't have access to either version. I guess you'll just have to come for a visit :-).

Dear Mr. Powdered Sugar,

(sorry I don't remember your name; I deleted the HBD from last week with your response in it. 8^o

Yes, the powdered sugar with the cornstarch is often called confectioner's sugar, but not always (I checked at the grocery store last night). I originally pointed out the cornstarch issue so that people wouldn't blindly buy powdered sugar and end up with the cornstarch version.

By the way, I mis-quoted the sugar/cornstarch ratio. It's not 70%/30%, but rather 97%/3%.

Subject: Weat beers

Having read Eric Warner's book (good beginning), Chuck had some questions about weizen yeasThe Yeast Culture Kit Co. (I think that name is right) has an authentic weizenbier yeast strain you might want to track down; unfortunately, they are no longer selling retail so it will take some sniffing. But I believe you will have better results with that than with the Other wheat beer strain, for the time being.

I don't believe any of the wheat beers currently imported fm Germany use the fermentaion strain in bottling, and in any case most have been pasteurized. The strain Warner used was brought back from Germany. (By the way, I was on the panel in Milwaukee that awarded his blue ribbon and I vouch for the fact that the man knows exactly what he's talking about in regard to weizens.) In the fall, Admiralty Distributing, here in Portland, will be imported Schneiderbrau, which Warner mentionsand the importer assures me the fermentation strain and bottling strain are the same (he just got back from a visit). You certainly can't ask for a more authentic yeast than that!

Although I view some claims about decoction mashes with considerable skepticism, I would certainly take Warner at his word!

Subject: Slotted Copper

Subject: Slotted Copper Time:8:39 AMDate:3/11/93
According to Mr. Bliss on slotted copper manifolds:

>If you try to slow it down, you're only draining wort through the
>slots nearest the outlet.

My manifold has about 10' of 1/2" pipe overall with slots every 1/4",
everywhere. It exits the tun and connects to a 5/8" hose which has a
tubing
clamp across it which controls the flow. I sparge by running the water
onto the
top of the grain bed allowing an inch or more of standing water to cover
the
bed. I then drain at a rate which gets me about 10 gallons of wort in an
hour,
keeping the inch of water on the grain bed until I'm within a gallon or
so of
my desired total. Then I shut off the sparge water and drain the bed dry.
I
typically get a yield of 31 or 32. On my last batch, 14 gallons of mild,
I got
35!

I don't see how I could be getting these numbers if I wasn't getting good
coverage of the sparge flow through the grain bed. Nor do I see why
restricting
the flow out of the manifold would have the effect described by Brian.

>effective sanitization than doing the same with a small amount at the
>recommended concentration.

I didn't see any definitive comment on this while I tried to find some
quotes from microbiologist acquaintances. But, I didn't want to leave it
alone.

My information is that sloshing "a small amount around for a minute", no
matter how high the concentration, is generally ineffective for
sanitization.

That is why people use 5 gallons of sanitizer in a 5 gallon container,
because "sloshing" doesn't work well. Of course, those of us who use
bleach use the 1-3 tablespoons of chlorine bleach in 5 gallons of water
as
our 5 gallons of sanitizer. It may take 15 minutes to effectively
sanitize, but at least it does a good job of that.

>As rinse water is not a problem around here, I don't mind more thorough
>rinsing and it is still far less than I had to do with bleach.

Of course, rinsing is only a problem with bleach if you use so much that
it
doesn't quickly evaporate. When you use the amount mentioned above and
then empty all 5 gallons of sanitizer out, you are left with a few drops
of
water that have at most 200 ppm of bleach in them. The little bleach
left
in those few drops evaporates very quickly and doesn't require any
rinsing
of any sort.

It clouds the issue because some people are able to "sanitize" with tap
water and not get infections, so even if you use a not-very-effective
method like sloshing pure bleach around for a minute, you might not get
bit
by an infection.

As others have mentioned, many commercial breweries use steam to
sanitize.

I remember that the Old Dominion Brewery here in VA didn't get that in
the
plans or something, and it cost them something like an extra \$60,000 or
more to get the steam piped ten or twenty feet to the vessels to be
cleaned.

OTOH, I have seen ads for used steam cleaning apparatus for under \$3,000
in
my local newspaper.

I say go for it!

>effective cleaner. Stubborn 'gunk' from a vigorous primary can easily be
>removed by just filling the carboy with water and adding a little
>bleach and letting it sit for a week.
>It is also safer than many of the more concentrated cleaners.

I've found this too, but my intention was to minimize the amount of un-natural chemicals I was dumping down the drain. Acetic acid and H2O2 seemed much more "green" than Chlorine Bleach or Iodine. Am I right? Perhaps in the concentrations we are using them (and given the concentration of the Acetic Acid needed for it to be useful), perhaps 200ppm Chlorine bleach solution or 25ppm Iodophor is more "green?" Can someone who really knows confirm or correct this assumption, please?

Remind me not to trust the Copley News Service. You see, there is a third method, which is used by at least one mega-brewer, in which a semi-permeable membrane is used to extract the alcohol by osmosis and a fourth method in which a special yeast is used that does not produce much alcohol.

Temperature

>has been 58-62F for the duration. Don't pick on me for using corn sugar

Several possibilities:

1. 58-62F is pretty cool for some yeasts, although I was under the impression that Edme was a voracious fermenter.

2. Could the apricot wine flavoring have some preservatives in it? Did its instructions say to use it in the ferment or at botting?

3. You may have a wild yeast in there that's eating the more complex sugars. It may not be your sanitation -- the Edme may have had a small amount of wild yeast along with the primary yeast.

I have a yeast that takes six or more weeks to ferment out even at 68F!

Chris writes:

>

> -what is a protein (enzyme) rest and at what temperature?

A protein rest is a time period in your mash schedule in which proteolytic enzymes break large proteins into smaller proteins and amino acids. The larger proteins will give you chill haze so you want them out of your beer. The smaller proteins that are created from the big ones will give you head retention and bigger mouthfeel. The amino acids are needed by the yeast for nutrition. Most malted barleys currently available are fully-modified, so a protein rest is not really necessary. Historically, only undermodified (which is rare these days) pilsner malt *required* a protein rest, but many brewers still incorporate one in their mash schedules. The temperatures for a protein rest are between 122F and 131F according to Charlie, if my memory serves correctly.

>

> -what is a good temperature to keep your mash so that the enzymes don't >break down the complex sugars? I am more concerned about a heavy >malty taste (not caramelly taste) than the alcohol content.

You would want to do the saccharification rest at the higher end of the saccharification range which is roughly 148F to 158F. Therefore, mashing at 158F will give you the most dextrinous wort, which appears to be what you are seeking. Along with this high mash temperature, you may also want to increase the malt in the recipe to achieve this "heavy malty taste."

>

> -what temperature converts starches over to sugars?

That's the saccharification range, above.

>

> -what "normal" order or succession should each of temperature >categories be in? does it matter?

(Optional) protein rest, followed by the saccharification rest, followed by mashout at 168to170F. You *must* work from the cooler rests up to the warmer rests or, for example, you will denature the proteolytic enzymes if you do the saccharification rest first. There is also an acid rest, which I believe is at 95F, used to lower the pH of the mash (this is if you want to strickly follow Reinheitsgebot and avoid chemical acidification of your mash).

^^^^^^^^^^

If you brew a sweet stout, I've got a suggestion for its name.

Tony writes that he would avoid dried orange peel in his next Witbier recipe.

Yesterday, I was reading Pierre Rajotte's Belgain Ale in which he mentions that the brewers there use *dried* orange peel. Well, this makes sense, because I don't think there are many Curacao Oranges growing in Belgium. I used fresh orange zest (4 oranges) in the last 5 minutes of the boil in a semi-recent batch and it was not very noticable -- I'm just saying that switching to fresh zest doesn't automatically mean you will get more out of it. I will be trying dried next time, primarily because making fresh zest

is a pain and also because commercially-made dried zest is more consistent, making the recipe more reproducible.

From: kurka@bmcw.com

Subject: A few observations regarding cleaners and sterilizing agents.

Experiences I have had with chlorine as a sterilizing agent is that it has the possibility of giving an "off" flavor to the brew. Whether or not

this was a case of not rinsing the equipment well enough after the chlorine soak is not known.

Soon after an experience like this, I switched to Sodium Bisulfate as my primary sterilizing agent and have had fine success with it. If the equipment is not rinsed well, a white residue can be easily seen and dealt with.

(I find it to be a fair check on if the equipment has been cleaned well enough).

A boiling water dip for bottles and caps is also recommended. Sterilizing glass jars and lids during any food canning process is done in this manner. (Since we are "Canning" liquid food, we can look to the food canning process for a few tips). This step also will crack bottles that may be weak and might crack when actually put under pressure.

Does anyone have a list of any Homebrew mail order catalogs?

Also, If any of you have used them, Your comments would be appreciated.

Thanks for all the postings to HBD. We in Boise Idaho need contact with the "real" beer drinkers of the world.

From: Richard Saunders <richsa@microsoft.com>
Subject: Two Seperate Questions on: Kegging and Bitterness

1. My friends and I have twice attempted the Fraternity House Ale (a 5 gallon version) from the AHA Winner's Circle recipe book. Both times the beer has come out alright except for a kick-you-in-the-zipper bitter after taste which, as you can imagine, is very unpleasant.

While this recipe is kind of heavy on the hops I have a hard time thinking that this is the problem. I have boiled lots of hops for more than an hour before and had it turn out fine. Also, for the second batch instead of adding the finishing hops to the boil we just strained the wort through them at the end. I did read something recently (can't recall where) that said boiling crystal malt can result in bitterness. It is possible that we let the one step mash heat up too high. There were several times when we had to reduce the heat. Any other ideas or suggestions, or has anyone else seen this with crystal malt before?

2. I have just started kegging my beer (xmas present resulting from heavy-handed hinting) and love it. There are basically two recommended ways of carbonating that I have come to know. One is to prime with 1/3 cup corn sugar when transferring into the keg - essentially treating the keg as a big bottle. The other (recommended by the local brew supply where the kegging system is from) is to simply let the beer ferment out, shoot it with 25 - 30 lbs of CO2, shake well, and let sit in a cold area for 3 days.

The second method is the one that I just used (unfortunately it was on the problem batch mentioned above). This turned out great. Wonderful, full creamy head and just enough carbonation in the beer.

My question is - there must be merrits to both but I can't seem to find them spelled out anywhere. Could people please edjamacate me?

Hasta,
Rich

Subject: RIMS Summary

I have been following the recent RIMS discussion with interest, and hope to build a system in the near future. Thus I have gone back through the digest and collected all RIMS posts that I could find (I looked back to Jan 91) I edited the collection of posts down so as to ommit repeats (One design was given if full twice) and comments by people who have not actually built a system

Since I have gone to the effort, I am more than happy to share the results with all those who are interested in designing a system, or improving their own. Simply write me, and I'll send it out to you (It is too long to post).

Also I would much appreciate a copy of the original Maltose Falcons RIMS aricle I have no idea of how to get it, and would love a copy from someone.

Finally Questions:

- 1) what pumps have people sucessfully used?
- 2) ditto for thermisters and vessels (does everyone use a keg?)
- 3) has anyone checked for thermal gradients?
- 4) channeling is always an issue for sparging, but I've not seen it for RIMS, has anyone checked?
- 5) mention has been made about automated mash systems of different design what are they? (What is Milspaw's design?)
- 6) if anyone around the bay area has set up a system, or simply wants to share plans, I'd see them (a bay area RIMS conference??)

Date: Thu, 11 Mar 93 17:32:19 -0600
From: sagard@digi.lonestar.org (Steve Agard)
Subject: Re: Cleaning Bucket/Cleaning Bottles

In HBD #1094 Markham Elliot asks:

Q: [paraphrased] how do you clean the oil and soy sauce out of a food grade bucket?

A: I would suggest using TSP. I am thankful that it had been recommended by many of the homebrew experts on the net for removing labels.

One night, I obtained 30 1-pint beer bottles (previously Sapporo, Kirn, & Asahi) from a Japanese restaraunt. They make homebrew look good, are smaller than wine bottles, require less capping than U.S. domestic bottles, and are the perfect size for Bitter, Stout (and my SNPA-like). ;)

Getting these bottles was not fun, but getting them clean and label free was easy :(> The bottles all had lables (both paper and foil), as well as, tobacco & food particles (fish, ginger, wasabi, soy sauce, grease, etc.) on them.

I added 1 lb TSP (from hardware and paintstores), and 1 1/2 cups chlorine, to a trashcan with the beer bottles (which had been filled with just enough warm water to cover all the bottles).

I let this covered for 2 weeks, and then removed the bottles (while wearing rubber gloves - chemical resistant ones from a hardware store). Most of the lables had simply fallen off. The 4 or 5 lables that were still on were removed by rubbing the ridged fingers of the gloves across them once or twice. None of the lables had any ink left on them. The food parts had been broken down.

I rinsed out/off each bottle, and then placed in a bathtub of warm water & let sit for 2 hours (probably overkill, but someone at a homebrew shop warned not to get any in the bottle or I'd never get a beer head). I then ran the bottles through the dishwasher twice (I usually the dishwasher to sanitize the bottles, but I don't like to ignore advice from those of you with more experience...). I bottled with these 3 1/2 weeks ago. Had one yesterday... tasted great, with lots of carbination and great head retention.

Hope this info helps. Cheers!
Steve

Subject: Pumps

>From: gjfix@utamam.uta.edu (George J Fix)

> 2. Top flight pumps are also crucial. Most pumps will eventually give a laminar flow. Some, however, will cause foaming at the start and at the end.

I am still waiting for an answer to my question, "Why RIMS?" but as a chronic tinker, I can't resist following the discussion.

I now pump my beer from lauter tun to kettle, from kettle to primary and from primary to secondary and have solved the foaming problem in a very simple manner. I simply put the appropriate resistor in series with the motor and a separate switch to provide a low voltage startup. Once the beer has driven all the air out of the system, I switch to the normal voltage and foaming is no longer a problem. Perhaps some such system could be used for the RIMS system.

I am using the pump from the kitchen sink of my motor home so it is 12 VDC and makes it pretty easy. However, I assume a standard light dimmer would work on most small AC pumps and would be even more flexible.

Subject: Sanitizing

With all the continuing talk of sanitizing agents, I'm suprised there hasn't been more talk of my favorite agent- boiling water. It doesn't require rinsing, is environmentally safe and must be effective as it's all I use - even for mead batches which sit in the secondary for months and I've never had an infected batch. I just boil the water in my wort container for 10 minutes or so and then use it to sanitize the primary.

I sanitize my secondary by pouring hot tap water into the carboy- letting it warm up and then adding about 2 gallons of boiling water. It seems to work great.

Date: Fri, 12 Mar 93 9:41:36 EST
From: Lee Menegoni <necis!lmenegon@transfer.stratus.com>
Subject: Keg sanitation / carbonation

Some of the text of my recent post on keg sanitation was missing:
After filling the keg and letting some out of the 2 connectors
I top it off with water and shake to ensure good mixing of the
Beed Brite. (this is the missing part) I let this sit over nite.
I then drain the sanitizer into a carboy or another keg and
proceed with the boiling liquid rinses.

Since I forced hot water out with CO2 the keg is filled with it,
its heavier than air. I rack into the keg the CO2 blanket helping
reduce the potential for aeration. To force carbonate I set the
keg in my refrigerator, ideally it would be about 32F and
pressureize to 30lbs. I DO NOT SHAKE THE KEG. This could cause
your clear beer to get cloudy due to particles racked in. I then
adjust the pressure 2 more times in 12 hour intervals. I raise the
fridge temp to serving temp. and pour off about a quart or two of
foam this lowers the pressure and removes solids from the keg.
As the foam settles I drink the beer.

From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
Subject: sanitize keg, "German" porter

I've been sanitizing kegs by filling them with a couple of gallons of boiling water, seal, pump in some CO2, open the tap to let some hot water out, and then let sit for 30 minutes or so. The heat will kill off any nasties, and there's no rinsing involved. The keg should already be clean, btw.

Rob asked about "German" hops (Hallertauer/Mt.Hood) being used in a porter. Just so happens in my younger/dumber days (before I became an all-grain snob ;-), that I went even further, making an extract porter with Hallertauer hops *and* Wyeast German ale yeast, #1007 I think it is. Certainly not a "classic" porter, but perhaps the best extract brew I ever made: clean, creamy, malty, and a wonderful hop nose. Isn't it perhaps likely that in the early days of porter, continental hops were used? Perhaps even German yeast? What does Foster's Porter book say?

From: jeff344@voodoo.lerc.nasa.gov (Jeff Berton)
Subject: Doppelbock Names

It's well known that, traditionally, doppelbocks are named using the "-ator" suffix, as in the familiar "Celebrator" or "Salvator" doppelbocks.

Just for fun, I decided to generate a nearly comprehensive list of English words that end this way. On my Unix box, I simply used "grep" for the string "ate" on the dictionary file (usually in /usr/share/dict on most Unix machines), and changed "ate" to "ator" globally in an editor.

There were, of course, a few words I rejected. Some obvious misspellings occurred, such as "watermelon" becoming "watermelon"; and also a few occurrences of senseless words, such as "roommator" and "prostator." I made a single pass through the list and deleted these obvious mistakes.

Here are a few potential doppelbock names my search turned up. Apologies if they have been used before....

-Names Schwarzenegger or Eastwood would be proud of:
Annihilator, Assassinator, Dominator, Eliminator, Eradicator, Exterminator,
Devastator, Detonator, Liquidator, Gladiator, and, of course, Terminator.

-Names for scientists and engineers:
Accelerator, Collimator, Correlator, Numerator, Denominator, Differentiator,
Lubricator, Exponentiator, Evaluator, Radiator...

-Names relating to the alcoholic nature of beer:
Decimator, Exhilarator, Hallucinator, Incapacitator, Intoxicator, Sedator,
Perspirator...

And many others. Some examples I don't think anyone would want to use. For example: Nauseator, Regurgitator, Urinator, Flatuator, and a few other more offensive names I will avoid mentioning. :-)

The complete list is 594 records long, and hence, too lengthy to post here.

I would be happy to e-mail the file to anyone who is interested.

> How do you build a Phil's Phalse bottom, a screen type false bottom
and
> a slotted copperpipe manifold? How do you use each type?

I don't know anything about Phil's, but a screen type false bottom requires installing a controllable spigot in the cooler. IMHO, a copper manifold is easier to build, more effective for sparging, and doesn't require modifications to your cooler.

I have fairly detailed plans for my manifold system. They're long, so I won't post here unless there is a great demand. Email me if you'd like them. BTW, this system is a scaled down version of the lautering system used at New Belgium Brewing here in Fort Collins CO.

At the risk of sounding snobbish :-), if you're going to outfit your cooler this way, you'll already have most of the equipment you'll need to go all-grain. A large kettle for boiling is the only other thing you'll need, and

> Can I use two 4 gallon stock pots for boiling the extract instead
> of one 8 gallon stock pot?

yes, you can use two pots in a pinch (I've done it myself). A risk is that you won't get consistent hop extraction between batches, since the volume of wort being boiled is a factor in the extraction rate. A larger kettle will make life much easier, though.

>my desired total. Then I shut off the sparge water and drain the bed
dry. I

>typically get a yield of 31 or 32. On my last batch, 14 gallons of mild,
I got

>35!

I sparge in a 1' & 2.5' square cooler, with a grain bed depth anywhere
from 7"-14". The pipe is only 5/16" id and 7" long, with slots every
inch. The last time I tried keeping the H2O above the top of
the grain was with ~20 lbs of grain => 10"-12" deep. I verified by
taste testing that different areas of the bed were better rinsed than
others. I only got 20 pts/lb (this is based on the wort that actually
makes it into the primary - If you count spillage & the gallon of trub
that I leave behind you get significantly higher figures).

What are the dimensions of your cooler? How deep is the grain bed?
Is the pipe 1/2" inside diameter or outside? (that's a big pipe).

>Nor do I see why restricting

>the flow out of the manifold would have the effect described by Brian.
Its kind of hard to explain, especially w/o graphics. The problem is
analogous to that encountered with your auto's exhaust manifold.
Compare with a set of racing headers. Visions of "sparge headers"
fill my mind...

I still need more experimentation with my new setup.

Subject: lautering

I finally tried my first all grain batch. Everything went fine. My extractin.....
extraction was a little low I got 23 pts/lb. I used the step mashing procedure given by Papazian. Mashing was easy, complete conversion occurred within 40 mins...
But lautering was a little more tricky. I am using a Zapat (bucket in a bucket) lauter tun. While filling the tun it over flew a little. Another problem I had was getting the proper crush for the grain. I am using a Corona mill. The
How long should I recirculate the wort?? I recirculated about 4 gallons. The
wort never seemed to clear more than after the first gallon or so.

Questions:

- 1) What does a good crush look like?
- 2) How to achieve a good crush using a Corona?
- 3) How clear is clear when lautering?
- 4) How long to recirculate using a Zapat tun.

Recipe:

8# British 2-row pale ale malt
1/2# crystal malt
1/2 teaspoon gypsum in mash
1 teaspoon gypsum in sparge water
4 oz Heshaberker Halertau(sp??) (60min.)
1oz Heshaberker Hallertau (steep 10 min)
1 teaspoon Irish moss (boil 15 min)
Whitbread ale yeast (started early in the morning)

og 1039

HBU's = 11.6

I used two 14 quart ss stock pots to mash and boil in. The recipe was taken from the Cats_Meow. It is Frane's House Ale. Thanks Frane

>I didn't see any definitive comment on this while I tried to find some quotes from microbiologist acquaintances. But, I didn't want to leave it alone.

Me either/too.

>My information is that sloshing "a small amount around for a minute", no matter how high the concentration, is generally ineffective for sanitization.

Well, I would certainly like to see the details of that information. Frankly, I have my doubts. Pure bleach, sloshed around a keg or bucket would leave a thin film on the surface that would be far higher in concentration than a full keg of weak solution. That film would remain on the surface, long enough before evaporating, to provide an effective bactericide. I also suggest that in a closed container, either a keg for a few minutes only, or a plastic carboy with a lid, indefinitely, the gas evaporated inside would provide ample security.

I switched from dry to liquid yeast so I can be convinced but someone is going to have to try harder on this one.

>From: korz@iepubj.att.com
>Remind me not to trust the Copley News Service. You see, there is a third method, which is used by at least one mega-brewer, in which a semi-permiable membrane is used to extract the alcohol by osmosis and a fourth method in which a special yeast is used that does not produce much alcohol.

And a fourth which nobody wants to talk about. Once the alcohol is reduced to the lowest practical level by what ever method, they simply dilute it with water to get at least a 50% reduction.

Perhaps you were being polite when you tasted mine but it does certainly seem to be one of their dirty little secrets.

From: atl@kpc.com
Subject: Sanitization Survey

I have been following the threads on sanitization with great interest. I have been brewing for about 10 years off and on, and am now all-graining and yeast culturing (please no snob thread!). I have yet to get an infected batch, even though my sanitization procedures are *very* lax compared to most of what I read here. I use a solution of a couple of tablespoons of household bleach to a couple of gallons of warm water, wet the walls of my scratched plastic fermenters let it sit a couple of minutes (usually, sometimes shorter) and rinse it out with unfiltered, unboiled tap water.

The only tyhing I can think of that would explain my complete lack of problems is that I have always lived in areas with chlorinated city water. I would like to run a survey, asking folks to send me email with the following info:

- 1) How many batches have you brewed?
 - a) > 10
 - b) 10-50
 - c) > 50
- 2) How many infected batches have you had?
- 3) What source of water do you use?
 - a) city
 - b) bottled
 - c) well
- 4) Do you filter any tap water you add to your wort?
- 5) Do you boil any tap water you add to your wort?
- 6) What sanitizer do you use?
 - a) Chlorine bleach
 - b) iodophor
 - c) b-brite
 - d) other (please describe)
- 7) Do you rinse with tap water?
- 8) Please describe (concise please) you sanizitation method (exposure length, rinse method, etc.)
- 9) if you think I have missed any critical info, please tell me.

I'll post a summary as time allows!

Thanks,
Drew

Subject: On Brewing Sugar

As penance for quoting an author while relying on memory alone, I have typed the following material on brewing sugars from H Lloyd Hind's "Brewing Science and Practice", which was written in the 1930s and stands as the best source of information on traditional British brewing practice. There is a great deal of very technical information about the production of various sugars and their chemical/physical structure, some of which may not even be accurate given advances in the physical sciences, and in any case is well beyond our needs. There is also information about specific sugar blends produced for the British brewing trade, but without brand names; in any case, the information is more than 50 years old so I left it out.

=====
BREWING SUGARS

230--Sugars as Malt Adjuncts

Various sugars and starch conversion products can be added in the copper to supplement the fermentable extract formed in the mash tun by conversion of the starch of malt, but similar restrictions in respect of the quantity used apply as with cereal adjuncts, on account of the lack of nitrogenous yeast nutrients. They provide a means for varying the composition of wort, within limits set by the requisite balance between sugars and non-sugars, supply extract which may be either entirely or only partly fermentable, give characteristics of fullness and flavour that are appreciated in some cases, increase the stability of beer by replacement of nitrogenous extract and yield beer that will become more readily and rapidly brilliant than when brewed with malt alone. Primings are strong solutions which must not, in this country, exceed 1150 specific gravity but should not be much less. They are sometimes added in the fermenting vessel at the close of primary fermentation but, more frequently, in storage tank or cask to promote rapid condition and, in some cases, on account of their flavour. The sweet and luscious flavour of some sugars does not entirely disappear when the sugar has been fermented but gives additional fullness to the beer. In some cases, sugars which are not entirely fermentable are selected.

The sugars used in brewing comprise

- (1) Cane sugar, derived from the sugar cane and, much less frequently, from sugar beet.
- (2) Invert sugar, made by inversion of cane sugar.
- (3) Starch sugars, including corn syrups and glucose, manufactured by the conversion of the starch of cereals, usually maize [that's _corn_, Norte Americanos].
- (4) Mixtures of these, their utility in copper or cask depending on their flavour and fermentability.
- (5) Caramels, made from cane sugar or glucose.
- (6) Lactose or milk sugar, which is only used in very small quantity in some milk stouts.
- (7) Honey, even less used.

Maltose, which might appear to be the most suitable sugar to replace

that formed from malt in the mash tun, is not used in the pure state, but exists as a constituent of corn syrups with dextrin and glucose. Lactose differs from cane sugar, invert sugar, maltose and glucose in that it is unfermentable by ordinary brewery yeasts, while certain of the higher starch conversion products are appreciated because they are only partly or slowly fermentable.

(231) Cane Sugar

The sugars obtained from the sugar cane, sugar beet, sugar maple, certain palm or the stem of sorghum are, when purified, of identical chemical composition. All of them are sucrose. The natural juices from which they are derived, however, differ very considerably in flavour owing to the many other substances which they contain. For example, the root of the beet contains a larger proportion of mineral salts than the sugar cane and decomposition products are formed with the larger quantities of lime necessarily used in the course of clarification, which give an objectionable flavour to the juices and raw sugar. These render the latter unfit for consumption until refined. The raw sugars from the cane are, on the other hand, very luscious but they do not all taste the same, varying considerably according to the place in which the cane was grown or the treatment they received during extraction and preparation, characteristic differences being found in sugars from Cuba, Java, Barbadoes, Trinidad, St. Domingo, Mauritius, etc. Since the value of cane sugars in brewing depends so largely on the flavours they communicate, even after all the sugar itself has been fermented, the principal source must be the sugar cane, which yields juices possessing these properties in their most attractive form. The final product of the refineries, from whatever source it originally came, is among the purest substances commercially obtainable, but it lacks the distinctive characteristics of flavour demanded in brewing. As a source of carbohydrate extract it is unexcelled and can be used without hesitation under circumstances in which those flavours are not required, but the raw or partially refined sugars from the cane are more attractive in most cases.

[... some technical information on the refining process deleted ...]
Usually the lusciousness of the sugars increases with greater proportions of other substances derived from the cane, some of which are in a colloidal state, and many such sugars, among them West Indian and Brazil sugars of comparatively low polarisation, are used in brewing on account of the fulness and sweetness they give. Other low polarising sugars, such as that from Mauritius, have a somewhat acrid after-flavour. On account of these different flavours, great care must be exercised in selecting brewing sugars, fermentation tests being desirable as the original flavour is not always a good guide to that left after the sugar is removed.

[...]

Cane sugar is used both in the copper and as a priming. Raw sugars of good class are generally employed for the former purpose and when of good class are generally employed for the former purpose and when of suitable purity should not contain excess of undesirable substances or micro-organisms. Sugars of this type and pure crystals can also be used for priming but candy sugar is preferred by many. Cane sugar is rapidly inverted when added to cask, the change being generally complete in about 24 hours. This process is believed to be an essential preliminary to fermentation. It is carried out by the enzyme invertase or sucrose secreted by the yeast and does not appear to affect the fermentative activity of the yeast or influence the rate of fermentation. Baker and Hulton found that cane sugar and invert primings were fermented at sub-

stantially the same rate in beer under ordinary cellar conditions and that about one-third of either sugar still remained unfermented after 7 days in cask when added at normal priming rates.

[Hind goes on to offer technical information about the cane sugars used in brewing: refined crystals, candy sugar, brown sugar and yellow crystals. "The yellow crystals represent the high grade products turned out at many cane factories, and of which Demerara sugar is well known."]

Subject: **Texas BPub Legalization Update**

Texas Brewpub Legalization Guide - March 12, 1993
Action Item: Call & Write The House Committee by Monday, March 15!

Brewpub n. A brewery that sells its own beer on premise. Or a Restaurant that brews its own beer. Legal in 42 states. Something Texas needs to legalize to join the rest of the civilized nation.

*** The House Licensing and Administrative Procedures Committee is bringing up the bill Monday, March 15. Call and write to the 11 members of that committee ***NOW (March 12, 13, 14,15)***, before the bill leaves the committee. Then hammer the Senate Committee. The Bills are House Bill #1445 & Senate Bill #622. Any other "brewpub" bills are superfluous and shouldn't be refered to at this time.***

What to tell the legislators:

Key consideration: BE BRIEF! These folks are busy. If as many folks call in as we hope, we could possibly end up alienating some V.I.P.'s if we drone on. Please limit your calls to the following three statements.

1. "I support brewpub legalization in the TABC Sunset Bill"
The bill considered is referred to as the T.A.B.C. Sunset Bill. There are identical bills introduced in the Senate and the House. (House Bill #1445, Senate Bill #622). The Brewpub portion of the bill is section #74.
2. "I want brewpubs to have the right to sell for on and off-premise consumption."
3. "I want brewpubs to have the right to limited self-distribution."

Who to contact

This is a priority issue! The House Bill will be going to committee the week of March 15!

Write to and call the following important people: (and communicate the 3 phrases listed above)

****House Licensing and Administrative Procedures Committee (House Bill 1445)***Priority****

Ron Wilson, Chair...512/463-0744, Delwin Jones...463-0542, Dan Kubiak, ViceChair...463-0600, David Cain...463-0476, Tony Goolsby...463-0454,

Ben Campbell...463-0478, Bill G. Carter...463-0482, Mario Gallegos...463-0614, Paul Hilbert...463-0572,...Garfield Thompson...463-0716, Ken Yarbrough...463-0648

Your local Senator and House Representative

Write to them at the following addresses:

The Honorable [Representative] The Honorable [Senator]
The House of Representatives The Senate of Texas
P.O. Box 2910 P.O. 12068

Austin, TX 78768-2910 Austin, TX 78711-2068

If you aren't sure who your legislator is, call 1-800-253-9693. They may

be able to tell you your Senator & Representatives' names.

Attend the Public Hearings:
I'll post when the Public hearing is. Stay tuned.

Remember, the bills in question are referred to as the "TABC Sunset Bill". HB335 is NOT "the" Brewpub bill. At this point in time neither is HB1425. Remember, please BE BRIEF.

Other Questions can be referred to: Joe Barfield, Southwest Brewing News at ifby546@ccwf.cc.utexas.edu 512/467-2225 Address mail to 406 W. 35th, Austin, TX 78705. -FAX (512) 282-4936
Watch for future updates to the SWBN BREWPUB LEGALIZATION GUIDE

Sample Letter:

VOTE YES FOR BREWPUBS
The Honorable
The House of Representatives (or The Texas Senate)
P.O. Box 2910 (or P.O. Box 12068)
Austin, TX 78768-2910 (or 78711-2068)

Dear Representative (or senator)

As an avid beer connoisseur, I would like to endorse economically viable brewpub legislation.

Brewpubs provide jobs, increase the tax base, increase tourism, increase capital investments, and stimulate interest in locally-produced products served straight from the brewery. They do not threaten the existing system.

Please consider revising the TABC Code to allow small breweries: 1) the right to sell for both on and off-premise consumption, and 2) the right of limited self-distribution. The great State of Texas will benefit from a burgeoning niche industry currently enjoyed in 42 other states.

Please vote YES for the Sunset Bill's expanded brewpub legislation.
Sincerely, JoeTax-payer&voter&beer-drinker

Subject: Boiling pots?

After several boilovers using a small enamel canner on my stovetop, I am ready to get a larger pot. I have read (Papazian, Miller) that Aluminum is to be avoided.

If not Aluminum, then the only choices seem to be enamel or stainless. Where can one obtain a reasonably priced 32 qt. boiling pot?

I checked the local (Baton Rouge, LA) restaurant suppliers, they only carry Aluminum. Since restaurants apparently use predominantly Aluminum for boiling, what's the difference between wort and restaurant food that makes Aluminum unsuitable for wort? Is it the acidity of wort and/or its contact time w/the Aluminum? Or what?

Thanks,! What's the difference between a used car salesman
Bruce Ray ! and a software salesman?
Deep C Software ! One knows when he's lying, the other sells software.

Subject: second mail-order hop source for Canada

There was some talk a while back about where hop rhizomes could be found in Canada. Well, just received my March/April copy of Harrowsmith magazine and noticed an ad for a mail-order brew store in Ottawa called the "Hop Stop" advertising hop rhizomes for sale. Therefore, I decided to pass on the two sources I know of for hop rhizomes in Canada.

mail: Hop Stop, 1661 Montreal Road, Ottawa, Ontario K1J 9B7
FAX: 613-748-3052
Tel: 613-748-1374
Don't know anything about this business but they offer a free catalogue.

The other source of hop plants I know of is Richter's in Goodwood, Ontario. They list the beer hop varieties: Cascade, Hallertauer, Mount Hood, Nugget and Willamette for sale as plants at \$7.00 a plant in their 1993 catalogue. Their stock is really expanding so it quite possible that more varieties will be available in the future. I have ordered from them before and the plants while often pricey were very healthy and arrived in perfect condition. Get them to throw in their catalogue. It's probably the most informative and interesting herb catalogue produced by anybody.

mail: Richters, Goodwood, Ontario, L0C 1A0 Canada
FAX: 1-416-640-6641
Phone: 1-416-640-6677
They accept Visa and Mastercard for payment and ship to the States as well.

As always I don't have any involved with either company. Hope this is of help.

Subject: Indoor boiling

Hi all,

There's been some discussion lately of boiling indoors on electric stoves. One poor fellow was boiling in 4 pots on his stove, another was burning out his elements. Well I did 2-pot boils for about 25 batches. And then I saw the light. As a new convert, I feel that I must share my happiness with all of you:

I converted an old scratched 7 gallon plastic primary bucket into a boiler. I used 2 1kW heating elements from a scientific surplus company @4.50 USD each, so this is definitely a cheap approach. The great thing about it is how effortless the boil becomes - no boilovers, easy cleanup. I cannibalized my counterflow chiller, which was tough to sanitize and constantly clogging with hops anyway, and now just sanitize an immersion chiller during the boil. The trub and hops drop to just below the level of the spigot, and from there I splash it out into the primary. MUCH easier! I have been brewing my brains out since I switched.

If anyone would like more info on the supplier, just drop me a line: <poirier@inrs-ener.quebec.ca>. And thank you to all who responded to my coriander question.

While I'm at it, I'll be in San Francisco, San Diego, and all points between in April. (I've already booked a tour with Anchor!) Any beer type suggestions (sent privately, of course) would be greatly appreciated. Thanks.

Deb

I don't think that the amount of bleach we use in sanitizing is significant compared to other uses. One bottle of bleach from the store will last me for quite a while. Bleach used to wash white clothes seems to go much faster.
(Note: We can't use bleach at home in the wash due to the iron in the water...it makes some really nice rust colored clothes)

> Acetic acid and H2O2 seemed much more "green" than
> Chlorine Bleach or Iodine.

I would agree with that assessment. Both CH3COOH and H2O2 will decompose in somewhat more friendly products. Using *DILUTE* versions of this may be alright. By dilute, I mean vinegar and hydrogen peroxide that you can buy in the pharmacy or grocery store. I'm not sure on the specifics of using these two in a mixture at low concentrations. Then again, as I was informed in e-mail, using vinegar and steam is an old and accepted method in Germany and it seems safer to me. Steam cleaning/sterilizing may be a good way to do it. But not everyone has a steam line in their house.

kurka@bmcw.com write:

chlorine
> soak is not known.

Something else that was just being discussed in e-mail. One possible drawback to using bleach as a sanitizing agent is the formation of byproducts that you can taste. You probably formed some chlorophenols; they are readily tasteable at the ppb level. Rinsing the chlorine out better should solve the problem.

I've heard that Draino has other stuff in it besides Sodium Hydroxide or
Potassium Hydroxide. I've heard that Red Devil brand Lye is all NaOH or
KOH (I don't recall which). Check the label and use the pure stuff.

Further, Jack writes:

I've read the opposite, but would note that the usual way that a mild
bacterial/wild yeast infection becomes apparent to us homebrewers is
gushers. Now I don't mean to imply that Jack has infected beer (I've
tasted recent batches and indeed it does not taste/smell infected), but
I know that Jack kegs rather than bottles. A minor infection in a keged
beer would not be apparent, whereas the same level of infection in a
bottled
beer would cause gushing. It also depends on how long you keep the beer.

Certainly Stainless Steel is a much better choice for a fermenter than plastic.

Boiling crystal or any other barley malt will give you astringent flavors which are, sort of bitter, but sort of not. Peel a dark grape and just chew the skin -- that's tannins -- is that the flavor you reported? If so, then it's the boiling of the grains. Also note that bitterness (especially in the finish) can be intensified considerably by hard water -- sulfates especially. Are you adding a lot of Epsom Salts, Gypsum or other sulfates?

Al.

Subject: PH meters / Lauter Tun design

Recently there was a thread on PH meters. I would like to know wher can I get one, what is the price and what comments do people have on specific models. I have heard of one model called " Check It" any details??

I currently use a 5 gallon plastic bucket with a 1" high false bottom and spigot on the side as a lauter tun. This container is jacketed with 1" of foam so it does a good job of maintaining the temp of the grain bed. I have considered building a new lauter tun with a copper tubing manifold and center drain using a 5 gallon food grade bucket. Is this an improvement in design, cent vs side drain. I also have a Cornelius keg with a seam leak near the top. I have considered cutting the top off and making a lauter tun out of it. What is the ideal height of grain bed for a 5-6 gallon batch? Would this keg tun be better for 3 gallon batches is it to narrow and tall for 5 gallon batches.?

>While this recipe is kind of heavy on the hops I have a hard time
>thinking that this is the problem. I have boiled lots of hops for more
>than an hour before and had it turn out fine. Also, for the second

I think the heavy hops is exactly the problem. I considered brewing this
beer
last fall, but, beforehand, I went through the math to determine the
bittering
levels, using Jackie Rager's wonderful equation from the Zymurgy special
issue
on hops. I recall ending up with something like 110 I.B.U. for Ron
Page's
Fraternity House Ale. That's not beer - that's beer-flavored bitterness!

I think the recipe is bogus (I don't implicitly trust any of the award-
winning
recipes that Zymurgy publishes). Change the hops bill, down to about 35-
55
I.B.U. (use one-third to one-half the bittering hops recommended). Or,
design
your own recipe, based on F.H.A.

Fred Scheer (Frankenmuth Brewery) wrote a short article on this yeast
strain in
American Brewer, Summer 1989, pg 19. He uses this yeast for his lagers.
All
his beers tend to be very clean, rich and malty in a broadly Bavarian
style.
This yeast was chosen because of the use of 6-row malt, high available
amino
acids, low zinc, 20 BU with a good dose of hop aroma, 7 day primary
ferment,
and need for good flocculation in the lagering tanks.

Here is the data from the article.
Wort analysis:
plato-11.5
apparent attenuation-83.20%

The article indicated that he pitches 1/2L yeast suspension per hL of
wort
(12-14 million cells/mL) due to the low (41F, 5C) pitching temperature.
Primary fermentation is 7 days. Fred makes the following points and
considers
them to be required.
-good aeration of wort (8-20 mg/L)
-wort free of hot trub
-minimum of cold trub
-34/70 works best at low temp. (41F-45F, 5C-7C)
-after 2 to 3 generations a higher than normal ester component appears.
Don't
pitch >6 times.
-low lagering temp (0-2C) to encourage good flocculation.

The bottom line is that if you are using domestic malt like Fred (Breiss,
I
think) and want to make Bavarian style dark, bocks or amber (Vienna or
marzen)
beers, this culture should do nicely if you ferment COLD and pitch lots
of
yeast.

Good brewing
DanMcC

>"Turbinado" and "Demerara" are the "real" brown sugars. They are
>both partially refined cane sugars. I've heard it said that they
>are, respectively, the American and British names for the same thing.
>However, turbinado is very pale, lighter than a brown paper bag.
>Demerara is about as dark as a brown beer bottle.

There's another "brown sugar" available that hasn't been mentioned yet,
probably because it's not commonly seen (at least I'd never seen it
before last fall). It was brought to my attention by Steve Stroud, who had some in
his cupboard. It's a product called Sucanat (r), and it's 100% evaporated
sugar cane juice. It is unrefined, dried, granulated cane juice, with no
additives and no preservatives. On the container is written "All vitamins,
minerals and other nutrients of cane juice retained, nothing added, only water
removed". There's a chart on the back comparing it to brown sugar, white sugar,
dried maple syrup, liquid honey, and dried malt extract. It is loaded with
minerals and nutrients! It has twice the potassium of brown sugar, 250 times the
potassium of white sugar. It still contains Vitamins A, C, B6, zinc,
magnesium, and calcium, while white sugar has none of those. Yeast
should love it.

It is manufactured by NutraCane, Inc., 5 Meadowbrook Parkway, Milford, NH
03055.
Phone is (603) 672-2801.

I got a 2 kilogram can of it at Bread and Circus in Cambridge, MA for \$8.
69. They have since gotten it in bulk, and with your own container it's even
cheaper. I have never seen it sold retail anyplace else (I just left a
message on NutraCane's answering machine about availability - I'll report back
what I find out).

My intention was to brew a Triple using it, but so far it's only gotten
as far as my coffee cup. It has a wonderfully assertive toffee-ish, caramel
flavor. It's not crystalline like turbinado sugar - it's more powdery/
granulated and the flavor is much stronger. Good stuff, and highly
recommended in coffee - you'll have to wait until I brew my Triple to get a report on
that.

Subject: Water filter questions...

Salutations all!
I have decided to filter the water I use for brewing in my apartment. Because it is an apartment and my wife and I will be moving in the summer, I didn't install it to the water lines, instead fitting a temporary attachment to the faucet. I've heard of others using such a temporary filter system and was wondering if anyone had suggestions as how to store the wet filter once I am finished with it? I am thinking of just letting the thing sit out 'till dry then putting it away. Perhaps in the freezer. Sounds wierd, I know, but since I want to filter out Cl, I thought it would be rather stupid to store it in some kind of solution. I should mention this is a charcoal and poly filter. (Water Pic's Under sink IF-10 model to be exact.) The freezer, I'm thinking, would inhibit growth of anything, and if I were to get most of the water out, there shouldn't be any problem with cracks from ice pressure... Well any ideas would be helpful.

From: bradley@adx.adelphi.edu (Rob Bradley)
Subject: First and second runnings

Back in December, I posted a speculative article about brewing in the traditional British "three runnings" method. To summarize, using information from Dave Line's Big Book of Brewing and a little algebra, it appeared that one could make:

Strong ale @ 1072
Pale Ale @ 1046
Shandy @ 1043

by using, per US gallon of final yield for each of the three, 5 pounds UK 2-row malt and 2.2 US gallons of mash water.

As a variant, I scaled the recipe up to 2 gallons and collected and brewed the first runnings according to the posted recipe. I decided to sparge afterwards and collect what amounted to the second and third runnings together. Given the desirability of a 5-gallon batch size, I figured I'd add a little water and malt extract to the kettle to stretch the brew length up to 5 gallons. (No all-malt fixation here :-)

Summary: overall success!! As I suspected, I got more yield in the first runnings than predicted from Line's figures. And that was despite cutting the mash water down to 2 gallons. I compensated by adding a little more than a pound of dry malt extract. Here are the details:

Strong Ale

10 lb Munton & Fison 2-row mild ale malt
1 1/2 oz Willamette whole hops 60 minute boil - 4.2% alpha acid
1/4 oz Willamette whole hops 30 minute boil - 4.2% alpha acid
1/4 oz Willamette whole hops 10 minute boil - 4.2% alpha acid

Wyeast 1056, second generation, half of a one-quart starter

Mash with 2.5 gallons water at 151-154F. Mash-out at 172F. Transfer to lauter tun with 1.5 gallons foundation water at 172F. Recirculate, let settle 30 minutes. Draw off first runnings (a little more than 2.5 gallons).

Yield: 9 quarts. Original gravity: 1080
Estimated bitterness: 48 IBU

Primary ferment: 7 days. Rack to two one-gallon jars.
Specific gravity at racking: 1025.
This beer was racked on February 11 and hasn't been bottled yet.

Celtic Ale

Spent grains from strong ale
5 oz Chocolate malt
19 oz Light dry malt extract
1 oz Bullion pellets 60 minute boil - unknown alpha acid
1/2 oz Willamette whole hops 10 minute boil - 4.2% alpha acid
1/2 t. Irish moss 10 minute boil

Wyeast 1056, second generation, half of a one-quart starter

Steep chocolate malt in 1 pint water. Add to mash tun after draining first runnings for the strong ale. Add 2.5 gallons water at 172F to mash tun and let settle 15 minutes. Sparge as usual with water at 172F to collect 4.5 gallons. Add dry malt extract and sufficient water to boiling kettle.

Yield: 5 gallons. Original gravity: 1035.
Estimated bitterness: 24-37 IBU (based on bullion @ 5-8% alpha acid;
Line estimates 4-9%, Papazian 8-9%).

Single-stage fermentation: 9 days.
Bottled with 5/8 cup corn sugar. Final gravity: 1011.

If I do say so myself, this is a great low alcohol beer.
It was ready to drink after about 5 days. It's 4 weeks in the bottle today and there's hardly any left :-)

Fred eckhardt, in The Essentials of Beer Style, lists Grant's Celtic Ale at-----

OG 1034, FG 1008, IBU 38.

Subject: Where Did My Saaz Nose Go ?

When I bottled this batch of Alt Bier last week, it had a wonderful Saaz nose to it, from dryhopping in the secondary. Now, a week later, it's carbonated, ready to drink, and has no Saaz aroma at all...

Where did it disappear to ?

Other than the loss of nose, it's quite good! Tasty and bitter.

Partial Mash Recipe

=====

2.0 lbs Klages 2 Row,
0.75 lb Crystal, 40 Deg. L
0.5 oz Chocolate Malt
4 quarts water

30 min 122F Protein Rest, 1 Hr. 152 F Starch Conversion,
5 min 168 F mash out. Sparge with ~ 2 gallons 170F

Then add 5.375 lbs Telfords light english extract, total volume
of boil, 5 gallons.

1 oz. galena (12%), 0.5 oz Nothern Brewer (7.1%) 60 min
0.5 oz saaz (3.8%) 30 min

Boil 1 hr, chill with wort chiller to 60F

Repitch with Wyeast 1056 from secondary of an Irish Ale. (Bottled previous
day)

OG=1.042

After 13 days, Dryhopped with 0.5 oz Saaz (3.8%) for 8 Days more.

FG = 1.012

Wonderful Saaz aroma at bottling (3/4 cup corn sugar used)

So where did it go ?

Tim

Subject: Metallic taste, old hops

I cultured yeast from the bottle of Chimay White. Now it has been one week in the bottles and I wonder the strong metallic taste it has. I remember somebody remarked the same thing in HBD sometimes ago. Is it peculiar for the Chimay yeast to produce metallic tastes, or is there something wrong in my procedures? It was fermented in glass carboy and temperature was about 22 Celsius. Fermentation was single stage and it lasted two weeks.

I have also another question concerning old hops. I have Saaz hops which a friend of mine brought one and half year ago from Germany. They are stored in room temperature. At first there were no problems with them, but later I noticed that beer brewed with them was cloudy, not clear. Could the old hops have caused this? I think I have read somewhere (HBD?) that there can be problems with old hops.

Subject: Extract Efficiency

We have pretty well beaten to death the topic of extract efficiency but I don't think we have discussed the most obvious way to determine what is going on in our beer.

We all know how to divide gallons by pounds and multiply by gravity to come up with points/pound/gallon. Some even apply this to some arbitrary numbers of available starch and arrive at a percentage efficiency.

Well, the other way to do it is to weigh the grain before mashing (easy and routine) and then compare this with the weight of the spent grain after mashing and drying (not so easy). If dried to the same moisture content as the original grain, we arrive at an absolute figure for conversion of grain to beer stuff.

This past weekend I made a batch with 10 lbs of malt and ended up with 8 gallons at 1.040 for a calculated extraction of 32pts/gal/lb.

After drying the spent grain and allowing for trub solids and a small amount lost in the drying process, it weighed 2.7 lbs. This means that 73% of the malt ended up in my beer. This is exactly the figure reported by Noonan as what can be expected from the types of malt I used.

I am not sure just what this proves other than the fact that the EASYMASH process works as well as any other far more complicated methods of mashing and sparging.

Subject: publications from the AHA

Just received my first ever Zymurgy and the accompanying catalog of stuff the AHA offers. And I have some questions.

1) Anyone have an opinion on "Winners Circle?" How many recipes are in this? What is the ratio of extract to grain recipes? Is it better/worse/same/just-different from Cat's Meow?

2)How about Terry Foster's "Pale Ale?" How many all-grain and extract recipes? The description given says "Recipes and data given in English and metric..." English as in American units, or english as in imperial units?

3) They offer a Special Issue six pack which includes the all-grain, troubleshooting, gadgets, yeast, hops, and beer styles special issues, but does not include the malt extract issue. Is that one worthwhile? Since some of these date back to the mid 80's, and I keep hearing how things keep improving for the homebrewer, are any of these out of date? Does anyone feel that any of these could be skipped, or conversely, that any of these are the best thing ever committed to paper?

Any opinions are welcome. Please use private email. Thanks!

Subject: sparge manifolds

I use a 10-gal Gott cooler, with a "three-pipe" manifold of 3/8"OD copper, slotted every .75 - 1 in. It's arranged as a circle with one diameter. One end of the diameter connects to the spigot, the other end has a "down pipe" that I use for underletting and suction breaking. I have a ball valve on the outside that lets me easily control flow rate.

I get great flow and decent extraction from this setup. This weekend, I made a "wit" beer (thanks to Phillip Seitz for the recipe). Depending on whether I counted the unmalted wheat, I got somewhere between 28 and 31pts extract in a 45minute sparge (5lbs Belgian Pilsener malt, 3 lbs M&F wheat malt, 1 lb soft wheat "berries"), stopping at 1.010. The grain bed was about 6" deep (to the 3.5 gallon mark in the cooler). I opened the valve so that I got between 2 and 3qts/5min flow. I recycled about a gallon. I had absolutely no problem with sticking, despite the wheat (there was a layer of icky gray-brown sludge on top of the grain bed when I drained the cooler).

I won't belabor the advantages of the slotted-pipe system, except to note that I think the "downpipe" is a fantastic addition to the usual setup. I find that underletting my infusions makes it a lot easier to get a consistent temperature throughout the mash because you're putting the hot stuff at the bottom, whence it will rise, instead of on top, where it will just sit.

I'm happy with this system, that's for sure.

Subject: Oxygenated Water?

I live in an area where the tap water is cloudy when it first comes out of the spigot, but if you let it sit a few minutes, it clears up. A friend of mine told me the water is cloudy because they "oxygenate" it. I have never heard of this before. Is my friend right or is he full of it? If he is right, is it bad for brewing? I know I could boil the water if I am worried about water quality, but as an extract brewer, I would rather not spend the time boiling all that water. Thanks in advance.

Subject: Wyeast Abuse !!

I hope noone takes action, but I may have been guilty of Wyeast abuse !!

I broke the seal on my Bavarian Lager package and let it bulge. Unfortunately, my week didn't go as planned and the package had to bulge to full proportions. I definitely expanded the package to maximum size! The week really fell apart and the Wyeast package not only travelled several hundred miles, but also was put through several temperature changes of more than 30-40 degrees. When I finally had a chance to make my starter, I opened the package and it didn't smell 'clean.' It seemed that there was some odor there that I didn't feel comfortable with. I decided to make the starter anyway and the yeast developed nicely in the starter, but I am very hesitant to use this yeast for brew. Does anyone think my worries are valid or is yeast hardy enough to go through all my abuse ??

Please don't take away my brew kit, I'll be better to my yeast next time !!

Subject: ?SS Cleaning Agents?

?SS Cleaning Agents?
OK, now that were on to this cleaning agents thread I've got a question.
I've recently developed a problem with really stubborn scorchs and stains on the inside of my SS boiler.

The problem stems from the method I use to achieve a good stove top boil. I straddle the pot over two gas burners and use some heavy duty aluminum foil to direct the flames that poke out from under the pot up its sides es. Well this works GREAT as far as getting a good boil goes.

The problem is that the top of the pot, above the level of the liquid, gets very hot and any wort splashed on that part of the pot gets really burned on.

I can take off the crudge with a copper scrubber but some dark black stains remain. Is sodium hydroxide an appropriate cleaning agent to use in this case, i.e. will it remove the stains and is it safe for SS? If not are there other alternatives?

Thanks,

—

> used?

I can't comment on the history of porter, but I can say that a porter
of mine that used Kent Goldings, Hallertauer, and Cascades (!!) just
won a 2nd place at the Fort Collins, CO Mashfest. My original recipe
uses Perle and Cascade, but I was out of Perle when I made this batch.
The Hallertau were used solely as bittering hops, so the English and
American hops dominated.

I think I'll switch back to Perle next time, but isn't being able to
tinker with elements like that part of the fun of homebrewing?

>that I leave behind you get significantly higher figures).

>What are the dimensions of your cooler? How deep is the grain bed?
>Is the pipe 1/2" inside diameter or outside? (that's a big pipe).

First, it is my understanding that in order to accurately compute yield
you
MUST CONSIDER THE TOTAL VOLUME of wort, either pre or post boil (the
yield will
not change since the concentration goes up as the volume decreases during
boil).

I mash in a 48 quart Igloo cooler with interior dimentions perhaps 12"
wide by
24" long. My manifold is made of 1/2" ID copper pipe. The shape of the
manifold
is the same as the bottom of the cooler with 2 additional lenghts of pipe
running in the long direction. That makes a rectangle with 4 long runs
spaced
about 4" apart. The long pipes are joined at both ends with a network of
tees
and elbows and 1'2" pipe. There is an exit tee in the middle of one of
the end
assemblies which couples to a fitting which runs through the wall of the
cooler. All of the pieces of pipe (including those used in the end
assemblies)
are slotted half way at 1/4" intervals. The tees and elbows are left
intact.
The manifold is placed in the cooler with the slots facing down. The
concept is
to create a flow similar to that of a false bottom so that the sparge can
flow
through the bed to an "exit" at any point in the mass.

I have mashed as much as 35 lbs of grain in this set-up and as little as
15
lbs. My worst yield so far has been 26 points. I attribute it to a too
fast
sparge (maybe 20 minutes).

Subject: re: beer, root beer and cancer

In HBD1095 John Sampson brought to our attention a very interesting article appearing in Science, (vol. 258 pg 261) on natural vrs. synthetic carcinogens. The fact that wine and beer were at the top of the list alerted me to read the article myself.

In that article "Rodent Carcinogens: Setting Priorities", the authors try to support their hypothesis that naturally occurring chemicals have not been as rigorously tested as synthetic chemicals for being potential carcinogens. This was done by using an index (HEPR) measuring the percent of the equivalent (by weight) amount of daily lifetime rat dosage required to halve cancer free rats at the end of a standard lifetime. Some of the values are:

HEPR (%)	HUMAN EXPOSURE (PER DAY)	RAT CARCINOGEN
4.7	Wine (250ml)	Ethanol (30 ml)
2.8	Beer (12 oz; 354 ml)	Ethanol (18 ml)
0.3	Lettuce, 1/8 head (125 g)	Caffeic acid (66.3 mg)
0.2	Real Root Beer (12 oz; 354 ml)	Safrole (6.6 mg)
0.1	Apple, 1 whole (230 g)	Caffeic acid (24.4 mg)
0.06	Diet Cola (12 oz; 354 ml)	Saccharin (95 mg)
0.04	Coffee, 1 cup (from 4 g)	Caffeic acid (7.2 mg)
0.001	Tap Water, US avg (1 liter)	Chloroform (83 ug)
0.00003	Approximate HEPR of upper-bound risk estimate used by US regulatory agencies to control exposure to man-made chemicals.	
0.000000006	Captan (synthetic pesticide), US daily avg residue intake	Captan (11.5 ng)

g = gram, m = milli-, u = micro-, n = nano-, l = liter

One of the conclusions of this paper is:

"Our results indicate that many ordinary foods would not pass the regulatory criteria used for synthetic chemicals."

They also point out that items which are high on the list may not actually be a risk for human cancer even though they are thousands of times the HERP equivalent to the one-in-a-million worst-case risk used by the EPA.

One conclusion John made was

>Thus, all it seems you can say is that drinking one bottle of real root
>beer entails about the same risk of cancer as eating two fresh,
>unsprayed, organically-grown apples.

Due to the non-linear and sometime non-monotonic effects I think all you can say is: if we have similar metabolisms as rats then drinking 500 root beers a day entails the same risk as eating 1000 apples a day. Non monotonic effects occur in fruits and vegetables, which actually reduce your risk of cancer (when taken in moderation) due to the presence of anticarcinogenic antioxidants and vitamins.

Fortunately for us, (and the reason I'm posting this article to HBD) is that these non-monotonic effects also occur to some degree with beer (alcohol).

According to studies based on the drinking habits of over 275,000 middle aged men drinking one beer a day actually reduced their risk of cancer by about 10%. Details of these studies can be found in "Alcohol and Heart Disease", in Nutrition Action Health Letter, Vol 19, Nov. 1992, published by the Center for Science in the Public Interest (Someone in the HBD forum gave a nice summary of this article a few months ago but I forgot who it was). At two beers a day your cancer risk is back to what it is with no alcohol, but your risk of heart disease remains lowered by about 20%. According to the HERP table if you drink 36 bottles of beer a day and have a rat's metabolism you have a better than even chance of developing cancer at some time in your life. However, as long as we drink in moderation we can follow our first commandment of "Relax, Have a Homebrew" without worry of cancer. (Of course if you drink 36 bottles of beer a day you probably won't worry too much either!)

As far as root beer goes, I personally wouldn't worry about having one made with real sassafras, but I am unaware of both any beneficial effects from moderate studies, nor of other studies that (I should hope) have been done on other aspects of safrole toxicology which put it on the EPA hit list in the first place.

Steve, this is a classic case of overkill. From my own experience with TSP, you could have gotten away with a few tablespoons added to the water (without the Chlorine, especially since you're going to sanitize the bottles later anyway) and pulled the bottles out (without gloves) within a couple of days -- and gotten the same results. Not that what you did was wrong, just that you could have save yourself money, trouble and time.

> of warm water & let sit for 2 hours (probably overkill, but
> someone at a homebrew shop warned not to get any in the
> bottle or I'd never get a beer head). I then ran the bottles
> through the dishwasher twice (I usually the dishwasher to
> sanitize the bottles, but I don't like to ignore advice
> from those of you with more experience...).

As you suggest -- overkill. Rinsing the bottles thoroughly under the tap (or with a jet bottle washer, better yet) for a few minutes is plenty -- the homebrew shop was Wrong. TSP washes out thoroughly and easily (especially if you hold your concentrations now a bit from the 1# level) and shouldn't have any effect on your beer's head. Forget the bath, forget the dishwasher, rinse them thoroughly and sanitize them in the oven (350 for 90 min.).

I would like to second Bruce Ray's query about the use of aluminum in brewing kettles. The only truly "authoritative" voice I've heard on the subject is Dr. Michael Lewis, at the UC Davis' brewing program. Lewis says the only thing wrong with aluminum is that it's a crummy metal-- in other words that it dents easily and is not as strong as stainless steel (or as beautiful as copper). A year or more ago there was a raging argument here about Alzheimer's Disease, with the more reliable voice being someone (Russ?) who worked in a University hospital where the conclusion was that there was no link.

I have recently mashed a couple of batches in an aluminum kettle with good results (although I forget what they were...) -- there is definitely NO tinny flavor, which is one of the claims made against aluminum.

How about some real data?

>At the risk of sounding snobbish :-), if you're going to outfit your cooler this way, you'll already have most of the equipment you'll need to go all-grain. A large kettle for boiling is the only other thing you'll need, and

At the risk of sounding commercial, if one has a large kettle and an easymasher (note lower case, indicating that one purchases the stuff to build it at the hardware store for about \$10) installed in it, one does not need the cooler or the manifold.

>From: woessner@psych.purdue.edu (Leo Woessner)
>Subject: lautering

>I finally tried my first all grain batch.

HURRAY! Another snob is born.

> 1) What does a good crush look like?

Less than 10% flour... Defined as that which passes through a 100 mesh screen and lots of husks intact or minimally broken. The major source of problems is with grinders that pulverize the husks.

>2) How to achieve a good crush using a Corona?

To be technical, one does not crush with a Corona, one grinds. Having said that, they can be adjusted to minimize the amount of husk ground up but the price one pays is a course grind on the malt. For repeatable results, use a set of gages or shims about .050" in thickness, inserted between the plates on opposite sides. Adjust the wingnut tension so that they can just be slipped out. Ignore all other advice suggesting that washers or shims be placed between the main frame and the adjustment frame, they do nothing but move the point at which the "proper" setting is achieved.

> 3) How clear is clear when lautering?

Just about as clear as the beer you are hoping to drink.

> 4) How long to recirculate using a Zapata tun.

Until it runs clear. When you get around to building an easymasher, it will

take about one cup, sometimes two.

>I've heard that Draino has other stuff in it besides Sodium Hydroxide or Potassium Hydroxide. I've heard that Red Devil brand Lye is all NaOH or KOH (I don't recall which). Check the label and use the pure stuff.

Good advice. I was only making a point of reference. I use only lye. BTW, I got so excited about the stuff that I tried a number of things over the weekend.

I was cleaning a keg that had some sediment that did not want to squirt off so I poured a little lye in it and it washed right off after less than a minute of contact.

While cleaning up the mash tun to prepare it for fermenting I decided to attack some long ignored scorches with the lye and it worked like magic.

I filled my cruddy looking coffee pot with a strong solution and after about an hour and a rinse, it literally sparkles.

>A minor infection in a keged beer would not be apparent, whereas the same level of infection in a bottled beer would cause gushing. It also depends on how long you keep the beer.

I have developed the habit of bottling a sixer of each batch I make just to check on shelf life. Although there has been no infection thus far, we have noted a significant drop in the flavor quality of the beer. We opened a four month old bottle last week and both agreed it "tastes like extract beer".

That is not snobbery, just part of our lingo here, reminiscent of the bad old days. Most of them also seem to lack much ability to retain a head and seemed lacking in carbonation. This is all beer bottled since I started c/p bottling. Beer drunk within a few weeks of bottling is as good as draft but it seems to lose a lot over time.

The good news is I have to discipline myself to save it that long and the bad news is if you want it to keep forever, you will have to make BUD.

 Subject: My Lauter Tun

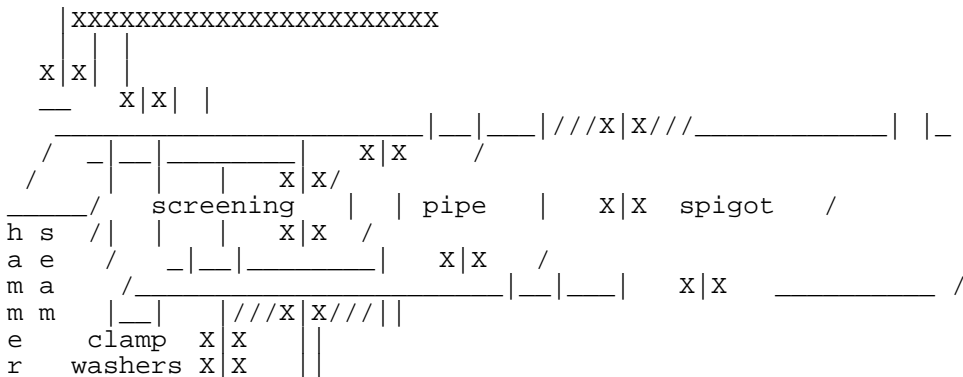

Hello Fellow Brewers,

I would like to share an invention of mine with you. I was having trouble with a the double bucket later tun so I made a new one. I took a 7 gallon pail and used a knife to cut a 1/2 inch hole near the bottom. I then went to the hardware store and bought a brass spigot for an outdoor faucet, some steel 3/4 inch threaded washers [the kind used by electricians to attach things to the outlet box], 2 inches of copper pipe, a clamp, and a 6X6 inch sheet of galvanized door screening.

I put the thing together by first putting a washer onto the spigot. Then I screwed the spigot into the bucket, after heating the hole with hot water. I then screwed the second washer into place and tightened the whole thing so that the spigot did not twist. I then rolled the screening to give me a diameter of 1/2 inch and I used a clamp to attach it to the 2 inch piece of pipe. Using a hammer, I folded over the edges and banged them flat to produce a seam...but keep the 1/2 inch diameter inside the rolled up screening. The 1/2 inch pipe fits perfectly into the back of the spigot and can be easily removed for cleaning.

I also attached a 3 inch piece of garden hose to the outflow side of the spigot and fitted into it a 4 foot section of 1/4 inch clear tubing. This tubing goes right into the boiling pot to reduce HSA.

Now I have a later tun that is easier to control the outflow and really easy to use. I am now considering using this as a mash/lauter tun, much like the cooler method. But first I have to learn to do that type of mashing. Right now I still only use this as a lauter tun and a hopback to remove hop leaves from the cool boiled wort.

```
e |   ><
d _____|   ><
   bucket wall>_____<
```

I hope this ascii drawing shows what I was trying to explain.

I remember a post some time ago showing the pro's and con's of the different lautering methods. For this single point drain, it stated that the grain near the edges did not get sparged. I have found this not to be true. I tasted the grain from the edges and it was not any sweeter than the grain found at the top of the grain bed, but this may only be true for me and I know some others will disagree with me. But, I am very happy with this setup and I also managed to get 32 pts/lb/gal using this method, compared to 26 pts/lb/gal using the double bucket technique.

From: atl@kpc.com
Subject: Reduction of Wort volume during boiling

After sparging, I usually end up with 6-8 gallons of sweet wort. I usually boil for 90 minutes total, 30 minutes before hop addition, 45 minutes for boiling hops and 15 minutes for flavor hops. I also do not cover the pot, as I find it impossible to keep a vigorous boil going without boilover if the pot is covered. After this, I usually end up with about 4 gallons of bitter wort, and must top up with filtered cold tap water. I do not see any dramatic hot or cold break, and end up with about 1" of precipitated goop (tm) in the bottom of the primary fermenter. Am I boiling too vigorously? Should I put the lid on the boiling pot? I would really rather not have to top up the fermenter.

Subject: Re: Stuck fermentation?

Hi, all,

I have a question about a batch I'm brewing at the moment. I think the fermentation is stuck, but I'd like some input from the rest of you out there.

I'm making an American Pale Ale using Wyeast #1056. I broke the inner seal of the yeast package, last Tuesday night, intending to brew on Thursday. By mid-Wednesday, the package was ready for use. Thursday afternoon, after the boil, the wort took quite a while to cool. Since I don't have a chiller at this time, I put the bucket outside, surrounded by snow (Minnesota). It still didn't cool very fast, and I was running low on time, so I pitched the yeast at about 83 degrees and placed the vessel in our basement which is about 64 degrees. 24 hours later there was no sign of fermentation, so I brought it upstairs, hoping that a change of temp would get it kick started. After a few hours in a 75 degree room, it started bubbling. It reached a peak of about 2 bubbles per second Saturday afternoon, then fell off to almost nothing. The other batches I've brewed, had a much longer and healthier fermentation than that. Any suggestions or comments would be appreciated. Please send replies to my email address. Thanks.

I think I'm going to go get some more yeast, and see if that works.

Later,
Colin

Subject: Cara-pils haze

I've been reading the digest for a few weeks now, and it seems to be very helpful in answering novice questions. So, here is my first posting:

My first attempt at a lager was a modified version of Papazian's Crabalocker German Pils, and I brewed it on 2/21/93. The ingredients were 3 kg (6.6 lb) Ireks Munich light unhopped extract, .5 lb Cara-pils malt, 1.5 oz Hallertauer (boiling), .5 oz Saaz (boiling), .5 oz Hallertauer (flavor), .5 oz Saaz (flavor), 1 oz Hallertauer (aroma), and 14 gm European lager yeast (G.W. Kent).

The Cara-pils was put in a muslin bag in 1.5 gal water and removed when water began to boil. Then the extract and boiling hops were added. The flavor hops were added at 30 min, and the aroma hops were added for the last 2 min of a 60 min boil.

It fermented for 5 days at room temp in plastic primary (it just wouldn't start in the cold 50 degree closet). I guess this makes it a steam beer, right? Anyway, then I moved it back to the cold closet until 3/10/93 (10 days in primary). It was then racked to the glass secondary. At that point it was very cloudy, and disappointingly an amber color. It has been five days now, and the haze has mostly settled.

My questions are: Did the Cara-pils cause the haze? (I used it to give it a little more body, but have since learned that it is not like other specialty grains.) I've heard of using gelatin for trapping the haze, is this a good idea, and if so how to do it. And lastly, if I do use gelatin should I be concerned that it would trap all the yeast too? (I do need some yeast in my bottles for carbonation.)

Thanks for the help.

From: sagard@digi.lonestar.org (Steve Agard)
Subject: Help: Teflon a problem?

I've followed previous threads about stainless vs aluminum pots, and read papazian's and miller's recommendations. I've used a 5 gal SS brewpot (\$24.95) up til now.

The problem with this size pot is that I can only brew 4-1/4 gal wort. I'd prefer to brew a full batch (for reasons I've read), and when I start doing all-grain batches, I'll need a larger pot.

I've found a 6 gal aluminum pot with "Silver Metallic" interior coating. I suppose this is Teflon with a name intended to suggest of Silver Stone. The pot has insulated handles. The lid is see-through, and has 1 small (sneaker shoe-lace eylet) vent in it. It was only \$60.

My question is this: If anyone has tried brewing in a Teflon or Silver Stone coated brewpot, what were your results? If you haven't tried this, your opinion is still welcome.

Thanks in advance,
steve

>Page's
>Fraternity House Ale. That's not beer - that's beer-flavored
>bitterness!

Ah, I didn't know that the recipe is Ron Page's, but that certainly
explains
it. Ron is a great brewer from New England, but he has also admitted
that he
likes to keep his recipes secret and rarely puts down the exact recipe
formulation on an entry form. This recipe is clearly one of those cases
where
he fudged the numbers on the hop bill.

It also points out the need to analyze a recipe and see whether it is
reasonable before you brew it. The AHA definitely should have done that
to all
of the recipes in the 'Winner's Circle' before they published it.
Beginning
brewers don't need nasty surprises like Ron's FH Ale.

Subject: Succanat (tm)

Well, since Dan Hall let the cat out of the bag:

I've been using Succanat (tm) for the last few years. It's a great (even better) substitute for demerara or turbinado sugar in brewing. It is organic, unpurified, evaporated cane juice with no additives. It looks like a brown, powdery/crystalline solid, similar to dark dry malt extract though less homogeneous in appearance. According to the info on boxes of the stuff, it has a nutritional make-up very close to malt extract with similar calorie, fat, and protein counts. It is also chock full of trace minerals and vitamins, unlike any processed sugar. Expensive perhaps??? Nahhh, at the Bread and Circus (in Central Sq., Cambridge, MA) it is in the bulk bins for \$1.49/lb. I've also seen it on shelves of local health food stores.

I've successfully used it many times in British-style ales - bitters, pale ales, scotch ales - and the yeasties love it. As Dan surmised, it does seem to have a toffee-ish, caramel flavor. I'm not sure that I'd use it in a tripel (I'd go for straight corn sugar to keep the color down) but a dubbel might do well from its addition.

Give it a go.

Well, without getting into an argument here, my experience with a
camp-cooler mash tun, using British malts, is that I get a clear runoff
in about the same volume. There is occasionally a little flour in the
first pint or so but from then on it's clear sailing.

Once again, without trying to start a fight, I would say that using lye
requires more than a little caution. It's not that the stuff doesn't
clean, just that it can also do a number on soft parts of the human body
- -- like eyes. If you observe careful brewers in micro- and
macro-breweries, I think you'll find them using highly caustic compounds
only in closed systems; when they're used for cleaning small parts,
etc., they are handled with a great deal of caution, using rubber gloves
(and hopefully safety glasses). Personally, I'm a little absent minded
(must be the aluminum), and I prefer to use cleaners that take a little
longer but aren't likely to melt my eyeballs.

I think the reality is that beers that are bottle-conditioned last --
well, not forever -- but far longer than cp-filled bottles that haven't
been filtered and stabilized to death. Of course, those of us in the
Great NW are known to hop our beers to a point of petrification, so
that's probably a factor. Then again, it's definitely not Bud.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>
Subject: Copper lautering manifold, Part 1

I've had enough requests for instructions for my sparge manifold that I decided I'll go ahead and post them. The article will be split into two parts so the digest daemons won't reject it due to length.

The manifold is made up of 1/2" copper tubing, along with tees, endcaps, and elbow fittings. It looks sort of like a tree branch; a main stem with arms coming off of it, alternating left and right. One end of the stem is capped, the other end leads to an elbow that angles up 90 degrees to a standpipe. Here's an ASCII pic I hope will make it clear:

```

  | end cap
  |
  | tee +-----] cap
  |
  | [-----+
  |
  | +-----]
  |
  | [-----+
  |
  |
  | elbow /
  | 90 deg up ----->=====
  | standpipe siphon hose
  | (this would be coming out of the screen)

```

The length of the stem and the length and number of arms can be adjusted to fit whatever kettle or cooler you use. The manifold should fit exactly in the the bottom of the vessel when you're done.

The arms of the manifold each have a number of slots cut in them, spaced a couple of centimeters apart, not quite halfway through the tube (I used a hacksaw to make them). You can also use a hacksaw to cut all the other pieces of tubing, but buying a \$5 tubing cutter will make life a lot easier. The tees, caps, and elbow fitting will already fit very neatly, so you don't even have to solder anything together.

When assembled, the slots will face down to the bottom of the vessel. This is to keep the grain from clogging them, and so you don't leave a half inch of wort in the bottom. The standpipe should come up the side of the vessel to just below the rim, so you can put the lid on.

You will need to come up with some way to connect your siphon hose the the 1/2 inch standpipe. We found a 1/2" to 3/8" ID reducer fitting and a short piece of 3/8" OD tubing will connect nicely to a standard vinyl siphon hose:

```

-----==
| /___ 3/8" _____|-----|siphon hose
1/2 inch copper|redu |-----|
| cer_|-----|_____
| /
-----==

```

Also, the reducer and 3/8" OD copper need to be soldered so they don't suck in air, since they're the only fittings that sit above the liquid level. [Note: soldering copper is easy; it requires a few cents worth of plumbing-safe solder and flux and a \$15 propane torch. Ask the

friendly folks at your local hardware store.]

(to be continued...)

Subject: Copper lautering manifold, Part 2

(...continued)

As you might have guessed by now, you don't need a drain hole in your vessel at all; just have the standpipe up the side of the kettle and siphon from there. You could somehow attach the manifold to a drain, but I don't think it's worth the trouble.

The manifold rests right on the bottom of the vessel, and my "spigot" is simply a hose clamp at the end of the siphon hose. Buy one of the plastic hose clamps that has variable click-stops.

Clean the manifold with hot water. Since it isn't soldered, you can just disassemble it when your done. You can clean it with a small bottle brush if you like, and if you're worried, you can soak the pieces in a metal-safe sanitizer like ChemPro. Whatever you do, *don't* try to clean it with bleach. Bleach and copper don't get along very well. And clean the manifold thoroughly with soap and hot water before using it for the first time to remove oils and such used while manufacturing the tubing.

Here's how the thing works: assemble the manifold and place it in the vessel, slots down. Add your mash water and grain on top of it. When the mash is done, attach the siphon hose to the standpipe and start the siphon going into another vessel. As the level of the mash water drops, add your sparge water so the water level stays an inch or two above the grain bed. When you run out of sparge water, or decide to stop adding water, let the siphon run until all the water has been siphoned out. You'll be amazed, this system gets almost every single drop!

This manifold system has a number of advantages:

1. No need to modify your pot/cooler, so it can still be used for other things.
2. You don't have to transfer the mash to another container
3. No transfer means your grain bed won't get compacted, so your sparge won't stick.
4. No transfer means your grain bed won't drop in temperature.
5. You're using the suction of a siphon, not just gravity, to draw off the liquid. This also lessens the chance of a stuck sparge.
6. The wort runs off clear after only a quart or so.

Of course, this isn't the only lautering system that has these advantages, but it has worked well for me.

Subject: SNPA culture beginner questions

I have a couple of beginner questions on culturing yeast from Sierra Nevada Pale Ale.

I have tried culturing SNPA yeast using the following procedure:

- 1) Prepare an SG 1.040 highly hopped wort, strain out hops, and return to boil for another 15 minutes in covered pan.
- 2) Carefully sterilize a pyrex measuring cup by boiling for 30 minutes. Cover with Al foil which has been flamed. Cool wort by placing covered pan in ice cubes.
- 3) Open SNPA, pour out almost all beer, sterilize bottle top using alcohol and flame. Pour cool wort into SNPA bottle, add airlock, wait.
- 4) After 1 day, contents of SNPA bottle at high krausen. Step culture into Erlenmeyer using similar paranoid sterilization procedures.
- 5) After 1 more day, culture in Erlenmeyer at high krausen, looks good.

At this point everything seems OK, but when I went to pitch, I smelled the starter, and it smelled vaguely of bubblegum, which I have been told is a sign of possible contamination. Lacking an alternative, I pitched it anyway.

I would appreciate any comments on the above procedure, especially if accompanied by alternatives which are known to work. I have used liquid cultures before, with success, by the way.

Also, provided I can get the procedure to work, I would like to know if anyone uses cultures from SN Porter or Stout. I haven't seen this mentioned anywhere.

Thanks a lot for all your help.

Subject: Lye, Vierka yeast

greetings.

About lye: I discovered last weekend that lye is the principal ingredient in the rubber-gloves species of oven cleaners, so Jack's experience with shining up everything in sight doesn't surprise me. Personally I am of the opinion that violent chemicals have no place in food prep, so I don't use 'em, but to each their own....

About Vierka yeast: Has anyone used this stuff before? I used one of their wine varieties for a mead last weekend, and it still ain't bubblin'. The weird part was, instead of the little yellow globs I'm used to in dry yeast packets, there were what looked like dried herbs in the package. I assumed they were the equivalent of Budweiser's beechwood chips, i.e. flocculation assisters coated with yeast, but then they could have been dried leaves sold as yeast, too.... Is this normal, and does it require special treatment?

thanx

>When I bottled this batch of Alt Bier last week, it had a wonderful
>Saaz nose to it, from dryhopping in the secondary. Now, a week later,
>it's carbonated, ready to drink, and has no Saaz aroma at all...

A year or so ago, I heard of the results of a test that was done by several brewers from Chicago Beer Society, in which they bottled part of a batch with Zapata Smartcaps (now called PureSeal) and part with regular caps. A blind tasting by experienced BJCP judges resulted in the following determination: the hop nose of the PureSeal bottles was much fresher and prominent. For those unfamiliar with PureSeal (aka Smartcaps), they are made with an oxygen-scavenging plastic which also is an oxygen barrier for up to (I believe) 6 months. It appears as if the first thing that oxygen reacts with and ruins is the hop nose. Tim: Could the loss of the Saaz nose be due to air in the headspace?

Subject: Plastic boiler info

Hi all,

Well I was inundated with requests for more information on my plastic boiler setup, so I'll just post the basics here:

I took an old plastic primary, 6.5 Imperial gallons, originally from my local homebrew supply shop, now well past retirement age. I drilled a hole for the spigot (a used plastic drum tap) about 1 inch from the bottom, and for the two heating elements, I drilled holes 90 degrees CW and CCW from the spigot, about 2 and 3 inches up.

The elements are "1 kW, 115 VAC. Chrome plated copper heating element. Features automatic shutoff when not immersed in water. Complete with mounting nut and gaskets. Designed for through wall installation in a 1-9/16" dia. hole (3/16" thick approx.). Electrical connection via recessed 3-wire socket; supplied with mating 3-wire stub cord, 12" long; opposite end stripped. Size 4-3/4" long x 3-1/2" wide. New. Wt, 1 lb. Order No. TM89HVC5702...\$4.50 US." H & R Company, 18 Canal Street, P.O. Box 122, Bristol, PA 19007-0122. Sales 1-800-848-8001 Fax 215-788-9577 Business Office 215-788-5583.

Things to keep in mind:

- The gaskets suck. I made my own with the stuff you buy in sheets at the hardware store. And the gasket that came with my drum tap turned to mush.
- You'll have to put your own plug on. The nice thing about the electrical connector through thw bucket wall is that you just unplug the element when you're manipulating the bucket, so there are no cords in your way.
- It takes the 2 elements to get a good boil going, but only one to keep things humming nicely. I plug one in the outlet on my stove, and one in a countertop outlet.
- So far no leaks or problems. My local homebrew shop is now trying them, with good success, and in fact plans to sell them to customers (gee, maybe I could ask for a commission....Maybe some 2-row....). It's true that the plastic is not rated for these temperatures, but I've been told that neither is the electrim bin.
- No scorching so far. The elements get coated in hot break material that needs to be cleaned off, but that's it.

I only picked plastic because it was easy. I'll stick with it as long as it works. When I get around to it, though, I have a 12 gallon SS Labatt's keg that I got at a scrapyard for 25 bucks (about 1.50 US...), which I'll

fit with the elements.

If anyone has any questions or suggestions, please let me know.

Congratulations of proving that you have a world class mind, capable of re-inventing the easymasher.

Just a few suggestions that you may find useful. If you use soft copper tubing instead of pipe, you can put a double bend in in so that the screen sits right on the bottom.

Upon reading it again, that is the only suggestion I can offer. You will get mountains of mail wailing about your use of window screen but I used it for months and it works just fine.

Aside from the simplicity, the advantages of this system are as follows:

The wort will run clear almost immediately and re-circulating gallons of turbid runoff becomes other people's problems. This leads to the other advantage...

You can thoroughly stir the mash several times during the sparge without disturbing the "filter bed" because it re-establishes itself so easily.

You thereby know for certain that you are getting maximum rinsing of the grain by the sparge water. Contrary to popular opinion, the potential for extract efficiency with this system is greater than in any other, as of result of this feature.

>I hope this ascii drawing shows what I was trying to explain.

Thanks for the stimulus. I have been too lazy to make one but as they say, a picture is worth a thousand words. So here is what I came up with...

```
 /  _____X_____  _____  //
   / /  ****  _____  / /  /SS SCREEN
  /_/  |  / /  |
 | / /  /-----#####
 | /-----#####
 -----BOTTOM-----
```

>Subject: Reduction of Wort volume during boiling

> After sparging, I usually end up with 6-8 gallons of sweet wort. I usually boil for 90 minutes total... end up with about 4 gallons of bitter wort...

First of all, there is a big difference between 6 and 8. If it is 6, ending up with 4 after 90 min is just about right. Frankly, I do not think there is such a thing as too vigorous a boil. If you lose too much wort, just start with more. I would figure on about a gallon per hour of boil.

Under no circumstances, do you want to cover the kettle. Part of the reason for boiling is to concentrate the wort.

Subject: weisse bier and decoction

Hello all,

Thanks to those who responded to my questions regarding Weisse Bier. Anyway, This weekend I brewed a 1/2 batch (2.5 gal) using a single decoction process (my first time). My recipe for this was

3 lb german wheat
1.5 american 6 row
1/2 oz hallertau pellets
yeast bavarian weisse (3056 I believe)

I saved about 1.25 quarts of wort for kreusen.

I mashed in with 1 quart/pound of water. My first question is: when I pull my decoction for separate heating and boiling it is not very liquid, and indeed, during boiling it gets pastey(starts sticking to bottom). Should I have added more water during this phase so it is not so dry?

Also, re: lautering and extraction effeciency.... is there a relationship between duration of lauter and extraction rate. My lauter for this exercise was fairly quick (10 min) and I ended with a 1.038 wort.

It is currently fermenting nicely and doing fine.

From: woessner@psych.purdue.edu (Leo Woessner)
Subject: yeast culturing

I am trying culture the yeast from several bottles of SNPA. I boiled up three cups of water with six tablespoons of DME and cooled the mixture. I then poored the wort into a steril half-gallon jug. I then poored all but the last inch of the SNPA out of five bottles. I shook the remaning inch of SNPA in order to get the yeast in solution and poored the dregs into the half-gallon jug. Nothing happened for 2 1/2 days, the brew never fermented very fast. At the peek it fermented at maybe 1 bouble per 30s. Is this slow fermentation normal?? By THE Way (BTW) I did vigorously shake the wort to ariate the wort before adding adding the SNPA yeast. How do you culture yeast from a bottle? Should I assume it is OK?? How can I tell if it is infected?? Is the yeast OK?
Thanks in advance

From: Carlo Fusco <G1400023@NICKEL.LAURENTIAN.CA>
Subject: Dry Rye Stout and my lauter tun

Hello fellow brewers,

Yesterday I posted a message about a new lauter tun I made. I forgot to mention that a dear friend or mine, Glenn, had a lot to do with the original design. Also, I would like to acknowledge Jack for his Easymasher which was unintentionally reinvented.

Well, since recipes in the HBD are becoming few and far between, I thought I would share a great stout with you all. It happens to be the first product of my new lauter tun.

Dry Rye Stout

Author: Carlo Fusco <g1400023@nickel.laurentian.ca>
Digest: ?????

Ingredients:

8 lbs 2 row malt
1.1 lbs flaked rye
1/2 lb cara-pils malt
3/4 lb roast barley
1/4 lb black patent malt
1/4 lb chocolate malt
1/4 lb crystal malt [80L]

3 oz Fuggles leaf hops [4.2%- for 60 min. ->12.6 HBU]
1 oz Goldings leaf hops [5.2%- for 10 min.->0 HBU]
pinch Irish moss

WYeast London Ale[1028]--starter made from new packet

Procedure:

Grind all grains and place them into the mash.
Mash in at 71C (160F). Temperature should drop to 66C (152F).
Mash for 2.5 hrs at 66C (152F). Mash out for 5 min at 76C (169F).
Sparge 6gal @71-76C (160F-169F). Boil for 1 hour. 3 oz of Fuggles for 60 minutes. 1 oz of Goldings and Irish moss for last 10 minutes
Cool, remove trub, and pitch.

Ferment at room temperature 20C (68F) until fermentation ceases. About 10 days. A single stage fermentation was used. Then bottle or keg as desired (I kegged it).

Comments:

This has got to be the best stout I have ever made. Since I have made the move to all-grain, this will be the only stout recipe for me. The flavour is dry and what you would expect from a stout. The rye and the cara-pils has made it very thick, just like Guinness. If I have to adjust

anything, I would add more hops...say about another 1/2 oz of Fuggles for the 1 hour boil. This stout is thick, very dark, overly smooth and won't stay in my glass for very long.

Method All Grain
Original Gravity: 1.060
Final Gravity: 1.020
Single Stage Ferment: 10-14 days

Carlo Fusco.....g1400023@nickel.laurentian.ca

SMITH@EPVAX.MSFC.NASA.GOV (The Ice-9-man Cometh) writes:
Subject: Lye, Vierka yeast

> About Vierka yeast: Has anyone used this stuff before?
I used Vierka's Dark Munich yeast for the batch of Dunkle
thats sitting in the secondary right now. (First attempt
at an all grain batch. It was pretty easy).

I haven't had any problem with it so far.

> The weird part was, instead of the little yellow globs I'm
> used to in dry yeast packets, there were what looked like dried herbs
> in the package.

The Dark Munich is white in the packet.
Its a dark tan/brown in the secondary.
Pretty good flocculator too. As primary ended, the yeast nicely sank
to the bottom and stayed there.

> I assumed they were the equivalent of Budweiser's
> beechwood chips, i.e. flocculation assisters coated with yeast, but
> then they could have been dried leaves sold as yeast, too.... Is this
> normal, and does it require special treatment?

Don't know about your yeast, but all I did was rehydrate in 1 cup
of 110F water. And they happily were fermentin' away in under 24 hours.

korz@iepubj.att.com writes:

the
> Saaz nose be due to air in the headspace?

Oxygen was suggested as the culprit in some email I received too.
The wort underwent minimal aeration during racking. (Siphoned from
secondary into bottling bucket, then into bottles with a
bottle filler). Air in the headspace could be the problem.
I'll have to see if any of the nose recovers or if its gone for good.

Subject: bleach and precipates on glass

I usually use bleach as a sanitizer, but have had some slight misfortunes, besides smelly hands and spotty clothes.....

Some comments on soaking things overlong in bleach, one is that is corrosive to metals, or perhaps the term is that is a metal oxidizer. In any event it will eat away at metal. The other regards bleach solution in glass containers. I sometimes leave a bleachy solution in the glass carboy to soak, then forget about until I need it again. The problem is that something precipitates out of the solution onto the glass and won't rinse off. I tried scrubbing the precipitate off with a carboy brush and was surprised when the brush popped out the side of the carboy. What usually works is to empty and rinse the carboy and soak it in a strong vinegar solution, I suppose someother acid solution would also work. That gets rinsed out well, then I again sterilize the carboy w/ bleach. I also got a nasty precipitate on some grolsch bottles I left to soak in strong bleach sol'n. They are still waiting for a cleaning. I plan to try TSP. Does anybody have experience w/ this problem? I live in Syracuse, NY. We don't have especially hard tap water (at least judging by how soap suds up in the shower), but we do live over massive limestone deposits.

Right now we're living under 3 ft of new snow!!!!

P. S. I have to agree w/ Jeff Frane about working with strongly alkaline solutions. They have the potential to be more caustic than acid solutions, partly because they do NOT rinse off very easily, as all of us working w/ bleach should know. I have a small scar from ONE DROP of NaOH sol'n that jumped out of the beaker while the sol'n was being mixed. SO BE WARY!!!!

Lisa St. Hilaire <MARS@SUVVM.ACS.SYR.EDU>.....YES, I'm using Ming-Chung's account.....

Status: RO

I was hoping to brew a lager this past weekend when I ran into trouble getting a yeast starter going. I was hoping that someone out there in HB land could shed some light on the situation and perhaps save me starting over. Here are the particulars:

Thursday evening I broke the inner package on a pack of Wyeast pilsen lager yeast (sorry, forgot the number). The package of yeast was dated 8 February. By Friday morning the pack had expanded to about 3/4 to 1 inch in thickness. I pitched this into 3/4 quart of wort I had prepared the evening before. The wort starter was made by mixing 3 Tbs of an amber DME with 3/4 quart water in a 1 1/2 quart clean juice jar. I capped the jar and shook vigorously to mix well. I then uncapped the jar, covered with tin foil, and put into a 16 quart kettle with about 4 inches of water. I brought the water in the kettle, with the jar of wort, to a boil and simmered for about 1/2 hour to sterilize. The kettle was covered during the boil and simmer. I then let the wort cool to room temperature (65F) overnight. The next morning was when I pitched the yeast from the pack. That was last Friday. To date nothing, nadda, zilch, has happened. I've kept the supposed starter capped with aluminum foil and in a paper bag to avoid exposure to light. The wort has remained around 65F. Nothing!!!. I did shake vigorously after adding the yeast. Several times since I've sloshed the wort around thinking that maybe it needed more aeration, nothing. The only thing that has changed is that when I slosh the wort around it does foam (some gas coming out of solution?)

Does anyone have any ideas. I don't want to brew 5 gallons of wort only to pitch a dead starter but then again I have no way of telling if this starter is dead or not.

I called the supply house where i got the yeast and they mentioned that the low pressure storm system which just came through Phila may have caused the starter to mis-start. This seems suspicious to me, however, because I've never heard of problems at higher elevations where atmospheric pressure is also less than at sea lever.

[CAny help you'all can give would be immensely appriciated [D [D [D [D [D [D [D [D [Dreiciated. I don't have a cooling system for brewing lagers and this may be the last chance of the season I have. If I have to get another pack of yeast then so be it but I'd like to have the advise of some of you experts before doing so.

cheers,
JW

From: rri!jreid@vtserf.cc.vt.edu (Joe Reid)
Subject: Falling Krausen

I have a question about when the krausen begins to fall after 2-3 days of very active fermentation. As the krausen falls I am left with (real technical term here) "brown sludge" stuck to the sides of my primary (plastic bucket).

The fermentation slows rapidly after this, and if I scrape the sludge into the beer it begins fermentating again.

The question is, should I be scraping this sludge back into the beer? Am I doing something wrong to be getting the sludge in the first place? This has happened to all of my batches (batch #5 should be falling today or tomorrow) and all of my batches are extract/DME (kits with DME not corn sugar (though this did happen on my first batch with was cornsugar)). My method is bring 1.5 gals of water to a boil, add about 4 lbs of liquid extract and about 5 cups of DME (about 2 lbs) and boil for 10-15 minutes. Cool in a sink of cold water (bath style) and transfer into primary, top to 5 gals, stir vigorously, and pitch (my tap water is about 45F, so 3-2 gals of 100F wort and 2-3 gals of 45F water cool nicely once in the primary.

Any hints would be appreciated.

Also looking for "Killian's" style recipes (Irish red ale/lager, ales preferred, extract or partial mash preferred though an all-grain might lure me into starting do to all-grains (I have a wort chiller on the way, should be here today))

Subject: Follow up on Succanat

I've been following the thread on Succanat and have a few follow-up questions. My main question is if anyone has any thought as to the SG/lb/gal number. I have been trying to duplicate "Old Peculier" with out much success. I have re-read Dave Line's book and he suggests that the secret is with the priming sugars used. He recommends using Black Treacle for priming. I've been told that Molasses is similar to Treacle, and that using it for priming is not the same as using it for primary fermentation. Apparently, alot of the aroma+ of the molasses is scrubbed during primary fermentation, whereas it is trapped when priming at bottling. From Charlie's book (TNCJOHB) he recommends using 1 cup of molasses for priming, when substituting molasses for the standard 3/4 cup of corn sugar. Does anyone think that using Succanat for priming will help in simulating "Old Peculier". Any suggestions for the amount to use at priming would be appreciated!

Thanks in advance,
Chris

p.s. I did call the manufacturer, and was told it can also be purchased at the Rockingham Mall in Salem, NH. (but only sold in 1 & 2 lb quantities there).

> trap all the yeast too? (I do need some yeast in my bottles for
> carbonation.)

Mike,

The Cara-pils may have contributed to your haze but it may be other factors too. Haze is nothing to worry about. It is easily removed.

Standard

haze precautions are (1) a good rolling boil to produce a hot break in which whiteish brown gunk seems to come to the surface (2) irish moss. It's

a good idea to boil this for the last 5 min or so of your boil to give the

protein something to stick to which will sink. (3) Cold break. Snow is not

very good at cooling things down. In fact it's a pretty good insulator.

Some snow melts but then a layer of air will form between the pot and the snow and it will take a long time to chill. Putting the pot in the bathtub

or sink with ice water works better. (4) The beer may clear on its own.

Wait until it's done fermenting and see if it's clear. (5) If none of those

work then gelatin can be added to the fermenter. Mix a pack of unflavored gelatin with about a cup of warm (but not boiling water). Just pour it in the fermenter. If you keep the fermenter cold after that it will precipitate even more quickly. It may take some yeast out of suspension but

I usually add the gelatin a day or two before I'm ready to bottle. There will definitely be enough yeast left for conditioning. I've had numerous haze problems (usually because I forget or skip one of the steps above) but

I've always been able to clear my beer eventually.

Good Luck.

Geoff

I've read some posts regarding the use of lye as a cleaning agent. I use it regularly on my glass primary fermenter... but a definite word of caution.
Water alone will NOT entirely clean this stuff off the glass, and it took a batch of soap-suds beer (which went down the sink) to make that point. I now rinse with a weak citric acid solution after using lye and have had no further supprises.

Subject: Sterilized bottles

I have been following the thread on sterilization/sanitization, but have yet to read anything regarding what to do once the bottles have been sterilized, other than fill them with homebrew. ;-)

Once the bottles are boiled, bleached, NaOH'ed, etc. . .where do you keep them before they are filled and capped? I am concerned about nasties falling into the bottles while they are waiting to be filled. Should I bottle a six or twelve pack at a time to make sure no bottles are waiting too long?

I have been cleaning the whole bunch and then filling and capping. I believe I have run across an infection in one or two bottles (not the whole batch). Therefore I have concluded that either the bottles weren't sterilized well enough, or something got into the bottle after sterilization.

Any help/advice on the subject would be greatly appreciated. All grain snobs and lowly extract brewers responses are more than welcome! ;-)

I asked this question some time ago when I tried the Vierka mead yeast.
It seems the funny stuff is rice hulls used as the culture medium.
While this might work ok when the yeast is fresh, it seems to get in
the way of drying/processing. So you get a lot less active yeast
than other brands, which are all yeast and no rice.

In practical terms, these yeasts need a starter to work up to reasonable
pitching quantities. Or you could pitch multiple packets to get enough
for a shorter lag. Even with a starter, the one I tried took 3-4 days
to get going in 500ml. I don't think the yeast is very viable to begin
with. I did end up plating out the culture to make sure I had something
clean. It turned out to be one of my best meads ever.

Subject: Murphy Creek Brewery, Fast mashing & stolen kegs

Well I finally got up to Murphys with Micah to see the brewery he is working on. Well there is a lot of work to be done, but Micah says he could brew beer now if he had to. They (Murphy's Creek brewery) are waiting for the wheels of BATF and all the assorted agencies to do their thing for liscensing. While I was there I was looking at some of the specs on malt, hops and yeast etc. and a quote from GW malt stated that the conversion time for their pale malt (Harrington) is 5-7 minutes! Has anyone ever tried to sparge after a 10 minute mash? Sounds like a good test for Jack S. with all that time to burn!

Micah also relayed a comment he heard from a supplier of kegs. The supplier said that the big boys are going after some people who own thier kegs. We're talking about both the 15 gal sanke and the 5 gal cornelious style. The guys comment was that even if you bought the keg legally from someone, they did not have the right to sell their property. Therefore you purchased stolen property. I would imagine the likelihood of coke or pepsi going after someone is remote, since they are going to the bag approach for their syrupes. However, I wouldn't say the same for the megabrewerys, about their 15 gal SS kegs. I know a lot of micros are using these kegs and have seen cases where they have bondo over the original owners name. Micah is buying all new LEGAL kegs for their operation. Does anyone know of a case where the megabreweweys have went after someone? I hear tale that it HAS happened on the east coast.

Subject: questions on yeast/priming sugar for a barleywine

Last December I made an all-grain barleywine which appears to have some promise. My questions are: 1) how much priming sugar should I be using (I currently have the barleywine racked off to 2 - 1 gal glass jugs fitted with airlocks). 2) I used CWE Plus Wine Yeast, ala Dave Line, which seemed to handle the fermentation OK...my question is "will this yeast sufficiently reactivate in the presence of the priming sugar or should I be looking at some alternative?"

I have a pretty good idea for priming sugar amounts, but am honestly looking for opinions as this is my first attempt at a barleywine. I admit to being particularly nervous about the ability of the CWE yeast to see its way through the bottle conditioning/carbonation phase, if only because I've never tried this stuff before. Any comments would be appreciated.

FWIW, all of my other beers are kegged -- I hate washing bottles 8-(

- paul -
P_LABRIE@UNHH.UNH.EDU

p.s. I gave the second runnings of the barleywine sparge to a neighbor who brews extract beers...it provided a nice adjunct (probably a poor choice of terms here) to a batch of his stock bitter.

Subject: sugar request, data point on aging

I recently brewed an extract-based Bass-alike using Demarara that I really like. My only thoughts on improving this beer next time around are, "more of everything"! (My motto is, moderation in all things, but especially in moderation.) One thing I would especially like more of is the effect I perceive from the brown sugar stuff, and from the descriptions given of "succanat" recently, I'm itching to try it. However, I haven't lived in Boston for a few years, and consequently I don't get to Bread and Circus all that much. Can I mail order this stuff from somewhere?

And how do you pronounce "succanat"? Suck a gnat? Sue can not?

Secondly, for what it's worth I cracked open a couple of bottles of extract brewed steam beer last night that were about a year old. They tasted pretty crummy (but still better than Bud :) !!) I'm not using oxygen-eating caps, but it might make an interesting experiment - not that I let brews sit around for very long at my house, anyway....

From: tims@ssl.Berkeley.EDU
Subject: Culturing Sierra Nevada Yeast

Dear Joel,

Your procedure for culturing sierra nevada sounds fine, as far as amateur homebrewing goes (which is certainly where I stand as well). Real yeast culturers do much more, isolating single colonies on specially prepared slats and all, and some homebrewers do this too. Short of going that far, I think you are doing the right thing.

HOWEVER, I have stopped doing what you do after I lost too many contaminated batches. When I stopped culturing the yeast at the bottom of the bottles, I have had no contaminated batches. I began to suspect that it was not my culturing procedure, which was similar to yours, but that maybe the yeast at the bottom of the bottles wasn't all that pure, and culturing it adds exponentially to the bad population. Due to the easy availability of good SN yeast (Wyeast 1056 is close to SN) in packages, I just get this. Usually, I make a starter.

When I added in all my bad batches, it was certainly not cost effective to culture the yeast.

Relax, ...

From: envkas@sn370.utica.ge.com (Karl A. Sweitzer)
Subject: ...more manifold ideas

Here is my variation on Jeff Benjamins system...

```
/ flush tube to clean out manifold before sparging
/
e--t-t-t--e   -
|             | = 1/2 in rigid copper tubes w/ slots
|             | T = 1/2 by 3/8 t fitting
|             | e = 1/2 in elbows
|             | t = 1/2 in t fitting
|             | - = short pieces of rigid copper tubing
e--t-T-t--e   -
|
| 3/8 in clear plastic drain tube thru end of cooler
```

The flush tube runs vertically up the end of the cooler and has a cap on it during the mash stage. When I am ready to start sparging, I run water thru the flush tube until the run off is clear. The run off is recycled onto the top of the mash to filter back thru the mash.

This flush idea came from Brewing Lager Beer by G. Noonan.

I adapted it to the cooler manifold concept and have been very happy with the outcome... until my last batch. The flush tube came off while I was stirring the mash. I then fished the manifold out with a bent coat hanger and put the flush tube back on. The only problem was that my drain tube came off without my knowing it. I ended up with a open ended 3/8 in plastic tube for a manifold. The grain bed formed the filter, but the rate at which the wort ran off was painfully slow, only a very fine trickle. At the time I thought it was because I had ground my grains finer to get a higher extract (last time I will do that again anyway).

The next time I plan to dimple the end of each copper tube with a center punch (punch from the inside of the tubes). This will form a tighter fit that can still be disassembled.

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)
Subject: Re: Copper lautering manifold

In HBD1099 Jeff Benjamin describes a sparge manifold system which connects to a siphon hose as follows:

>You will need to come up with some way to connect your siphon hose the
>the 1/2 inch standpipe. We found a 1/2" to 3/8" ID reducer fitting and
>a short piece of 3/8" OD tubing will connect nicely to a standard vinyl
>siphon hose:

```
>-----  
>| /___ 3/8" _____  
>|1/2 inch copper|redu |-----|siphon hose  
>| cer_|-----|_____  
>| /  
>-----
```

>Also, the reducer and 3/8" OD copper need to be soldered so they don't
>suck in air, since they're the only fittings that sit above the liquid
>level. [Note: soldering copper is easy; it requires a few cents worth
>of plumbing-safe solder and flux and a \$15 propane torch. Ask the
>friendly folks at your local hardware store.]

Instead of soldering on the reducing coupling you could also use a brass compression reducing coupling. To go from 1/2 inch copper tubing to 3/8 OD flexible copper tubing you will need a 5/8 to 3/8 reducing coupler since the OD of stiff 1/2 copper tubing is 5/8". (Bring samples of you tubing to the hardware store to make sure.) Before siphoning you must make the fitting tight using two wrenches.

I've been using a similar setup for my last 2 all grain batches except I use an "I" formation with the standpipe coming up from the center:

```
Looking down from the top  
tee  
    cap[----x----]cap  
    |  
    |  
    |  
O tee with standpipe coming up  
|out of the page  
|  
    cap[----x----]cap  
    tee
```

I stole ideas from this forum, possibly from some remarks Jeff made a few months ago, and agree with the advantages he mentions.

>had a much longer and healthier fermentation than that.

You certainly gave the yeast a shock if you dumped them from room temp
into
83 degrees, but not nearly as bad as if you would have suddenly LOWERED
their
temperature 10 degrees. I recently started a batch with Wyeast #1056 and
I pitched a 500ml, 72F starter into 72F wort (the great thing about
immersion
chillers is that if you overcool, you can easily warm the wort up with
hot
water just as easily). I then set the fermenter into a 61F room (DUH!)
and
let the yeast do their thing. They promptly did absolutely nothing, for
two
days. When I moved it upstairs to the study (69F), they started in a few
hours. When I closed the door, to keep the carboy (covered with a couple
of brown garbage bags) darker, the temp dropped down to 60F (DUH!!). The
yeast slowed down again. When I opened the door and warmed up the room,
they started again. They've probably rebelled against me and spewed all
kinds of phenolics into my ESB. Let's hope not. I know much better than
to do this (really), but I haven't been giving my beer the attention
lately that it deserves or used to get. Back to the question...

At 75F, I could see the 1056 fermenting out the whole batch in 2 or 3
days. This would not be surprising. The beer would jsut tend to be
a bit frutier than if the ferment was done at 70F throughout. Check the
gravity. If its gravity is 35% to 25% of the original gravity, then
it's done. If the gravity is significantly higher than this, then you
may have a stuck ferment, but I doubt it. Stuck ferments are usually
caused by sudden changes in temperature in the *middle* of a ferment,
not the beginning. Once the yeast starts, if the temp doesn't vary
widely, the yeast will just ferment till they run out of sugars.

>And lastly, if I do use gelatin should I be concerned that it would
>trap all the yeast too? (I do need some yeast in my bottles for
>carbonation.)

If it's cloudy in the fermenter, it's most probably the yeast. Perhaps this yeast you used is not a good flocculator. I suggest not worrying, bottling it when it's ready, letting it carbonate at room temp for two weeks, and then lagering it in the bottles between 35F and 40F to settle the yeast. Another cause for the haze may be bacterial, but let's hope it's not. If the beer was clear at room temp, but threw a haze when chilled, that would be chill haze and would be partly due to the tannins you extracted from the husks of the Cara-pils. I remove my specialty grains (in extract+specialty batches) at 170F. I was tasting three of my beers last night and one seemed more astringent than the other two. I checked my brewing log, and there it was: "accidentally boiled grains for 10 minutes." No haze by-the-way, probably because I used a wort chiller and got a great cold break. I've even stopped using Irish Moss -- I felt it was reducing my head retention.

Now, who was it that started the rumour that Cara-pils is not like other specialty malts? I have been treating it just like any other Crystal malt with no problems. The one difference is that U.S. Dextrin Malt (another name for Cara-pils) which is made from scrawny 6-row grains is hard as ball bearings! You could break a tooth on that stuff! The DeWolf-Cosyns Cara-pils is made from 2-row and is nice and plump and not at all like US Cara-pils. Bottom line is, that Cara-pils is just very pale Crystal Malt (7.87L or 15 EBC for the DeWolf-Cosyns).

Andrew writes:

1040 is a bit high. I suggest 1020 and I don't hop my starters at all.
You can if you want -- the hops will reduce the chance of bacterial
infection, but I would avoid "highly hopped," but that's just a gut
feeling, not based upon anything I've read.

Perhaps a result of higher-than-usual temperatures. I suspect that
everything was okay.

>Also, provided I can get the procedure to work, I would like to
>know if anyone uses cultures from SN Porter or Stout. I haven't
>seen this mentioned anywhere.

I've cultured from SN Porter (I believe it is the same OG as the SNPA)
but not the Stout (which is only a few points higher in OG, so I don't
see a problem with it). Culturing from SN Celebration Ale and Bigfoot
Barleywine is not recommended.

Jack writes:

> up with 4 after 90 min is just about right. Frankly, I do not think
> there is
> such a thing as too vigorous a boil. If you lose too much wort, just
> start
> with more. I would figure on about a gallon per hour of boil.

I disagree. A vigorous boil we want, but in most cases (i.e. for most

styles) we don't want to caramelize the wort. The higher the heat, the more the wort caramelizes. This would not be good in a Pils style.

> Under no circumstances, do you want to cover the kettle. Part of the reason
> for boiling is to concentrate the wort.

I agree, but for a different reason. When the wort is above 140F, SMM (inherent in malt) is being converted to DMS, which gives your beer a cooked-corn aroma. DMS, luckily for us, is quite volatile and boils off, but only if you boil at least partly uncovered. A simmer won't cut it -- it has to be a good, rolling boil, however, the kettle does not have to be completely uncovered. I partially cover my kettle (about 1/2 to 2/3) to reduce heat loss so I can get a good rolling boil with *less flame*, thereby reducing caramelization. Before I ripped out my electric stove and put in a gas one, I would need to partly cover the kettle just to get the water to boil!

Leo writes:

>half-gallon jug. Nothing
>happened for 2 1/2 days, the brew never fermented
>very fast. At the peek it
>fermented at maybe 1 bubble per 30s. Is this slow
>fermentation normal??

Consider the size of the batch and the gravity (which, by the way, was good for a starter). Consider that a regular 5-gallon batch would have almost 27 times the wort. That equates to almost a bubble per second. Not bad. If the wort was 1040 or 1050 or 1060, you could have expected 2 bubbles per second, but 1 bubble/30 sec for a 24 ounce, 1020 starter is just fine.

>By The Way (BTW) I did vigorously shake the wort
>to aerate the wort before adding
>adding the SNPA yeast.

Good.

>How do you culture yeast from a bottle?

Just like you said, but in a Erlenmeyer flask, in which I boil and cool my wort -- I let the wort sanitize it's fermentation container. Just another great suggestion I snagged from the HBD (by the way -- don't try to sanitize a plastic airlock with the steam from the boiling wort -- it will melt -- I know... glass airlocks are on order.)

>Should I assume it is OK??

Cautiously assume it's OK.

>How can I tell if it is infected??

Taste and smell, apart from microscope work and plating on differential media. I use my tastebuds and leave the lab work to George Fix and Mike Sharp.

>Is the yeast OK?

Sounds like it's just fine.

End of HOMEBREW Digest #1100, 03/18/93

Date: Wed, 17 Mar 93 16:42:36 -0500
From: Timothy J. Dalton <dalton@mtl.mit.edu>
Subject: sterilization, aeration, filtration.

I've been reading an interesting book the last week:

The Biotechnology of Malting and Brewing, by J.S. Hough
(Cambridge Univ Press, 1985)

Anyway, while reading it, i've run across a few things that
answer recent threads on r.c.b and in HBD

All are quoted without permission.

Steam Sterilization: (p.49)

"Steam is also use for sterilisation but can only be fully effective if
it is saturated and operates in hot equipment. There must be ample
opportunity for the condensate to escape as the equipment heats up.
At least 30 min steam treatment at 1 bar over pressure after the
equipment
has heated to 100C is necessary to achieve sterilisation of a
cleaned piece of equipment."

Wort Aeration: (p. 91)

"Aeration of wort is needed for yeast growth. Specifically it is
required in small amounts (5-15 mg/l) by the cells in order to
synthesise unsaturated fatty acids and sterols for intracellular
membranes...Air will provide a maximum of 8 mg/l dissolved oxygen.
Some strains of yeast however require more than this and oxygen is
substituted for air."

Yeast Size: (p. 96)

"A typical brewing yeast cell will, when fully grown, be between 8
and 14 um diameter and have a mass of about 40 pg when dry. Thus,
10¹² dried cells will weigh 40 g."

Control of Infections: (P. 111)

in austenitic stainless steel vessels,
"The sequence is wash thoroughly by water, using high pressure
revolving jets or static spray balls in the vessels. When the
water has drained, hot caustic soda (usually with
some sodium hypochlorite) is used as a detergent-sanitizer.
The caustic soda kills microbes effectively and is an excellent
dissolver of protein. It is not however suitable for dissolving
and keeping in suspension calcium salts, therefor additions
of various polyphosphates, metasilicates or guconates may be made.
The hypochlorite is a source of free chlorine and therefore a strong
bactericide; it also enhances the cleaning power of the
detergent. Free chlorine is however a dangerous agent of corrosion
of stainless steel if the pH of the solution falls to neutrality or
below."

Filtration: (Pg. 143-147)

Several filtration techniques are talked about. Its too long to post.
Bottom line is that diatomaceous earth (kieselguhr) is the
most popular filter type. This, in combination with a secondary
membrane filtration does a great job. 1.0 um membranes will be expected
to prevent yeasts from be penetrating, and a 0.2 um membrane would be
expected to hold back bacteria.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: crystal malt in muslin bag

In HBD 1099 Mike Rego asks about Cara-pils haze. This prompts me to ask a more general question regarding the addition of other malts to an all-extract brew. Up until now I've been putting these in a tightly-woven hop bag, but am convinced that the bag is too small, packing all the grains in much too closely and restricting the extraction I get.

I'm thinking of using a much larger bag made out of muslin, but am wondering if the much coarser weave will allow undesirable things into the wort. My procedure is generally to steep the grains for 20 minutes or so at 170 degrees, then remove the bag prior to bringing the wort to the boil.

The grain crushing process (either a rolling pin for me, or sometimes I buy it pre-crushed from my brew shop) produces powder along with broken grains. How important is it to sift all this powder out? If it gets into the wort will it cause any problems?

My thoughts are that the muslin idea would work, because in full grain brewing all this stuff is thrown in with no strainer bag, right?

Any comments/suggestions are most welcome.

Peter

Here are some answers (even to questions you didn't ask): the amber color is not surprising, really. You'll find that one company's "light" is another's "amber" and that truly pale beers are tough to make from extracts. In part, this is because the evaporation process necessary to create syrup from wort often is allowed to darken the product. But the German syrups are particularly dark, or they were several years ago when I did an experiment for Zymurgy and compared a dozen brands of extract.

Carapils does not cause haze, although there seems to be an odd train of thought out there to this effect. On the other hand, regardless of what Charlie Papazian says, you shouldn't be boiling your specialty grains. Far better to get them out earlier, and even better to simply steep them at about 150F for an hour or so, then rinse them and use the resulting liquid along with your extract. Carapils will give your beer more body if it's properly used; I can't imagine what "not like other specialty grains" means in this context, but it sounds as though someone was giving it a bum rap. Carapils also has the added benefit of enhancing the "maltiness" of beer, which is why microbrewers often use it in conjunction with American pale malt.

I'm a little confused about what you mean by "haze" in a fermenting beer. Was it hazy when it went into the carboy, and did it not clear at all (with a large deposit of solids) within an hour or two. After the yeast takes off, of course, there's a whole new "haze" which is just two or three ***illion yeast cells performing their mating and working rituals. If the beer never looked bright in the kettle (taking into account all the stuff floating around in it -- take a spoonful out and look to see if the liquid itself is clear when the hop particles etc have a chance to settle), it's possible your boil is not vigorous enough.

=====
On another note, has anyone ever gotten results anything like Charlie's from one of his recipes? He seems to bat them out at a fairly high rate, and I've wondered over the years how much time goes into

developing each one, and whether he's ever brewed one of them more than once (or better yet, more than three times) before publishing them. What really struck me was his recipe in the most recent Zymurgy, which calls for (not having it in front of me, and whoops, here we go again relying on memory) something in the neighborhood of 3.5# of dry malt extract and about 3 pounds (maybe a little more) of specialty grains. This to produce five gallons of a beer over 1.065. Does anyone else think this is unlikely?

Subject: pH meter questions

Nicks asks:

>1) can I just use distilled water to calibrate at pH7?

No. Distilled water is NOT pH 7, it is acidic due to dissolved CO₂. You need to buy (or make) buffer solutions to accurately calibrate your meter. Your meter should also have some instructions about calibration. Many of the meters have two-point calibrations where you adjust the pH reading at, say, pH 4 and 9. Since pH varies with temperature, you also need to make sure that you calibrate it at the temperature specified by the manufacturer (unless your model has auto-temperature correction).

Subject: Temp. Controls / Freezer

Re: Temperature Controls

I would like some feedback on what people think of their temperature controls for their refrigs/freezers. Has anyone used the digital one from American Brewmaster? I like the idea of the digital ones, but I've only seen ones that go down to 40 degrees. I know Williams beverage sell one that goes down to 20 degrees but it does not have a digital display.

Re: Refrig/Freezer

Any recommendations on refrigs/freezers that have worked well for people? I seem to think that a chest freezer would allow the best utilization of space and it would allow the temperatures for lagering. Also, what results have people gotten lagering with just their refrigs (down to 40 degrees I believe)?

>too long?

I use a technique I saw here on the HBD once and has worked well. After
cleaning, rinsing, and drying the bottles with your favorite method, take
a
small square (~ 2"x2") of aluminum foil and seal up the bottle opening.
Then
bake the bottles (theoretically nothing lives over 60C, but I use just
over
100C) for 15 minutes and let them slowly cool. When you're ready to
bottle,
just take the foil off. I've done this up to 3 days before bottling and
have never had an infection yet.

Subject: Rye Malt and the Extract Brewer

Hi folks,

I'm wanting to try my hand at making the Finnish beer Sahti. I've found the malted rye (a tricky thing) but have a question. You see, I'm still an extract brewer and am not ready to go all grain right now. So I was wondering how I handle the rye malt. Should I treat it like a speciality grain by steeping it in near boiling water and then adding it to the regular malt? Or will I need to do a partial mash? How would I go about this?

Thanks,

Julie

>of an amber DME with 3/4 quart water in a 1 1/2 quart clean juice jar.

I think your problem was that you used only 3 tbs of DME. Are you sure you gave the yeast enough to eat?

Chris Dukes asks about suggestions on what to do with bottles after they've been sterilized:

>Once the bottles are boiled, bleached, NaOH'ed, etc. . .where do you keep
>them before they are filled and capped? I am concerned about nasties
>falling into the bottles while they are waiting to be filled. Should I
>bottle a six or twelve pack at a time to make sure no bottles are
>waiting
>too long?

I suggest that you keep the bottles with the open end down to prevent stuff falling into them. I can get about a case of 16 oz. bottles into a standard dish drainer. That's a pain since a 5 gal. batch takes about a case and a half of bottles. So, I picked up a drying rack. It's a plastic tower that holds up to 45 bottles and is expandable in increments of 9. I wipe it down with a bleach solution while my bottles are soaking, rinse the bottles with a bottle washer attached to a faucet, and then let the bottles drip dry on the rack. It works great and doesn't take up much counterspace. You might be able to make one out of wood, but I'm not sure you could keep it as clean as the plastic version. I bought it at a local homebrew supply shop for around \$25.

I've heard of other folks using the dishwasher set on rinse and dry, but that's not an option for me since I don't have a dishwasher or any room in the kitchen to put one.

Subject: Chili Pepper Beer

Greetings.

I usually put half a chili in each bottle before sealing the crown.

First slice the pepper lengthwise.
Then remove the seeds (but not the inner white membrane)
Rinse
Put half (or two halves) chili in each bottle you want to "pepperize"
Seal crown

I have found that as soon as the beer is carbonated and conditioned it is at it's best "pepperness." The chili aroma and flavor seem to mellow with age. I cracked open a chili beer that had been sitting for a couple of months, and the flavor was there, but it was very subdued. So, maybe wait a couple of weeks if you want a beer that is at it's greatest pepper potential for cinco de mayo.

I have tried putting chilis in with the boil, but the finished product did not have any "pep," just a bit of peppery flavor. Also, with the pepper in the bottle trick, you can make less than a batch of pepperized brew. Perhaps if you plan on crating more than one batch of beer to be consumed by may 5, then pepperize some of each and do a side by side by side comparison of all the pepperized/non pepperized beers.

Subject: Maltmill and Easymash source

A number of brewers suppliers (chandlers?) carry these things. Last I knew, you could also order them directly from:

Jack Schmidling Productions
4501 Moody
Chicago, IL 60630
+1 312 685 1878

You can also E-mail Jack for more info on current prices, retailers, etc. He is a little reticent about posting commercials, but will probably reply privately.

I use both these devices and am quite pleased with them. You can build an Easymash yourself--Jack posts directions from time to time. If you want it done right the first time, Jack doesn't charge that much over the cost of parts for his kit, which has had some die work done on the air cock.

The Maltmill is another thing again. It has custom castings, from recycled aluminum cans! I have no idea how Jack grooves the rollers, or where he gets the stock. It also is well-made and worth the investment. I have the non-adjustable version and have had no problems crushing various malts and even raw rye.

I seem to recall that the Maltmill is about 120-125 dollars and the Easymash is about 25 dollars. If you order direct there is a small shipping charge, but only one charge for both ordered together.

disclaimer--I have no interest in any of Jack's businesses. I am just a satisfied customer and amused observer.

Subject: Re: Chili Pepper Beer

I've not been incautious enough to make one, but I've judged several, and the palatable ones all had a high residual maltiness which balanced the pepper. So many of these are awful, but I tasted one which was actually good - and the trick in the recipe was to use Wyeast 1338 yeast (European Ale/Dusseldorf Altbier) which will naturally leave a high maltiness. Gravity was in the normal range around 1.050.

Tim Sasseen says:

>that maybe the yeast at the bottom of the bottles wasn't
>all that pure

I have done the bottle culturing bit from SNPA for quite some time without any problems. The yeast is a washed version of what was used to ferment the beer. It is added to filtered beer to provide for the bottle conditioning. If there were faults with this yeast or the culturing method I would expect we'd hear about lots of problems from lots of homebrewers. I'd also expect there would be some evidence of such a problem in Sierra's products. I can't say I've ever had a bad bottle of anything that Sierra Nevada produced.

As for the OG recommended for starters:

I believe George Fix did some research (or at least referred to somebody's research) which indicated that the performance of yeast was best when begun in a starter which was close to the OG of the batch to be pitched. This was especially true for higher gravities. George?

Subject: local brewmaster on sparge time/mashing dark grains

I know Micah's no longer with us (gee, that sounds like he's dead--you know what I mean: He's no longer with the DIGEST), but before he left he made the argument that dark grains should only be added at mash out, rather than for the whole mash. The subject came up at our homebrew meeting last night, and Fred Lang, the brewmaster at our local micro, agreed with Micah. He said to put the dark grains in for just ten or twenty minutes at the end, while mashing out.

Also, not too long ago, Joe Stone and I wondered about sparge times. This subject also came up at our meeting last night. One guy said he aimed for 2 and a half to three hour sparges. Another person said, "Gee, I just do it for about twenty minutes." Again, the question was put to Fred. He said that the length of time is really irrelevant, because it depends on your grain bed, temps, and other things. He maintained that you should use the gravity to determine when to quit sparging. In particular, do not go below 2 degrees Plato, and in fact you should quit a little above that since it would be better to throw out a little extract rather than get the tannins. So what's 2 degrees Plato? Like 1.008 maybe?. Looks like those of you who stop at 1.010 have been talking to Fred...

Just thought you'd be interested,

What was the SG of the starter? I always use ≥ 1.040 starters, and
3Tbs
to 3/4 qt seems awfully thin to me. I also pitch WYEAST packets into
300-500ml starters and then step up to 800-1000ml starters. It seems
that you
are using too large of a starter with too low a DME content. With any
luck,
your yeast should still be viable, I might try boiling up some really
thick
wort, and adding it to your existing starter.

Subject: Bock recipe

Well, I was going to wait until after this beer won the Bock is Best competition :-)) to post this, but a friend asked for the recipe, so I'll kill two birds with one stone. Since this was the first batch in my new mash/lauter tun, the procedure required some fine-tuning. Thus the multiple infusions, etc. This may make it difficult to exactly reproduce the recipe!

I made this on Dec 26, so it's

Boxing Day Bock

10# Belgian Pilsener Malt
3# Belgian Munich Malt
 (above Corona crushed)
 .5# M&F Crystal malt
2 oz chocolate malt
 (above pre-crushed by roller mill at the HB shop)
4oz Hallertau plugs @ 2.9%
2oz Saaz plugs @ 3.1%
Wyeast Munich Lager yeast (2308)

Procedure:

Mix Pilsener & Munich malts in mash tun, infuse 10.5qts H2O@170F (mash temp 137F -- oops!), infuse additional 3qt @boiling (mash temp to 145F - -- sigh!), decoct 3qts (pretty thick) to boiling (mash temp to 156F -- finally!) Meanwhile, steep crystal in 1qt H2O @165F. Mash 1hour. Infuse 3gal @boiling to 165F, add crystal & chocolate malts & stir. 15min rest. Start sparge, recirculate 6 qts. Sparge to 6.5gal (ending sparge gravity 1.010@150F == 1.026??)

Boil 1.5 hours. Hop schedule
2 oz Hallertau @ 30 min
1 oz each Hallertau & Saaz @ 60 min
1 oz each @ 75 min

Chill & rack. Yield approx 4 gal @ 1.066.

Pitch yeast from 1pt starter. Move to cellar @58F. After two days, krauesen is evident, move to fridge @50F.
Primary time: 6 weeks
24 hour diacetyl rest at end.
Bottled at FG 1.022, lagered in bottle.

Comments:

It came out as a borderline "Helles Bock." Probably should have left out the chocolate malt.

This stuff is yummy. Wonderful malt nose & flavor. Nicely hopped. Friends have said it's one of the best beers they have tasted.

I have to attribute much of its goodness to the ingredients: Belgian malts and hops plugs. This is the first time I've ever really smelt the "spiciness" of Saaz hops. I wonder whether the little decoction I did to get the mash temperature up had some effect on the maltiness.

From: Paul Andersen <ECZ5PGA@MVS.OAC.UCLA.EDU>
Subject: Beer and Cancer

Hello fellow brewers, Now I could be wrong, but, while doing research for a paper in my Biology of Cancer class here at UCLA, I found some articles which described studies being done in Europe regarding the effects of beer and alcohol in general on the risk of colorectal cancer. What they seemed to be saying was that spirits and wine did not increase the risk of colorectal cancer, but they found that beer did. Of course the risk was substantially increased only in subjects who drank large amounts of beer regularly over the course of a lifetime. There was also a link to dark beers and smoked foods, such as fish.

I did not end up writing my paper on this topic, so I cannot give any references, however, it would not take me long to look them up again if anyone is interested.

If anyone else can shed some light on the subject, feel free.

By the way, I tried the new Pub Daught Guinness in the can for the first last weekend and I loved it. Just for fun I ripped open the can to check out the doohickie on the bottom: pretty cool. If you haven't tried it yet, and you like Guinness, go out and get some. It is amazing how it looks and tastes like it came out of the tap. My only gripe is that you have to open it cold (otherwise you have beer all over the place: like homebrew). I haven't seen it in too may stores though. In southern california you can get it at the Price Club (although it may be seasonal). It sure made my St. Patricks Day.

Homebrewers do it sanitarily

I think that this may be your problem. 3 tbs in 3/4 quart is an *very*
low gravity wort. Even the 1020 wort that I use barely if ever shows
any krausen -- besides there being very little sugar for the yeast to
get excited about, the viscosity of the wort is so low that no "head"
forms. You probably have a fine yeast starter, albeit a bit weaker than
it could have been. If you want to continue to use the juice jar for
your starters, get a one-hole stopper to fit the top and put an airlock
in it. The airlock will show you activity a lot more accurately than
watching the surface of the starter.

Ridiculous. Perhaps all the yeast in the US is now dead thanks to this
low pressure storm system? Find a reputable supplier.

The sludge is a combination of hop petals that made it through, hop
resins,
dead and dormant yeast and probably a couple of other things. Leave it
be. The sludge is expected, but if you still think you want it in your
beer, taste it and decide for yourself.

waiting
>too long?

I bought a bottle tree and a sanitizer thingamabob. It mounts on the top of the tree. I pump bleach solution into the bottles (30 pumps) and then set the bottles onto the tree. When I've got two cases on the tree, I rinse the first bottle, fill it, cap it and then go on to the next bottle. Perhaps you may want to sanitize all your bottles (even if you leave them face up) and then rinse just before bottling. This way, if anything falls in, the residual sanitizer will kill it.

That should have been 2 bubbles per 30 seconds.

> to 1 inch in thickness.

Sounds like you were a bit hasty. The package should be more like 3"
in thickness before it's pitched into the starter.

I pitched this into 3/4 quart of wort I had
> prepared the evening before. The wort starter was made by mixing 3 Tbs
> of an amber DME with 3/4 quart water in a 1 1/2 quart clean juice jar.
> I capped the jar and shook vigorously to mix well. I then uncapped the

kettle
> was covered during the boil and simmer. I then let the wort cool to
room
> temperature (65F) overnight.

I think this is another case of overkill. You should be able to
sterilize your starter by simply boiling the DME and water for 15
minutes in a pan on the stove. Then force-cool it in the sink by
putting on a lid and running cold water around it. This cooling takes a
matter of minutes. Transfer into your sterilized jar, aerate and add
the yeast. The problem, though, as I said above is that you didn't get
enough growth before you pitched into this volume. Given time it may
well come up to sufficient yeast volume to use for brewing. Bear in
mind, however, that you need roughly twice as much lager yeast for
pitching as you do ale yeast.

The next morning was when I pitched the
> yeast from the pack. That was last Friday. To date nothing, nadda,
> zilch, has happened. I've kept the supposed starter capped with
aluminum
> foil and in a paper bag to avoid exposure to light. The wort has
remained
> around 65F.

Some more overkill. Put your starter somewhere warm and don't worry
about light. If you've used hopped DME (which some people recommend),
there might be a concern about light struck smells, but yeast don't have
any objection to light that I've every observed.

>

Well, now that's a creative suggestion. Ridiculous, maybe, but creative.

Aha! This is exactly the problem with any system but my own. (Sorry. I couldn't resist the "snob" approach.) (But it's true.)

If you take your clean bottles, and put little aluminum foil tops on

them and then put them in a cold oven, raise temp to 350 for 90 min., let them cool and put them back in the case, you will not have to worry about nasties. I have let bottles sit like this for days and then bottled without problem, and could probably let them sit for weeks -- as long as none of the kids stuck their fingers through the foil. Another advantage of the system is that you don't have to empty the dishwasher first.

Subject: Miller Ale, Yeast Slurry Reuse

I have several questions for the readers of the HDB.

1. Has anyone heard of a "Bass type" ale that Miller Brewing Co. was going to market? A friend of mine was on a tasting panel about 1 year ago. He said they were going to call it, tentatively, Miller Ale, Copperhead Ale, or God knows what.

Flame me if you want, but it is (remotely?) possible that this could be a decent beer. After all, Detroit is making good cars again. Maybe the American mega-brewers can get their act together too.

2. A while back I read a post asking if the yeast slurry in the bottom of a fermenter can be used to make bread or any other food products for human consumption. Any suggestions? (My friend's dogs are currently the benefactor of his yeast slurry. They love it!)

3. Is the infamous Jim Koch related to the brewers of Koch's Anniversary Beer (from the New York area)?

It's one "c", Sucanat. It's a contraction of the words sugar cane natural.

And I pronounce it sue can gnat. It might actually be shoo can gnat. I'm eating some now. Yum!

Subject: Yeast Lab, Hallertau in porters

Has anyone tried "Yeast` Lab" (tm) liquid yeast cultures? They just turned up at my local brewshop. They're distributed by G. W. Kent, so I imagine they are/soon will be readily available.

They come in litte 35 ml vials. They cost the same as Wyeast. The selection is similar. They have most of the Wyeast strains, and a couple that Wyeast don't seem to have. There are 8 ales: Autralian, American, London, British, Irish, Dusseldorf, Canadian, Trappist. 5 lagers: Pilsner, Bavarian, Munich, St. Louis, California. There's a Bavarian and Weizen and two mead yeasts: dry and sweet. I guess Autralian and Canadian ales and the two mead yeasts are the only varieties not availbale from Wyeast. I'm looking forward to trying the mead yeasts.

Thanks to all who replied on the subject of Hallertauer in porters. In particular, thanks to Jeff, Russ, Nick, Kieth, Jim and Walt. The use of Hallertauer, Mt. Hood or Tettnanger as a finishing hop or dry hop for porter seems quite popular. I had originally been planning to do the same, but then I got thinking about using them (Hal. and Mt. Hood in this case) for bittering and flavor as well. Only Kieth MacNeal seems to have tried this. He bittered with Hallertauer and Tettnanger in a porter that was also flavored with ginger and juniper. Wish I could try some!!

So I think I'm going to go for it: I plan to follow the recipe "Foster's Entire Butt" in Foster's _Porter_, except that I'll use Hallertauer and Mt. Hood (possibly a touch of NB as well) for all hop additions, and tone down the chocolate malt a little. The hope is to get something like a Bavarian dark beer in hops and color, but with the ale characteristic of a porter. Wyeast London, in case you were wondering.

Cheers,

Rob (bradley@adx.adelphi.edu)

Subject: AHA/Pete's Press Release

PRESS RELEASE

The American Homebrewers Association (AHA) announces Pete's Brewing Company's sponsorship of the 1993 Ninkasi Award to be presented at the 1993 National Homebrew Competition being held July 27-29 in Portland, Oregon. Named after the Sumerian Goddess of Brewing, this premier honor is awarded based upon brewing proficiency across several categories of beer. Scoring is based upon the greatest accumulation of points across all style categories.

In addition to this year's trophy, judges and Pete's Brewing Company will choose one of the Ninkasi Award winner's beers to be brewed as the first Pete's Wicked Winter Brew which will be distributed coast to coast.

Compliments of Pete's Brewing Company, the award winning brewer will also receive:

**Name recognition on every bottle of Pete's Wicked Winter Brew.

**Registration at the two week Short Course in Brewing Technology at the Siebel Institute of Technology in Chicago (tuition, travel and lodging included)

**Attendance at Pete's Wicked Winter Brew's first brewing at Pete's Brewing Company (travel and lodging included).

"As a homebrewer, I am excited to offer this opportunity to a fellow homebrewer," remarks Pete Slosberg, founder of Pete's Brewing Company. Pete's homebrewing led to Pete's Wicked Ale, now a nationally acclaimed microbeer and the 1992 Gold Medal Winner of the American Brown Ale category at the Great American Beer Festival. He continues, "This is the chance for someone's homebrewing skills to be recognized across the United States."

The American Homebrewers Association, a division of the Association of Brewers, is dedicated to promoting public awareness and appreciation of the quality and variety of beers through the collection and dissemination of information. For more information about the National Homebrewers Conference or Competition, please contact the AHA at (303) 447-0816.

Subject: More AoB Bashing

Back on 8 February, I ordered some books from the AoB. Among them was The Practical Brewer.

When the package arrived a few days later, Practical Brewer was not in it and was, according to the invoice, backordered. Of course I was charged for it anyway. When I called (the day the package arrived)

' I was told the book was out of stock and would be in around the first of March. I said, OK, but I'm not too happy that you have invoiced me for something you aren't going to ship for another three weeks. (No response.)

Mind you, I wasn't told about the backorder when I phoned my order in. :-||

So weeks and weeks roll by. No Practical Brewer.

I called again today. This time I was told "the book isn't back from the printer yet ... it's a new printing." I can now, they say, expect the book to ship around the first of April.

None of this would bother me if AoB, which purports to run a high-class mailorder operation, would do the usual high-class thing and INVOICE ONLY FOR ITEMS SHIPPED. I could wait for months (not that I would like to) if they weren't holding onto my money. As it is, though, I am getting more and more pissed about this, as well as silliness like "15% off" a \$10 book...I mean, the mailing probably cost half of that discount per member!

I plan to send a written complaint shortly, and encourage any of the rest of you who have had trouble with the mailorder service, or other aspects of the AHA/AoB/etc. to do the same with your gripes.

Help stamp out poor service in OUR organization.

Subject: pH meters

Nick says:

-) I finally broke down and bought a ph meter.[The
-) hanna unit that American brewer sells if it matters]
-) I now have three questions:

I have one of these. It works reasonably well for something so inexpensive.

-) 1) can I just use distilled water to calibrate at
-) ph7?

No, positively not. You must use a buffer solution of some sort. I recommend getting a pH 7 buffer and another buffer around 5.5. The CRC Handbook has a table that tells you how to make up buffers of any pH your heart desires. I have 4, 5.5 and 7 in my cabinet. You can also find premixed buffers (generally expensive) and buffer capsules that you mix with some quantity of distilled water.
