I noticed this too, but it was long after I had heard about Jack's EasyMasher. If this was to go to court (ha!), it would probably end up in Jack's favor. Sorry if I spoiled any Jack-haters' day ;^).

Subject: boiled wort/water ratio

A few nights ago I was brewing up a batch of David Smith's Porter from the Cat's Meow...a recipe I had made once before with fine results.

The recipe for 5 gallons calls for adding grains and extract to 1.5 gallons of water (the amount I used the first time) for the boil; however, this time I chose to use only 1.25 gallons. I did this for a couple reasons. First, I have a relatively small (4 gallon) brewing kettle and thought it would be easier to control potential boilovers with a smaller quantity of wort... which turned out to be true. Second, recent batches of mine have taken several hours to cool (1.5 gallons of hot wort added to 3.5 gallons of cold water) to pitching temperatures, which has made me nervous about possible infection. I thought that adding less hot water to more cold water would help alleviate this delay, which also turned out to be true as the mixture was immediately at pitching temperature.

So here's the question. Are there any disadvantages to reducing the volume of boiled wort? The resulting mixture was noticeably thicker as I poured it through a strainer into the primary, but other than having to rinse the hops in a couple extra times, there were no obvious problems. I did notice, however, that my O.G. was somewhat lower than the first version, suggesting I left some good stuff behind in my spent hops.

Any thoughts?

From: John Glaser <glaser@analog.ece.arizona.edu>  
Subject: Brewpot questions / I are a college student!

I have been brewing about a year now, and have some questions/ideas about brewpots.

1) I just picked up a enameled steel canning pot (8 gal.), but it has a few chips in it, maybe about 1-2 square inches

worth of exposed metal. Will this be a worse problem than

that created by using 3 gal. boils in my smaller pot. Is

there anything I can do to cover the chips? (for example, using hi-temp enamel like they sell for repairing outdoor BBQ

grills and such).

2) Has anyone ever considered electroplating the inside of a steel or aluminum pot with copper, to allow its use as a boiling pot. Is it too expensive, too difficult, etc., or could it work? What about anodized aluminum? Anyone know

anything about this?

Anyway, just started reading the digest, and enjoy it thoroughly. Also, regarding the earlier post about college students, I am one who brews out of necessity (of course, who doesn't?). Can't afford to buy decent beer :(, so I am forced to make all the beer I drink. Oooh, life is so tough!

Subject: Sake

A short time ago,

>Bryan Kornreich <bkornrei@welchlink.welch.jhu.edu>

Asked about:

>Subject: sake-brewing

>Does anyone know anything about brewing sake? I'd like to try it 'coz I  
>love it and I've got a lot of rice. Any recipies? With its high alcohol  
>content(15-18%) does it require any sort of distillation? Or are there  
>yeast that can pump out that high ethanol content?

Well, if you want to brew sake, my first suggestion would be to buy and read Sake, USA by Fred Eckhart. Without repeating everything he goes into there, I will outline a few of more salient points about sake brewing here:

- 1) You need a large portion of rice infected with a fungal amalyse. This stuff is called Koji, and you can either make it yourself or buy it. I'm using Cold Mountain Koji at the moment, and I got a local shop to special order it for me. It needs to be refrigerated and should be used when fairly fresh.
- 2) You can use a sherry yeast, or some other alcohol tolerant strain, though the proper sake yeast is available from Wyeast (in liquid form) and perhaps from others. If you use the Wyeast, Fred suggests that you NOT pop the nutrient pouch inside. Just clip the package and use as is.
- 3) In order to make the best sake, you should use highly polished japanese short grain rice. Without going into all the whys and wherefores, long grain rice is not as good. Brown rice can be used, but you probably won't recognize the end product as sake. You can usually get this rice at an asian food store. You'll also need to steam the rice, so you should get a rice steamer while you're picking up the rice. For a small batch of sake, about 2 gallons, the last addition of rice is 5 lbs, so you need a reasonably large steamer if you want to do large batches.
- 4) No distillation is required to achieve high concentrations of ethanol. In sake brewing, the koji turns the rice starch to sugar, and then the yeast ferments it on the spot. This is similar to adding a little more sugar to a wine, for example, as the fermentation is proceeding and has the effect of coaxing the yeast into producing more and more alcohol.
- 5) One adds more and more rice to the ferment as time goes on, and Fred suggest that you mix the freshly steamed rice with the sake using your hands. Make sure they're clean, and remember this means you'll have to do the initial fermentation in a plastic bucket.
- 6) You may want to look into using a press near the end to press the lees when you rack to the secondary. Be sure to top up your secondary (1 gallon glass jugs work well for sake secondaries).
- 7) You will need to pasturize the sake. Fred explains how to do this and why it is important.

My first batch is well on the way to being completed. When it is done, maybe I'll post the results.

Hope this helps...

From: aa680@freenet.carleton.ca (Geoffrey Burd)  
Subject: A new twist in chiller design

This past weekend marked the inauguration of my new immersion wort chiller (after two years of reading the digest and many trips to the archives). It uses a design which I have not seen mentioned here before which proved to be very effective. I used 50' of 1/4" I.D. copper tubing wound in a cloverleaf shape around 3 48 oz. juice cans, like so:

```
— / /
  / / /
 / // /
/ // //
```

There are about 12 full turns, resulting in a coil height of about 8" and a diameter of about 12" which fits nicely in my pot. Several positive features of this design are: Structural stability due to the overlapping of the coils and the fact the the inlet tube goes down the middle. The overlapping of the tubing spaces the individual coils to permit better circulation and heat distribution. Higher "tubing density" within the wort due to the tighter coiling.

The only disadvantages I can see are: harder to clean and harder (though less necessary) to stir the wort.

When I get a bigger pot, I plan to rebuild it with more tubing--either as a parallel system with 3 interleaved tubes, or as a 6-lobed design (or both), but for my current 20 liter pot this works great (roughly 10 minutes to cool to pitching temperature--if anyone wants more accurate measurements, let me know and I'll be more scientific with my next batch!)

Subject: Chillers

>From: "Robert H. Reed" <rhreed@icdc.delcoelect.com>  
>Subject: Hot Break/Hops in CF Chiller

>I wanted to comment that my boiler has a spigot several inches above the bottom of the kettle. My CF chiller attaches to the spigot via a flare fitting. Twelve to fifteen minutes after the boil is concluded, I begin runoff through the heat exchanger. By this time, hops and hot break have settled below the level of the spigot and are not drawn into the runoff. The price paid is the loss of a few quarts bitter wort: this can be reclaimed and canned for use as starters if one is so inclined.

The price paid in this discussion is to give up one of the few "unarguable" advantages to the CF chiller. I conceded that a CF chill is probably faster than an immersion chiller but if you sit around and wait for the hot break to settle, you have lost that advantage. And just for the record, several inches in my 16 gal kettle is several gallons but the easymasher sits on the bottom and less than an inch is left behind.

The fact is that if it is chilled with an immersion chiller, the hot/cold break will settle to below this level and be much more dense than if settled hot. The trub stays put and only that immediately surrounding the screen get drawn out and this can be discarded as it is only the first few ounces.

>From: gummitch@teleport.com (Jeff Frane)  
Subject: Re: Wort Chillers, Redux

>Without trying to quote from Jack's posting responding to my posting..

You really should to get the proper intent sorted out.

>Jack, I know the difference between hot and cold breaks -- they happen under different circumstances.

I never suggested that you don't know the difference, I suggested that from my understanding of what you are doing, the two could become combined in the end product.

> I leave my hot break behind in the kettle because at the end of the boil I create a whirlpool... and then draw the clear (very clear) wort off from

\*around\* the mountain of protein and hop debris on the bottom of the kettle.

Apparently, I did not understand your technique but now my vision of the "mountain or protein" geive me pause. I see you standing there with a sipon tube with a pot scrubber on the end poking around in the kettle to keep it in just the right position, not too close or you suck it up. Then when you are all done, I see this mountain again with a large pool of clear wort around it that you can't quite get at for fear of sucking up the crud. I trust you have all this figured out but never having done it that way, thinking about it gives me a headache.

(no problem with HSA, because I don't splash),

Wishful thinking. The major air/wort interface is the surface. The continually changing surface area provides orders of magnitude more aeration than a little (or even a lot of) splashing. I am not convinced that either will cause any serious harm but don't hide under the splashing blankie.

> dogmatism has no place in brewing.

Unless, of course, it comes from me.. :) That's for Norm.

Continuing the discussion on Matt Rowley's post in HBD #1267:

>What about Australia? anyone know of aboriginal beer drinks  
>there? Hawaii? Didn't Cook make beer of breadfruit on  
>landing, which the Hawaiians thought foul? There was a  
>Polynesian kava drink, but to my knowledge it wasn't  
>intoxicating. Anyone know?

As mentioned in my earlier posting, no known alcoholic beverages were made by Australian aborigines, at least according to the literature I've seen. I'll happily stand corrected if anyone comes up with a reference to the contrary.

I'm unfamiliar with specifics of the Cook story, but there's no reason why breadfruit couldn't be successfully fermented. There's no mention in the literature of modern breadfruit fermentations.

The Polynesians brewed a drink from masticated kava root. Unfortunately, like most indigenous beers in which saliva is used as the starch-converting agent, the beer is not often seen these days. The amylolytic enzymes in saliva are quite efficient, however, so my guess is that kava beer had a fair amount of alcohol.

>We were also comparing rates of alcoholism to length of  
>contact with alcohol.

>I guess I'm not looking just for nasty stuff, but also odd  
>things. Any recipes'd be appreciated, either private e-mail  
>or posting here.

I'll leave you with two references. The best book I've seen on indigenous beers (and other fermented foods) in general is Steinkraus, Keith et al, "Handbook of Indigenous Fermented Foods", NY, Marcel Dekker, 1983 (Thanks, Eric Urquhart!)

The best book on the role of alcohol in primitive societies is Aasved, Mikal, "Alcohol, Drinking, and Intoxication in Preindustrial Society: Theoretical, Nutritional, & Religious Considerations", Santa Barbara, Univ. Calif., 1988 (Thanks, Alan Eames!)

I believe the latter is a doctoral dissertation, but you should be able to get both of these through interlibrary loan at your college.

Hope this information helps you on your way.

Sorry I forgot the .sig in my previous posting.

From: Bob\_McIlvaine@keyfile.com  
Subject: Keg Insulation

Dennis Lewis asked about insulation for  
15 1/2 gal converted kegs.

Since, presumably, this will be sitting on  
a heat source such as 'Cajun Cooker'  
normal water heater blankets probably  
won't take the heat if the flame leaks up  
around the bottom.

There is a type of high temp blanket  
used in the foundry industry for insulating  
foundry furnices. I've use this with very  
good results. Since its rated for use  
between 1400F and 2000F it won't burn.  
Also, since it sort of resembles a 1"  
thick piece of felt its easier to handle and  
cut.

I've used it for brew kegs as well as for  
refractory lining in a small foundry. With  
the foundry you can actually hold the outside  
of the foundry while the inside has been  
heated enough to melt aluminum between  
900F and 1200F.

Subject: Brew-pub, what's involved...

Hi,

I'm trying to estimate what it would cost to start a Brew-pub in the state of Pennsylvania. I'm new to this mailing list so if this has been discussed in the past, let's kill it here.

I'm also pretty new to homebrewing. I've made several batches (just add water) and a couple that were a combination of extract and grain and they all turned out pretty good.

I know I have a lot to learn but my goal is to operate a Brew-pub. My father-in-law already owns a bar so that part is licked. The Pennsylvania LCB sent me some info a while back and from what I remember the a brew-pub license is \$2,000/year and you are limited to ~500 kegs or something like that.

What I'm interested in is equipment..... I want to brew the beer myself, not hand a recipe to a brewery and call it mine. I have some reference books but I would like to talk to anyone that has real experience in this.

I assume that since good beer has a shelf life and I won't be selling large quantities (since a Brew-pub can only sell on-premises), we would brew small amounts often as opposed to large batches infrequently. Just to pick a number my guess would be (1) keg a week per flavor to start. The bar is in a resort area and I already know the locals won't touch it.

I still have a lot of research to do but if anyone knows where I can find old brewing supplies or have ideas/plans for making my own, I would appreciate the help. If I can get this off the ground, and your ever in Vowinkle, PA. please stop by and see what you've help create.

Thank you.  
Dave Benrardi

>The Isinglass that I've found is pre-mixed and I specifically asked the  
>wholesaler if it needed to be re-fridgerated. He said no. Now, I'm  
>questioning this because of what Norman wrote. Could the pre-mixed  
>isinglass be stabilized somehow or does my distributor need to change  
>their instructions?

I believe the distributor needs to change their advice, but Norman's  
figure  
of 50F is a bit restrictive. I use isinglass quite a lot and the  
manufacturers'  
instructions (here in the UK that is) say that the storage temperature  
must not  
exceed 20C (68F). The pre-mixed isinglass then stays as a gel - if it  
spends  
any time at high temp it breaks down, becomes more liquid and doesn't  
work  
anywhere near as well. I keep mine in the fridge, and I know of one  
homebrew  
shop that doesn't stock it in summer. For me it's no problem storing it  
in  
there amongst the yeast, hops, white wine, lagers ....

Subject: Pilsner Urquell

I just finished reading C.R. Saikley's submissions on Czech beers and PU. I found it interesting in that I visited the brewery in August and noticed the changes taking place. At any rate, it was his description of brilliantly clear that struck a chord in me. I've noticed recently the proliferation of beer being sold in 22-24 oz. bottles and cans - at least around here anyway - and PU is no exception. I was examining one such bottle the other day and noticed some sediment on the bottom. I didn't really expect this in a bottle of PU so I had to try it. It turned out being the best example of PU I've ever had here in the states. Usually the stuff you get here is overly bitter IMO and is probably meant to be so for preservation reasons. In this instance the diacetyl was noticeable but a great compliment to the hop character as C.R. described in his post. The sediment disappears with little perturbation and as such the beer is not brilliantly clear. So what is the sediment? Is PU exporting something different now or is this an aberration? BTW the batch number (?) as stamped on the bottle is 11A2 if that means anything.

Certainly sounds like some sort of lacto- or peddlo- bacterial infection. In fact, it sounds identical to an infection that plagues my brewery from time to time (unfortunately, I don't brew p-lambics :- ( ). I haven't positively identified the bug, but it does form a stringy beige rope on top of the krausen. Fortunately, it doesn't have a huge impact on the beer -- a slight astringency, some sourness, and cloudiness, but not much in the way of off odor. BTW, if someone has ideas on how to combat such a beast, besides the usual "sanitize the heck out of everything", I'd appreciate the info.

> Guinness and..... Pabst Blue Ribbon. Call it a Black and Blue if you like.

When I was in college, we drank "Sheaf & Shafe" -- one-sixth bottle of Sheaf Stout mixed with each can of a six pack of Sheaffer (sp?). Back then, it seemed like a pretty good way to stretch your beer dollar.

From: Drew Lynch <drew@chronologic.com>  
Subject: Re: Adding spices to beer

I have made Christmas Ales about 4 years in a row now, using about the same recipe(based on Papzian's Christmas ale recipe, I forget the name). What I have varied is when during the boil the spices are added. Usually, I try to figure out long it will take to extract the desired essences from the spice, and how easily they will boil off. This time, (for 5 gallons) I added 4 cinnanmon sticks at the beginning of the (60 minute) boil, and added 4oz chopped ginger, and the peel from 4 oranges and 1 lemon 5 minutes from the end of the boil. I assume it will mellow a bit in the bottle, but tasted from the secondary, the cinnamon and ginger come through like gangbusters.

From: carlsont@GVSU.EDU (TODD CARLSON)  
Subject: small batch brewing

This fall I started brewing one gallon batches of beer and found it to be very enjoyable. The problems I had with the traditional 5 gallon batches were that I didn't have time to process that much beer. While handling 5 gallons is more efficient (less time/bottle), it does take bigger blocks of time that I don't have. The other problem was that I don't drink enough beer to go through 5 gal. very fast. If I made an average batch of beer I found myself drinking average beer for 6 months. The alternative (dumping \$25 worth of beer down the drain) was equally unapealing. By brewing one gal at a time I am able to experiment more often. My beer is improving 5 times faster since I brew 5 times more often. (and it is still improving - I still consider myself a beginning brewer)

My questions for the more experienced brewers are

- 1) Are there any hints for adapting traditional 5 gal recipies to a 1 gal size (other than dividing amounts by 5)?
- 2) Why is the 5 gal batch so standard? Is there any one else like me who finds advantages in small batch brewing?

Subject: Handling hops/Priming lagers/Crabtree effect/Language in the HBD

Alan writes--

>I start out by measuring an amount of hops and putting them into a large  
>glass mixing bowl. Then I stick the jar down in the hops and stuff them  
>in with my hand.

I've read that the amount of bacteria on your hands can be orders of magnitude more than in your mouth! Thus, I've taken to handling hops with a sanitized surgical glove. I get the hops in quarter bales (whole) or 11lb vacuum-sealed packages and then go directly into new, oxygen-barrier bags (I can only assume they are relatively sanitary), purge with CO2, squish out excess CO2 and then heat seal the bags. When I use the hops, I sanitize the SS weighing dish, usually with boiling water, and then pour the hops back and forth between the dish and the bag till I have the right amount in the dish. Thus, I've never handled the hops with bare hands. Not a problem for boiling or flavoring hops, but it could be a potential problem area for dryhops.

\*\*\*\*\*

Carl writes--

>I plan to bottle my first lager over Thanksgiving weekend. Particulars since  
>my post in #1240: Primary at 45F for 3 weeks, secondary at 45F since. Am I  
>likely to need more yeast (after Wyeast #2007) for conditioning and, if yes,  
>what type(s) are least likely to affect the character of the beer?

I'm primarily an ale brewer, so I don't have much recent lager experience, but the latest Traditional Bock I did was made with Wyeast #2308 (Munich) and spent two weeks in the primary and about 8 weeks in the secondary and did not require any additional yeast at bottling time to produce carbonation. The beer carbonated well, within two weeks and long before it was ready to consume (4 months of lagering at 40F in the bottle was needed to make the perm-solution nose to miraculously disappear!).

The most important point to my response is this:

**DON'T CHANGE YEASTS AT BOTTLING TIME!!!**

Unless you are 100% sure that the yeast you are adding at bottling is LESS ATTENUATIVE than the fermentation strain AND that you have no chance of even trace bacteria in the bottling strain, I recommend relying on the fermentation yeast for conditioning. If you add even a very small amount of bacteria or if you use a more attenuative yeast at bottling, you will make yourself a couple of cases of glass grenades. At best, you'll get gushers. This is especially important for lagers since they will be stored for a while before consumption.

\*\*\*\*\*

Carl also writes:

>Also on priming, has anyone else heard of or have more info on the  
"Crabtree  
>effect" described by Troy Howard in #1264? Sounds like a good reason to  
>abandon use of corn sugar for priming on the face of it.

Look in George Fix's book, Principles of Brewing Science for more on the  
Crabtree effect (although, I believe there's a few missing words in that  
paragraph (George?)). However, I don't agree with Carl that it's a good  
reason to abandon corn sugar. I switched from corn sugar to DME priming  
and then switched back because I found little difference except for what  
I think was protein scum (ring around the collar) in the bottles when I  
used DME for priming (note that I did not force-cool the DME priming  
solution, perhaps that would have helped).

\*\*\*\*\*

My view on the issue of questionable language in the HBD is that I feel  
it  
should be avoided. I'm not offended, rather, I feel that it is rather  
"unprofessional" to have such language intermixed amongst world-class  
brewing knowledge. It sort of cheapens the HBD. The combined knowledge  
of us here on the digest (and that includes even the beginners, who can  
contribute interesting questions and discoveries, as well as the  
seasoned,  
advanced brewers), far surpasses the knowledge in even the most respected  
single book. To me the HBD is like a living book... in print... each  
day.  
How much respect might we have for Malting and Brewing Science if Hough  
et. al. had stuck the occasional four-letter-word? My rule of thumb is,  
"does this sound appropriate for a magazine article or a book?" Let's  
continue to have fun, but let's also not write anything that cheapens the  
HBD... these are not mutually exclusive goals.

Al.

From: dougy@icad.COM ( Doug Lethin)  
Subject: Beer Labels

For beer labels, I also suggest a program called  
KeyDrawPLUS for windows. I paid \$28.00 for it.

It has features for aligning text to curves, creating perspectives,  
extruding text, and other actions that vary text shape. Although it  
does not have a feature to shape text to a inputed shape, if the shape is  
simple, you could warp the text into that shape.

Drawbacks are :

Its not as user friendly as other programs I have seen, and its user  
manual also is not the greatest.

I used it to define a logo for musical group, and the size became so  
large, that at times it would use all of my memory and crash my PC.  
Memory management was not done well with that program.

Other than that, I would still recommend it.

Doug

From: npyle@n33.stortek.com  
Subject: Dry Hop Bitterness from Beta Acids?

Darren Aaberge replied to my Byron Burch/dry hop question via email:  
(Darren, my reply to you bounced!)

DA>Byron Burch says something to the effect of:  
DA>  
DA>To calculate bitterness  
DA>(A) Multiply the number of ounces of hops per 5 gallons by their  
alpha  
DA>acid rating.  
DA>(B) Divide by 7.25  
DA>(C) If the hops are boiled for more than 45 minutes multiply by 28-  
30. If  
DA>they are boiled for 15 to 40 minutes multiply by 8-12. If they are  
boiled  
DA>for less than 15 minutes or are dry hopped multiply by 5.

I ran some quick numbers based on a recent brew. I was surprised to see something this simplistic come fairly close to the IBUs from Rager's formulae.  
"Fairly close" means within 10 - 15% overall. This formula appears to take into account the utilization for different boil times, etc. Interesting. The part about dry hopping, though, deserves further thought and discussion.

DA>He says that these numbers assume a rapid chilling at the end of the boil.  
DA>Also, he defines dry hopping as adding hops (and he implies only pellets can  
DA>be used) to the fermenter prior to fermentation. He goes on to qualify this  
DA>method of calculating bitterness by saying that it is the system of the  
DA>American Society of Brewing Chemists.

I'm going to assume what I've read is true, and that alpha acids (which are neither soluble nor bitter) will not give up any bitterness without being isomerized by boiling. The fact that he adds his dry hops to the fermenter prior to fermentation may be a clue. Beta acids do not need isomerization to become bitter. The oxidation products of beta acids are soluble and bitter, although I don't have a good feel for how much bitterness they contribute. Malting and Brewing Science indicates that they may contribute a considerable amount. The common wisdom says that when hops are exposed to oxygen, the alpha acids oxidize into non-bitter products, and are no longer available to isomerize into bitter iso-alpha acids. MABS indicates that oxidized beta acids in the same hops may counter a considerable amount of the lost alpha acids, and that the formulae for lost bitterness in old hops may not be accurate. I don't

have the book (I need more books!) so I am justing passing on what I've been told on this.

Back to Burch:

At the point where Burch adds his dry hops, there is lots of oxygen in the wort, or there should be for yeast reproduction. This will allow the beta acids to oxidize and become bitter until reproduction uses up all the oxygen and/or fermentation drives it all off. This may be where Burch gets his bitterness from dry hopping, and it may be where others in this forum have seen it as well. Long lag times would contribute to the bitterness.

In recent times, I've restricted my dry hopping to after primary fermentation and have had no bitterness associated with it. This supports my theory, in that there is no oxygen for beta acid oxidation at that point. To those who've reported bitterness from dry-hopping: when do you dry hop? Does your data support my idea?

DA>While all of this is taken from the book "Brewing Quality Beers" by Byron Burch, none of it is direct quotes. If you want more information or direct quotes, let me know. You may, of course, post any or all of this to the DA>HBD if you wish.

Direct quotes would be nice, if you have the time and inclination. Is anyone a ASBC member? Is this their method for estimating IBUs? Enquiring minds want to know...

Hoppy Trails,  
Norm

From: David Atkins <ATKINS@macc.wisc.edu>  
Subject: breweriana

Some digests ago, a subscriber wished to identify brewery labels and graphics. Check your local libraries for some of these titles (if your libraries do not have any of these items, see if they can provide the items via interlibrary loan).

Periodicals:

American Breweriana Journal: Official Publication of the American Breweriana Association, Inc. Colorado Springs Colo.

All About Beer. Anaheim, CA. McMullen Pub.

Beer Can Collectors News Report. St. Louis, Mo. Beer Can Collectors of America.

Breweriana Collector. Los Angeles, CA.

Books:

Check under the subjects Beer, Brewing, and Breweries at your local libraries. There is a publication, whose title escapes me, that provides a geographic listing of hundreds of breweries that have winked in and out of existence during the history of the US. If you wish to research a local history and see what breweries have been around, try a local historical society as well. As for the mystery title, I'll try to find it to post at a later date... or if any other subscribers could post more info, that would be just as dandy.

And to the list has a collective...

1) has there ever been compiled a bibliographic FAQ or book & periodical list concerning beer, brewing and breweries?

2) if not 1) would there be any interest in having one compiled?

Please feel free to respond personal email as well as to the digest.

Happy beering,  
David Atkins

From: aa680@freenet.carleton.ca (Geoffrey Burd)  
Subject: Re: THE BEER MACHINE

taylor@e5sf.hweng.syr.ge.com (taylor) asks:  
"Has anyone tried or heard off "THE BEER MACHINE"??"

They were sold in many stores around here last Christmas (I don't know how well they sold--the local hardware store still has a couple gathering dust: I'm waiting for them to be sold off half price!). I inspected one and it looked pretty sturdy: it looks like a small barrel on its side made of brown rigid plastic. It consists of a top and bottom half which clamp together, and so would be easy to clean. There is a tap on the front that looks like the tap on a coffee urn, and a lid on top for adding ingredients. During fermentation you attach a pressure regulator which maintains enough pressure to allow natural carbonation. For dispensing you replace it with a CO2 cartridge.

I agree with you that I wouldn't use it as intended since the beer would end up sitting on the trub, but it would make a great little dispensing keg provided that it could retain pressure and not leak.

I did try the malt extract that they sell to use with it: it comes in 3 styles in about a 4 pound can. You're supposed to pour it into the machine, top up to 10 liters (2.5 USG) with water and pitch the yeast. I tried the same procedure in my carboy using the dark ale extract. It was dreadful: the extract was thin and watery and smelled like prune juice. Guess what! The resulting beer was thin and watery and tasted like prune juice. It's the only batch I've made that even I wouldn't drink!

I still, though, would give the keg a try if I could get it at a good price.

Subject: Mash Temp, Batch Size

>From: Mike Peckar 10-Nov-1993 0909 <m\_peckar@cscma.enet.dec.com>

>1. Air Cock, yes. thanks. I also didn't use the proper plumbing jargon to describe what I referred to in my article as a "stand off". Its called something else, I forget what....

Shoulder is the word. On outdoor hose connections, they are round and prevent the spigot from being pushed through the wall from outside. Unfortunately, they only come in sizes too large for homebrew applications. The shoulder on the air cock is hex shaped so a wrench can be applied to tighten it. It presses tightly against the outside of the kettle to provide a leak proof fit.

>2. The "lower temps" I had trouble at were under 154 degrees. In later batches, when I would raise the temp at the end of the mash (Mashout) flow would increase significantly with my version of the screen sparger. Any batches where the mash temps did not exceed this, it'd get stuck.

Good argument for mashout. For those who can not or do not want to mashout, there is another approach to the problem. I typically get thrashed for suggesting the use of boiling water for sparging because the books recommend a temperature of 170F. However, sparging with very hot water on a cool mash will only serve to maintain the mash at a manageable level and at most, raise it a few degrees which will cause no harm at all.

>From: WESTEMEIER@delphi.com  
>Subject: zymurgy recipe correction

>All of the recipes list ingredients for making "six US gallons" which is plainly wrong if you examine the quantities. In fact, the quantities shown are for making one (UK) gallon.

After reading it several times, I was going to write to you and see if you would do a testimonial to the fact that those fantastic extract rates were the result of using a MM. It would have made a great ad.

>From: Spencer.W.Thomas@med.umich.edu

>You CAN make moderate gravity beers with a small boiler. Sure, it's not recommended, and you leave a lot of sugar behind, but it can be done..... lousy hop utilization, lousy extraction.....

Not sure why any of the above need be but what seems to have been left out of

the discussion is the presumption that one is making 5 gallon batches.

As far as extraction is concerned, I get the same yield in one gallon test batches as I do in ten gallon batches. There is no reason why batches smaller than 5 gallons can not be made successfully. You will find a number of them in the "Winners Circle" from the last International.

>From: snystrom@aol.com  
>Subject: Hunter Airstat modifications NOW I'm looking for someone who would be kind enough to repost the instructions that will allow the Airstate chill below 40 degrees. ...it may have been a 10K ohm resistor in series with the thermistor/sensor, but he didn't save the posting.

I saved only the hard copy and I am not about to retype it but he used a 180K in series with the sensor. This got him (Mike Kenny) down to 35F. I used a 130K but I was only trying to get the readout to agree with the actual liquid temp instead of the air temp.

From: cjh@diaspar.HQ.ileaf.com (Chip Hitchcock)  
Subject: quality under twist-top

pgillman@pomona.edu asks whether twist tops affect the quality of the commercial beer underneath.

<enter prejudice mode>

The standard rap on this is "twist tops take special cappers"---i.e., homebrewers can't get a tight seal but commercial brewers can. The difference in beer quality is probably a matter not of connection but of parallelism: only swill is drunk in such haste that a twist-off top is a significant selling point.

I have no data, but I suspect that swill actually averages less time between brewing and drinking than good stuff, due to the amount of swill sold (higher turnover). There's also the fact that swill is often brewed closer to the retail seller than good beer is; e.g., if I drank Bud or Michelob it would have been brewed in Nashua (~50 minutes drive ~north of Boston); my mother in DC would get it from near Williamsburg VA; my late grandfather in Jacksonville FL would get it from Tampa FL; in all cases the beer would have left the brewery the same day it hit the stores. If we wanted Anchor or Fuller's it would come from CA (taking a few days, probably in an unrefrigerated truck) or UK (taking several weeks on ship---except that you can now get draft Fuller's in at least one pub in Orlando). Both of these factors would reduce any ill effects from twist-tops---the beer would have less time to oxidize. (It would also have less time exposed to fluorescent lights, which is a problem in many beer stores.)

<exit prejudice mode>

The above assumes that beers are shipped when they're ready to drink and/or that there's no improvement in the bottle (as there often is for homebrew, due to (among other factors) bottling on-the-yeast and when-it-stops-bubbling.

Subject: Kriek/Sour Mash

First, I would like to thank those who responded to my question of whether or not the p-Lambic recipe in TNCJOHB was worth the effort. Unfortunately the responses I got were not first hand. I said they knew someone who brewed it and thought it was great. Another said that they had heard just the opposite. Another response I got included a catalog for Sheaf & Vine which had 3 Belgian yeasts for \$18. This would make this a rather expensive experiment. I think that unless I hear from someone who has tried this first hand or has had a good homemade p-Lambic, I will hold off on this endeavor. Again, if anyone has tried one of these, please let me know.

From: gmeier@ncsa.uiuc.edu (Gary Meier)  
Subject: brewing small batches

Todd Carlson asked about brewing batches smaller than 5 gallons in order to save time and permit more experimentation. I can't address the first question, since I have only brewed in 5 gallon batches, but I get my fill of experimentation by trying things after the primary fermentation is finished. When I select a recipe I start thinking about modifications that might work well with that style, and I generally divert a gallon or so (after brewing) for the experiment. Must be all that chemistry training during my misspent youth. I've had good luck with bottling part of a batch into bottles each containing a sanitized jalepeno pepper while bottling the rest normally--two styles of beer with virtually no additional work. More typically I'll siphon a gallon or two from the primary into gallon glass jugs while putting the rest into my usual secondary fermenter. Most of the batch finishes normally, while in each of the one gallon secondary fermenters I'll add fruit (made a killer raspberry ale recently), spices (my Christmas Ale is coming along nicely) or experiment with things like dry hopping, all depending on the style of my starting brew. Transfers, bottling, etc are done at the same time for everything, so almost no additional work is required, but I end up with several distinct styles of beer when it is all over. Only investment was a couple of extra airlocks and the time spent drinking the apple juice that came in my gallon jugs.

Gary Meier, Meier's Femtobrewery and Woodshop  
(The Boston (tm) Beer (tm) Co. spills more beer in a day than I make in a year).

Date: Fri, 12 Nov 93 12:36:58 EST  
From: Ulick Stafford <ulick@stravinsky.helios.nd.edu>  
Subject: flame

Sorry that the content of this is pure flame, and takes up valuable bandwidth, but that is partly the reason I am posting it. I started to notice last week when hbd was backed up that some people are seriously addicted to posting, and while much of the information posted is useful some is not. One poster in particular who I have decided to question is Al Korzanos (sorry if this is wrong, but it would be nice and professional if posters identified themselves properly). Anyway, some of the information this expert posted in 1270 really got my goat. He stated that there were fewer errors (well actually, his disagreements) in Papazian's book. While this may be true, I don't know that Miller has disseminated the massive clangers Papazian has. I don't know how often the meaning of kraeusening has to be corrected - and gypsum in every water supply, and the now famous pouring of hot wort into cold water in a carboy. Papazian's book is a good starter for the nervous, but for anyone who has brewed before and wants to get a good handle on water treatment and all-grain, Miller is a better choice. Noonan is not for beginners, and while riddled with errors, the people to whom it's aimed can usually work it out.

In his second posting, Mr. Korzanos, advocated the handling of hops with sanitized surgical gloves, based on the notion that there are more bacteria on hands than in the mouth - hardly a scientific determination, and considering the antibacterial properties of hops, I doubt if many bacteria would survive - and what would they eat? I imagine stored hops are too acid for bacteria. I wonder why someone like me who dry hops by stuffing hops with by bare hands through carboy openings has never had an infected batch attributable to dry-hopping?

He then admits he is primarily an ale brewer and does not have much recent lager experience, but nevertheless responds to someone enquiring about pitching fresh yeast when bottling a lager (a correct procedure), DON'T CHANGE YEASTS AT BOTTLING TIME!!! because his home perm solution carbonated OK. I can say categorically that I have made several strong beers, (Ales, actually) that have not carbonated satisfactorily because I failed to add fresh yeast. The reason Mr Korzanos gives is 'glass grenades', especially for lagers - those beers with which he is so intimately familiar, without any examples at all - just his vague suspicion.

Also, I considered the crabtree effect a good reason to abandon corn sugar, but of course there are other good reasons to stick with it. One must balance everything. Some people are quite happy carbonating with sterile wort or kraeusening, and for lager there is no topping the latter method (IMHO). Even Anheuser-Busch do it!!

Of then he really gets on his hobby horse - "unprofessional language" in HBD. This self-proclaimed expert and HBD police man was the single complainant that led me to bleepify my sig. Somehow it is unprofessional to use a little colourful language, but giving bad information as a self-proclaimed expert is not? Yes, it is terrible that the "world class brewing knowledge" is mixed up with some colour. Mr. Korzanos, hbd is not a professionally written magazine. If it were most of your postings wouldn't get past a junior editor. It is a computer bulletin board, that occasionally has great info, mixed up with anecdotal advice such as yours and other subjects not directly homebrew related, and is meant to be more current, and lively. I wish you lived by your rule of thumb  
'My rule of thumb is,  
"does this sound appropriate for a magazine article or a book?"'  
and didn't make postings with statements like your  
DON'T CHANGE YEASTS AT BOTTLING TIME!!! in bold caps, before you  
criticise  
the unprofesssional postings of others.

Dave Benrardi  
wants to start a Brewpub in Pennsilvaniae  
.... in Vowinkle, PA.  
^^^^^^^^^^

You sure this is a place and not a cartoon character?

But really. Contact the AHA 303-447-0816 in Boulder CO. They have some info you can buy\$ regarding the "how to's" of starting a brewery. I haven't seen any of 'em me-self.

Look for magazines for the Brewery Industry,

e.g. American Brewer, the business of beer. (510) 538-9500 mornings.  
\$5 for a sample issue, \$18/yr (in '92). (no connections and all that crap)

They have lost of ads on equipment and supplies for breweries. A bit out of scale for the average homebrewer. But I seem to be quoting my one issue of it a hell of a lot. ;-&Zymurgy (AHA) commonly has ads for larger scale brewing gadgets. Also articles on why you should or shouldn't start a brewery. It's quite an ordeal from what I understand. I'd love to start a real one here in Loga UT, but I'd hate to be stuck making 3.2 beer :(

So... you looking for brewpartners?? :)'  
I originated in Penn State aloooooong time ago.

\*\*\*\*\*

Al Korz... sez:  
> How much respect might we have for Malting and Brewing Science if Hough et. al. had stuck the occasional four-letter-word? My rule of thumb is, "does this sound appropriate for a magazine article or a book?"

Or a radio station? A local country station just canned a dj for saying the big three letter word.....yes that's right...while doing a live on site broadcast from a local fast food restaraunt Lewis Collins exclaimed,

"God, even I could afford that!"

Can you tell which three letter word the "good" employers objected to? Yes that's right. The owner of the station couldn't even tell the reporter exactly WHAT word the dj had said.

That's the kind of thing local customs and restrictions can put on actions and language! The poor dj was new here, from CA, and didn't know that use of THAT word was offensive to some. It's not like they gave him a list of words that were ok, and which weren't. Amazing the think the name of the Lord has become a swear word in this state. HMMMMMM.....

I wouldn't want that to happen on the holy ground of the HBD. I do agree some personal censorship is valid. We should curb "ourselves", but is the

hbd to set out a mandade of what is suitable/not? Make a new faq. 8-`  
How about we say- anything that would be acceptable on daytime tv...

Subject: Beer labels (and soon other stuff) in the "Web"

If you've got Internet access, and are running on a Mac, PC, or Unix box, you should check out Mosaic, from NCSA. It gives access to on-line information via the "World Wide Web", which subsumes gopher, anonymous FTP, and lots of other stuff. I am putting together a beer-oriented Web site, and have started with a nice point-and-click interface to the beer label & coaster images at Sierra. Open URL <http://guraldi.itn.med.umich.edu/Beer>.

**Subject: No Pot Scrubber**

I have to post this to relieve Jack's mind. I know he worries about me, standing around my kettle with a copper pot scrubber on my siphon hose. No, no, no, Jack! I've told you before: I have an uptake copper tubing that run entirely around the inner perimeter of the kettle, and sits right on the bottom. Lots of teeny-tiny holes are drilled in the underside of this coil. The mountain of matter is \*inside\* the coil. The siphon draws up every last drip of wort (another reason I prefer pelletized hops, as this process is much easier than with loose hops).

It works very well. So don't worry, Jack! I'm fine. Really.

From: "Andrew D. Kailhofer" <a907932@nast0.bdy.wi.ameritech.com>  
Subject: Wort aeration, again...

I'm going to start by appologizing to the r.c.b'ers who've seen this already, but I didn't get much of a bite with this when I posted it over there (though thanks to the three of you who did respond). Anyway...

Based on some allegedly good advice, I got an aerator (Whisper 200 air pump into an good air filter into the wort via an SS tube into a plastic boilable fish-tank air stone). I started a brown ale (extract + Belgian B, OG ~= 1.048) by pumping about 8 minutes of air through it in my bucket (Mr. Carboy is busy with cider---wow! great!) and pitching with 1 pkg fresh Edme dry yeast rehydrated as usual.

In about 2.5 hours I could detect fermentation (although not very strong). That's a little quick, but not too weird. However, in less than 12 hours I awakened to find foam oozing from the airlock that I've been using on my bucket (hey, with 1.7 gal headspace, I figured I was going to be ok---it's worked for all of the other batches starting in the bucket). I rigged up a blow-off tube, and proceeded to observe the most abbrupt, violent fermentation I've ever seen. 30 hours after pitching it's pretty much stopped fermenting and ready to rack.

This leads me to believe that aeration is extremely good for the yeast, but is it good for the beer? From reading the "Beer & Yeast" zymurgy (Just got it. Read the article to the dulcet sounds of my gurgling blow-off jar.), especially the Guinard, Miranda, and Lewis article, I see that fermentation in the presense of good O2 concentration may lead to incresed biomass and decreased flavor/alcohol production. Does this mean that I just shot myself in the bucket? Could someone with a little more experience shed a little light on this?

< And then a few days later >

Well, after 48 hours my 1.048 OG beer is at 1.012, and I've racked it off to glass. It's pretty tasty, too. If I had to define the taste (mentally subtracting the yeasty flavors of unclarified beer in the primary), I would say that it was very straighforward and beery, with no traces of fuesils---an all-around good flavor. It's still flat and yeasty, but it seems quite good. We'll let it sit for a week in the secondary and bottle. So, in about two weeks I'll be able to report (at least preliminarily) on this power-aeration thing.

I'm going to go back to my original worry, though. My SG is now such that it seems "done" according to (my) conventional wisdom. When one uses a hydrometer to measure alcohol levels, one is actually measuring the SG and subtracting potential alcohol levels, right? To get the right measurement, aren't we assuming that the yeast does the standard 90%/10% alcohol production/reproductive respiration levels? Does this hold true for highly oxygenated wort? How far to the right does it shift? Does it matter (am I misunderstanding some of the literature?)? Since it seems to work, I'm more curious than worried, but... I really enjoy a little worry---It's part of Science!

< and finally >

It's now Thursday night, and the S.G. is still 1.012, and the yeast has settled out very nicely. While it seems a little soon, I expect

to bottle tonight (Friday) so that the beer will be ready during Wisconsin's gun deer season (my Bambi Blaster Brown :-). I'm pretty flabbergasted at how fast it went, and it tastes good, too.

So, other than asking me to be a little less long winded, and to refrain from making any comments that might offend anybody who was just too uptight for words, does anyone have any advice?

Andy

Subject: books

Al writes:

> I recently re-read Papazian's "The New Complete Joy of Homebrewing," Miller's "The Complete Handbook of Homebrewing" and Noonan's "Brewing Lager Beer." While reading, I was scribbling my disagreements with the books in the margins and dog-eared the corners of these suspect pages.

...and later...

>My advice is to buy all three, but read them in the order I listed above. After reading all three and brewing a dozen batches, you will probably scribble the same notes in the margins that I did.

My caveat is that trying to critique Miller is not going to be possible unless a substantial number of those batches are all-grain. Working from memory, where Papazian and Miller overlap they tend to contradict each other.

\*\*\*\*\*

Brian writes:

>Second, recent batches of mine have taken several hours to cool (1.5 gallons of hot wort added to 3.5 gallons of cold water) to pitching temperatures, which has made me nervous about possible infection.

I had the same problem when I used that process. Since learning about Hot Side Aeration (HSA), I now cool the concentrated wort to pitching temp before mixing. Takes 35-45 min by immersing the kettle in cold (45F) tap water in my kitchen sink with two water changes. The hot/cold mixing is a piece of bad advice in Papazian's book which I'm sure Al has marked...

> Are there any disadvantages to reducing the volume of boiled wort?

Decreased hop utilization, increased caramelization. The first can be compensated for with more hops, the second is inevitable until you can switch to a full volume boil. As I recall, Miller's book has a table for computing the effect of increased S.G. on utilization.

A very interesting comment. While I've kind of been taking the side of  
the "chill out" camp in this debate, your post reminds me of one of  
the things I found annoying about Papazian's TNCJOHB: the junior high  
school level humor, especially in the recipe names. I'm not a prude  
nor am I easily offended...I just thought it was stupid, and detracted  
from the quality of the book.

Subject: keg pressure questions

Dear diary... it's been a long time since I've written. Eh... I mean, digest, of course.

Hi folks...

in the last couple of weeks/months, I've aquired a complete kegging system.  
I'm using 5 gal soda kegs of the ball lock persuasion...

One of the kegs I got wasn't quite empty, has some 7up in it. So I thought I'd try my hand at pressurizing/dispensing that before I actually tried beer.

Well, it's not working... I pressurized the keg at 30psi for 3 or 4 days in a 50 degree garage... then dropped down to a dispensing pressure of 12-14psi. When I hit the tap, I get 7up gushing from it. Foams like crazy, but the finished product in the glass is pretty much flat. I.e., all the CO2 comes out at dispensing time.

What's wrong?

Could it be my dispensing line is too short? I've heard I need a foot for every 3 lbs of pressure in the keg, and I do have about 4 feet. Does the length really make that much difference?

From: phil.brushaber@lunatic.com (Phil Brushaber)  
Subject: Decoction Question

I asked this question on other forums but got no response. I KNOW there is someone out there in HBD land who can help.

I want to do a decoction mash. I now accept that a controlled temp kettle mash will not substitute for staged boils.

The instructions I received would suggest that you take a portion of the mash (grains and all) move it to a separate kettle and boil it for the specified length of time and return it to the main mash. I was pleased to hear this as when mashing with a kettle which has no bottom spigot it is extremely difficult to press off enough liquid wort from the top to boil liquid only. If this is right... (is it?) then I have another question.

Wouldn't boiling with the grains cause a problem with increased astringency and the leaching of excess tannins into the beer?

Thanks in advance!

... .. If they put malt in beer and malt in milk. Why not beer in milk?

Subject: MASHERS and RUST

>From: korz@iepubj.att.com

>Norm writes that he noticed an EasyMasher-like device in the Gadgets  
and  
Equipment Special Issue of Zymurgy.

I dug up that issue to see what you guys were talking about and it is a  
"Slotted T" device, very similar in concept to the easymasher. It is  
interesting to note though, that the author's main interest in it is to  
filter out hops in the boiler. When used as a mash tun, he still uses a  
false bottom over it. I wonder if he ever tried it without the false  
bottom.

It takes a bit of reckless spirit but that is how I found out that it  
was  
totally unnecessary with the easymasher.

Just for the record, Zymurgy had an EASYMASHER (tm) for review long  
before  
even that issue (Fall 92) went to press. I have been assured that it is  
coming soon.

>From: John Glaser <glaser@analog.ece.arizona.edu>  
> I just picked up a enameled steel canning pot (8 gal.), but  
it has a few chips in it, maybe about 1-2 square inches  
worth of exposed metal. Will this be a worse problem than  
that created by using 3 gal. boils in my smaller pot.

You will get a lot of opinions on the evils of exposed iron but I think  
most  
will agree that it is less of a problem than 3 gal boils.

> Is there anything I can do to cover the chips? (for example,  
using hi-temp enamel like they sell for repairing outdoor BBQ  
grills and such).

This is a problem I encounter on a regular basis as I buy them from the  
manufacturer and install EASYMASHERS in them for resale. Every shipment  
includes several damaged kettles which I clean up as well as possible  
and  
give them away for the price of the EM alone. I also used one for years  
with, not only exposed metal but rust, prior to splurging for stainless.

I do several things to these kettles before giving them away. I lightly  
sand  
the damaged area to remove any loose ceramic and then lightly coat the  
inside  
with Vaseline to prevent rust. This is wiped off before use and if the  
kettle is kept clean and dry between use, it will remain rust free. The  
Vaseline or any food grade oil can be reapplied between use if brewing  
is  
sporadic or the kettle is stored in a damp area.

The outside damaged areas, after sanding, are sprayed with "STEEL IT"  
and  
cured. This is "High temperature 1200F, anti-rust, stainless steel in  
a

can". I contains "100% stainless steel pigment" and lots of other stuff.

After drying to the touch, it needs to be cured at 400F for 15 minutes. You

can play a torch on the side opposite the paint or it seems, that simply using it provides all the cure it needs.

Although it is listed in the McMaster Carr catalog as FDA approved, it doesn't say for what nor does it say anything about this on the can. As I do

not wish to lose my happy home over something I give away, I only use it on

the outside but it may well be safe on the inside when properly cured and seasoned.

From: "Phillip R. Seitz" <p00644@psilink.com>  
Subject: Air Stat problems

I have a Hunter Air Stat and a small refrigerator. As far as I can tell both are in good working order. The problem is that when the temperature reaches the appropriate point the fridge will frequently make several abortive attempts to go on, or will run for a perhaps 10 seconds before cycling off. After 3 or 4 attempts the fridge comes on and stays on.

I can't tell whether this is related to the fridge or the air stat, but I've wondered if the air stat is cutting the current to the fridge due to small variations in temperature at the sensor. I moved the sensor and got a partial improvement (I think) but the problem persists.

Any recommendations?

From: "Andy Schultz @1490" <ASCHULTZ@MADMAX.MPR.ORG>  
Subject: making mead

>>David Slade asked about using extracts for mead, and how much honey to use.

I've got a couple of batches under my belt, and they've all turned out great.  
(If you've just been brewing beer, you're missing out - although I'm just an extract + grain weenie..:) ).

>From the way your post was worded, I assumed that you were talking about using malt extract vs. fruit, spruce, etc. extracts. I've never used any malt extracts for mead, nor have I ever seen any recipes for mead with malts - sounds interesting though. Anybody wanna start a thread on this?

I've used blackberry and raspberry extracts added at bottling time a couple of times. The results are ok, but I think I prefer honey-only mead. I've used Red Star champagne yeast for all of my batches, and I've been quite pleased with the results. It ferments out rather dry though, so if you're looking for a very sweet mead, you may want to try a different yeast, or use lots of honey. I've mostly used the recipes from TNCJOHB, with some minor variations, although I just picked up a booklet called 'Making Mead' by Bryan Acton/Peter Duncan, which has lots of good looking recipes, but I haven't tried any of them yet.

I generally use about 14 lbs of honey (the lightest you can find- I get mine at farmers markets or the local beekeeping supply store) for a 5 gallon US batch. Honey weighs about 12 lbs/gallon. I ferment about 3 weeks or so before racking into secondary - I haven't had any need for blowoff tube with the red star yeast - it just fires right up and ferments very steadily w/o any krausen - no big peak, just a long, solid plateau (sp?) of activity. Be sure to use yeast nutrient, or the yeast may poop out on you - I had to feed my first batch in mid-fermentation. Also throw in some acid blend to counteract the hotness of the alcohol - they get up to 15 percent or so.

Ready to bottle in six weeks or so - waiting to drink rounds out the flavor (how we suffer for our art:) ) Good luck - you'll get hooked on mead, I'm sure!

Oops, just remembered your post wanted metric quantities - sorry about the slip up.....

PS - Actually, not all my batches turned out great. I got silly once, and made a test batch using buckwheat honey, just for the (insert least offensive but still appropriate phrase ) of it.

I wouldn't if I were you :)

> ...Any suggestions would be appreciated.

Unfortunately you have just missed the Oktoberfest. Better timing next year.

Most tourists visit the Hoffbrauhouse. It is very close to the City square at Frauenkirchen.

The place I would recommend is Kloster Andechs. It is south of the city and you will need to drive. Ask at any tourist office for directions. This is a monastery and the monks still brew their own special beer which they drink themselves and sell to the public. It will be cold for the beer garden this time of year but there is plenty of room inside and I would recommend a visit to their very old highly decorated church at the top of the hill.

The story told by the monks is that back in the 17th century, the monks were brewing beer, and the abbot forbade them to drink during lent. The beer has a very rich flavour a cross between a stout and a Guinness. The monks decided to send a barrel to Rome to request special permission from the Pope. The journey took 3 months by horse and cart and needless to say the beer spoiled. The Pope tasted some of this beer and said "If you want to drink 'that' during lent then the church has no objection."  
The last time I visited the place was 1982. At that time the head brewer was 92 and still drank four litres of their beer each day including lent.

From: "Steven W. Smith" <SMITH\_S@gc.maricopa.edu>  
Subject: Best extract for mead

Davin Slade <10692851@eng2.eng.monash.edu.au> asks:  
>Can anyone tell me what a good extract to use for making mead. Is it  
>better with a heavier or lighter beer.

IMHO, the best extract for making mead is... honey! Saves one endless  
hours  
going from flower to flower with a capillary tube, not to mention the  
aging  
required ;-). Lest I be branded unduly snide, I'm including a recipe  
that's  
been acclaimed by my friends who've tried it. It's not really "mead"  
since it  
includes fruit (melomel? I dunno) - tasty, sweet high alcohol content  
beverage  
anyway- 5 U.S. gallons:

15 pounds honey (5 3-pound bottles light amber)  
1 pound fresh-frozen unsweetened strawberries  
1 pound fresh-frozen unsweetened blackberries  
good sized chunk of ginger root, sliced (a few ounces)  
1 oz. Fuggles hops.  
1 package Montrouchet wine yeast.  
1 package Polish Mead yeast  
1 tsp yeast nutrient.  
water to make 5 gallons.

I boiled the honey and ginger root for about 45 minutes in 3 gallons  
water,  
skimming off the white foam, added hops and boiled 15 minutes more.  
Smashed  
the berries in the packages and poured in when heat was turned off -  
bring  
volume up to 5 gallons. Started the yeasts in some of the liquid (not  
wort,  
I forgot the word) and pitched when the bulk reached about 75 degrees.  
Sorry about the vagueness of the recipe and procedure, consistant results  
weren't the goal, just an alternative to what my girlfriend calls my  
"beer  
syrup" - damned sparse appreciation for doppelbock in Coors country...

>Also how much honey should i use for 25 litres of mead.  
A matter of taste, I guess. I've found that when using 12 pounds or  
less  
honey, the yeast will metabolize all of the sugars and make a dry  
beverage.  
BTW, it's a nightmare to rack into the secondary with all the fruit and  
hops  
floating around... Hope someone gives it a try though.

From: Mark Garetz <mgaretz@hopstech.com>  
Subject: Dry Hopping Risks/Alphas/Latin

Al Korzonas mentioned that bacterial contamination might be an issue for dry hopping. A rather extensive study was run by Jean-Xavier Guinard, Michael Lewis and host of grad students at Davis on this issue. It was reported in the Master Brewers Association of America Technical Quarterly Vol. 27 No. 3 in an article entitled "The Microbiology of Dry Hopping". I also referenced this study in my article on the topic in Zymurgy. I'll summarize a bit of it:

They took cultures from the hops and found they contained wild yeasts of three kinds and many different kinds of bacteria - some gram positive and negative, mostly "Enterobacteriaceae" whatever that means. They then dry hopped some beer and cultured the beer daily to see if any of the organisms survived. None did. The longest was still detectable after three days and then died. It did not grow during this period, just took three days to die.

I'll now quote from the article's conclusion: "These results suggest that the practice of dry-hopping is microbiologically safe, especially after three days of fermentation."

What we learn from this is that you should dry hop only after you have a vigorous fermentation going and the beer has a reasonable alcohol content and low pH. Adding raw hops to the primary at pitching time (as recommended by Byron Burch in his book, for example) is definitely risky!

\*\*\*\*\*

Norm Pyle stated that "alpha acids aren't bitter." Just a nit here, but alphas are indeed bitter. They just don't dissolve in beer very well (max 5 mg/ltr or ~5 IBUs).

He also asked "Is this the ASBC's standard method for estimating IBUs?" I'm not sure what Norm wanted here, but the ASBC methods don't "estimate" IBUs, they measure them (at least they *claim* to).

\*\*\*\*\*

Lastly, a question of my own: Can someone let me know what the Latin and/or Greek words and/or prefixes would be for "taste"?

Mark

Subject: Airstat modification instructions

Thanks to all the great brews who took the time to search their files for the modification instruction for the Hunter Airstat. As a new digest member, I was amazed at the number of replies to my request. I also xxreceived a large number of requests for the modification instructions, so here they are: (Thanks a million, guys!)

>From Mike Kenney in HBD#1157

I originally posted this last November and have been using it with the mod very happily ever since. I use the airstat to control a 13cf chest freezer. I put the airstat in a manual "HOLD" mode and simply set the temperature up or down as desired. The airstat is designed to control a compressor driven refrigeration device (a room air conditioner) so it is right at home with a refrigerator or freezer. It turns the attached unit on when it senses a temperature 2 degrees above the setting and off 1 degree below the setting. It has a built-in timer with a 4 minute delay to keep the attached unit from cycling too rapidly. At 45F my freezer runs less than 2 hours total in a 24 hour period and about 3 hours at 35F.

You cannot change the Air Stat range but you can offset the sensor calibration. In other words, performing the following modification will allow you to set the Airstat at 40F yet the fridge/freezer temp will be maintained at 35F.

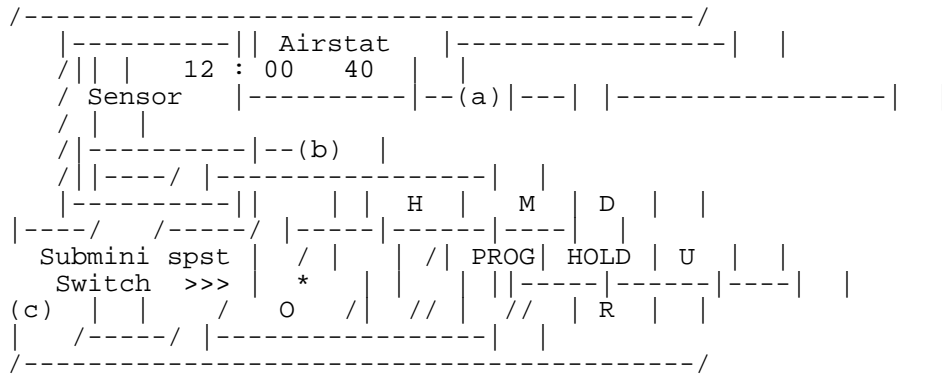

The sensor is a thermister that provides 10K ohms of resistance at 25 degrees C. According to the thermister data sheet, at 32 degrees F the resistance is 27.28K and 22.05K at 41 degrees F. The resistance decreases as the temperature rises so if you make the air stat think the sensor is 22k when its really 25k the air stat will say 41 but the sensor temp will be around 35 degrees F. This is done by simply putting more resistance in parallel with the sensor. Using ohms law,

$R_t = 22K$ ,  $R_{th} = 25K$  (Thermister), and  $R_p$  (parallel resistor) =

$$\frac{R_{th} (25K) * R_t (22K)}{R_{th} (25K) - R_t (22K)} = 183K \text{ Ohms}$$

With this resistor in place the the range of the air stat is effectively shifted about 5 degrees lower. Just keep in mind that the temperature reading on the air stat will not match the fridge temp.

The thermistors change in resistance is not linear. It will change about 20k ohms going from -13F to -4F and only 2k ohms going from 68F to 77F. Therefore the desired range of use should be considered before determining the magnitude of offset. Although, in the 12 degree swing between 33F and 45F this should not pose a problem.

I installed a 180K ohm resistor in series with a sub-mini spst toggle switch mounted on the front panel just left of the AC outlet and below the pocket that holds the sensor. It is fairly easy to do since the sensor leads are readily accessible. This switch lets me use the airstat normally above 40 degrees when off and down to 34-35 when on. The airstat seems to sample the sensor about every 5-10 seconds and will indicate the change in this timeframe.

\*\*\*\*\*  
>From Jack Schmidling in HBD#1215

I dug up the article by Mike Kenny on modifying the Hunter for lower temps and decided to give it a try. Upon opening the unit, I "discovered" a temp cal pot but found this had only about a two degree range and it was already in the middle of that.

Mike explains how to calculate (Ohms Law) the exact resistance for any temp, along with adding a switch to disable the mod. I took the Schmidling way and simply soldered a 150K resistor across the sensor lead terminals and got

lucky. When programmed for 40F, the temp in the pint of water is exactly 40F now. The air temp is about 35F but I just ignore that and the beer temp is just the way I like it.

It is a very simple mod and requires nothing more than removing two screws and soldering the resistor to very accessible terminals. Getting it back together takes a little "feel" because the battery terminals have to be fitted back into their connector but anyone with a little more finesse than a gorilla should be able to do it.

Subject: Louis Pasteur

Hola, all.

I just got a catalog from an antiquarian bookstore in Kansas City called Glenn Books. No I don't work for them: I work at one of the Borders bookshops, and stand to gain nothing for passing on this info. Anyway, item 238 in their latest catalog is listed as "Pastuer, Louis. Studies on Fermentation, the Diseases of Beer, Their Causes and Means of Preventing Them. (title). Macmillan, London, 1879. First English edition. 8vo. Original cloth, front flyleaf lacking, else a very good copy. Contemporary woodcut portrait of Pastuer added as frontispiece with catalog clipping & notes on re cto. \$300"

I was drooling until I hit the three bills part. That's a month's rent for me, a poor grad student. Their address is 323 East 55th Street, KC, MO (816)444-4447. I have founf that their are a bit overpriced (!), but not unreasonable about negotiating. Sorry for the typos: I'm recovering from a weekend of mead, oatmeal stout, Duvel, Traquair House, MacAndrew's, SA "Lambic" and a neb. of Corsendonk. Me fingers aren't yet working right.

It just occured to me that I might have been able to afford the book had I not blown my cash on the beerpool fund. Oh, well. Hope someone can use this.

From: Jeremy Ballard Bergsman <jeremybb@leland.Stanford.EDU>  
Subject: Re: ASBC and IBU's

Norm wrote that Byron Burch's methods were based on ASBC methods (according to Burch) and asked what those were. I don't have my copy of Malting and Brewing Science with me, but no homebrewer's method has anything to do with the ASBC method. The ASBC method is a MEASUREMENT of the amount of the amount of bittering compounds in beer. Methods like Burch's are ways of trying to produce beers with a certain amount of bitterness. The units used by Burch and Rager are the expected IBU of the beer, if such a measurement were made.

My recollection of the the ASBC method is some kind of organic extraction of degassed beer (with isooctane?) and single wavelength spectrophotometry of the resulting organic phase. Note that even this measure is only a surrogate for bitterness, as the ratio of bitteresses of the various bittering compounds is not the same as their ratios of absorbances.

What this means to me is that we, as homebrewers, needn't care how many IBU's we really would have if we measured our beers. All we need is a system that produces a number that is approximately linearly related to perceived bitterness and is reproducible from batch to batch. With such a system one can make beers to a desired PERCEIVED bitterness, which is all we really care about.

I guess we care about one more thing, namely being able to communicate with other homebrewers. In this case IBU's are nice since (I think) most people can at least convert to these "units". Personally I find the discontinuity of the Burch method distasteful; it seems very unrealistic. The Rager as modified by Garetz utilization curve seems the most intuitive to me.

>  
>1. Is CO the ONLY gas/ byproduct I should be worrying about?  
>  
>2. Is this a problem with both propane and natural gas?  
>  
>3. When they say OUTDOORS ONLY, do I take that literally, or does an  
open  
>garage qualify.

I ran this one by my local homebrew supply retailer. Propane  
cookers of the "Cajun Cooker" type are prodigious consumers  
of oxygen. No problem outdoors, but a big problem inside  
a room without adequate ventilation. Quote: "In a sealed  
room, the lack of oxygen would kill you before the carbon  
monoxide did."

Note that the above applies specifically to propane  
burners of the >150,000 BTU variety. I assume that the  
number of BTUs, rather than fuel type, is the major  
factor in oxygen consumption.

Of course, you probably wouldn't be running this in a sealed  
room. I seem to recall, quite recently, a posting from  
someone who brews in his basement (presumably with the  
doors wide open). And one brewer I know permanently installed  
a natural gas burner in his garage. But I would respectfully  
suggest, and prudence would dictate, that you not try  
operating any reasonably powerful burner inside an enclosed  
room without first ensuring beyond any doubt both an adequate  
oxygen supply (for both you and the burner) and adequate  
ventilation for the exhaust gases. (Remember, CO2 isn't harmful  
in and of itself...unless it's all you have to breathe.)

Subject: Re: good for yeast/good for beer

Andy Kailhofer wrote asking about his experience with aerating beer. Here in the Bay Area we have three brewpubs called Gordon Biersch (sp?). (Those in Pasadena, keep your eyes open.) They make very good (IMHO), traditional German Lagers. I know they use regular Briess and GW malts and I always wonder how they get their wonderful maltiness. (It's not decoction mashing because only some of their beers are decoction mashed and the others are at least as malty.) Unrelated to this question I was talking to the brewmaster of the San Francisco outlet about pitching rates. He told me that he likes to underpitch and aerate very well!

Then I had a flash of insight: what if you can get the yeast to undergo a bit of extra growth? You can use more malt for the same amount of alcohol. This might give you a bit more maltiness. I asked him if this was the reason, and he almost looked as if I had caught him in bed with my wife or something. Then he answered that this was just the way he liked to do it; the rhythm of the brewery or something. In retrospect it doesn't seem like this would make much of a difference. What does the digest think? What about an experiment?

Subject: Volcano Beer

Hello Fellow Homebrewers,

I need some help diagnosing a batch that went from bad to worse.  
I made a Czech Pilsner using a can of BREWMART Czech Pilsner extract.  
I also used 3 lbs extra light DME. The can came with a dried yeast and  
a pilsner enzyme. At 68 degrees I pitched both the yeast and the enzyme.  
It took the normal 1-2 days to start foaming but stayed extremely active  
for 2 weeks. A local brew shop said bottle it anyway and that it would be  
considered a dry beer. I drank 2 sips and decided to dispose of the  
entire  
batch. I could pop the cap and sit the bottle upright in the sink and  
watch  
it empty its self from the bottom up. Help !! What did I do wrong ?

Thanks in advance !

Subject: barleywine

barleywine

I am interested in brewing a barley wine from an O.G. of 1.100 or higher, but don't want F.G. above 1.030. Does anyone out there in HBD-land have personal experience using champagne yeasts for barleywine? If so, do you use only champagne, or use ale yeast and pitch the champagne when the ale yeast poops out? Do you wait until the ale yeast completely poops out? Do you rack the wort before pitching the second yeast? Do you need a starter for dry champagne yeast that is to be put in a wort that is already 8 percent alcohol or higher? Does using champagne yeast by itself produce a barleywine with less "beer" flavor? Considering the cost of a batch of barleywine, I don't want to experience too much "trial and error".

Thanks in advance to those who reply,

Brian Seay

From: Eric Saidel <SAIDEL@macc.wisc.edu>  
Subject: hard cider/mead

Here's the recipe I use for hard cider -

put your cider in your fermenter, add sugar (normal granulated sugar is fine) up to about 11-12% potential alcohol. Add yeast and yeast nutrients commensurate with how much cider you've got. Seal and wait. I've got about 30 gallons going right now - needed about 40 pounds of sugar, and it'll ferment for about 3 months before bottling. I bottle with more sugar so it gets a nice sparkle.

I also do about a case a year in which I bottle with honey - about a third of a cup for a champagne bottle. That gives it a nice apple mead flavor. The best honey, I find, is wildflower honey.

From: William Swetnam <wswetnam@capcon.net>  
Subject: Wort chiller construction help

Having read in for the last few weeks I have seen numerous messages about wort chillers and their construction. I think I have a good idea as to the design of my coil, but I still have a few questions about materials and other things. I am going to make an immersion chiller and am planning to set it up as follows: Hose from kitchen sink to copper coil in either a bucket of ice water or a cooler with ice water, hose from that to my immersion unit, then hose back to sink for drainage. My questions are as follows:

1. What are the recommendations on size of the copper tubing, 1/4 3/8 or 1/2 inch. A quick stop by my local hardware store raised the question of fittings, I'm wondering more about what may be the most efficient for heat transfer.
2. Some commercial wort chillers that I have seen do not put the water through an ice bath first. Is there a problem in chilling the wort too fast?
3. I'm planning on using 25' of tubing in my immersion section, is this too much, too little?

Private E-Mail would be appreciated unless you think it would be good for the masses. I feel I've taken up enough space on a simple query....

Thanks in advance....

From: mkenny@bcmlg01.attmail.com  
Subject: RE: Hunter Airstat Modification

In HBD1156 Bruce Ray asks how to modify a Hunter Airstat to maintain temperatures below 40F.

I originally posted this last November and have been using it with the mod very happily ever since. I use the airstat to control a 13cf chest freezer. I put the airstat in a manual "HOLD" mode and simply set the temperature up or down as desired. The airstat is designed to control a compressor driven refrigeration device (a room air conditioner) so it is right at home with a refrigerator or freezer. It turns the attached unit on when it senses a temperature 2 degrees above the setting and off 1 degree below the setting. It has a built-in timer with a 4 minute delay to keep the attached unit from cycling too rapidly. At 45F my freezer runs less than 2 hours total in a 24 hour period and about 3 hours at 35F.

You cannot change the Air Stat range but you can offset the sensor calibration. In other words, performing the following modification will allow you to set the Airstat at 40F yet the fridge/freezer temp will be maintained at 35F.

The sensor is a thermister that provides 10K ohms of resistance at 25 degrees C. According to the thermister data sheet, at 32 degrees F the resistance is 27.28K and 22.05K at 41 degrees F. The resistance decreases as the temperature rises so if you make the air stat think the sensor is 22k when its really 25k the air stat will say 41 but the sensor temp will be around 35 degrees F. This is done by simply putting more resistance in parallel with the sensor. Using ohms law,

$$R_t = 22K, R_{th} = 25K \text{ (Thermister)}, \text{ and } R_p \text{ (parallel resistor)} =$$
$$\frac{R_{th} (25K) * R_t (22K)}{R_{th} (25K) - R_t (22K)} = 183K \text{ Ohms}$$

With this resistor in place the the range of the air stat is effectively shifted about 5 degrees lower. Just keep in mind that the temperature reading on the air stat will not match the fridge temp.

The thermisters change in resistance is not linear. It will change about 20k ohms going from -13F to -4F and only 2k ohms going from 68F to 77F. Therefore the desired range of use should be considered before determining the magnitude of offset. Although, in the 12 degree swing between 33F and 45F this should not pose a problem.

From: J Paschel <bigstar@augustus.csscr.washington.edu>  
Subject: Question re: raspberry wheat beer...

Last week I started an extract batch based on the following recipe:

6 lb can Ireks wheat  
1.5 lbs light malt extract  
1 lb honey  
1 oz Tett (boil)  
1/2 oz Cascade (boil)

same as above (finish)

I then cooled the wort, dumped it onto roughly three pounds of frozen raspberries, and pitched with wyeast weizen (liquid).

Vigorous fermentation started in 18 hours and subsided in three days.

Now my questions:

1) Upon racking to the secondary, I found a noticeable sourness and a slight tinge of sulfur odor. Now I realize that Weizens are supposed to be a bit sour, so I'm not all that worried. Question is, how does one distinguish the difference between sourness due to style and sourness due to infection? Also, will sourness mellow in the bottle??

2) Papazian says a sulfur odor is "normal" depending on yeast types and conditions and claims it can be rectified by changing temperatures. The primary was at ~ 65 F and when I racked to 2nd, I put it in a room at about ~ 60. Will this help?? Any suggestions??

3) Lastly, the raspberries haven't (yet) imparted as much fruity sweetness as I have experienced in some other raspberry Weizens... Is it possible to use something akin to a raspberry syrup instead?

From: gummitch@teleport.com (Jeff Frane)  
Subject: Long Ago Lager

I don't usually post recipes, but I thought this particular beer was interesting enough, and good enough to pass along. I became intrigued with using flaked maize after Phil Seitz reported the Rochefort monks using it in their strong ale, several months back. I've been using it as they do, and getting remarkable results. While researching its use, I found George Fix's excellent article in the 1985 All-Grain Special Issue of Zymurgy (an article in high contrast to the articles on adjunct use in the most recent Special Issue, btw). In there, George outlined a pre-Prohibition lager, with a fairly high O.G., and a decidedly high hopping rate to counteract the slight residual sweetness imparted by the maize. I thought I'd take my own shot at this style of beer, and am extremely pleased with the result.

Because of the use of maize, and the lack of any specialty malts, the beer is remarkable pale. It's also quite bright, and refreshing. Although the OG puts it in the bock range, the high hopping rate and the lower malt profile creates something altogether different. I also made some changes from George's recipe and took some liberties with history, but in essence, it should be close to what grandpa (or maybe Greatgrandpa) could have sipped on his way home from work.

To be completely authentic, I should have used Clusters in the boil, but couldn't bring myself to do it. And I should have used 6-row American malt -- but I haven't any use for 6-row, and Belgian 2-row is what I had in the basement, so... The next time, I will use Great Western's 2-row, if only for a slightly closer touch of authenticity. The finishing hops are a believable mix of imported hops (as called for in old recipes for the better lagers), in this case using Mt Hood as a reasonable substitute for Hallertau.

I followed George's prescription for using the maize, and added it after the protein rest. The yeast was Wyeast's #2007, a thoroughly American lager yeast. Thoroughly American, too, was the lagering period, a mere 2 weeks--mostly because of impatience. I think another week or so would have helped, but the difference may be insignificant.

For five gallons:

Belgian pilsner malt 8#  
Flaked maize 2#

Water (very soft) 3.5 gallons/ treated with 4gms gypsum

Mash in 115F, raise to 127-130. Hold for 30 min.  
Add flaked maize, raise to 154F for approx. 60 min. Test with iodine.

Boil 90 min.

Hop additions:

Northern Brewer 2 oz. @ 15 min  
Mt Hood .5 oz @ 75 min  
Saaz .5 oz @ 75 min

Irish Moss (1/2 Tb. - rehydrated) at 60 min

OG - 1.072

Date: Mon, 15 Nov 93 11:51:13 EST  
From: Dave Lame <dlame99@prog.c4.gmeds.com>  
Subject: Malt Extract for Mead

When grain is used with honey to produce a non-sparkling drink, the resulting beverage is known as braggot. There are references to it in northern Europe as old as the first century A.D., and there is a reference to it in Chaucer's "The Miller's Tale." I've made four batches of the stuff, with some considerable success. While not everyone really likes it, some people who drink it have said it is the best stuff I make.

My basic recipe calls for one pound of honey and one pound of malt extract per gallon of braggot, but I have seen variations on the theme with more and with less of either ingredient. So, for twenty five liters, I would say about 6 1/2 pounds of each ingredient.

If you have a recipe for barley wine available, you could just substitute honey for sugar, and that would almost certainly work perfectly well.

I prefer amber ale extract, unhopped, for use in braggot, but that is personal preference. I'm experimenting with different styles. I've seen historical references to both hopped and unhopped beverages, and varying quantities of fermentables.

The one complaint about braggot that I hear frequently, and with which I concur, is that it tastes "thin". It doesn't have the character of a good beer or ale, but it doesn't have the clean taste of a pure mead. In an attempt to correct this, on the advice of an acquaintance who also makes braggot, I used buckwheat honey instead of clover honey once. The resulting product was certainly not "thin". In fact, the first person who tasted it suggested it would taste good on pancakes.

Returning to my friend who had recommended buckwheat honey, he explained that you weren't supposed to use all buckwheat honey. In a five gallon batch, he recommended five pounds malt extract, four pounds of clover honey, and one pound of buckwheat honey. For my next batch, I'll try that.

Does anyone else have any recommendations?

**Subject: Noche Bueno**

Good news! Joe Barfield of Southwest Brewing News has just informed me that Noche Bueno is back. It is being brewed in Monterrey by the Cuauhtemoc group, and will be distributed in selected test markets by Guinness Imports. Laurie is currently forming a flavor panel, and we will write an article for SWBN summarizing the results along with related information. I will also post it on HBD.

George Fix

P.S. The many people on this network who live in the Chicago area will be happy to know that your fine city is one of the test markets.

From: D S Draper <D.S.Draper@bristol.ac.uk>  
Subject: Yeast culturing--an update

Hiya friends,

A while back, I posted an anguished thread on my troubles culturing yeast from bottle-conditioned beers for use in my homebrews. This is a summary of the experiments I tried in an effort to improve the situation. I gratefully acknowledge the very helpful input of the following respondents (alphabetically listed <g>: Conn Copas, David Gallardo, Brendan Halpin, Drew Lynch, David Maxwell, Jack Schmidling, and Rob Thomas. Thanks a million, guys!!!

Brief recap of the earlier problems: pitched three batches of beer with cultures from bottles beers; the first was not properly sanitized, so got an infection. The second was properly sanitized, but resulted in a wild yeast infection that can only have come from the yeast that was inside the bottle. The third batch had a sour taste that was a mild wild-yeast infection. In each case, less than a pint of starter was pitched, just at high krauesen (I don't know how it's supposed to be spelled <grin>). The bottom line here is that 1) one cannot be sure what one is getting in any bottle-conditioned beer yeast, and 2) less than a pint starter volume of such yeast is woefully insufficient.

In my experiments, I pitched 1 gallon splits with these <1-pint starters, and in two cases got great results: in a bitter and in a raspberry pale ale. A third 1-gal split had an infection: again it must have been in the bottle because I was dead careful about everything. Finally, I pitched a full batch with a yeast that I'd stepped up from a <1-pint starter to a half-gallon. This was a keg bitter that was really good, much better than any I'd made with Edme dried yeast (the only thing readily available to me here in the UK). The yeasts that I got good results from were Eldridge Pope's Thomas Hardy Country Bitter, and King & Barnes's Festive Ale. Bad results came from Hanseatic IPA and Worthington White Label, and an earlier use of K&B. However, I do not think that these beers will give consistently good or bad results; I think it is mostly hit and miss.

My final experiment used a pure culture from Brewlab at the University of Sunderland, and I have just transferred it to the secondary. Tasting it as I did so, I can state with total assurance that is by far the best beer I've ever made (about 60 batches to date), with a "real beer" flavor that I've never achieved before, except my two successful experiments above. UK brewers: try this stuff. Usual disclaimers, void where prohibited, no parking, the white zone is for passenger loading and unloading only.

An additional note: The wild yeast taste I got in my first two batches, which I described as sort of medicine, is EXACTLY the main flavor I have gotten from several very reputable beers: Chimay blue, Leffe Blond (both Belgium), Pschorr-Brau Weisse, and Maisel's Hefe-Weizen (in Bayreuth, Franconia). This taste was identified as definitely being wild by my homebrew suppliers (who run a brewpub, so they know what they're talking about I reckon), and it is a dead ringer for that in these beers. Go figure...

Conclusions: If using bottle-conditioned yeast, step the starter up to

about a half gallon, and TASTE IT before committing it to your brew--  
keep  
a dried packet or whatever on hand in case of failure. In future, I will  
take the plunge into yeast culturing, isolating good colonies from these  
bottled beers, and growing them into starter colonies that I then make  
actual starter solutions from. Getting viable yeast from  
bottle-conditioned beers can be done, but one must be careful.

Cheers, Dave in Bristol (until the New Year)

**Subject: Answers to brewpot questions**

>Date: Wed, 10 Nov 93 15:10:42 -0700  
>From: John Glaser <glaser@analog.ece.arizona.edu>  
>Subject: Brewpot questions / I are a college student!

>1) I just picked up a enameled steel canning pot (8 gal.), but  
> it has a few chips in it, maybe about 1-2 square inches  
> worth of exposed metal. Will this be a worse problem than  
> that created by using 3 gal. boils in my smaller pot. Is  
> there anything I can do to cover the chips? (for example,  
> using hi-temp enamel like they sell for repairing outdoor BBQ  
> grills and such).

The biggest argument against using the enamel on steel pots for brewing  
in is  
that they chip and the chipped areas will leach iron into the brew. I  
don't  
think there is anything you can do to cover the chips. The hi-temp  
enamel for  
BBQ grills will not work. All it is is a high temperature paint and I  
don't  
think anyone would recommend painting the inside of a cooking vessel.

;2) Has anyone ever considered electroplating the inside of a  
; steel or aluminum pot with copper, to allow its use as a  
; boiling pot. Is it too expensive, too difficult, etc., or  
; could it work? What about anodized aluminum? Anyone know  
; anything about this?

If the pot is stainless steel, there would be no need to copper plate it.  
As  
for is it too expensive, too difficult, etc. the answer is all of the  
above.  
Anodized aluminum is stable over a pH range of 4.0 to 9.0. Heat and  
agitation  
may have an adverse effect.

Bottom line is to either invest in a stainless steel pot, or get another  
enamel on steel pot and take care not to chip it. This is a perfect  
excuse to  
upgrade the size of your brewpot to take advantage of doing full boils.

From: Aaron Morris <SYSAM@ALBANY.ALBANY.EDU>  
Subject: Making Mead

It was mead making that got me into homebrewing in the first place. Being a beekeeper, I had a surplus supply of honey. The article I started with came from Zymurgy and was given to me by my bee landlord (the man who owns the land on which my hives are located) in hopes that I would brew it and give him a few bottles as rent. The article was written by Brother

Adam (the guru of mead making) and was informative but limited in scope. To augment the article, I picked up a book called 'Making Mead' by Roger Morse (from Cornell). I highly recommend this book as a reference.

Concerning suggestions as to what extracts to use, mead contains no malts of any kind. Mead is simply a wine that uses honey instead of fruit. I have been quite successful brewing straight mead (honey and water with a champaign yeast), spiced mead (called methylgen sp(?)), and I've brewed raspberry meads (using fresh raspberries - no extracts please) that have been superb! This summer I brewed a carboy of peach mead, although I have yet to rack it for a second time and don't expect to taste it until next spring. Brewing mead is a much slower process than beer. Brother Adam suggests aging for five years, although my oldest bottle is three years, and there are only five left out of 24.

There are a number of beer recipes that use honey in the wort. Two of note from 'The Complete Joy of Homebrewing' are Rocky Raccoon's Crystal Honey Lager and Holiday Cheer. Both are excellent! I entered the former in a local competition and took third in show. The latter is a holiday brew, includes a lot of spices (cinamon, ginger, cloves(?)), orange peels and honey. The recipe sounded strange, but the results were well worth the gamble. If it sounds good, brew it now and it will be ready for the holidays. Rumors have it that Holiday Cheer is Santa's favorite (next to mead, of course)!

Subject: Taste by any other name

In HBD 1271 Mark Garetz asks:

> Can someone let me know what the Latin and/or Greek words and/or  
prefixes  
> would be for "taste"?

I think you are looking for the Latin root "gustus," which enables the mellifluous phrase:

De gustibus non est disputandum.

Which is roughly "there is no arguing (or accounting) for taste." Very useful as a way of expressing mild disdain. Sadly, when applied to beer, "gustus" reminds me of one of the megabrewers' (Schlitz?) old ad campaigns.

Date: Mon, 15 Nov 93 13:57:57 CST  
From: richard\_h@SMTPGATE.BCSEW.EDU  
Subject: Yeast starters and aeration

Greetings,

When I brew I usually make up a yeast starter (about a liter), and wait until the starter is foaming away before making up the wort and then pitching. This has generally worked quite well and I have had no reason to complain - noticeable fermentation has always started within 24 hours of pitching the starter.

The other day, as I was brewing up a batch of beer, the following observations did a mental pile up in my neural net:

- Yeast reproduction begins as an aerobic process ("Gimme O2!"), for about the first 12 hours. This is why we are told to aerate the wort before pitching - the yeast will have a nice oxygen rich environment to begin reproduction in.
- The yeast starter has probably finished the aerobic cycle and is now in an anaerobic state ("We don't need no stinkin' O2!") at the time it is pitched into the wort.

So, why doesn't the yeast in the starter (anaerobic phase) object to finding its environment changed by being dumped into the oxygen rich wort?

Inquiring minds ...

From: gt6179d@prism.gatech.edu  
Subject: trub separation

i recently got miller's book and was wondering if anyone out there has firsthand knowledge of how separating the trub from the wort before fermentation improves the beer. how dramatic is the effect? does anyone pitch the yeast BEFORE this step or is it a good idea to wait until the trub is separated before pitching? if you pitch the yeast first and wait long enough for the trub to settle (1 hour..?) before separating from the beer, is aeration of the beer at this point still okay, since the yeast is in the respiration stage? as i recall miller's book (ch.3), he pitched the yeast before separating the trub. is this unusual or am i confused as to the order of these steps?

also, i've noticed strange behavior sometimes when racking beer regarding my airlock. just after i fill the carboy with beer and put the airlock on, the water starts to get sucked into the fermenter, slowly. i only have one theory on this, to wit:

i generally rinse the carboy out with hot water from the bathtub just before filling it with beer. i'm sure the air in the carboy is fairly warm compared to ambient conditions outside. as the beer fills the carboy, is it unreasonable to assume that the final airspace above the beer is still warmer than outside and when it cools the pressure drop is what causes the water in the airlock to get sucked in? does this ever happen to anyone else? can this same thing happen if the room temperature changes? i'm an apartment brewer and i sometimes have temperature fluctuations beyond my control. i'm also not home during the day so i worry about putting bleach in my airlock for this reason. i sanitize it but i just put distilled water in for fear of the dreaded fermenter suck. any advice concerning these matters would be appreciated.

just curious

From: Kieran O'Connor <koconnor@mailbox.syr.edu>  
Subject: Fridges

The problem with using a fridge and an external thermostat is that you have two thermostats going at the same time--the fridge's and the Hunter (or whatever). The fridge thermostat usually will only allow the fridge to cool to 38 or 40 or so (F), and the Hunter device will try to continue to cool, but can't. To solve this--remove the internal thermostat--wire the two wires together and let the Hunter do the job. Just don't try to run the fridge with out the Hunter--you'll ruin the compressor

I have a short attention span and at my age, if you didn't say it in the last five minutes, you didn't say it.

> I have an uptake copper tubing that run entirely around the inner perimeter of the kettle, and sits right on the bottom. Lots of teeny-tiny holes are drilled in the underside of this coil. The mountain of matter is \*inside\* the coil.

Sounds pretty slick. However, I got flamed because I based my opinion of immersion chillers on one mounted in the lid. Seems it was too sophisticated and I was taking advantage of people who were too lazy or hadn't thought of doing it that way. Seems you are guilty of the same sin on the other side of the argument.

>It works very well. So don't worry, Jack! I'm fine. Really.

That's a relief. What's your name again?

>From: phil.brushaber@lunatic.com (Phil Brushaber)  
>Subject: Decoction Question

>Wouldn't boiling with the grains cause a problem with increased astringency and the leaching of excess tannins into the beer?

Perhaps it's time to look into another momily. I get trashed every time I suggest using boiling water for sparging even though I always use decoction for my Pilsners. Astringency is a knee-jerk response that needs an objective look-see.

>From: "Phillip R. Seitz" <p00644@psilink.com>  
>Subject: Air Stat problems

>I have a Hunter Air Stat and a small refrigerator. As far as I can tell both are in good working order. The problem is that when the temperature reaches the appropriate point the fridge will frequently make several abortive attempts to go on, or will run for a perhaps 10 seconds before cycling off. After 3 or 4 attempts the fridge comes on and stays on.

If it is random and runs normally most of the time it is probably the overload control on the fridge. If the compressor is VERY hot when it

happens, you have some other problem but if it is only warm, give the little black box a rapping with a small hammer.

Mine does this and I had a digital thermometer on the compressor for weeks and there never was a real problem. I keep a piece of wood handy and whack it when it gets flakey. You can buy replacement controllers for about \$30 at appliance parts houses.

>From: Mark Garetz <mgaretz@hoptech.com>  
>Subject: Dry Hopping Risks/Alphas/Latin

>I'll now quote from the article's conclusion: "These results suggest that the practice of dry-hopping is microbiologically safe, especially after three days of fermentation."

>What we learn from this is that you should dry hop only after you have a vigorous fermentation going and the beer has a reasonable alcohol content and low pH.

I think what I learned is that the anti-bacterial characteristics of hops are either a myth or greatly exaggerated in the brewing folklore. Clearly, if yeasts and bacteria live on the hops and can inoculate a culture dish, it is not very bacteriocidal.

It would have been interesting if there was a control using a handful of grass clippings or leaves to find out if it was the nature of the fermented beer or the hops that prevented contamination.

prune juice.

Sounds like a good base for Klingon Ale. Add lots of honey! ?

\*\*\*\*Ok./ On to REAL BREW TALK!

Andy was straining about his Bambi Booster Bomb quick brew he made. :)  
(I didn't say "stressing"....but the main theme...is....r e l a x )

> Aeration of wort. Using a gas-bubbler. ...

My question is how long did it sit with the bubbler bubbling?  
(Glad I didn't have to pronounce that. It might'a come out wierd!)

I would think that you really just want to get the solution full of air  
to the max which will dissolve at the beginning of the ferment, then  
shut it off, say after a couple hours. Longer than that shouldn't be  
necessary, unless you have a very high starting gravity. I know of  
several wines/meads of mine which needed to have a big blast of air  
before they would take off.

BTW: This IS something I've tried, so I'm not speaking thru my shoe!

My inclination is to add air until the ferment becomes active, then shut  
it off and let the yeast do their thing. If it ferments strongly you  
might drop all your s.g. in a couple days. I generally like to complete  
the ferment with a secondary for an additional week. Overall most are  
2 to 3 weeks duration. If it's fermented, and has dropped out the yeast,  
"heck" go for it! Bottle away. You can always let it age longer in the  
bottle. But generally things age/balance better in larger volumes.

Bottom Line: If it tastes good. Drink it! and then have another...

\*\*\*\*\*

Mike sez of a keg of 7-up:

>Well, it's not working... I pressurized the keg at 30psi for 3 or 4 days  
in  
a 50 degree garage... then dropped down to a dispensing pressure of  
12-14psi. When I hit the tap, I get 7up gushing from it. Foams like  
crazy,  
but the finished product in the glass is pretty much flat. I.e., all the  
CO2 comes out at dispensing time. What's wrong?

\* Drop 'em baby! I mean...uh...er...drop the PRESSURE. Yes that's it.  
Beer is commonly dispensed at 2-5 psi once carbonated. If it foams, turn  
it down. HINT: Drop pressure on keg FIRST, then drop pressure in  
regulator. A very full keg can back beer up the gas line. Not good. :(

Oh- and I don't care HOW long your dispensing line is! It's not my

Date: Mon, 15 Nov 1993 13:45:15 -0600 (MDT)  
From: COYOTE <SLK6P@cc.usu.edu>  
Subject: Cider, Mead / Strength and Yeast #'s

\*\*\*\*\*

From: "Christopher J. Lacenere" <cl38+@andrew.cmu.edu>  
Subject: HARD CIDER? How to's

\* Don't boil cider. You'll get jello haze! You can pasteurize, but easier is to treat cider with campden tables (Na -bisulfate...). Crush, dissolve, add. Don't breath the gas! Sulfur hurts! Give it 24 hrs, then pitch a good yeast starter. Champagne is a good one.

Other good things to add: Grape tannin, yeast nutrient, pectic enzyme..  
.

HONEY! I've found my ciders to have a fuller, more balanced flavor when I add honey to the ferment.

Typical Recipe: 4 gallons cider. Treat w/campden.  
Heat 5 # honey in water- to 1 gallon. Add other goodies.  
Add honey mix to cider, and pitch yeast.

I usually ferment for a month, and rack several times. Bottle straight-apple wine/ Cyser, or sparkle it by priming.

\*\*\*\*\*

Mead Extract? There actually is a kit sold by Williams (no connectn.. blah)  
for making mead. (800-759-6025) \$6.90, everything but the honey.

I've made meads for about 4 years now. I've never made a Mead w/malt, but I have made beers with honey. :) On the order of 2-5 pounds into a brew. I like it. Brown sugar is another favorite.

Suggestion for both Mead and Cider: Treat it like a wine. Get a wine book and learn about acid-testing, stabilization, adjusting sweetness...  
"The art of making wine" Anderson & Hill is a good one.

You'll be able to get much better balanced products that way. Just count on time. The best advice: Be Patient. Leave it alone!  
Rack several times, to get it cleared properly.

Personally I don't like adding hops to mead anymore. I've tried it, and found the bitterness out of place in an often sweet beverage. In dry meads there is nothing to balance the bitter, and it bites thru 2 much. Considering the potential strength of most wines/meads the added bacterial inhibition from hops should not be needed.

FYI: There is a Mead Lovers Digest, and a Cider digest. They (at least the MLD) are/is archived at sierra.stanford. pub/mead or are distributed by e-mail. The NEWS group red.crafts.wine commonly discussed mead/cider from a wine perspective.

\*\*\*\*\*

From: Jeremy Ballard Bergsman <in%"jeremybb@leland.Stanford.EDU">  
Subject: Re: good for yeast/good for beer

>...in the Bay Area we have three brewpubs called Gordon Biersch (sp?).  
(Those

in Pasadena, keep your eyes open.)

\* Drool pant sputter....Really? I'm headed that way over X-mas. Am I too early for their arrival? I've been to the Crown Brewery, and the John Bull Pub has some NICE imports on tap.

Do you know what the name of the brewpub will be down there? Location?

I'd love to know! :)

>Then I had a flash of insight: what if you can get the yeast to undergo a bit of extra growth? You can use more malt for the same amount of alcohol. This might give you a bit more maltiness. I asked him if this was the reason,

\* I don't think it really works that way. Product production (e.g. etoh and co2) are related to the substrate concentration. The rate will be affected by the amount of enzyme/~= cell numbers. BUT the amount of product will depend on the amount of substrate...i.e.fermentable malt sugars.

\* So I don't think that the brewmeister there really has to worry about you sleeping with his wife! Besides, you shouldn't do that on the hbd!

acid  
>for bacteria. I wonder why someone like me who dry hops by stuffing  
hops  
>with by bare hands through carboy openings has never had an infected  
batch  
>attributable to dry-hopping?

Luck may have a lot to do with it, but indeed, the chances of an infected batch from dryhopping are quite low provided that the dryhops are added once the beer has mostly fermented out. See my Technical Communication in the first issue of Brewing Techniques for my reasoning. I posted what I do and why I do it. I \*sell\* hops -- I feel a responsibility to my customers to give them the best product I can and that includes reducing any risk of contamination. If my methods are overkill, then too bad for me, but I don't see why you need to get upset about what I do.

In a related topic, Mark writes:

>They took cultures from the hops and found they contained  
>wild yeasts of three kinds and many different kinds of  
>bacteria - some gram positive and negative, mostly  
>"Enterobacteriaceae" whatever that means.

It refers to enteric bacteria, which means "bacteria that reside in the intestines."

>The reason Mr Korzanos gives is 'glass grenades', especially for lagers  
-

>those beers with which he is so intimately familiar, without any  
examples  
>at all - just his vague suspicion.

Read my post again, you obviously missed my point. Perhaps I was  
unclear.  
With any beer, ale or lager, it is risky to pitch a \*different strain\* of  
yeast at bottling time, because if you pitch a more attenuative yeast  
strain,  
you will have gushers (at best -- depending on the yeasts, you could  
create  
exploding bottles). My contention was that fresh yeast at bottling time  
was  
not an \*absolute\* requirement for lagers in general (as you contend) and  
was  
based upon personal experience, the experiences of others in the HBD, and  
the experiences of members of local homebrew clubs.

>Also, I considered the crabtree effect a good reason to abandon corn  
>sugar, but of course there are other good reasons to stick with it.  
>One must balance everything. Some people are quite happy carbonating  
with  
>sterile wort or kraeusen, and for lager there is no topping the latter  
>method (IMHO). Even Anheuser-Busch do it!!

Did I slam Carl for abandoning corn sugar? No, I just posted what I did  
and some of my reasoning. Frankly, IMHO, your opinions don't sound so  
humble.

I stand behind everything I wrote in those posts. If you disagree, then  
please post civilized rebuttals.

For the record, it's Korzonas, but you can call me...

From: rknight@qualcomm.com (Bob Knight)  
Subject: Flying homebrew

Over the last few weeks I've seen a couple of articles from HBD'ers who tried taking homebrew on airplanes in their carry-on luggage; one got stopped by airport security who for some reason objected to his carrying unlabeled bottles of dangerously murky brown fluid onto an airliner, and one was simply warned that he should not drink it in flight.

Has anyone else had any good or bad experiences carrying homebrew onto a plane? Or, for that matter, checking homebrew in their luggage?

Thanksgiving is rapidly approaching, and I suspect that Enquiring Minds Want To Know.

**Subject: Sanitation FAQ**

Does anyone know if there's a sanitation FAQ out there? It seems like every time I get one problem cleared up I get another one (like the 50 bottles of butterscotch I now have in the basement). I'm pretty sure it's not the yeast, it tasted great when it went into the bottle.

From: thutt@mail.casi.sti.nasa.gov  
Subject: Treacle & Other Brit Sugars

I'm getting tired of seeing the Great Treacle Question posed and pondered time and time again. In HBD 1273, Bruce Beck wondered what Golden Syrup is (I dunno) and once again mentioned the mysterious Treacle.

No, you cannot buy treacle in the U.S., but that is not the full answer. To get the full answer, we must first find out exactly what Treacle is.

Once and for all, Treacle is simply blackstrap molasses. You can get this in many places in the U.S.

Demararra, which I also have sitting in my house, is simply a light brown sugar with molasses added. It looks similar to the US brown sugar, but is not as moist (I've not opened the package yet, so I cannot give taste results).

The U.K. also has a light brown granular sugar that I have never encountered before I went to London in June. I've not tried it either, but I am hoping to use them all in some sweet brown ales this season.

Someone was making a 'Sugars FAQ'. They may want to update this information....

Date: Tue, 16 Nov 1993 10:12:47 -0500 (EST)  
From: gelinas@ekman.unh.edu (Russell Gelinas)  
Subject: fast ferment/chiller/etc.

Wyeast 1098 (Whitbread ale), dated 11/3/93, fully puffed up 24 hours after breaking inner seal. A couple of starters later, it fermented out 5 gallons of 1.050 wort in 36 hours at 68F, including a 12-24 hr lag time. That's healthy yeast.

Tell me if this makes sense. Since most homebrewers underpitch, we don't want to pitch fermenting yeast (ie. high krausen), we want to pitch reproducing yeast (ie. pre-krausen). That way when they hit the fresh (well oxygenated!) wort, they continue to reproduce, ensuring a large colony and a healthy ferment when it's time. The way to ensure this would be to pitch a starter shortly after it has been inoculated, before the krausen begins.

In the 1098 case above, the fully-puffed packet was pitched into a starter that was allowed to ferment out. 1/2 of that starter was pitched into a new starter. Before this had a chance to show any signs of ferment (3-4 hours later), it was pitched into the full 5 gallon batch. The relatively long lag time seen may be an indication of the yeasts initial tendency for reproduction in this scheme. The very large amount of yeast that flocculated out after the ferment would also support this theory.

Btw, none of this was planned; it was purely chance. Next time it will be planned.

- - - - -

Thanks to the person who recommended hanging an immersion chiller over the sides of the brewpot, to allow it to sit in the top of the hot wort (the hottest part). Not only did the wort cool faster, but the cover sat tighter, and it did not need to be stirred at all. Thanks again.

Subject: Filtering update

Last Feb, I posted about my experience using a 5 micron cartridge filter to remove excess yeast in an Altbier I made. Since then, I have recently filtered 6 cornelious kegs, 3 pale ales, and 3 "Dunkles Wicked Ale" (my lab is named Dunkles). I was really happy with the results. My current brewing practice is to use a SS open fermenter, skimming the American yeast off the top as the ferment ends, and skimming the initial junk off the early fermentation. Since I keg directly from my primary, I have been carrying over a significant amount of suspended yeast. I was getting a bit tired of the yeasty beer, so I pulled out my 5 micron filter

bought from the Filter Store, and went at it. Some of the kegs were carbonated, and while they filtered fine, the flow rate seemed quite slow.

The two flat kegs filtered much quicker. The resulting beers are a nice "polished" look, similar to many breweries that filter, but dont overdo it.

One of my main objections to filtering is the need to clean and sanitize more equipment, drag. To simplify things, I cleaned and sanitized 3 kegs, and as I emptied a yeasty keg, I just rinsed the yeast out with real hot water, and cooled it. This keg then became one of the receiving tanks for the next filtered beer.

Since I was filtering two quite different beers, I back flushed the filter between beer types, and tons of yeast came out. I still think that a 5 micron filter is perfectly adequate for removing excess yeast.

The best thing is the true beer flavors, malt and hops, come through much better in the filtered version than in the unfiltered. I think this is one the suprising things about filtering.

BTW, I used a "quat" based sanitizer, VigilQuat, and stored the filter in a solution of this sanitizer.

Good brewing,  
Jim Busch

If you dont streak the "yeasts" into single colonies , you were not  
"culturing" , just growing whatever is in the bottle.

>  
> An additional note: The wild yeast taste I got in my first two batches,

> figure...

Phenols are produced by wild yeasts in large quantities. Phenolic notes  
are often evident in Belgium Ales, and German Weizens. The more brewpubs  
I  
visit, the less I feel "who run a brewpub, so they know what they're  
talking  
about". The quality in Micros is far greater than in many Brewpubs,  
sadly.

Pouring the dregs of a bottle into the pint starter and then into fresh  
wort is certainly risky, as your experience attests. In the US, people  
do this with SNPA, but this is a filtered beer that is force carbonated  
prior to the addition of fresh bottling yeast, the ferment yeast is not  
left in the bottle. It is also most likely a cleaner brewery than many  
in the UK.

> finding its environment changed by being dumped into the oxygen rich  
> wort?

Actually, it does. If O2 is present, the cells will revert to the  
respiration  
phase, until the O2 is gone, then the anerobic phase returns. If the  
starter is allowed to ferment, the yeast is ready to respire again. This  
is  
why some brewers prefer to let the starter ferment past high krausen, and  
decant the still beer off the starter, pitching the slurry.

from JS:

<I think what I learned is that the anti-bacterial characteristics of  
hops are  
<either a myth or greatly exagerated in the brewing folklore. Clearly,  
if  
<yeasts and bacteria live on the hops and can inoculate a culture dish,

> regulator. A very full keg can back beer up the gas line. Not good. :  
(

Actually, No. If one increases the delivery pressure then you are  
"pushing"  
the beer out, as opposed to letting the beer "push itself" out. By  
letting  
the beer "push itself" out, you are decarbonating the beer. You need to  
reach equilibrium of , usually, around 2.5 volumes of CO2 in solution,  
and

maintain 12 psi on the tank. IF the beer is gushing out at 12 psi, it is most likely overcarbonated, and indeed the answer is to bleed off excess pressure, then return to 12 psi.

>

First part true, second part false, no problem adding gypsum. It all depends on your intial water chemistry, amount of dark malts to be used and lager versus ale yeasts.

From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>  
Subject: chillers, bottle yeast, Miller's method, Papazian picture

In hbd1273 William Swetnam asks about chiller construction. I would recommend 1/4" copper tubing - it is cheaper to get more surface area by buying more length of 1/4" than bigger tubing and it is easier to shape.

The reason one should use tubing of a larger diameter for counterflow chillers (high pressure drop) does not apply to immersion chillers, and the greater pressure drop across the narrower tubing may help conserve water where that is an issue. For clamps I just used a scrap of hose clamped outside with a regular hose clamp, although I am sure compression fittings are available.

I have never seen a two stage chiller like you suggest - first through an ice bath prior to circulating through wort, although I have thought about it. For ales in the winter it is unnecessary, but for lagers and summer brewing a better cold break would be nice. If using such a setup, to conserve ice, I would recommend not adding ice till the wort is chilled close to tap water temperature, and then add the ice. What I sometime do, is disconnect my water once tap temperatures are approached and connect a pump recirculating ice water. RE length 25" is fine for the wort chiller, although considering the length of copper tubing in the average box, you may use a longer length.

Dave Draper relates his experience with culturing from bottle conditioned beers. I recently retired an ale yeast cultured from a bottle of Guinness (purchased in Ireland) because of suspected wild yeast contamination - gushing. However, I had used the yeast for many batches top cropping or bottom cropping along the way. Contamination with bacteria was an early problem, again probably because the brewery practice was not perfectly sterile. What I did after the first batch and then every second batch or so was acid wash with ammonium peroxydisulfate solution (a procedure outlined in 'Brewing Lager Beer' by Gregory Noonan). I made many excellent batches (and some less than stellar ones) with this yeast and these procedures.

Keith McNeil worries about chipped enamelled canning pots. My well used pot has suffered the odd chip but it doesn't seem to be a problem. The chipped areas are well blackened with a thick carbon coat from many burnt decoctions - much as cast iron cookware is. So long as one doesn't clean the pot too well, it is my experience that chips are not a big problem.

I was in one of those religious Miller vs. Papazian discussions at a homebrew tasting this weekend and the procedure mentioned by Mark Bayer - of Miller recommending pitching yeast on trub and then racking prior to Krausen is lovely on paper, and if one's yeast tends to be consistent good advice, but I remember one batch, an underpitched lager, for which I did this - racked after 6 hours or so, and had a 5 day wait till krausen (good job I don't worry too much!). I prefer not to rack

till after krausen because of risks of infection and yeast loss.

In my last posting in 1271 I mentioned the recommendation in Papazian to pour the hot wort in cold water in a carboy as being bad advice and received a number of worried responses, to some of whom email responses bounced. I'll quote Charlie himself, RDWHAHB. While this procedure is not correct - chilling in a bathtub or with a wort chiller prior to pouring is recommended, the amount of damage that could be expected due to hot side aeration is so slight that it is unlikely to be noticeable.

From: esonnl@cc.swarthmore.edu

Subject: A real lager and "kegs"

Hello,

I plan to brew my first real lager in the coming months and am now considering what new equipment I may need to acquire to do this. My big question, is do you need a fridge to brew a real lager? I thought it would be ok if I put the carboy in the basement, sitting in a pan of water, with a big t shirt over it so the t shirt dangled into the pan of water. My idea is that shirt would act as a wick and draw the water up over the carboy and evaporation would keep the carboy cool. I realize I would not have any real control over the temperature of the carboy, but it seems it would work. Anyone tried this? Am I kidding myself?

Second question. I have seen some plastic "kegs" in local home-brew shop which come from Europe. Supposedly, they can be used to carbonate in and draft beer from. Has anyone tried these? They seem like only a glorified beer ball.

Thanks in advance,  
Eugene esonnl@cc.swarthmore.edu

Date: Tue, 16 Nov 1993 11:55:31 -0600  
From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)  
Subject: Dispensing from Kegs (was keg pressure questions)

John Wyllie COYOTE gives some advice on using kegging equipment in response to Mike Fetzer's question in HBD #1272:

> Beer is commonly dispensed at 2-5 psi once carbonated.

Some veddy British ales served with VERY low carbonation at 50F may be stored under as little as 2 PSIG, but these will generally be dispensed with a beer engine (essentially a hand-pump) and not with CO2 pressure. So storage pressure in this case has absolutely nothing to do with dispensing. Some pubs will dispense this type of ale with a CO2/N2 mixture, but this is a whole `nother topic. Most beers have considerably more carbonation than these ales though. Note that even at 32F, 8 PSIG is required to maintain 2.5 volumes dissolved CO2. At a more-typical 45F, this jumps to 15 PSIG. The 2-1/2 volume carbonation level is typical of beer-in-general, and although some might complain that its too fizzy, it seems that most people like it just fine, no matter where they live. The COYOTE continues...

> If it [the beer -trl] foams, turn it [the pressure -trl] down. Oh- and I  
> don't care HOW long your dispensing line is! It's not my business :)!

I guess the COYOTE means that MIKE'S difficulty is not the COYOTE's problem. If your beer foams, there is only one thing wrong -- you are releasing the CO2 from solution too fast. This is caused mostly by agitation. Agitation can be caused by restrictions in the serving line, and by the beer hitting the bottom of your glass too fast. Now for a bit of physics. Since this is a recurring topic, I'll post a more complete set of data that I have by the end of the week. But for starters, this'll get us in the ballpark.

When storing beer, you want to keep enough pressure on it to maintain the desired carbonation level. For most British styles, we're looking for 1-1/2 volumes of dissolved CO2 (or so) and for most lager style beers, were looking for 2-1/2 volumes (or so). This can vary according to your taste. There are various pressure vs. temperature charts\* floating around, but as an example, my Pilsner was stored and served at 40F, and 2.5 volumes of CO2. This means I need to store the beer under 14.0 PSIG to maintain carbonation.

Now, since I want to serve directly from my storage vessel (the keg), I somehow need to "drop" or dissipate the 9 PSI in the dispensing system. My

beer faucet is about 18" above the center of the keg. A vertical lift drops about 1 PSI per 12", so this automatically gets rid of 1-1/2 PSI, leaving me with 12-1/2. 3/16" ID beer line drops 2.1 PSI per foot of length due to fluid friction. So, I need

12-1/2 PSI  
----- = 6 feet of 3/16 ID beer line  
2-1/10 PSI/Foot

So, I cut a piece of line 5-1/2 feet long to account for drops at various fittings in the system, and hooked it all up. Proper flow rate for beer dispensing is about 2 ounces/second. And indeed, it takes about 10 seconds to fill my 22 ounce mug with about 16 ounces of beer, and a nice head. The carbonation remains in the beer because the pressure at the faucet is nearly zero PSIG, and the beer is not violently expelled against the bottom of my glass.

> I don't think it'll cause any problems you can't compensate for with > adjustments to pressure.

Kludgy half-way "solutions" are always possible. Physics, I think, is preferable. The only way to use a dispensing system that cannot provide sufficient resistance is to:

- 1) Store under correct pressure
- 2) Release all the excess pressure
- 3) Dispense n servings
- 4) Re pressurize for storage (Go To 1)

If this is what you want to do, it will "work". But it sure is a hassle, don't you agree?

Part of Mike's original question:

> I pressurized the keg at 30psi for 3 or 4 days in a 50 degree garage..  
> then dropped down to a dispensing pressure of 12-14psi. When I hit the > tap, I get 7up gushing from it. Foams like crazy, but the finished > product in the glass is pretty much flat. I.e., all the CO2 comes out at > dispensing time.

Three or four days isn't enough time for CO2 to dissolve into the 7UP, even at 30 PSI, so it really wasn't very carbonated to start with. To carbonate, you need to agitate. I do this by rocking my keg back and forth over a softball bat until I can't hear the CO2 flowing in anymore. Thus usually takes 15 minutes or so of constant agitation.

so agitation under pressure ==> carbonation  
agitation without pressure ==> de-carbonation

And you really need your pressure/temperature/dissolved CO2 chart to get it right. Anyhow, what carbonation that \*was\* in the 7UP came out all at once

when the stuff hit the bottom of your glass at 90 miles an hour, leaving you with pretty flat 7UP. There have been many articles posted on the topic of carbonation.

Look for more data from me in a few days. I'll expand a bit on the topic. Maybe it'll turn into a keg-dispensing FAQ or something.

>From: phil.brushaber@lunatic.com (Phil Brushaber)  
>Subject: Decoction Question

>Wouldn't boiling with the grains cause a problem with increased astringency and the leaching of excess tannins into the beer?

JS>>Perhaps it's time to look into another momily. I get trashed every time I suggest using boiling water for sparging even though I always use decoction for my Pilsners. Astringency is a knee-jerk response that needs an objective look-see.

JS and Phil discuss extracted tannis, astringency and 'momilies'. Later the Coyote man says nope, it's the ACID REST, and I'd go along with that.

Decoction mashes are done with pre-sparge mash constituents, usually at a pH 5.3. From my understanding this level of acidity 'discourages' the extraction of tannins, making boiling a portion of the mash possible, without puckering results.

Further to this one could assume that it would be OK to sparge with boiling water, which is accurate as long as your grain bed pH doesn't raise above 5.3, ideally. In the real world, sparging raises mash pH towards the end of the run and continuing to rinse with boiling water would leach out tannins.

I made a mini-grain-tea-bag, boiled it for 10 minutes in tap water (pH 7.0) and it was what I would call astringent. That's enough proof for me. ;)

From: jimg@dcz.gso.uri.edu (James Gallagher)  
Subject: mash in temps

I have noticed that many recipes here and elsewhere describe a procedure where grain is added to water at one temp and then the mash is raised to another temp. However, there are also recipes where grain is added to water at a temperature such that the mash does not need a boost to the proper temperature. Is there any reason not to always use water at a temp such that the mash will be at conversion temp. or protein rest temp. without adjustment?

entire  
>batch. I could pop the cap and sit the bottle upright in the sink and  
watch  
>it empty its self from the bottom up. Help !! What did I do wrong ?

Bottled too early, probably, but there are other points in your post that  
I would like to address. 1. Pilsners are lagers and I've read that there  
currently is no true lager yeast available in dry form (lager yeasts just  
don't like to be de-hydrated, I guess). 2. What a two-week ferment has  
to do with it being a "dry beer" I don't know. 3. "Pilsner enzyme"  
certainly has nothing to do with a real Pilsner -- I believe that dry  
beers  
are indeed brewed with some kind of enzyme that breaks the complex sugars  
down to virtually all glucose, so maybe that's what they meant.

There is a chance that you introduced some bacteria with the dried yeast  
(some have very high bacterial counts) or the enzyme. This would explain  
why it tasted bad and why fermentation took so long. I advise to forget  
the enzyme next time, wait till fermentation is virtually over (I wait  
till  
there are 2 minutes between glugs) before you bottle and see if the beer  
turns out better.

>be a bit sour, so I'm not all that worried. Question is, how does one  
>distinguish the difference between sourness due to style and sourness  
due  
>to infection ? Also, will sourness mellow in the bottle ??

Actually, only Berliner Weiss are sour according to style (and that's due

to an intentional Lactobacillus infection). The raspberries added some sourness, I'll bet, but it could also be an infection. If the beer ferments out to be super-dry, it is probably a bacterial infection. There is a bacteria called Malo-Lactic Bacteria (Wyeast has it) which "converts harsher malic acid to milder lactic acid" but if the sourness is from a lactic infection, nothing like this will help reduce the sourness.

>2) Papazian says a sulfur odor is "normal" depending on yeast types and >conditions and claims it can be rectified by changing temperatures. The >primary was at ~ 65 F and when I racked to 2nd, I put it in a room at >about ~ 60. Will this help ?? Any suggestions ??

The sulfur odor will eventually go away if it is from the yeast, but I'm not sure if you need to keep it in the fermenter or if you can bottle it and wait for the smell to go away.

>3) Lastly, the raspberries haven't (yet) imparted as much fruity sweetness >as I have experienced in some other raspberry Weizens... Is it possible >to use something akin to a raspberry syrup instead ?

Raspberries will not impart much sweetness. The sugar in them will ferment away leaving mostly raspberry aroma. Some of this aroma will get scrubbed

-out by evolving CO2 if you add the fruit at pitching time. I recommend putting the fruit in after primary fermentation is over. This will also reduce the chances of infection. A raspberry syrup will probably be mostly

corn syrup, which will ferment away also. What you need to do is to add some unfermentable sugar to leave some sweetness. I added 8 ounces of lactose to a recent 15 gallon batch of raspberry/cherry ale. It did sweeten

it a little bit, but not much. I think adding 8 ounces to 5 gallons is more

reasonable for adding some residual sweetness. BTW, I'm not a biologist, but I'll bet that Lactose is fermentable by Lactobacillus, so be extra careful with sanitation!

\*\*\*\*\*

Bruce writes:

>In "Brewing Beers Like Those You Buy", Dave Line gives a recipe for >"Bishop's Tipple", a real ale. The recipe asks for "1 lb Golden Syrup". >Is Golden Syrup one of those things like Treacle which is unknown in the USA?

>Or is it what Americans call Corn Syrup?

It's a UK thing, as is Treacle. You can get it (along with Treacle) from some specialty food stores if you can't get it from your HB supplier. As for Tate & Lyle's Golden Syrup.

>Line also advocates sacchrine tablets to give residual sweetness. I understand

>Lactose is a "better" way to provide residual sweetness. Is there a rule of

>thumb for the amount of lactose to add? I see amounts like 10-12 oz given in

>Cat's Meow. Is it added to the boil? Is there something like "One sacchrine

>tablet = x oz lactose"?

Line's book was written at a time when there were much fewer choices for yeast and all the yeasts that he had to choose from were quite attenuative.

A less-attenuative yeast could be all you need. If you add lactose, you can

add it in the boil, or boil some up and add it at bottling time -- it's unfermentable, so it doesn't matter as long as you sanitize it. Adding at

bottling time also allows you to add it to taste, but be aware that the beer will become a bit more acidic when it carbonates, so you may want to make it a touch sweeter than you want the final product to be. See my note

above on Lactose and be aware that Lactose is not very sweet -- much less sweet than sucrose, fructose or glucose.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hops and Bacteria

Jack Schmidling writes (in response to my post):

>I think what I learned is that the anti-bacterial characteristics of hops are either a myth or greatly exaggerated in the brewing folklore. Clearly, if yeasts and bacteria live on the hops and can inoculate a culture dish, it is not very bacteriocidal.

The bacteriocidal constituents of the hops is in the lupulin glands. Lots of beasties can live on the petals outside the lupulin glands. These were whole hops in the study, so it's not surprising that cultures taken from the hops would grow stuff since the lupulin glands would, in large part, be intact.

>It would have been interesting if there was a control using a handful of grass clippings or leaves to find out if it was the nature of the fermented beer or the hops that prevented contamination.

Since at dry-hopping temps it takes quite a few days (more than three) for stuff to migrate out of the lupulin glands, I would say it points pretty conclusively to the fact that the beer itself is what did the trick, but it may have been helped along by the hop constituents already in the beer from the boil.

I'd have to double check my references, but I think the anti-bacterial action of the hops is largely bacteriostatic (meaning it prevents further growth) as opposed to bacteriocidal (meaning it kill the suckers outright). Again, I could be mistaken on this. My references are 40 miles away.

Subject: HSA+Papazian Method/Hunter Airstat/trub separation/dueling  
thermostats

Ken writes:

>I have not heard about the "problems" with HSA and have been using the  
>advice from Papazian's book. Could someone explain why I should use  
>the "Papazian" method or direct me to a source for the information.

Don't you mean "shouln't use the 'Papazian' method?" Well, the best  
source for Hot-Side Aeration (HSA) info, would certainly be George Fix's  
article in a recent Zymurgy (three or four issues ago). If you are using  
a carboy and pouring hot wort through a funnel into the cold water below  
and if the wort is really splashing around as it goes into the carboy,  
then

you probably are getting some HSA. I used to do something like this and  
the result was a sort of sherry-like, wet-cardboard aroma/flavor. If you  
use a plastic bucket as your primary and pour the wort in gently, the  
effects will be barely noticable. I can attest to this because I  
recently

made a few test batches of some "pre-measured kits" I designed for  
beginners  
and gentle pouring into cool water produced virtually none of these off-  
flavors

(I followed the beginner instructions just like I wrote them, just to be  
sure).

I noticed that when I switched from the "hot wort through funnel into  
carboy"

method to "adding 2 gallons of near freezing, sanitized water into  
kettle"

method, there was a big difference. Building an immersion chiller  
improved

my beer even further with respect to eliminating these off-flavor.

Build or borrow an immersion chiller and see if you can taste the  
difference.

I think you will notice a big difference.

\*\*\*\*\*

Also Ken writes:

>After all of this interest in the Hunter Airstat, I am kind of  
interested

>in taking a look at one. Could someone tell me where I can find one?

Too bad all this interest in the Airstat didn't come sooner... it has  
been

discontinued by Hunter due to poor sales. You may still be able to find  
a few at your local hardware store or Builder's Square/Home Base/Handy  
Andy.

Ask for a "window airconditioner thermostat by Hunter Fan Company." Many  
salespeople don't have a clue if you ask for an AirStat.

\*\*\*\*\*

Mark writes:

>i recently got miller's book and was wondering if anyone out there has

>firsthand knowledge of how separating the trub from the wort before

>fermentation improves the beer. how dramatic is the effect? does

anyone

There has been a lot of debate on this issue. Some say that if you use the blowoff method, you don't need to separate the wort from the trub. One reason for pitching before separation from the trub is that the yeast can use some stuff in the trub for nutrition. If you aerate well, the yeast can synthesize the materials they need and thus they don't \*require\* the trub for nutrition (sterols, I believe). You can aerate up till the fermentation begins, but aerating early is best -- why delay?

>also, i've noticed strange behavior sometimes when racking beer regarding my airlock. just after i fill the carboy with beer and put the airlock on, the water starts to get sucked into the fermenter, slowly. i only have one theory on this, to wit:

<snip>

Your theory is correct. The cooling/contraction of the airspace in the fermenter is what sucks in the airlock water. I suggest putting in just enough water in the airlock so it will work both ways (forward and backward). Once fermentation begins you can add a little more so it does not run dry due to evaporation.

Kieran writes:

>The problem with using a fridge and an external thermostat is that you >have two thermostats going at the same time--the fridge's and the Hunter >(or whatever). The fridge thermostat usually will only allow the fridge >to cool to 38 or 40 or so (F), and the Hunter device will try to continue >to cool, but can't. To solve this--remove the internal thermostat--wire >the two wires together and let the Hunter do the job. Just dont try to >run the fridge with out the Hunter--you'll ruin the compressor

I don't think you have to rewire the original thermostat. Recall that both thermostats will say "go, compressor, go" when they think it's too warm. If you set the original to 40F and the Hunter (or whatever) to 50F, the Hunter will tell the compressor to "stop" at 50F and to "go on" at 52F or so. Meanwhile the original thermostat is still saying "it's too warm in here" and will be permanently on. The Hunter only goes down to 40F without modifications. As long as you keep the original thermostat set cooler than the Hunter, you'll be okay.

Subject: trub,censor,...

1 - In New Orleans, I have only seen the Miller Reserve Lager and Light, but have heard you all mention ale. Whine.

2 - Mark Bayer is worrying about fermenting his beer on top of the trub. I brew with extracts and cool the wort in the pot in the sink full of ice water (takes about 30 minutes), then pull the cool wort off the settled hop pellet, cold/hot break debris. Even so, I get over 1/4" of trub in the carboy after the initial settling. I fermented my second batch on the trub for over a week, racked to a secondary for another week or so, and it came out great.

I pulled the third batch into a bottling bucket and let it settle for 45 minutes before siphoning into the carboy. I got less trub, but the beer was not as good. I haven't settled first again.

I use (chlorinated) tap water in the air lock, and it has never been sucked in and I haven't had infections.

3 - Lee M.: what about 'manual "HOLD"'?

4 - Bob A.: He said he would try the keg, not the extract.

>I also do about a case a year in which I bottle with  
honey - about a third of a cup for a champagne bottle.  
That gives it a nice apple "mead" flavor.

\* I wouldn't exactly call that a mead. A mead implies FERMENTED honey  
with possibly...other stuff. There is a "product" which tm's the name  
MEADE (tm!) that's actually wine, with honey added at bottling.

\*\*\*

Someone else said:

> Mead is simply a wine that uses honey instead of "fruit". I have been  
quite successful brewing straight mead (honey and water with a champaign  
yeast), spiced mead (called methygen sp(?)),

\* There are a number of types/styles of mead. The common component  
is HONEY.

Traditional Mead: Honey/water= ~2.5 # /gal  
Sack Mead: 20-25 % more honey than traditnl.  
Metheglin: Spiced with Gruit. (herbs, and or hops mixed)  
Sack Metheglin: Combine above 2  
Pyment-Claree: Grapes added.  
Hippocras: Pyment with spices.  
Cyser: Apples/cider added.  
Muslum, or Melomel: Fruit added. Numerous variations  
(other than grape and apple)  
Morat: Honey water and mulberries. (This ones a winner with me!)  
Mead Brandy: Oh...but that's distilling. \*\*

/--/

Braggot: Honey and malt. 1:1

There are other honey/beer/+ drinks listed in Acton's book.

A couple good-ish books:

Making Mead: Acton and Duncan  
Brewing Mead: Charlie Pap. (would be better titles- "History of Mead  
Brewing with just a little bit about actually brewing it")  
AHA Winners Circle has a chapter or recipes on mead.

\*\*\*\*\*

Lee posted some Hunter info:

>Some may find the following words offensive:  
Chest, down, desire, unit, mount, do.

\* I'll have you note please, there are NO three letter words in that  
list!

\*\*\*\*\*

js sez:

it is

not very bacteriocidal.

\* There's a difference between the leaf/flower surface of a plant and a solution made from extracting the inhibitory components of the lupulin glands. If you tested just the surface of the lupulin gland it might have no microbes, while the leaves had many.

Also: The distinction between "existing" and "replicating". Many bacteria and fungi can "sit" in a dormant state, then proliferate when conditions become more favorable.

I remember this thread starting with whether hands would transfer contaminants TO hops, and hence, into beer.

Again- the difference between existence, and replication. There are resident (generally unharmed) and transient (potentially harmful) microorganisms on hands and skin. But if your hands are clean the chance of transferring danger to brew is low (IMHO). Resident microbes generally do not let go very easily. If you wash well, you should remove most transient bacteria, and unless you have chicken fat under your nails you aren't likely to add much to your brew.

I would wager that commercial hops have been handled fairly frequently before they are broken down to homebrewer size packets. The hope of not adding more microbes at dry hopping time seems irrelevant. The hope of having created an inhospitable environment for other bugs is more realistic.

From: bliss@pixel.convex.com (Brian Bliss)  
Subject: Golden Syrup

Bruce Buck asks:

>Is golden syrup one of those things like Treacle which is unknown in the USA?

>Or is it what Americans call corn syrup?

Lyle & Tate are English sugar confectioners, and make both black Treacle and golden syrup. We can get Lyle's golden syrup here in Dallas. It is a cane sugar product, not corn sugar. as a substitute, I would recommend turbinado style (raw) sugar, which is not refined as much as white sugar, and does not have molasses added back like American brown sugar does. I used to get 2 lbs of turbinado sugar at the snuck's grocery store in Champaign, IL. A 12 oz bottle of golden Syrup is \$5 here in Dallas. They add about the same taste. Guess which one I (would) prefer...

>answer. To get the full answer, we must first find out exactly  
>what Treacle is.

>Once and for all, Treacle is simply blackstrap molasses. You can  
>get this in many places in the U.S.

Golden Syrup is a light golden sugar syrup, made by Tate & Lyle. Has a  
very  
smooth taste. You could probably make your own by \*slightly\* by  
dissolving cane  
sugar in a little water to make a syrup, and then carmelizing ever so  
slightly  
to get some color. My wife uses T&L Golden Syrup in her peanut brittle  
recipe  
instead of corn syrup.

Yes, you can find Treacle (also made by Tate & Lyle) in the US, but it  
may be  
scarce. I asked a grocery store to get some for me and they did, no  
problem.  
They still have a few cans. It also available in better HB shops, along  
with  
Golden Syrup. GW Kent used to supply it, but no more I've been told.  
And, no,  
I won't buy it and ship to anyone, I'm buying it for myself.

Treacle is most definitely \*not\* "simply blackstrap molasses". Anyone  
who  
has tasted Treacle and BS molasses side by side can easily tell the  
difference.  
Treacle is very smooth and not at all harsh tasting like any of the BS  
Molasses I've tried.

And, for Paul Hethmon, if a HB shop employee didn't even know what  
Treacle was,  
I'd find a different shop.

While this procedure >is not correct - chilling in a bathtub or with a wort chiller prior to >pouring is recommended, the amount of damage that could be expected due >to hot side aeration is so slight that it is unlikely to be noticeable.

I gotta disagree with your last statement. I hadn't done a brew without benefit of a chiller in a zillion years, but customers bring bottles of their beer to the local HB shop where I help out. I've tasted plenty of HB from beginning brewers who do the CP "partial boil and dump into cold water" immediately method, and the oxidation is definitely noticeable. So, some time ago, I tried it both ways - chilling pot in sink of ice water vs immediately pouring hot wort into cold water - in a split batch experiment (same yeast, same fermentation conditions, etc). The "hot pour" half had a \*noticeable\* oxidized flavor not present in the chilled-then-poured half. I teach beginning HB classes for the local parks dept, and for the above-mentioned shop, so I emphasize at least chilling wort in a sink of ice water, if they don't want to buy or make a chiller of some sort. Yeah, the "hot pour" batch was drinkable, but the other was much better, and chilling in a sink of ice water is so easy, and doesn't take all that long.

CP's book is great, esp for new brewers, but I'm disappointed he didn't update things more in the NCJOHB, considering all that's been learned since the first edition was published.

And lastly, all you keggers who can't seem to get your beer to dispense correctly, may I suggest that you get a copy of the transcript from the 1992 AHA convention in Milwaukee. Dave Miller gave a bang-up presentation on dispensing of kegged beer. As Tom Leith' post in #1274 pointed out, one must balance the keg pressure and the resistance in the tap line to get a proper pour. Line diameter, material, and length all come into play, along with the height the beer is lifted from the keg to the faucet.

-- PSE

Any chiller is better than no chiller!

From: EKELLY@admin.stmarys.ca

**Subject: sanitizing bottle washers**

Sorry for the encoded version on November 17. Here is the english version.

Does anyone know how to sanitize/sterilize a bottle washer. I am referring to the brass device that attaches to a faucet and releases a high pressure jet of water into a bottle (or carboy). This device has a small ball inside the end piece which acts as a valve to shut off the jet of water when the bottle is removed. It appears this ball prevents the residual water from draining from the device after its use. This water seems to be the source of contamination in a couple of my batches. I am not sure if merely running water through will flush the contamination. I have tried injecting bleach into the device followed by an overnight soak which resulted in the device turning a shade of green.

Any advice or assistance will be appreciated.

From: "TIMOTHY LABERGE" <LABERGET@gar.union.edu>  
Subject: hard water treatment

Hi All,

I've just received an analysis of my tap water.

Here are the important numbers:

Chloride 25ppm

Sulfate 38ppm

Calcium 54.5ppm

CaCO<sub>3</sub> 140ppm

Ph 7.7

The CaCO<sub>3</sub> seems high, particularly with the amount of calcium that is present. What is my best course of action, other than brewing only dark beers? E-mail replies are fine.

Tim LaBerge

No fancy sig, just good beer.

> adjustment?  
>

Good question. It all depends on your brewing style, equipment, style of  
beer to produce, and malt choice (simple, eh...?). Many lager brewers  
insist  
on a protein rest, certainly weizens need a protein rest. Many ale  
brewers  
do a single or two step mash, myself included. With Pale Ale malt, there  
is not much need for a step mash, and I use the \*shudder\* Briess 2 row  
malt,  
one of the \*low\* quality malts (as do Sam Adams, Dominion Brewery, and  
countless other "quality brewers"). I used to go for the upward step  
mash,  
but after noting that Dominion Ale is made from a single infusion, and  
some  
California micro mashes all of 5 minutes at 155 prior to lautering.....I  
changed my basic ale mash. One of the problems of using Briess is it  
will  
convert real fast, sometimes leaving the beer too thin, too low FG. To  
combat this, I have been using more Munich malt (deWulf) to boost the  
body  
and flavor. I also have tried mashing at 158F , and this has worked  
well,  
esp when I am making high gravity brews, and diluting them in the kettle  
and/or fermenter. One of the major benefits of doughing in at a lower  
temp  
is the acidulation of the mash can occur, prior to saccharification. I  
just use some Gypsum, and mash at 15X F for 60 min, then raise to 170.  
Works  
for me.

Good brewing,  
Jim Busch

From: phil.brushaber@lunatic.com (Phil Brushaber)  
Subject: Filtering

I agree with Jim Busch that filtering can really help your brew. I would make a couple of observations: 1) Make sure your beer is about as mature as you want it before filtering. IMHO the beer does not age much after it has had the yeast removed. 2) Filtering DOES seem to remove some of the "body" of the beer. As a result, while I tend to filter my light colored brews, I do not filter the dark ones.

As part of the message Jim suggests:

>Since I was filtering two quite different beers, I back flushed the filter  
>between beer types, and tons of yeast came out. I still think that a  
>5 micron filter is perfectly adequate for removing excess yeast.

Jim... How do you back flush the filter? Normally, between batches I first run some water through it, then some Idophor, then water again, and the start filtering again.

... Homeless... will work for beer!

From: gelinas@ekman.unh.edu (Russell Gelinas)  
Subject: batch sparge, astringency

It is known that high temperature is a good way to extract tannins from grain. It is also known that low pH inhibits that extraction. The latter is the reason decoction mashing does not cause excess tannin extraction.

Some (myself included) advocate using boiling water for sparging. This works well, but as the pH of the mash increases as the wort is run off (water has a higher pH than the mash), the amount of tannins extracted will also increase. One solution would be to use boiling water for the beginning of the sparge, and "cooler" (whatever that may be) water as the sparge progresses. Another solution would be to batch sparge, adding the boiling water all at once. As has been noted, sugar extract efficiency will suffer slightly with a batch sparge, but tannin extraction would likewise be minimized.

Subject: Aluminum Brewpot

With all this talk about chips in enamel pots I have a question. I have been brewing about a year, maybe 6 batches, all extract, some with specialty grains, etc. All batches have been pretty good, but nothing stellar (YET!). Lower cost and ease of use are important factors for me.

Anyway, I have been using a 22 qt Aluminum brewpot (Al. is much cheaper, especially for pots this size.) Is this really a major problem for the quality of my beer? Or is a stainless steel pot more like the "charismatic wooden spoon" thing? If Aluminum IS a real problem, why? Please remember that I am still a beginner, and subtle advantages to my beer will be lost among all the other mistakes I've been making! Any help of this would be greatly appreciated! Thanks.

From: oswald@columbia.sparta.com (Don Oswald)  
Subject: No-Hop Beer/Primus-Secundus-Tercius

For the person who was looking into brewing in a part  
of the world where hopps are not avialable (in hbd 9 nov):

Before the hop became a popular addition to beer, (12th  
century in England?-- I don't hve my books here) there  
were several other things which were added to beer to  
improve its storage life. The only one I have tried is  
spruce - about 8 oz of new growth for 60 minutes of boil  
- leaves the malt sweetest and adds almost a "cola" like  
flavor. Some early American Beers also used spruce.

Primus-Secundus-Tercius: An early brewing technique had  
several batches of beer made off of the same set of grains.  
The descriptions I have found make it sound like a simple  
infusion mash with no sparging, repeated to make several  
batches of decreasing strength. The recipes I have found  
make one 80 gallon batch of each of the "three threads"  
and use bushels of grain. Has anyone tried these methods  
at a scale closer to reasonable?

From: Brett Baumberger <bsb@hpuerca.atl.hp.com>  
Subject: Re: Flying Homebrew

Hello Fellow Brewers,

I have been successful taking homebrew on airplanes by simply checking the box as baggage. I used boxes acquired via a beer-of-the month club. There wasn't any breakage, but I did wrap the inner contents of the box in a couple of trash bags in case the worst happened. I did not mark the box fragile or put any other writing on the box that would cause undue attention. No questions were asked of me about the contents of the box. The friends I visited had never tasted homebrew before, and they were quite impressed.

From: bliss@pixel.convex.com (Brian Bliss)  
Subject: flying homebrew

I never fly without a bottle, homebrew or otherwise.

They've let me on the plane with homebrew, though usually I just take a couple of bottle of imports. The only time security has ever even looked closer was when I had a flask full of potent Gin and tonic. The guard just took a whiff to make sure it wasn't gasoline or something. Hell, it could have been everclear! Once a flight attendant said I wasn't supposed to drink on the plane, so just keep it low. Security guards who do not know what is in the bottle do have a point, though, so be prepared to check it, chuck it, or chug it.  
(the 3 - C's)

The only thing that I have been stopped for, beleive it or not, was for a set of darts (steel tipped). It was in Phoenix, I had already carried them on a flight, and they wouldn't let me go to a different terminal where I was supposed to meet someone, and all the lockers were in the security areas.

"Hello captain. I'm sorry, this flight IS going to Cuba. if you don't fly there voulutarily, I'll have to  
a) throw this dart at you.  
b) make you drink homebrew until you pass out."

From: chuck.wettergreen@aquila.com (Chuck Wettergreen)  
Subject: Golden Syrup

In HBD beb@pt.com (Bruce Buck) asked:

BB> In "Brewing Beers Like Those You Buy", Dave Line gives a recipe  
> for "Bishop's Tipple", a real ale. The recipe asks for "1 lb  
> Golden Syrup". Is Golden Syrup one of those things like Treacle  
> which is unknown in the USA? Or is it what Americans call Corn  
> Syrup?

I *\*believe\** that Golden Syrup is nothing more than invert sugar. I came to this conclusion after looking, tasting, and reading the ingredients. It looked and tasted just like the invert sugar that I *\*used\** to used as an alcohol booster in my younger make-it-as-strong-as-you-can college-brewing days.

Invert sugar can be made by adding four pounds of cane/beet (white) sugar to two pints of water and 2 teaspoons of citric acid. Heat until it comes to a boil. Watch it, the boilover of this stuff makes a wort boilover look like nothing. Continue with a low boil for one hour. Allow to cool, dilute to one gallon.

From: npyle@n33.stortek.com

Subject: Hops FAQ/Barley Wine/Immersion Chiller/HSA/Anti-Bacterial?

Patrick Weix of Yeast FAQ fame has done me (and all of us) a big favor and archived away the Hops FAQ to the stanford archive site. It is a new revision from the one seen here on HBD; there is a little bit of new information, and some minor corrections. Try the r.c.b FAQ for instructions on accessing it.

Thanks, Patrick!

\*\*

Brian Seay asks about barley wine fermentation. I have one in the secondary that is progressing (slowly) and I've learned a bit from it that I can pass on:  
PITCH LARGE NUMBERS OF YEASTIES!!! AERATE!!! This is especially important for high gravity beers. I think if you do this, you can use a good attenuative ale yeast and it will work fine. DON'T USE WYEAST LONDON ALE YEAST (1028)!!!  
I'd recommend the Wyeast American Ale yeast (1056) and a large pitching volume (maybe 1/2 gallon) of active starter. If this doesn't get to the FG you want, you can always repitch a wine or champagne yeast later (I did). My Old Lucifer is down to 1.029 after pitching a wine yeast a couple of weeks ago (it has been fermenting since Sep. 18) and is (finally!) starting to get kinda nice..

.

\*\*

William Swetnam asks some questions about building an immersion chiller:  
>1. What are the recommendations on size of the copper tubing, 1/4 3/8 or 1/2 inch. A quick stop by my local hardware store raised the question of fittings, I'm wondering more about what may be the most efficient for heat transfer.

I recommend 1/4" or 3/8" tubing. Whatever fittings work are the ones you need.

>2. Some commercial wort chillers that I have seen do not put the water through an ice bath first. Is there a problem in chilling the wort too fast?

No problem chilling too fast. My water is sooo cold that an ice bath is definitely overkill. Its just a question of whether you want to use more water or electricity for your cooling. I haven't compared the \$\$ costs.

>3. I'm planning on using 25' of tubing in my immersion section, is this too much, too little?

Just right (of course, you'll get a hundred opinions on this; you could do a bunch of physics and math to come up with some perfect answer...).

\*\*

Ken Theriault writes:

>I have not heard about the "problems" with HSA and have been using the advice from Papazian's book. Could someone explain why I should use the "Papazian" method or direct me to a source for the information.

Check out George Fix's article in the Zymurgy Winter 1992 issue...

Jack writes:

> I think what I learned is that the anti-bacterial characteristics of hops are either a myth or greatly exaggerated in the brewing folklore. Clearly, if yeasts and bacteria live on the hops and can inoculate a culture dish, it is not very bacteriocidal.

It may be iso-alpha acids (from the boil) which are anti-bacterial, or alcohol (we know this), or by-products of the (unknown, at least to me) dry-hops/wort reactions.

> It would have been interesting if there was a control using a handful of grass clippings or leaves to find out if it was the nature of the fermented beer or the hops that prevented contamination.

I agree.

thutt> No, you cannot buy treacle in the U.S., but that  
thutt> is not the full answer. To get the full answer, we

Up until recently, (two or three weeks ago) I was able to buy small cans of treacle and golden syrup from my local brewshop. When I last tried to purchase it, I was told that there was some sort of embargo on.

thutt> must first find out exactly what Treacle is. Once and  
thutt> for all, Treacle is simply blackstrap molasses. You  
thutt> can get this in many places in the U.S.

I have been unable to find any other commercial product which approaches the rich flavor of the treacle I was purchasing. It may simply be a quality issue, but that's enough difference for me. A more accurate statement would be "If unable to find treacle, commercially available molasses is an acceptable substitute"

Subject: cold chillin'

More tidbits--so much info to um, digest...

\* >Also, I considered the crabtree effect a good reason to abandon corn  
\* >sugar, but of course there are other good reasons to stick with it.  
\* >One must balance everything. Some people are quite happy carbonating  
with  
\* >sterile wort or kraeusen, and for lager there is no topping the latter  
\* >method (IMHO). Even Anheuser-Busch do it!!  
\*  
\* Did I slam Carl for abandoning corn sugar? No, I just posted what I  
did  
\* and some of my reasoning. Frankly, IMHO, your opinions don't sound so  
\* humble.  
\*

Now, play nicely, first of all.

Second of all, Papazian seems to poo poo the use of corn sugar, and I've  
certainly tasted the results of using too much (assuming that's what made  
it

so cidery), but he (Pap) does allow for reasonable use below 30% of all  
fermentable sugars. --Sidequestion-- in priming our bottle of IPA last  
night,

we used a mix of corn sugar (1/4 cup), LME (3/4#) and honey (2 tbsp) for  
a

five gallon. When trying to figure out total fermentable sugars, how on  
EARTH

does one reconcile the different units of measure, or at least compute  
the

total amount of ferm. sugars??

It (sugar) certainly does the job of giving one good carb and boosting  
pot.

alcohol, and it's cheaper than dumping additional extract for priming,  
but

you can overdo it. I suspect it's just another one of those things up for  
reasonable debate, EXCEPT: you are not making a Rheinheitsgebot beer when  
you

use corn sugar, for what that's worth to you.

\* Has anyone else had any good or bad experiences carrying homebrew onto  
a  
\* plane? Or, for that matter, checking homebrew in their luggage?  
\*

Some kind gent in the aviation industry has noted that pressurization  
extends

to the cargo bays for structural reasons, so you should be safe either  
way

you want to pack it.

\* In my last posting in 1271 I mentioned the recommendation in Papazian  
to

\* pour the hot wort in cold water in a carboy as being bad advice and  
\* received a number of worried responses, to some of whom email responses  
\* bounced. I'll quote Charlie himself, RDWHAHB. While this procedure  
\* is not correct - chilling in a bathtub or with a wort chiller prior to  
\* pouring is recommended, the amount of damage that could be expected due  
\* to hot side aeration is so slight that it is unlikely to be noticeable.

\*

---

While bottling that IPA I spoke of earlier, we began our first lagering attempt, having gotten a fridge to run at temps below 60. Anyway, we did what the fella above recommended--bringing the boilpot directly from stove to tub full of water and blue ice (this will save some money on ice for sure). After about 15 minutes it went to fermenter with 3 gal cold water (I know, I know, soon we'll go buy a pot that will allow for full volume boils) and was immediately pitching-ready. I would say for maximum compromise between full volume boil and the advantage of having the cold water help cool the wort, maybe a 4 gal - 1 gal makes good sense. It's primitive, but for us nontinkerers who are too poor to buy and too stupid to build a cf or immersion chiller, it works quite well and goes faster than we imagined.

And finally, my perception of the heinousness of Papazian's wort-into-water error was not that you risk HSA but having your carboy crack and break from the temperature change.

Peace all, from the city where Clear Beer was testmarketed and unfortunately received rave reviews.

\* Second question. I have seen some plastic "kegs" in local home-brew shop which come from Europe. Supposedly, they can be used to carbonate in and draft beer from. Has anyone tried these? They seem like only a glorified beer ball.  
\*

Oh yeah, this makes me think of the Beer Machine question. I think the guy who recommended buying one was thinking of its utility as a dispenser only. If anyone tries it let us know how it works for you. Yeah, I couldn't imagine drinking a Ronco-beer and having it taste good.

From: arf@mcs.com (Jack Schmidling)  
Subject: Astringency

>From: GANDE@slims.attmail.com

>Further to this one could assume that it would be OK to sparge with boiling water, which is accurate as long as your grain bed pH doesn't raise above 5.3, ideally. In the real world, sparging raises mash pH towards the end of the run and continuing to rinse with boiling water would leach out tannins.

That's a nice number but like so many things, it is only a bench mark.  
What

if the pH rose to 5.4 or 5.7... would it make a detectable difference? I doubt it.

>I made a mini-grain-tea-bag, boiled it for 10 minutes in tap water (pH 7.0) and it was what I would call astringent. That's enough proof for me. ;)

All that says is that boiling tap water with a pH of 7.0 will make astringent tea. As you did not convert the starch into sugar, the astringency could just be the way malt tea tastes without the sweetening effect of conversion.

In the real world, sparge water is run through the mash which has a powerful buffering effect on the water. I run 10 or more gallons of pH 7 sparge water through my mash and it doesn't raise the pH more than a tenth point or so. Furthermore, sparge water temp is not the same as mash temp nor does it bear any relationship to making tea with boiling water.

Finally, it does not address the fact that boiling grain in decoction mashing does not seem to produce astringent beer.

Subject: beer label software

>Dion asked about inexpensive software for designing beer labels

I have used Microsoft "Publisher" with satisfaction. It allows you to curve text instantly and import various bit-mapped images. Its price is around the \$100 range or lower, so it should meet the criteria of "inexpensive". I never got a chance to use it in great length but I was able to make a "Master" label, I would then go in and change the name of the particular brew, I would then have the original artwork copied at the printer and I changed ink colors with the various brews. Thus keeping things simple, yet each brew had its own look.

I am no longer working where they had the software on the network--so I'm forced to learn Coral Draw and triple my learning curve, but my labels will improve proportionally with their custom "look." Hope this helps, rob

Subject: hands across the border

The following appeared in #1274 as a uuencoded WordPerfect 5.1 document.  
Clear text follows.

Carl

\*\*\*\*\*

Does anyone know how to sanitize/sterilize a bottle washer. I am referring to the brass device that attaches to a faucet and releases a high pressure jet of water into a bottle (or carboy). This device has a small ball inside the end piece which acts as a valve to shut off the jet of water when the bottle is removed. It appears this ball prevents the residual water from draining from the device after its use. This water seems to be the source of contamination in a couple of my batches. I am not sure if merely running water through will flush the contamination. I have tried injecting bleach into the device followed by an overnight soak which resulted in the device turning a shade of green.

Any advice or assistance will be appreciated.

I have seen a huge improvement in flavor stability and beer quality since  
I  
started chilling the concentrated wort. Have you tried it both ways,  
Ulick?

For the record, I first heard about HSA in this digest with no  
explanation.  
I stumbled across the source of the information when a friend who  
(regrettably) had to give up brewing gave me some back issues of Zymurgy.  
There is an article by George Fix on the topic in the Winter 1992 issue.

An earlier rendition of this post seems to have vanished in transit. If  
it  
resurfaces, apologies for the redundancy.

I have used Lyle's Golden Syrup and it has a pleasant mild caramel-like quality. Actually I thought its flavor was similar to rock candy.

You *\*can\** get Lyle's Black Treacle and Golden Syrup in a well stocked homebrew shop. My homebrew shop in Indy carries these as well as the imported Demararra sugar.

From: Lee=A.=Menegoni@nectech.com  
Subject: Making Hard Cider

Many members of our club make "New England Barrel Cider"

To do we get fresh cider from a local orchard.  
Some add sugar , brown or white, to enhance the cidery flavor.  
We then pour it in a carboy and let the natural yeast ferment it.  
After vigorous fermentation has subsided it is racked in to a  
second carboy to settle. Raisins or other dried but unpreserved fruit  
may be added at this time as well as spices.  
Let it settle until spring, then bottle.

**Subject: Sour Noonan**

Interesting to note Greg Noonan's article in the special issue of Zymurgy. Noonan is now touting sour mashes as the secret ingredient in Bavarian weizens and Bohemian pilsners -- in spite of a complete lack of evidence that they are used at all in those areas. (The acid rest he mentions is a matter of a few hours or less, not days.)

Funny. In his book on lager beers, Noonan insisted that one couldn't have a real European lager taste without a decoction mash (in spite of the fact that a good many German breweries were doing infusions). Now it's sour mashes. Wonder what's the next big "secret".

In HBD #1270, Phil Gillman writes:

> I was wondering if pressure differences and retention are the reason  
> that there is a difference in the taste between commercial beers with

> twist tops and those with opener only tops. any one have another  
> explanantion or support for this one?

Well Phil, I can't say that \*I\* have noticed a difference in the taste of

beers based solely on how they are capped. Maybe my discerning palate has not yet developed that far(I'm still a rookie homebrewer). But your question \*does\* raise another one in my mind, something I've noticed recently among the craft-brew community.

Lately, many brewers have seemingly abandoned the "opener only" capping

method in deference to the "twist off" configuration. Most recent additions to the list of Twist Offers include Pete's Wicked, Sierra Nevada & Geary's.

My question is...WHY? Are these guys worried that we'll get out to the picnic ground before we realize we've forgotten our bottle opener?? Or are they worried we homebrewers will hoard their bottles for our own selfish purposes? Or is it possibly cheaper?

Maybe it's just me, but I'm perceiving a trend toward the commercialism once pioneered by Augie Busch, Adolph Coors, and all the other nationals who were trying to get a leg up on their competition. With the recent advertising brew-ha-ha at BBC, and now this, I'm worried that we may be coming to the beginning of the end. What will be next, rice in place of malt??

All shared thoughts on this subject, either direct or posted here, will be appreciated.

From: wood@ranger.rtsg.mot.com (Dan Wood)  
Subject: Dry Hopping and Infections

I'm confused. Nothing new, but maybe you can help. I realize that I could have sent this directly to the "Lighthouse of Wisdom and Truth", but figured someone else might have an opinion.

Anyway, it's pretty clear that the greatest risk of infection is before fermentation. No confusion there. Presumably the bacteria produce bad flavors, then are overwhelmed by the yeast, PH, and/or alcohol. Right?

However, the recent dry hop & bacteria thread has made me wonder about post-ferment. Some HBD articles have indicated that once fermentation is complete, the beer is hostile to bacteria, so no worries.

On the other hand, I've read several times that "gushers" are caused by infections. The idea there is that the bacteria eat stuff that the yeast don't, resulting in over carbonation during long term storage.

So, which way is it?

The dry hopping thread sparked my interest, because the only time I've had a problem with gushers was when I dry hopped. Two different batches, plus one of a friends all shared this problem. We both abandoned the process after these disasters, but I'll try again if someone can shed some light here. Thanks alot.

PS: Jack, when you going to run some experiments with fermenting on the hot and cold break material? The momily-busters fan club is getting impatient.

Regards, Dan Wood wood@rtsg.mot.com

From: Kieran O'Connor <koconnor@mailbox.syr.edu>  
Subject: Beer Analysis

In the latest issue of Breweing Techniques I saw something interesting: a firm which will do beer analysis. I called and here's the poop:

This place will do an analysis of your beer (or any beer for that matter) for \$24. here's what they do: IBU's, Color (SRM), PH, Titratable Acidity, Alcohol, Apparent Extract, Apparent degree of fermentation and original extract. Apparently it costs the same to do one as it does the others so it \$24 for the whole deal

They will ask you how many IBU's you intended in your brew--and you will be able to calculate your hop utilization--something which seems to me to be worthwhile.

The price is a bit steep--but a club could do this for education--or even for contest winning beers.

They promise one week turnaround:

After responding to this privately I realized that the only reason that I knew the original source of information on HSA is that I found it by accident in a friend's back issue of Zymurgy. So, for the curious, get a copy of the Winter 1992 edition and read George Fix's article. Then read the following article, which is related (sorry, forget the authors names and the magazine is 25 miles away).

Wrong. It is possible to buy treacle in the U.S. as it is a stocked item at my local homebrew store. I don't know when/where the proprietor aquired the stuff, but he does have both the treacle and the mysterious Golden Syrup called for in the recipes (from Dave Line's book?). I don't know if he could replace it if someone bought it, but it is currently available for sale in at least one location in the U.S.

Obviously it is not commonly available in the U.S. but that isn't what you said.

>before the krausen begins.

It makes sense, but it's not the way that yeast actually works. Just  
"before  
the krausen begins" the yeast have their glycogen level depleted.  
According  
to experiments done by Pickerell, Hwang & Axcell (and reported in their  
paper: Impact of Yeast-Handling Procedures on Beer Flavor Development  
During  
Fermentation, 1991 American Society of Brewing Chemists, ASBC Journal,  
volume 49, no.2.) you want to wait till the high krausen has just ended  
to pitch your starter. I have more info on this for anyone who is  
interested.

From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)  
Subject: The Crabtree Effect

Miller's book and previous discussions in the HBD on the Crabtree effect imply that the effect occurs when ONLY dextrose is available for fermentation. But, my recent perusing of Malting and Brewing Science (by Hought et al.) leads me to believe that the effect occurs when dextrose is in a high concentration, and is not related to dextrose being the exclusive fermentable available for the yeast. Thus, priming with 3/4 cup of corn sugar, which adds a relatively low concentration of dextrose to a five gallon batch, may not induce the Crabtree effect. I'm not sure of the percent dextrose in the average beer wort, but it is probably near 10%; if this is correct, then the average beer wort has a higher concentration of dextrose than does a fermented out beer that is primed with dextrose. If this reasoning is correct then the Crabtree effect is more likely to occur in the average wort than in dextrose primed beer.

Any comments? Perhaps we really don't need to be concerned with the Crabtree effect when priming with corn sugar. This would be supported by the common knowledge that dextrose primed beers do not appear to exhibit more oxidation characteristics than beers that are krausened or primed with fresh wort.

From: nathan@monolith.bellcore.com (Nathan Justus)  
Subject: Golden Syrup

In response to HBD #1273 - what is Golden Syrup? Well, true Golden Syrup is cane sugar syrup. I would imagine that corn syrup could substitute, however you might look for GS...my local A&P stocks it occasionally, and stores like William Sonoma (if you don't have them in your area, they're kind of yuppie cooking stores).

GS, since all that I've ever seen is imported from the UK, is quite expensive - expect about US\$3.00 for a 1 pound jar/can (I've seen it in a tin or in a jar).

It is possible that the hop flowers alone are not acidic enough to  
inhibit  
the bacteria. I would speculate that the preservative effect of hops  
comes from the alpha acids extracted during the boil, and the increase in  
acidity. You don't hear of the preservative qualities of hop aroma  
although you do hear of the preservative qualities of hop bitterness.

From: Alan B. Carlson <alanc@adb.gu.se>  
Subject: Xmas beer tasting (part 1)

I tried sending this yesterday, but I guess it was too long... so,  
I'll try again splitting it into two parts.

I just read a Swedish review of the christmas and winter ales that will be available here in Sweden this winter. Most of them are from Scandinavian breweries (and probably unavailable internationally) and some of them are not what one would commonly find in this class, but this might be interesting to people anyway. The test was staged by the Swedish daily called "Svenska Dagbladet" and appeared Wednesday, November 17th 1993. The panel, which was composed of "both experts and amateurs on the subject of beer" was led by someone by the name of Eric Kaellgren. No other indication was given as to their beer-tasting credentials. They blindtasted 16 different beers and rated them on a scale of 1 to 5 where 1 implied "poor" and 5 implied "excellent". All beers were bottled beers with the exception of Guinness Draught (can) and all were 33 centiliters in volume with the exception of Pripps Julioel which was 50 centiliters.

I did the best I could with the translations of the comments. Prices are in Swedish crowns (a crown is presently worth about 12.2 US cents). Most of these beers will not be available to the general public for another week or so, so I haven't tasted the majority of them myself. I hope the panel is wrong about Anchor's Xmas ale (according to the article it was the only beer which got a score of 1 from everyone on the panel), since I really enjoyed last year's version.

From: Greg D Blankenship <gdblank@magnum.acs.ohio-state.edu>  
Subject: help needed carbonating lagers

My first lager (Vienna) is about ready to be bottled and I am wondering if I am going to have any problems carbonating it because of the temperatures that I fermented at. The primary fermentation was done at 46 degrees F for 10 days, then I racked into the secondary and dropped the temperature to 33 degrees F. It will have been in the secondary 21 days next wednesday. Since I do not have a keggling system (yet) that I could force carbonate with I am going to have to bottle it. Now my questions

- 1) Will using the standard 3/4 cup of corn sugar be enough to carbonate it?
- 2) Will there be enough yeast left in the beer after the cold lagering period?
- 3) If not is it possible to add more yeast before bottling without creating problems?
- 4) Should I continue cold aging the beer after I bottle it or will this inhibit carbonation?

BTW I have a Penn thermostat from Willam's Brewing that works great. It has a temp control range of 20 F. to 80 F. and is very simple to use.

Thanks,

greg

Probably nothing.

I had exactly the same experience with Glenbrew Czech Pilsner. In retrospect, the fact that the beer was slightly carbonated at bottling should have tipped me off. The taste was good, though. Very good, in fact. It certainly did not taste infected.

I cooled the entire batch to just above freezing and opened it carefully. That reduced the gushing to more of an oozing. I let it stand for about 20 minutes, filled up the space in each bottle, and re-capped them.

This worked great. Unfortunately, a few weeks after that, the few remaining bottles were back to gushing again.

My guess is that the enzyme is responsible. I don't know what is in it, but I conjecture that it keeps breaking up the higher sugars very slowly, over a period of weeks and months, so that the yeast keeps finding new food.

Subject: hops address

Somewhere on HBD, I got "May Nursery, Box 1312, Yakima, WA" as a source for hop plants. However, I just got my letter to them returned by the USPO as undeliverable.

Does anyone have an accurate address for May Nursery? or another source for hop plants (note that I'm wanting "plants" rather than seeds).

Thanks,  
Ron Dwelle (dweller@gvsu.edu at Internet)

From: Drew Lynch <drew@chronologic.com>  
Subject: Invert Sugar

In yesterday's (I hope) HBD, Chuck Wettergreen posted a method for making invert sugar. Has anyone used this stuff as a priming agent? I was curious if the breaking down of the sugars would inhibit the oxygen generating crabtree effect. I don't like using most of the malt based priming agents, as the percentage of fermentables is unreliable, and produces inconsistant carbonation, however, I hesitate to revert to corn sugar due the the potential for oxidization of the bottled product.

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Re: Fruit Beer

You'll find there are almost as many ways to make fruit beers as there are brewers who have made them, but here are some guidelines that have worked very successfully for me.

- \* Use a light beer for a base. I often use a wheat beer base (50/50 barley/wheat), since I think the slight fruitiness of the wheat complements the fruit well. This is not a must -- I made a very tasty blueberry brown ale once; the recipe is in the Cat's Meow II -- but the lighter beer helps to really show off the fruit.
- \* If you use fresh fruit, use LOTS, typically around 1 lb/gallon or even more. My last batch of cherry ale was 9 lbs cherries for 6 gallons of beer. I can't say much about using juice or extracts.
- \* Add fruit to the secondary, after a week or so of primary fermentation, to avoid losing precious aromatics due to CO2 scrubbing.
- \* My general technique is as follows:
  1. Brew your base beer as usual, let primary ferment complete (a week or so).
  2. Remove any visibly damaged fruit (moldy, broken skin, etc) and puree. Add fruit to your secondary vessel, then rack the beer on top of it. The only sanitizing I do of the fruit is a quick sulfite rinse before pureeing.
  3. Allow to ferment again to completion. If the fruit contains a lot of sugar, this can result in some of the most spectacular fermentation you've ever seen!
  4. Rack off of fruit again, using a copper scrubber and/or hop bag over the end of your racking tube to keep things from clogging. It will probably clog anyway. It's a pain. Anyone have a better method? Anyway, the second racking is to a) Allow any remaining fruit bits to settle out, and b) to ensure any residual fruit sugar is completely fermented.
  5. After 2-3 days in the tertiary, bottle as usual.

Regarding Lindemanns and Liefmans, the Liefmans Kriek is based on their brown ale, so it's not a true lambic. Lindemanns is a true lambic, but IMHO it's very much on the sweet side. For a taste of what lambics are really like, try to find a Cantillon or a Frank Boon. Or better yet, visit Brussels!

the  
>boiling water all at once. As has been noted, sugar extract efficiency  
>will suffer slightly with a batch sparge, but tannin extraction would  
>likewise be minimized.

A third solution would be to acidify your sparge water. This can be done  
using Gypsum (which may not be a good idea if your water already has a  
lot of sulfates or if you are brewing something that requires soft water  
like a Czech Pilsner) or organic acids such as Lactic. My personal  
choice  
is the organic acid method AND using 170F sparge water (I've tasted some  
NON-astringent beers brewed by JS and I know he uses the boiling sparge  
water technique, but I personally feel more relaxed with 170F).

>that?

Lindeman's is a Lambic, but Liefmans Kriek is a Sour Brown w/Cherries  
or Belgian Brown Ale w/Cherries. You'll need a lot of cherries to  
give you flavors like these beers -- something on the order of 12-15  
pounds for a 5 gallon batch.

\*\*\*\*\*

Ben writes:

> Sam Adams Cranberry Lambic  
>It was crisp, smooth, and had sensational flavor.

I would encourage all homebrewers to discourage anyone from referring to  
this beer as "Lambic." It is by no stretch of the imagination a Lambic.  
Lambics are spontaneously fermented by local yeasts and bacteria in the  
Zenne Valley in Belgium. The Sam (tm) Adams (tm) product is nothing more  
than a Cranberry Ale and reference to the esteemed appellation "Lambic"  
is another unscrupulous marketing ploy by the Boston (tm) Beer (tm)  
Company (tm).

I continue my boycott of Samuel Adams products!

Subject: Updated Yeast.FAQ in the Archives!

Hi,

I have just finished updating the yeast.faq, and I put it to the pub/incoming dir today. It is much improved by the addition of a list of contents. There are also some refinements of yeast strain info, and Thomas Manteufel sent me a list of past HBDs with valuable yeast info--should anyone want a second opinion.:-) I also took a step into turbulent waters and added a small section on the importance of aeration in the rapid initial growth of yeast.

I also feel the need to comment on an aertation commment made in Thursday's digest, i.e. that it is possible to aerate any time up until fermentation begins, because I feel that it is slightly to the side of the point. To wit: Fermentation is what occurs during the \*anaerobic\* growth of yeast, so if one aerated, fermentation would just stop. They would go on living and turning sugars into CO2, but they would not make any \*ethanol\*. (They of course being the yeast!) My point being: aerate early, then leave it alone.

Reading you later,

Patrick Weix

From: Lee=A.=Menegoni@nectech.com  
Subject: Mo' Betta Decoction

A recent post describes the process they use for decoction in which they use a strainer to leave liquid behind and add water to the kettle mash. This may be a problem for 2 reasons.

- 1) The ph of this kettle mash may be high and tannin extraction may occur
- 2) The amount of enzymes in the kettle mash may be low and the conversion slow or incomplete

Using the strainer may be a good way of getting the "thickest 1/n" but I would add enough of the liquid from the main brew pot to keep the kettle mash from scorching or sticking. This assumes that the main mash's

PH has been tested and is in range. When its time to boil the addition of a little more liquid may be needed. Acidified sparge water is OK as is liquid from the main mash, which is at protein rest temp.

Most brewers I know don't use an acid rest, except after 6 Dead shows, they do a single decoction using about 40-50% of the grain. It is important to do a sufficiently long kettle mash since you are deactivating 40-50% of the enzymes. They mash out by adding boiling acidified sparge water to the cooler mash/lauter tun or heat the metal brew put on a stove .

To which I reply:  
BRIAN AND LINDA NORTH BREWED BEST-OF-SHOW BARLEYWINE USING WYEAST LONDON  
ALE!!!

No, seriously, perhaps Wyeast #1028 is a less alcohol tolerant strain  
than  
some of the others, but it can be used for Barleywines. I did see Brian  
and  
Linda at the CBS competition, but forgot to ask them the particulars as I  
had promised. Perhaps I should call.

\*\*\*\*\*  
Several posters have suggested that it's the alpha acids in the hops that  
are antibacterial. I'm confident that the antibacterial qualities of the  
hops are in the lupulin, but would hazard a guess that they are not in  
the alpha acids. Recall that Lambiek brewers use aged hops so that they  
don't impart bitterness, but (according to J.X.Guinard) their  
antibacterial  
qualities are still available. It's the oxidation of the alpha acids  
that  
kills the alpha acid's bittering potential (beta acids are a different  
story, but better left to another post) and I would imagine that if,  
indeed,  
the alpha acids were responsible for the antibacterial qualities, then  
the  
oxidation would have ruined them as well.

From: Mark\_Davis.osbu\_south@xerox.com  
Subject: Re: Treacle & Other Brit Sugars

>No, you cannot buy treacle in the U.S.,

Hmmm,

I just purchased Lyle's Treacle from a homebrew store here in California. If anyone wants the stuff(I would agree that it tastes like a strong Blackstrap molasses) then they can contact:

The Home Wine and Brewing shop  
22836 Ventura Blvd.  
Woodland Hills, Ca.  
(818)884-8586  
Store Hours: Fri-Mon 10:30-5:30

Lyle's Golden syrup is a pure, refined cane syrup(it has a wonderful, rich caramel flavor). I have been using this in place of Candi sugar(per a recommendation for a member of the Lambic digest) for Belgian abby ales. Works wonders for this as I do not have to boil all night to get that caramel flavor.

Cheers,  
Mark

- --disclaimer-- I have no ties, either personal or financial, to the Home Wine and Brewing shop. Just a happy customer :->

>Calcium 54.5ppm

>CaCO3140ppm

>Ph 7.7

>The CaCo3 seems high, particularly with the amount of calcium that  
>is present. What is my best course of action,

Tim, I would certainly try to reduce the CO3 concentration.  
The other numbers look ok. By adding 1/8 tsp. CaCl2 / gallon  
of water and boiling it for 20 minutes, you will reduce your  
carbonate to about 35ppm and your calcium to about 52ppm.  
Your chloride level will increase to about 78 ppm.

I prefer to use calcium chloride rather than calcium sulfate  
because excessively high levels of sulfate can have an adverse  
effect on hop bitterness. Also, my preference is to use this  
method on the mash water only, and treat my sparge water with  
lactic acid. I add acid until the pH reaches about 5.3.

All the chemistry info I use to adjust my water is contained in  
Dave Miller's Compete Handbook Of Homebrewing.

point or  
> so. Furthermore, sparge water temp is not the same as mash temp nor  
does it  
> bear any relationship to making tea with boiling water.  
>  
> Finally, it does not address the fact that boiling grain in decoction  
mashing  
> does not seem to produce astringent beer.

I know he's only baiting us, but I feel like a sucker this morning.  
The mash has a buffering effect, yes. As the goodies are drawn off,  
however, the pH does rise. This is quite variable, and depends on the  
mineral content and buffering ability of your water supply, the types of  
grain used, the mashing technique, where the grain was grown and so on.  
So  
jack has a nice acidic mash, and sparge water with low alkalinity. Great.  
If he tried his technique in, say, southwestern Ontario where the tap  
water  
is very full of carbonates, he would undoubtedly have very different  
results. So as one sparges, the pH rises as the sugars and acidic  
compounds are drawn off, and replaced by neutral water. The 5.3 figure  
is  
a guideline, and indeed a 5.4 pH might produce little or no more  
astringency. It does indicate, however, that your pH is rising, and soon  
will reach a level that will extract noticeable quantities of tannins  
from  
the husks. In the decoction mash, you have a thick mash which has not had  
the sugars and acids removed, so the pH stays low. Where's the problem?

Norm> What ever happened to the Kegging FAQ?

Oops!! I posted to rec.crafts.brewing yesterday, but neglected to post to HBD. Here is what I said.

My employer (to whom I owe my Internet Connection) has had me working harder than usual and the Kegging FAQ has been put on a back burner temporarily. Just about as this happened, I had decided on a different direction for it. I had been going through every back issue of HBD in the issues looking for questions and answers and had only gotten through half of what is archived. I finally decided that I would edit the contributions which have been made (which are substantial) and get that portion out, and then in a future release, add what has been gleaned from the archives. This is now my current strategy and I hope to have something by the end of this month. However, the bottom line is that I must keep my employer happy to keep my Internet connection, or I can't post anything at all.

Sorry for the delay,

From: msharp@Synopsys.COM  
Subject: HSA - another view

Hi folks,

Since HSA still seems to be a topic of discussion here:

Last night I was at the A-B plant in Fairfield, CA for the quarterly MBAA meeting. While there I was able to crawl through the bowels of the brewery on a VIP tour lead by one of the plant managers who has been in this business for ~21 years and worked his way up from the ranks.

So what does this have to do with HSA?

Well apparently there are two camps of thought. The one which George represented and the one which doesn't believe its anywhere near that much of a problem. Upon what do I base this? During part of the tour I was directly below the kettles looking at a large tank (~2 industrial stories high, 10'+ round) and I was told that this was used for hot wort aeration. This caught my off a bit so I asked for a clarification. I was told that immediately after boiling and prior to cooling the wort is slowly dripped down through this tank against an upward flow of 120F air. This is done to simulate the aeration effect of the old technology coolers which were just a few stories of tubing. Later in the evening I had a long talk about this with the same man over dinner where we got into why A-B does it this way, etc.

Date: Fri, 19 Nov 93 12:43:58 EST  
From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>  
Subject: Sour brown crabtree HSA scaremongery

In hbd 1276 Jeff Frane poo-poo's Gregory Noonan's excellent sour mash article in the Special Zymurgy (probably the article that makes the publication worth while, IMNSHO), but seem to be mixing up acid rests and sour mashes.

A sour mash, the procedure for which is well decribed by Noonan, is of part of the mash and takes place over days at 120F+. An acid rest is of the whole mash at around 100F, and uses enzyme reactions to reduce pH. This technique may take 20 hours and is only useful for soft water mashes. The technique described by Noonan is Reinheitgebot and works for harder water.

Try Howard asks about American Brown Ale. The excellent Pete's Wicked Ale won the GABF in 1992, so I assume it is a good example of the style. May the pedantics correct me if this is wrong :-).

Steve Zabarnick speculates that the Crabtree effect may not occur in dextrose primed bottles because it is only a small proportion of the sugar. However, since all other fermentable sugars are now gone, isn't it the only fermentable sugar??

Carl Howes was one of many to correct me when I posted  
> While this procedure is not correct - chilling in a bathtub or with a wort chiller prior to pouring is recommended, the amount of damage that could be expected due to hot side aeration is so slight that it is unlikely to be noticeable.

I have seen a huge improvement in flavor stability and beer quality since I started chilling the concentrated wort. Have you tried it both ways, Ulick?

I apologize for understating a risk. I should have said that the beer was likely to be drinkable, rather than saying that the effect is unlikely to be noticeable. This was toned thus because I had received email from first time brewers saying that they had just brewed like this wondering whether they pitch and batch now? I am sorry for erring on the side of RDWHAHB rather than erring on the scaremonger side that is the HBD norm.

Talking about scaremongery Al K responded to my critique of his postings with a repeat of his 'DON'T CHANGE YEAST AT BOTTLING /em[or your bottles will explode] ' earlier in the week. Considering that most yeast are similarly attenuative this is an exaggerated

risk, and I am sure most homebrewers who change yeasts are aware of the danger.  
Or are most of the Belgian brewers and Weizen brewers in the world wrong? (he also spoke of what was appropriate for hbd again, my posting not being, of course, which shows that he isn't totally cured of his superiority complex. Al K should consider that email response to me was running 80:20 in support of my posting, which may indicate that I wasn't the only one who found his style irksome, just as he finds mine. Which of us is right, or is neither of us???)

IMNSHO, Rheinheitsgebot was written to circumvent a free market economy  
(price  
controls) and as a protectionist measure against foreign imports. Oh,  
and it  
also helped keep some bad beer off the streets. It was later used as  
marketing  
tool and was made to sound like a very good thing. That's what its worth  
to  
me.

>maybe a 4 gal - 1 gal makes good sense. It's primitive, but for us  
nontinkerers who are too poor to buy and too stupid to build a cf or  
immersion chiller, it works quite well and goes faster than we imagined.

Too poor maybe, but nobody is too stupid to put together an immersion  
chiller  
(hey, even I did it!).

\*\*

Anyone tried this year's Coors Winterfest? It is (this is no lie!)  
robust,  
dark brown/red, balanced (surprise), and quite tasty. There are even  
some  
fruity components that make me wonder if it an ale. From Coors? No way!  
It  
certainly is an order of magnitude better than last year's boring amber  
lager.  
Oh, it is still marketed as a stout, HA! It is no stout but it is good  
beer.

\*\*

Troy Howard, American brown ale IS Pete's Wicked Ale IMHO.

Does anyone have any suggestions to give to a confused prospective  
homebrewer?

I suggest you follow the book you are reading. Homebrewing is an evolutionary process and if you are like me, you will continually change your processes and equipment, ad infinitum. Don't let endless debate keep you from brewing and enjoying your beer.

\*\*

Pardon my ignorance, but what is the Crabtree Effect supposed to do to my beer, and why would one avoid it? It seems it has to do with oxygen production, and of course I know why I don't want oxygen in my beer at bottling, but could someone explain the effect in greater detail?

Norm

From: fingerle@NADC.NADC.NAVY.MIL (J. Fingerle)  
Subject: Sanitation and Priming

Somebody (did not save the post) was interested in how to sanitize the brass "jet washer" he was using to clean his bottles. Evidently, he thought that this might be the source of some recent infections. I'd like to comment in a tangential way.

My bottle cleaning procedure is this: after I decant a beer, I immediately rinse the bottle and store it upside down in a spare beer case I keep in the kitchen. When ready to bottle, I use the jet washer gizmo with hot faucet water to rinse the bottle out, then let the bottle drain in the dish strainer briefly. I then place the bottles in the oven and bake them to kill off any nasties.

Generally, I start at the lowest setting, and raise the oven temp to about 300F or so in 50F increments every 15 minutes or so. I then let the oven cool several hours, or I crack the oven to speed the process.

End result, sanitized, and possibly sterile bottles. The only downside that I can see is that this temperature cycling might eventually stress the glass, but so far, I have bottled 19 batches in this manner, using about 12x24 bottles, so obviously, many of these have been through the procedure several times.

To give credit where due, this procedure did not originate with me, I got it off of the digest probably 18 months or so ago.

\*\*\*\*\*

Now a question. I'm in the mood to fool around with bottle priming. How much should I use to prime 5 gallons with molassass or honey? Does it make a difference if dark or light molassass is used? What about various honeys? Raw vs "processed" for example. Will the priming material effect the finished beer's taste (assuming a pale ale)?

Thanks!

Subject: Hop Oils as a Preservative

Date: Thu, 18 Nov 1993 00:05:58 CST

Darrell Simon writes:

**Subject: Hop Oils as a Preservative**

>It is possible that the hop flowers alone are not acidic enough to  
inhibit  
>the bacteria. I would speculate that the preservative effect of hops  
comes from the alpha acids extracted during the boil, and the increase in  
>acidity.

Yes from the alpha acids, but the acids themselves are quite weak and  
won't  
affect the acidity of the beer noticeably (otherwise we could use a pH  
meter to measure alpha acids).

>You don't hear of the preservative qualities of hop aroma  
>although you do hear of the preservative qualities of hop bitterness.

Actually there are studies that show that hop oils (responsible for the  
aroma) do have a preservative effect and do inhibit the growth of  
bacteria. And for an informal opinion, Fritz Maytag strongly believes  
that dry-hopped beers last much longer (like 10-20 years) than beers that  
are not dry hopped. He bases this on tasting his Christmas Ales from  
many years ago (that he has in his own collection and that people send  
to him). He claims that a 17 year old Christmas Ale he tasted was still  
quite good, but he admits it is not exactly the same as when it was  
brewed,  
but certainly not spoiled. Also historical data shows that IPAs (the  
real ones destined for India by boat) were called for (by contract) to  
have  
a high dry hopping level ("2 lbs of Kent hops per hogshead" which  
translates  
to 2.47 ozs per five gallons).

From: Drew Lynch <drew@chronologic.com>  
Subject: Re: Dry Hopping and Infections

I have recently gotten past a really bad bacterial contamination problems that left me with many gallons of beer for use in the meat smoker. All of these problems were evidenced by very low finishing gravities, as well as cloudiness, bottle bombs, bad taste, gushers, etc. I believe that the problems were due to sloppy brewing style, and not enough attention to sanitation. (I brewed sloppily for 10 years before I had any problems)

Two weeks ago, I brewed a ten gallon batch of brown ale. I got much better than normal extraction rate, and ended up with 12 gallons of wort split between two 7 gallon glass carboys, with a starting gravity of 1.080. I split a 1 litre starter of fresh Wyeast american ale between the two. After one week of fermentation, at 1.030, I racked to two 5 gallon secondaries. At this point, the two sub batches were identical in taste and gravity. I decided to dry hop one of the two secondaries. I sanitized some marbles in a mesh bag, and then filled the bag with fresh Cascades. I had a lot of trouble getting the bag through the neck of the carboy, but eventually it went in.

This morning, I took gravity readings and tasted both sub-batches. The non-dryhopped bottle was at 1.024, crystal clear, and tasted great. The dry hopped batch was at 1.014, cloudy, and astringent, and I can only assume, infected. There are three possibilities that I see:

- 1) unclean equipment used in the dry hopped sub batch - Very Unlikely
- 2) bacteria carried on hops into the beer - ???
- 3) Excessive handling with bare hands introduced bacteria into dry hopped batch - very likely

Since I use a CF chiller, I will be building a hop-back for this weekend's batch. I may attempt dry hopping again, but will use rubber gloves, and no bag or marbles.

Anyway, I feel that the idea that "bad stuff won't grow in fermented wort" is incorrect, and care in sanitation need be taken at all steps prior to drinking the beer.

From: COYOTE <SLK6P@cc.usu.edu>  
Subject: Lactose-Acid brew/ Ciders / REAL Bathtub Brew /BeerMachine

\*\*\*\*\*

Al. sez:

>BTW, I'm not a biologist,  
but I'll bet that Lactose is fermentable by Lactobacillus, so be extra  
careful with sanitation! ...snip... If you add lactose, you can  
add it in the boil, or boil some up and add it at bottling time -- it's  
\*unfermentable\*, so it doesn't matter as long as you sanitize it. Adding  
at  
bottling time also allows you to add it to taste, but be aware that the  
beer will become a bit more acidic when it carbonates, so you may want to

\* I am a biologist FWIW. And yes- lactobacillus will ferment lactose.  
If you added some yogurt to a lactose brew, you would most likely get  
a rather acidic product. So: Lactose IS fermentable, but NOT by  
Saccharomyces (beer yeast), so it can sweeten a beer.

Best idea is to minimize the time the lactose is available to wild  
bacteria. Add it at bottling (to taste) with good aseptic technique.  
If you add it to the wort you risk more by having it present longer,  
where  
an infectious bacterium could ferment it and produce acid. BUT  
if these fermenters are not present you should not see any additional  
acid as a result of the lactose. Bottle with usual priming sugar and  
lactose and you will NOT see additional acidity upon carbonation  
UNLESS there are contaminating organisms present!

Also- allows you to taste test the fermented beer and see how much  
sweetening it may require. You could end up with lots of unfermented  
sugars  
from the ferment, and not need as much, or it could have attenuated  
enough  
that lots of sugar could help. Depends on your preference.

\*\*\*\*

Just got another 5 gallons of fresh squeezed cider. Yummy.  
They made me a deal on pressing day- that if I brought a container  
for them to fill it would be cheaper. The guy wondered where I got  
the nice glass carboy. :) I don't know if they know what we plan  
to do with the liquid! I doubt good mormons would appreciate such  
a use. Although it IS a method of storing the cider for longer periods!

Maybe I should call it Armageddon Cider!

Another Note: I pitched a gallon of cider (unsterilized) with  
champagne yeast, and it's going like a bat out of "heck" .  
I also had another gallon sitting untouched. It started building  
pressure and making bubbles too.

The first smells appley, tastes sweet and yummy (2 weeks)  
while the second smells sour, rotten, but tastes ok.  
I think I can force the first to go quick, while the second will  
have to age for a long time. (based on past experiments).

A Question: Anyone have any tips of fast fermenting.  
It's been 2 weeks and I hope to race the first cider for thanx.

I was thinking of chilling it down, and clarifying (bentonite?) then bottling and hoping for a quick carbonation (since it's still active) and a quick drinking. I may be begging the issue to hope to have it so quick, but it tastes good now. Any ideas/experience?

\*\*\*\*

On a humorous horror story note, re: potential names and lost wort:

A brewing colleague called me yesterday in a panic. He had just conducted a terrilbe faux pah (SP! I ain't frech!:) ie screwed up!

Using the age old method of submerging hot wort/boiling pot in a bathtub of cold water he gave new meaning to the concept of "immersion chilling". He deep sixed the pot. Yes...that's right kids,

Boil pot was floating. Boil pot was submerged.  
Wort rushed out, bathtub water rushed in. Oooooooooooooops.

Went from a high gravity stout ... to....?

He was calling partially to ask whether he should re-boil. He sterilizes the whole tub with bleach water when soaking bottles. BUT He has two kids who bathe in there too! BOIL IT! He did.

He also wanted to know if he should add more fermentables upon re-boiling.  
He went for brown sugar. I also suggested honey, dme. He mashes.

I also suggested a few names for the brew: Deep Six Stout. BathtubBrew. Submarine Psuedo Stout...among others. Any more ideas?

I think he's embarassed and wants to forget the incident. :)  
At least he didn't lose the WHOLE batch. Could have taken it skiing (toot!).

From: prf@cherry-semi.com (Paul Ferrara)  
Subject: Stepping up to a 5 gallon boil

I began reading the HBD only two weeks ago and have already learned a great deal about the finer points of brewing.

I've decided that if my brew is going to improve any, I need to make the leap to boiling 5 full gal. and appropriately chilling. It's time to demote my 12qt aluminum pot to lobster boiling, and move on to something bigger. I've been considering purchasing a "Bru-Heat" thermostatically controlled boiler as a replacement brew pot ... my theory being that for approx the price of a quality 24-30 qt stainless steel pot, I can get a unit that will boil my wort now, AND, be used for my next leap: to all grain brewing.

Would this be a wise investment? Can the Bru-Heat bring a 5 gal batch to a reasonably quick boil? Is it the right way to go for mashing? Or should I really spend many \$\$ and buy a stainless steel pot, propane cooker, picnic cooler mash tun, sparging manifold, etc, etc, etc ....

If this has been discussed at length before, feel free to respond by private E-mail, or direct me to the proper archive.

Thanks.....Paul

From: tchm@gtx.ummed.edu (Chris Mix)  
Subject: for publication

I am new to brewing and my first batch is about 1 week old and sitting in a glass carbuoy as a single stage fermentation. As suggested by Papazian, I reconstituted my yeast by boiling approx. 1-2 cup water, letting it cool to 100-105 farenheit then adding the yeast and letting them sit for 30 min prior to pitching them. Within the first 12-18 hrs close to a quart of my beer-to-be came over into a bucked through a water-locked tube. I am concerned because the foam had fallen back into the carbuoy at 24 hrs and the smaller water lock now atop the carbuoy has passed a bubble only once every 1-5 min. I was under the impression most activity was to occur over 1-2or3 days. I am aiming for an ale with a Munson malt extract, 8 oz. crystal malt, 2 oz Kent Gouldings and some Cascade (hops, not detergent) thrown in 5 min prior to adding the wort to the carbuoy. The yeast are starting to settle now and otherwise things seem to look OK. Could there be a problem here?

Date: Fri, 19 Nov 1993 15:04:22 -0800 (PST)  
From: gummitch@teleport.com (Jeff Frane)  
Subject: Panic Over Sugar

You ever notice how easy it is to push the panic button here on the Digest? It looks as though it's happened again, this time with people starting to dither over the correct bottling sugar.

The Crabtree Effect is about as relevant as the Crab Nebula here. We are talking, after all, of truly tiny amounts of sugar compared with the total volume -- even leaving aside the fact that \*lots\* of beers have been made with 20-30% of \*cane\* sugar added, without any problems.

The British and the Belgians regularly prime with sugar, with sucrose, dextrose, invert sugar and combinations of the above, sometimes with a bit of caramel thrown in for variety. I have yet to see any evidence that this causes a problem. Sierra Nevada has been using dextrose to bottle for years, and I can't see that it's cut into their sales much.

Really, folks, relax. Worrying is one thing, but panic...

=====

And on subject of sugars, and British sugars in particular: I have to disagree with the poster who said that demerara sugar was less sticky than American brown sugar. At least, I disagree with it as a blanket statement. Eric Urquart (no, I know that's not spelled right) was good enough to send me .5 kilo from British Columbia, and this stuff is much, much stickier than brown sugar. It also has an unmistakeable molasses aroma that could be smelled through the plastic packaging five feet away. And yes, I fully intend to use it in brewing.

=====

Larry Barelo inquired about using adjuncts to lighten up a barleywine. I'm not entirely sure that it would still be a barleywine if it was lightened up, but I have been using sugar and flaked maize for the same purpose in my faux-abbeybiers and it really does the job. It is, I think, one of the prime differences between barleywines and the Belgian beers: the former have a very full body, rich and sweet, while the Belgian beers are deliberately made to have a high alcohol but to be less satiating. Really hard to do that with an all-malt recipe.

=====

Todd Jennings laments the increasing appearance of twist-offs in microbrewed beers. Although the criticism is well-placed, he mentions Sierra Nevada as a new offender -- SN has never had anything \*but\* twist-off caps on their bottles since they began in, what, 1984? 1983?

Here in the Great NW, the micros are split somewhat. Red Hook beers have twist-offs, Full Sail's and BridgePort's are true crown caps, um, so are Rogue's, Pyramids are twisted, etc. Then again, I've never had a bad bottle that I could attribute to twist-offs, so I'm not sure how valid the conventional wisdom is.

Subject: Acid rest

Jeff writes:

>Interesting to note Greg Noonan's article in the special issue of  
>Zymurgy. Noonan is now touting sour mashes as the secret ingredient in  
>Bavarian weizens and Bohemian pilsners -- in spite of a complete lack of  
>evidence that they are used at all in those areas. (The acid rest he  
>mentions is a matter of a few hours or less, not days.)

I have read the article and recall scribbling red ink all over it. For those who have not read it, Noonan talks about souring the beer with naturally occurring bacteria on the husks of malt. Indeed, this is sour mashing. I'd like to point out that it's NOT the "acid rest" that is used by some brewers. The "acid rest" is enzymatic (phytase, I believe) rather than bacterial -- I know Jeff didn't mean this, but it could have been confusing to some.

Subject: Dry Hopping Infections/Tate & Lyle Golden Syrup and Treacle

Dan writes:

>Anyway, it's pretty clear that the greatest risk of infection is before  
>fermentation. No confusion there. Presumably the bacteria produce bad  
>flavors, then are overwhelmed by the yeast, PH, and/or alcohol. Right?

Not quite. The greatest risk is, indeed, before fermentation and from two  
sources: 1) infected starter/yeast and 2) airbourne or fermenter-surface  
bacteria (in scratches, for example) getting a foothold in your beer  
during long lag times. Unless you \*sterilize\* everything, and work in a  
clean room, you will always have some bacteria and wild yeast in your  
beer.

The question is, if there will be enough of them to make a difference in  
the flavor and if they will survive long enough to make a difference. If  
you pitch a clean, healthy, viable, populous starter into a reasonably  
clean wort of a similar temperature, under good conditions (e.g. no grain  
dust in the air), your yeast will eat most of the nutrients, consume most  
of the oxygen and soon create a blanket of CO2 which will keep away new  
airbourne nasties. The wild yeast and bacteria are there and are  
creating

off flavors and aromas, but in such small amounts that it does not reach  
our perception threshold. When fermentation is complete, whatever  
bacteria  
have not been killed by the pH and alcohol, are (if everything went well)  
again in such small numbers that their products are below the perception  
threshold.

>However, the recent dry hop & bacteria thread has made me wonder about  
>post-ferment. Some HBD articles have indicated that once fermentation  
>is complete, the beer is hostile to bacteria, so no worries.

Don't worry, but don't be foolish -- maintain good, sanitary technique.  
Would you eat a sandwich you dropped on the garage floor?

>On the other hand, I've read several times that "gushers" are caused by  
>infections. The idea there is that the bacteria eat stuff that the  
>yeast don't, resulting in over carbonation during long term storage.

Back when I was a beginner, using dry yeasts that have since been found  
to have had big problems with bacterial counts (see the Yeast Special  
Issue of Zymurgy), I would (with certain yeasts) get gushers after a  
few months. In looking through that early logbook, I can't find a  
single batch that ended up a gusher that could not be attributed to  
infected dry yeast except for one. That one batch's problems are quite  
involved (clogged blowoff tube, whole cherries added, 8 hours of an  
open fermenter, etc. etc.) so data from it is difficult to extract.

In summary, if you pitch good, clean yeast and not shock them, and  
maintain good sanitation techniques, you can expect to not have  
bacterial problems. If you choose to add dryhops, do your best to  
keep them sanitary (within reason) and don't add them until fermentation  
is virtually over.

\*\*\*\*\*

Someone (sorry) mentioned something about an embargo regarding the  
Tate & Lyle's Syrups. My understanding is that several months ago,  
the US withheld the import of Tate & Lyle's products from the UK

because they would not (or could not) provide proof that they were not made with Cuban sugar. The embargo mentioned is obviously our restrictions on trade with Cuba. I don't know if the sightings of the T&L products are just existing stock or if the import restriction has been lifted.

\*\*\*\*\*

Drew writes:

> In yesterday's (I hope) HBD, Chuck Wettergreen posted a method for  
>making invert sugar. Has anyone used this stuff as a priming agent?  
>I was curious if the breaking down of the sugars would inhibit the  
>oxygen generating crabtree effect.

I think we need to first talk about the Crabtree effect. It does not produce oxygen, rather it is the effect by which yeast abandon respiration and perform anaerobic fermentation despite available O2 if the concentration of monosaccharides like glucose (dextrose) and fructose are sufficiently high. The issue, as it applies to us, is whether priming with malt extract will cause the yeast to respire the O2 introduced during bottling or whether priming with corn sugar (glucose) is equivalent in this respect. My experience has shown that, given my procedures, there were no problems with oxidation in my beers, regardless of whether I primed with malt extract or corn sugar. I therefore changed back to corn sugar. With all due respect to Reinheitsgebot, I prefer Belgian and English beers... beers that would have Delbruck and Sedlmeyer spinning in their graves.

Subject: Sam Bashing

Al writes:

>The Sam (tm) Adams (tm) product is nothing more  
>than a Cranberry Ale and reference to the esteemed >appellation "Lambic"  
is  
another unscrupulous marketing ploy >by the Boston (tm) Beer (tm) Company  
(tm).

>I continue my boycott of Samuel Adams products!

Al,

I'm glad your boycott has been so successful. I managed to score my first  
bottles of "Cranberry Ale" today down here in Florida -- even though the  
officials at B (tm) B (tm) C(tm) said there wouldn't be enough for  
distribution in our state. <G>

Sure, the lambic is not a lambic and the Octoberfest is not a true  
Octoberfest. And Samual Adams isn't the best beer brewed in America four  
years running. But I can remember not too many years ago when I refused  
to  
drink ANY American Beer because they all s \_ \_ \_ \_ \_! (censored for  
political correctness).

Sam bashing seems to be in vogue these days, but I think I can say most  
all  
of us at one point in our lives enjoyed the beer. And although I, too,  
have  
lost respect for the company due to marketing claims, I find it hard to  
name  
a company whose marketing practices are up to my standards. Budweiser is  
not  
the KING of beers, Hamms "land of sky-blue waters" commercials were  
filmed in  
Northern Califorina and Miller's "Lowenbrau" has little in common with  
the  
product from Europe.

You may not believe anything you read on a bottle from James Koch, and  
that's  
the way it should be. Taste is what counts. Anyone who believes anything  
they  
read without question deserves what they get. And I believe I'll go get  
another bottle of Sam's from my fridge. . .

From: chuck.wettergreen@aquila.com (Chuck Wettergreen)  
Subject: Invert sugar

All,

I've received some questions about my invert syrup recipe and after checking it I realized that what I posted was wrong (gasp!). The recipe is:

8 pounds of white cane/beet sugar

2 pints (US) of water

1 tablespoon (=3 tsp) citric acid

mix, heat to boiling (will FOAM! then turn beautiful clear golden color)

cool, then dilute to 1 (US) gallon.

one (US) pint equals 1 (US) pound of sugar

Add too much of this and you'll STILL get that "cidery" taste!

Chuck

I've been using a Bruheat to boil the full 5 gallons for years. It does work, but it can be slowwwwwwww. I recently insulated mine with that blue foam sheet insulation you can get at home stores. I cut thin bat and set them up vertically along the outside with cutouts for the thermostat and spigot. I also cut a piece for the bottom. It cut boiling time down to the point I was able to go from cold water to final cleanup in 2 hours. This is approximately half the time it took before. I can't help with mashing as I'm an extract brewer.

From: U-E68316-Scott Wisler <wisler\_scott@ae.ge.com>  
Subject: Post boil evaporation of DMS/initiators

In jack's (flick you in the forehead and see if you jump) post on chillers, he advocates sealing the boiler while chilling. While it pains me to admit the idea intriguing, I also immediatly wondered two things. I waited to ask partly because I realized we were being baited, and because I hoped to have time to study up on the topics involved. That not being the case (yet), and since the topic has not been addressed, here goes:

Are you sealing in DMS and/or its precursors during the time the wort is still hot?

I understand that the long boil has many purposes, among them evaporating unwanted volatiles like DMS and/or its precursors. Within my (admittedly spotty) understanding of the process, if the wort remains above a certain temperature, the reaction which produces DMS will continue until all the formation material is depleted. One's goal therefore is to boil off all the DMS possible, and then chill the wort quickly to prevent DMS from being further produced. Note that I did not say as quickly as possible, but merely quickly :)

What I do not yet understand are the details of the reaction, the precursor issues, the critical temperatures involved, how much DMS precursor material is left after an hour boil, and the implications of sealing you pot and thus preventing evaporation of this compound.

Further enlightenment would be much appreciated.

Second, how do you ge the lid off when its chilled. I know that when I leave a pot of hot peas with lid on the stove overnight (I hate it when I do that), its near impossible to get that lid off. Does the top of your lid bow in?

I don't mean to be abrasive but I don't "decant" beer, I pour it. Decanting is for that grape stuff.

\*\*

Chris writes:

Chris>I have to agree with Ben's comments. Maybe the "Sam Adams  
Chris>Cranberry Lambic" is not a true lambic, but it IMHO, it is a very  
Chris>tasty brew.

You are correct, it is not a true lambic, nor is it a pseudo-lambic, ersatz-lambic, imitation-lambic, anything-like-a-lambic. It should not be called a lambic, no matter how good it tastes.

Al>>I continue my boycott of Samuel Adams products!  
Chris>Your loss. Although Koch may be a slime bag, he makes a decent  
Chris>product.

Yes, he makes decent beer. But so do literally hundreds of good, decent people who avoid using the strong-arm tactics of the neighborhood bully to sell their product. Of the hundreds of brewers attending this year's GABF, the BBC tmtmtm was the only one in violation of GABF marketing rules. They were only allowed to attend because the GABF feared the threat of a lawsuit, which it certainly does not need. So, why would you want to buy beer from these people? You can buy good beer, better than Koch's, from good people. I'm with Al on this one:

BOYCOTT SAM ADAMS PRODUCTS!!!

\*\*

Coyote, how about Rub-a-dub-Dubble for that bathtub brew?

\*\*

Al writes:

>Would you eat a sandwich you dropped on the garage floor?

I'm not sure my personal habits are any business of yours, or that they have a

place in the digest, but here's my answer:

Yes, but I wouldn't eat it after dropping it on the garage floor and then putting it in a carboy for two weeks 8^0 ;-)

From: Mark Taratoot <SLNDW@cc.usu.edu>  
Subject: cider questions and screw caps

Greetings.

Coyote mentions a gallon of cider that has started to spontaneously ferment and smells bad. My advice: LET IT GO WILD!! Last year I tossed one of my gallons of cider into a jug and put an airlock on, just to see what would happen. It smelled terrible for a month or two or three. I let it sit in the cold closet, not wanting to throw it out and eventually after about 6 months it had cleared quite a bit. I was about ready to throw it away, but I racked off the lees just to finish the experiment. I tasted a bit... MMMMMMMMMM!!!

After about another month or so in the second (third?) jug, I bottled it with just a tiny amount of priming sugar. Now this cider is very nice. One of the best yet! I may do five gallons this way with some extra fermentables this year, but I don't want to start a long project like that since I will likely be moving in the next 6 months.

Regarding the cider that needs to be served soon: Kill it with vodka, heat, or cold, then either force carbonate and use a counter pressure filler or serve still. I don't like the sound of this method. Other method: Bottle it a day or three before you serve it and keep it cool!!!  
\*\*\*\*\*

Regarding twist off caps:

When I first started brewing I used some twist off caps since my bottle collection was not complete. I was using an old-fashioned bench capper at the time. I never had any trouble using twist offs. When my friend left Utah to move to Washington state, he took his capper :( . I then started using a wing-style el-cheapo Italian capper. I found that this capper did not seal the few screw top bottles I still used occasionally as well as the "real" bottles. (The main problem with the wing capper is that bottles must have a large collar for the capper to grab, so many of my bottles were difficult to cap).

Now I have an old-fashioned bench capper of my own that was found BRAND NEW at a second-hand store (Thanks John). I have not used screw tops since I have had this capper, but I think it would cap them fine. The difference: Wing cappers grab the bottle and squeeze the crown onto the bottle while bench cappers just push the crown down onto the bottle. Perhaps the cappers that commercial breweries like SN use cap the bottles like the bench capper and so screw tops are not a problem.

I think a bigger problem is cheap, thin-glass bottles. BTW... does anyone have any idea of the life expectancy of a bottle for beer. As we re-use bottles, they get pressurized (slowly) and de-pressurized (quickly). How much of this stress can an ordinary bottle take?

Subject: Bruheat vs. picnic cooler

Paul writes:

>Would this be a wise investment? Can the Bru-Heat bring a 5 gal batch  
>to a reasonably quick boil? Is it the right way to go for mashing?  
>Or should I really spend many \$\$ and buy a stainles steel pot, propane  
>cooker, picnic cooler mash tun, sparging manifold, etc, etc, etc ....

When I was ready to take the plunge to all-grain,  
several friends talked me into going with the picnic  
cooler setup. I'm glad they did; it's the closest you can  
get to unattended brewing. There is no worry about scorched  
grain, stirring, etc.

If your worried about the cost, you might be able to get off  
cheaper with the cooler setup. If you can dig up an old  
cooler, are willing to settle for an enamel pot, and have an  
understanding spouse who will let you use the kitchen stove,  
you can get started for under fifty bucks.

Word of caution though: some inexpensive coolers are made of  
plastic that cannot withstand the temperature of boiling  
water. I use a Coleman with the metal exterior, and it's  
still like new.

From: hollen@megatek.megatek.com (Dion Hollenbeck)  
Subject: Boiler siphoning

I am leaving too much wort behind in my boiler after siphoning to primary fermenter. I leave about .75 gal as a combination of what is held in the hops and what is left because the hop bed causes my siphon to "break". I use a Sankey keg as a boiler. It has a 1/2" pipe nipple coming in from the side and an elbow and nipple going down into the botto. Over the nipple is a screen (1/8" grid) to keep out the whole hops. When I let liquid out and there is no hops, then all but about 1/2 cup of liquid is removed.

- 1) How much liquid do you leave in your boiler including in the hop bed.
- 2) Any suggestions, or do I just figure in the excess wort needed to be left behind?

From: "Mark B. Alston" <c-amb@math.utah.edu>  
Subject: first all grain! (questions)

Well, I just brewed my first all grain yesterday. It was a blast! I have never done an partial-mash before this all-grain but it went fairly smoothly anyhow. However, after having actually done a mash new questions come up which I didn't even think of before.

I'll post a summary of my procedures and equipment later. I think that it might be useful to those thinking about going all grain. With the right equipment I think that it can be quite easy. As I just found out.

- 1) I brewed a porter because my water is high in bicarbs and I didn't want to worry about messing around with my water too much. Since Noonan and Miller and just about everyone else says that a dark mash has a higher p.h. I assume that they mean that I should add the dark grains to the mash at mash in. Otherwise, I will have a mash which is the same as a pale ale mash and will have p.h. problems. Is this not correct? This is where I ran into my problem. Having such a dark mash it was impossible to tell what my p.h. papers were telling me. The wort (or is it not called wort till after the mash?) simply stained them a dark color. Everything went fine anyhow. I achived conversion regardless of the p.h. but it was still confusing. How do you all check the p.h. of your dark mashes?
- 2) This dark color brought out another problem. There would be no way to tell if iodine went black or not. The mash was black on it's own. Thus, I could not test for conversion. I simply let the mash sit at conversion temp for almost 2 hours. The liquid tasted sweet at this point so I went on. I achived an O.G. of 1.061 so I must have gotten conversion. So, how do you check for conversion of a dark mash?
- 3) For checking my extraction efficiency do I use the total grain weight (pale, chocolate, patent, crystal) or what? It seems that by including all the grains dark mashes will always seem less efficient than pale mashes even though I might have extracted the same amount from the pale malt. Moreover, I boiled off more liquid than I had intended and was left with only 4.25 gal or so in my carboy. So according to miller it seems that I should do the following:

$$\text{Degrees} = (1.061 * 4.25)/10 = .45$$

since my total grain bill came to 10 lbs (8 lbs pale malt) and I was only left with 4.25 gal.

What does this mean. Is this good or bad or what. Miller gives me no idea as to how what numbers I should get.

Thanks for any and all info.

From: "David H. Thomas" <dhthomas@lis.pitt.edu>  
Subject: Liquid yeast storage

I am relatively new to brewing (ca. 10 brews) and am using liquid yeast for the first time.

I'm looking for info concerning the storage of liquid yeast cultures from one brew to the next. The folks who sold me the package of liquid yeast (Wyeast London) told me I could reuse the yeast by storing it. Papazhian says not a whole lot about this. What precisely do I save? How much do I save? What do I save it in? Where do I save it?

I seem to recall reading somewhere a bit about this--was it Dave Miller's book? (The title of which I can't seem to recall).

Any help on this would be useful.

Cheers,

Date: Sun, 21 Nov 1993 14:37:30 -0500  
From: tmgierma@acpub.duke.edu (Todd Gierman)  
Subject: crabtree effect

In digest #1277, the question was asked:

>Pardon my ignorance, but what is the Crabtree Effect supposed to do to my  
beer,  
>and why would one avoid it? It seems it has to do with oxygen  
production, and  
>of course I know why I don't want oxygen in my beer at bottling, but  
could  
>someone explain the effect in greater detail?

Quite simply the "Crabtree Effect" is really an observation that goes  
like this:

In the presence of high glucose concentrations (>0.5%), yeast will  
continue  
to utilize fermentation even when oxygen is introduced into their  
environment. This phenomenon is sometimes called "aerobic fermentation."  
"

I don't know whether this explains the phenomenon of carbonating through  
the addition of dextrose. It may actually be that the addition of  
dextrose  
provides a carbon source at concentrations below 0.5% and now the yeast  
respire giving off CO<sub>2</sub> and no alcohol (the addition of priming sugar does  
not increase alcohol content, right?)

You see, basically, yeast ferment whenever they can and respire only when  
they have to (that is, when fermentables are low). In a glucose based  
nutrient system, anyway, yeast grow primarily by fermentation - glucose  
itself represses the expression of the enzymes required for respiration.  
Once the glucose is depleted to very low levels the yeast then kick into  
respiration mode, which requires oxygen and which can result in the  
catabolism of alcohol and acetaldehyde in addition to glucose.

Well, you say, "my wort is mainly maltose, so I know they are respiring  
until the oxygen is depleted." There is actually glucose present in your  
wort prior to pitching the yeast, as well as other sugars (maltose,  
dextrins, etc). Glucose and fructose enter the yeast cell via passive  
diffusion. Maltose, on the other hand, is actively transported and can  
be  
consumed at a rate that exceeds glucose, in spite of the fact that it  
must  
be broken down enzymatically into two molecules of glucose.

So, do the yeast respire early after pitching? I seriously doubt it.  
Like  
I said, in a glucose-based environment they ferment their little hearts  
out  
(figuratively). Maltose is actually two glucose molecules coupled and  
once  
broken is actually catabolized as ordinary glucose. So the real question  
here is: does maltose affect yeast metabolism in a manner identical to  
glucose (does it also repress respiration)? I suspect that it does, but  
do  
not know for certain.

Why do we aerate then? Well, I understand that it is important for the

synthesis of sterols, which, I assume, act, in part, as regulators of growth.

This is an issue that should be cleared up (fermentation vs. respiration) as it gets thrown around these threads on a regular basis. Perhaps, someone with access to the real brewing literature could better address this question, i.e. the effect of abundant fermentables on respiration in yeast.

Subject: A Defense of Sam Adams

Chris (responding to Al) writes:

>> I continue my boycott of Samuel Adams products!

>Your loss. Although Koch may be a slime bag, he makes a decent product.

A slimebag? Really? Sometimes this guy comes off sounding like Hitler in the HBD.

You may question his marketing techniques regarding the GABF and his trademarking of the word "Boston".

Regarding the first...it seems to me that GABF got a heck of a lot of free advertising since 1986/7 when SA began running those radio spots that mention "winner three/four years running of the GABF." True, he may not have explained the ins and outs of the awards process. He should be chastised for it. But if I remember correctly, GABF didn't complain until much later. Meanwhile, their attendance has doubled and tripled. The first time I ever heard about GABF was via those radio commercials, and I've attended two of them now.

Regarding the second...as a marketing slimebag myself, I understand the need to maintain product identification. A guy walks into the store and sees "Boston Lager" and "Boston Stock Ale", both SA products, then sees "Boston Bock" or some other product by another manufacturer, and it stinks. Potential for problems for SA? You bet. Trademarking is as old as the hills.

The love of Sam Adams inspired my search for good beer. You may disagree with his techniques, but remember, this is a business. How many brewers go bust every year? How many make a real profit? And, more to the point, how many micros can claim the widespread distribution of SA? I walked into a small town bar outside of Decatur, Alabama last year and they had SA on tap! It certainly did beat a Bud.

This "slimebag" is the same guy who closed down his plant and took this entire staff to DisneyWorld to celebrate their anniversary. I don't know the man personally, but that sounds like a good boss to me.

I suppose I'm about to get flamed by all the pure-of-heart beer geeks out there,

and I'm ready. If you know something I don't about James Koch, something truly evil, then please let me know. I just think that calling for the boycott of a very good product and calling people really rude names in a public forum is silly.

Just a thought. Now lets get back to the real beer stuff.

-Kevin/Chicago

From: ulick@michaelangelo.helios.nd.edu (Ulick Stafford)  
Subject: bottle bomb weizen

I had my first ever bottle bomb. It was a weizen and the cause was quite obvious. I deliberately followed every step in Warner's book, even when I questioned it. One such point was to do with carbonation and for 5 gallons he recommends priming with either 1.6 qt of Speise or 1.8 quarts of wort. Obviously there is more sugar in the former (21B first runnings from Laeuter tun) than in the latter, ~13B, but I used the former anyway. I couldn't bring myself to bottle after 2 days - the ferment had been low ~60F, but I bottled after 4 without bothering to change yeast. Anyway, after a week I had a perfect, if overcarbonated Weizen. A German friend of mine and another Irishman who lived for a while in Germany thought it was spot on.

Anyway, while milling grain for a new batch down in my basement (now a 5-10 minute job with the MM instead of the previous 20+ with the Corona), a bottle blew - a longneck returnable, although probably flawed. I immediately made space in my 40F lager for the rest to stop yeast activity and dissolve more CO2. Later that evening my German friend called and asked me to bring over some weizen as his party guests wanted to try it. I told him of the mishap and he responded that usually one case in three of commercial weizen in Germany would have a bottle bomb - so it must be good! Anyway I brought it over and it was a hit with 'genau richtig' being a typical comment. This would seem to prove what a good book Eric Warner has written. He won the best weizen in 1992 at the AHA national, I think, and a brewer following his procedure won this year, although all the judges said his beer was a gusher. My next batch - 2 days old now so about ready to bottle will be primed with just one quart of Speise.

In 1277. Lee Menegoni comments that saccharification rests for decoction mashes should be longer because enzymes have been denatured. I'm not sure if this is the case. A decoction procedure should involve a rest at 150-160 for 15 minutes, which should be long enough with modern malts to convert all starches in the decoction that are available, and the actual boil will make the other starches much more accessible. I have found that 20 minutes after combining the mashes is plenty to complete conversion with modern malts. If malt quality is poor, a double or triple decoction should be employed.

Norm Pyle asks about the Crabtree effect, but Al K gave a good explanation to which I will only add that when disaccharides such as maltose are present in high concentration the yeast cells enter their respiration phase consuming oxygen, so that they can release extracellular enzymes that then split the disaccharides into monosaccharides, that can then be absorbed through the cell walls. When monosaccharides (well glucose anyway) predominate the yeast cells do not need to respire as they can absorb the monosaccharides through their cell walls without the need to excrete enzymes.

I have one question. As mentioned that the Crabtree effect will occur if monosaccharides predominate. Is this true for fructose, and if so what happens when sucrose is present? Would the sucrose become invert (fructose and glucose) if added to the slightly acid beer as a bottling sugar, or would the respiration phase be initiated as in the case of maltose or maltotriose?

Date: Mon, 22 Nov 93 09:06:07 -0600  
From: gjfix@utamat.uta.edu (George J Fix)  
Subject: HSA

Mike Sharp in HBD#1277 correctly points out that there are two schools of thought about HSA. In its defense is the well established point that HSA definitely increases the colloidal stability of beer. This has been demonstrated in the excellent article by Morton in MBAA Tech. Qr., Vol. 23, 1985, to cite but one reference. Since materials oxidized by HSA are derived from malt (melanoidins, phenols, et al), HSA does find selected application for light beers having a low malt fraction.

I, on the other hand, remain very negative about HSA. Removing HSA from my system has lead to a discernible increase in overall beer quality. This is not only a subjective evaluation, but indeed the performance of beers I have brewed in sanctioned competitions has dramatically improved since the change was made. While yeast quality and proper sanitation are by far the two most important issues, in my system avoidance of HSA comes in third ahead of many other issues.

>So, why would you want to buy beer from these people? You can buy good  
beer,  
>better than Koch's, from good people.

I just had to add my \$.02.

In the past year or two, I have not considered S.A. (forget the TM junk)  
a real  
microbrew. To be technical, I'd say it is rather a MINIBrew. I make this  
comparison like comparing computers. A Mainframe is Bud, Miller, etc. A  
Micro  
is Mendocino, Celis, and the like. S.A. is more like a Mini, it is bigger  
than  
a Micro but smaller than a Mainframe. Lets face it, once you begin to  
sell  
your brew "all over the country" and have (can afford) radio commercials  
"all  
over the country", you're not a "little guy" any more. S.A. is good, "but  
[there  
are] literally hundreds of good, decent people" out there that make a  
beer as  
good or better than S.A. (IMHO). As far as "Boston" being a trademark, I  
don't  
think that single word is anybody's trademark. "Boston Beer Company" is  
Jim's  
trademark, but I feel you could call your beer Boston Lager, Boston Ale,  
etc  
and would not be violating any trademarks. Lastly, saying you are going  
to  
boycott S.A. is fine. It is your choice. But asking other people to  
boycott it  
is ridiculous. It would be like saying "Boycott Budweiser because they  
aren't  
really the King of Beers", or on another subject "The Washington  
Redskins,  
Cleveland Indians, and Atlanta Braves have to change their names because  
they  
are demeaning" is just as ridiculous. IMHO, I don't drink S.A. because  
I'd  
rather pick up some other obscure name that I haven't tried before, like  
Fat Tire Ale, or another well known but true micro brew like Black Hawk  
Stout  
or S.N. Porter. Lets quit all of this Jim Koch and S.A. bashing.  
The only thing he can not say any more is "four years running". He can  
still

say "four years in a row" though. Lets get more politically correct.  
Jim Koch may use "slime bag" advertising tactics, but I don't think he IS  
a  
"slime bag".

Time to go to the fridge for some Chimay.....

>That's a nice number but like so many things, it is only a bench  
>mark. What if the pH rose to 5.4 or 5.7... would it make a  
>detectable difference? I doubt it.

I'd have to agree with you regarding a slight raise in pH such as  
that. But, the pH 7.0, boiling water is in fact in contact with the  
top 1/2 inch of the grain bed. I agree that at the bottom of the  
mash it's likely to be in the mid 5's due to the grain buffering  
action, yet this is not a true statement about the top portion,  
especially at the interface between the 200+F water and the grain  
bed, namely the top half inch or so.

>>...boiled for 10 minutes in tap water  
>> (pH 7.0) and it was what I would call astringent. That's enough  
>> proof for me. ;)

> All that says is that boiling tap water with a pH of 7.0 will make  
> astringent tea. As you did not convert the starch into sugar, the  
> astringency could just be the way malt tea tastes without the  
> sweetening effect of conversion.

Not sure what you mean, but a major component of judging beer is  
being able to separate flavors. If astringency is present it makes no  
difference how sweet (or sour, salty, bitter, etc..) the remainder of  
the liquid is.

> In the real world, sparge water is run through the mash which has a  
> powerful buffering effect on the water. I run 10 or more gallons  
> of pH 7 sparge water through my mash and it doesn't raise the pH  
> more than a tenth point or so. Furthermore, sparge water temp is  
> not the same as mash temp nor does it bear any relationship to  
> making tea with boiling water.

As long as pH is measured at the bottom of the grain. Try this. After  
about 45 minutes of sparging (in whatever fashion you prefer).

- a. add some boiling water to the top of the grain bed.
- b. remove about half of a cup of grain/water mixture (from the top)
- c. check the pH

I'd bet the temperature is up around 200F and the pH is not much  
under 7.0. One can assume that tannins are being extracted and  
astringency created. This may seem trivial to a 20 LB mash, but those  
that do partial mashes (say a couple of pounds of grain and extract)  
may notice the astringency.

> Finally, it does not address the fact that boiling grain in  
> decoction mashing does not seem to produce astringent beer.

Yes it does. My statement is that pH in the mid 5's (optimum 5.3) will prevent/reduce tannin extraction. Boiling a pH 5.3 mash portion is different than adding boiling, pH 7 water to grain. Not sure what you mean here.

I am not trying to convince anyone that this is fact. It is my understanding of how astringency is created and why astringency is NOT created in decoction mashing.

From: graham%spock.dnet@SEDSsystems.ca  
Subject: Burners ?

I have been brewing all grain for several years now, the last few using a 38 qt. stainless pot. I am using a large electric stove element mounted on a piece of .25" aluminium connected to a 240 volt 40 amp source as my burner. This has proven to be barely adequate to boil 6-7 us gallons of wort. Getting the already warm wort up to a boil can take an hour (45 min if I cover the pot with an old sleeping bag). My question is what are the alternatives for burners? Would 2 (or for that matter 3) small stove elements provide more heat than the single large one?

I suspect that a gas burner would provide more heat and have been considering stealing the side burner off of the propane BBQ. (After a massive boil over on the kitchen stove I now brew in the garage, so ventilation is not a concern). Any suggestions would be appreciated!

Thanks in advance.

> no idea as to how what numbers I should get.

I include all of the grain bill in my calculations, which I suspect, is one of the reasons I get lower extract rates than claims here in HBD land (procedural/equipment differences accounting for the rest). Anyway, I would like to see this answered by those claiming 30+, 32+, etc. points/pound/gallon. The dark malts, in my understanding, do not add sugars to the liquor, and really probably shouldn't be added to the grain bill when measuring efficiency. I add them in anyway, but I suspect others do not. I guess one question would be: if you don't include all grains in the calculation, which ones do you exclude? You did the calculation wrong, BTW. For future reference/comparison:

```
Extract = (61 pts * 4.25 gal)/(10 lb)
= 26 pts...
```

I get around 25 points using the entire grain bill (of course, higher for pale beers, lower for dark beers), so you are in the ballpark. You can probably do better with a "normal" sparge (I do a batch sparge), but it is a good starting point. Also, you apparently measured the final volume in the carboy, which takes into account losses after the mash/sparge (i.e. volume left in the kettle, soaked up in the hops, etc.). For a more accurate measure of your mash/sparge you should take this reading from the kettle. At this point, you more concerned with your mash efficiency, not the efficiency of the entire

brewery. I think it makes for a better comparison with other brewers,  
too, to  
take the gravity readings from the kettle liquor.

Mark-

Have these beers that last this long been carbonated via  
priming or forced carbonated? I was under the impression that beers  
that are carb'd via priming last only about 2-3 months, due to the  
presence of the spent yeast sediment in the bottle. Please "clarify"  
whether these long lasting beers were primed or forced and other  
necessary specifics.

Thanks In Advance-

Glen

P.S. Thanks for the catalog, are the '93 whole hops in yet?

Subject: Just made a wort chiller - any break-in required?

I just made myself a wort chiller. I bought 50' of 3/8" ID copper tubing (\$29), a plastic hose, some clamps, etc; total cost about \$37.00 or so.

Now, if there any sort of break-in procedure I need to use to avoid having any sort of reaction between the fresh copper and my wort?

Thanks,

Subject: Bay Area Brewoff Competition Announcement

\*\*\*\*\* Competition Announcement \*\*\*\*\*  
\*\*\*\*\*

Well it's that time of year again for the Bay Area Brewoff. The  
catagories  
this year will be :

India Pale Ale  
Pale Ale  
Bock (Traditional, Helles & Dopplebock)  
Porter  
Dry Stout  
Barleywine/Wheatwine  
Holiday beer (specify spices/herbs and special ingredients)  
Mead (melomel, cyser, metheglin - sparkling or still)

Competition date : Jan. 22, 1994  
Entry fee : \$5 per entry.  
Entry - Two 12oz. bottle per entry. Label with name, address, phone  
number &  
club affiliation, catagory and sub-catagory if any.  
Place : Lyon's Brewery Depot, 7294 San Ramon Rd., Dublin, Ca. 94568  
Entries accepted : Jan. 1-8, 1994 (ship to arrive this week)

This is a good competition with good judges, and always a lot of fun.  
Judges  
comments will be sent to all entrants. Prizes and ribbons are awarded.

I'll make this announcement one more time in December. Thanks for  
listening.

From: Lee=A.=Menegoni@nectech.com  
Subject: Decoction: Conversion times

RE: My suggestion that one should kettle mash longer than 15 minutes.

I should have prefaced my comment on kettle mash times with the fact that I use under modified German Pilsner, Vienna and Munich malts for brews with a decoction mash. I have found these take longer than highly modified US or Belgian malts to convert. My primary motivation in using these malts is from George Fixes analysis of the Belgian malts in Brewing Techniques in which he notes that they are lower in the precursor that produces the malty flavor and aroma compared to good German malts. Since I am doing a decoction to develop these components I use the malt with the greatest potential.

RE single decoction step with 50% of the grain.  
If the intent is to produce a rich malty aroma and flavor then why don't you do 2 decoctions of 1/3 each like Noonan?

It takes too long. With the under modified German malts each decoction adds 45 to 60 minutes to the brewing process.

way! It  
> certainly is an order of magnitude better than last year's boring amber  
lager.  
> Oh, it is still marketed as a stout, HA! It is no stout but it is good  
beer.

Yes, I've tried it and like it! However, I feel the balance leaves a  
little to be desired - too bitter and too little malt. I like my  
brews bitter, but there's not quite enough malt there to offset the  
bitterness. It is quite a bit darker this year, but, the most  
impressive thing is: THE LABEL! Check it out! It's laser-etched  
or something like that. Also new for this year, is a larger bottle  
size. You can get it in the usual 12oz. bottles, or the larger  
micro-brewery style bottle of about 26 ounces - I don't remember  
the actual size.

Date: Mon, 22 Nov 93 13:12:10 EST  
From: carlsont@GVSU.EDU (TODD CARLSON)  
Subject: Re:Crabtree effect

Several recent messages have questioned the type of metabolism taking place in bottles primed with dextrose (glucose). The question:

Is the concentration of glucose in primed beer high enough to inhibit respiration (the Crabtree effect)?

or as stated yesterday:

>It may actually be that the addition of dextrose provides  
>a carbon source at concentrations below 0.5% and now the  
>yeast respire giving off CO<sub>2</sub> and no alcohol (the addition  
>of priming sugar does not increase alcohol content, right?)

Not an insignificant question since the CO<sub>2</sub> yield from respiration is 3 times higher than the CO<sub>2</sub> yield from fermentation (see equations 1 and 2 below)

eq 1: fermentation of glucose

$C_6H_{12}O_6 \rightarrow 2 C_2H_5OH + 2 CO_2$   
(ethanol)

eq 2: respiration of glucose

$C_6H_{12}O_6 + 6 O_2 \rightarrow 6 CO_2 + 6 H_2O$

(pardon the lack of subscripts in all chemical formulas)

Perhaps this analysis will help. You must also remember to include the other character in the respiration reaction - oxygen. Three quarters cup of glucose is about 145 grams which (at 180 g/mol) converts to 0.805 moles of glucose. Respiration of that much glucose would require 6 times as many moles of O<sub>2</sub> (4.83 moles of O<sub>2</sub>). Assuming ideal gas behavior (using PV=nRT, P=1 atm, R=0.0821 L-atm/mol-K, and T=298K or 25C) that converts to 118 L of oxygen gas! But 5 gal (18.9 L) of beer saturated with O<sub>2</sub> at a concentration of 3.16 mL O<sub>2</sub>/100 mL of water (as per the CRC Handbook of Chemistry and Physics) would contain only 0.597 L of dissolved O<sub>2</sub>. In other words, aerobic respiration of glucose in a closed bottle of O<sub>2</sub> saturated beer could only account for the consumption of 0.5% of the added glucose. It seems to me that primed beer must be carbonated with anaerobic fermentation (eq 1).

If so, then the complete fermentation of the 0.805 moles of glucose would produce 1.61 moles each of ethanol and CO<sub>2</sub>. At 46 grams/mol, this increases the ethanol concentration by 74.1 g or 0.4% (based on 18,900 g for 5 gal of water). I would guess the actual increase would be less at aerobic respiration is negligible (see above) and glucose metabolism is probably incomplete. As for the CO<sub>2</sub>, the 1.61 moles produced would increase the pressure to about 2 atmospheres or 30 psi (again using PV=nRT) assuming the beer is already saturated with CO<sub>2</sub>. As for the ethanol, this would be a

maximum estimate. What is the desired CO2 pressure of finished beer? Does this sound about right?

>to "break". I use a Sankey keg as a boiler.

>2) Any suggestions, or do I just figure in the excess wort  
needed to be left behind?

I had the same problem and recently solved it to my complete satisfaction. I was leaving up to a gallon in the boiler especially when large amounts of hops were used. It really bothered me so I installed a copper false bottom in my boiler that has thousands of 1 mm dia holes and is supported by a ss grid. It was purchased from Pico Brewing Systems. My drain has a Cu dip tube that goes to the very bottom of the boiler and will siphon out all but a few ozs of wort. If you use whole hops, then most of the trub sticks to the leaves and acts as a filter. Pellets can be used in small amounts (I've used up to 2 oz), but they will plug the false bottom (I'm told) unless some whole hops are used. I have had no problems with carmelization of high gravity initial run off, although if you use extracts, I would be very careful to dilute the extract well before adding to the boiler.

\*\*\*\*\*  
>From Patrick Weix weix@swmed.edu

>Fermentation is what occurs during the  
>\*anaerobic\* growth of yeast, so if one aerated, fermentation would  
>just stop. They would go on living and turning sugars into CO2, but they  
>would not make any \*ethanol\*. (They of course being the yeast!)

Not exactly. High concentrations of sugars REPRESS the ability of the yeast cell to undergo aerobic respiration even at high oxygen levels. This is catabolite repression. In aerobic conditions the yeast DOES produce ethanol, but it is oxidized to CO2 and water when the sugar is gone. In ANaerobic conditions the yeast can not oxidize the ethanol produced and it remains in solution.

>My point being: aerate early, then leave it alone.

Still an excellent point.

From: John DeCarlo<jdecarlo@homebrew.mitre.org>  
Subject: Re: Defense of Jim Koch

Well, Hitler may have loved his pets and family--we just judge by his actions  
<grin>. Trademarking may be as old as the hills, but "Boston" is a silly thing to try and trademark (read, you can't) and besides, \*no one\* knows that the word Boston is part of any Sam Adams products. I did a survey of 35 people drinking the stuff and none of them had any idea. Every single one thought it was brewed by the Sam Adams brewery.

So, Jim may be a good marketer, but he is not an honest one. That's basically what we are judging him on. Dishonest and disreputable marketing tactics, whether law suits intended to damage competitors, mislabeled beer styles, attempts to subvert competitions, or lies in radio ads, can have only a damaging effect on a company or executives reputation.

The sad part, as so many defenders point out, is that he makes a half-decent beer. There are lots of restaurants/bars in the U.S. that carry SA and nothing else even close in quality (usually megabrews). If Koch simply refrained from the underhanded activities he could have a slightly bigger market and some respect.

Right now, Sam Adams \*worst\* customers are educated consumers. They know there is lots of stuff out there head and shoulders above his and that his tactics are dishonorable. It may be a tiny percentage now, but I think lots of microbreweries out there are learning the lesson from this and emphasizing good consumer relations through truthful advertising and proper labeling.

From: Drew Lynch <drew@chronologic.com>  
Subject: Spice usage information

Now that you've all already started your Christmas ales, I thought I'd toss out a little info based on my latest Christmas brew. I altered my spice boil schedule based on my guesstimate of how volatile the desirable compound in the spices were. Also note that I use a CF chiller, and take 10 minutes to chill the 5 gallon batch. You may want to add that time to the times listed below. The base beer was a lightly hopped (Cascade/Willamette) high gravity brown ale (1.080 SG - 1.020 FG), using Wyeast American Ale Yeast

Spice: 4 cinnamon sticks at the beginning of the boil

Result: Warm underlying cinnamon flavor as desired

Spice: 4 ounces coarsely chopped ginger, added 5 minutes prior to end of boil.

Result: Walloping fresh ginger taste - too much. I think this is the correct boil time for ginger, but I would reduce the amount to 1-2 oz.

Spice: Peel from 4 juice oranges and one lemon Added 5 minutes prior to end of boil

Result: No discernable orange/lemon flavor. I will add these at the very end of boil, or possibly via a hop back.

Subject: RE: A Defense of Sam Adams

Al writes:

>>> I continue my boycott of Samuel Adams products!

Chris writes:

>>Your loss. Although Koch may be a slime bag, he makes a decent  
>>product.

Kevin writes (In Defense of Sam Adams):

>A slimebag? Really? Sometimes this guy comes off sounding like Hitler in  
the  
>HBD.

... summarizing additional comments (I'm going on a limb here, but the  
following is my interpretation of Kevin's comments):

James Koch is not a slimebag, but a successful business man doing what  
is necessary to promote a successful product.

... (I hope I got that right)

I'm not sure I disagree. Please note in my initial comment I used the  
phrase "MAY BE a slime bag" and not "IS a slime bag". The general tread  
on  
these forums is that he "is" a slimebag. I can't say from personal  
experience that this is true ... I don't know. I do know that Koch  
distributes a first rate product and I continue to purchase it as one of  
the many quality brews I purchase. In short, if a manufacturer makes a  
quality product at a reasonable cost, I'll support it. It may take  
unpopular practices to advertise a product to the mass-public, but a  
product's cost+quality performance will determine its ultimate fate once  
it  
is sufficiently advertised. I for one am glad to see that the mass-  
public  
can recognize a quality brew after the many years of drinking the typical  
american guzzle beer.

**Subject: Siphoning Problems**

I've got a glass racking crane, which I stick a flexible plastic hose onto, the other end into the secondary/bottle filler.

I used to have problems every now and then with gas building up in the siphon and eventually stopping the flow. Then, I figured out that the junction of the hose with the crane wasn't always completely airtight. Even a slightly imperfect fit will result in allowing some air in. Take a look. If the gas is building up at the top of the crane, and you have a similar setup, this might be the problem. I have always been able to fix it by twisting the hose just a little bit, and get a perfect seal.

From: sdlsb.dnet!73410%sdicc@swlvx2.msdl.ray.com (Carl Howes)  
Subject: crabtree redux

It looks like an experiment is in order here. The question still is whether or not the Crabtree effect is relevant to priming homebrew. The evidence so far is that priming with maltose (from DME, krausen, gyle) will cause some (all?) of the headspace oxygen to be consumed and priming with corn sugar will not. General opinion (from those who expressed one) runs to "it makes no real difference". Has anyone tried such an experiment? If not, stay tuned and I'll report back in six months or so. BTW, what good is a PureSeal (tm) cap considering that it has been shipped/stored in a 20 percent oxygen atmosphere for some indeterminate period before use?

From: "Mark T. Berard, Dow Plastics, LAD, TYRIN\* CPE R&D"  
Subject: PET soda bottles/Aluminum brewpot

Hello all,

HBD seems mighty unfriendly these days, especially considering that the holiday season is upon us, but I'll chance another beginners question.

Do people out there use PET Coke(tm) bottles to bottle beer in? They seem ideal. They are obviously gas impermeable. They come in a variety of sizes, my favorite being 2 and 3 liter (cuts down on bottling time alot)

The caps seem to hold pressure, and you don't have to worry about breaking them (should be ideal for travel or mailing them). Plus, if you over-carbonate, it shouldn't be that hard to release CO2 without having a gusher. I've only used them a couple of times (I normally use champagne bottles with PE corks). So, other than the complete lack of charisma, is there something wrong with them that I'm missing?

On another note, thanks to all who responded to my aluminum pot question. The consensus is that the acid wort can extract the aluminum, resulting in a "metallic" taste in the beer (which I don't seem to have.) Also, several people noted that the Aluminum/Alzheimer's connection was shown to be false, something about the staining procedures for the brain cells was introducing the Aluminum. i.e. Aluminum doesn't give you Alzheimer's (I never could spell).

Special thanks to Drew Lynch for his post in 1277 on dry hopping. A actual experiment! No snide comments! A sure sign that HBD is "not dead yet!" ;-)

**Subject: Lovibond color scale**

Am hoping for some answers (or at least appropriate references in order to answer) the following questions regarding degrees Lovibond.

Is the scale completely linear? That is, does 1 lb. of 50L grain result in twice as much color in a beer as does 1 lb. of 25L grain used in an identical manner. Does 1 lb. of 500L grain give 50 times as much color as 1 lb. of 10L grain?

Does dilution of a beer with equal parts water result in a halving of the color rating?

Do formulas exist that will allow one to accurately predict the final color of a beer based on the Lovibond rating of the grains going in?

Answers to unasked questions may also be appreciated.

> I can find one?

In Canada, the Hunter Airstat is imported by Melnor Manufacturing Ltd. and it is sold under a different name. It is model number C42215 and is called the Hunter Energy Monitor AC. I found only one store which carries it, Canadian Tire. It's a bit pricey at \$80, but if you want it bad enough ...

> Has anyone else had any good or bad experiences carrying homebrew  
> onto a plane? Or, for that matter, checking homebrew in their  
> luggage?

Not homebrew, but that other stuff known as store bought brew. This happened a few years ago, flying out of Halifax, N.S. I loaded up my carry on with an assortment of different brands of six packs (cans). Nothing out of the ordinary, just different from what is available here. That was one HEAVY bag. As my bag went into the X-ray machine, I glanced over at the video screen. The cans showed up as a LARGE black blob. The security person rolled her eyes into her head and looked up at the ceiling. After about half a minute, I assumed she just wanted me to leave, so I picked up my bag and walked away. No questions asked.

> this point so I went on. I achieved an O.G. of 1.061 so I must have  
> gotten conversion. So, how do you check for conversion of a dark  
mash?

Mark,

What I do is put one or two drops of mash liquor on the edge of a  
white dish. Tilt the dish so the dark liquor drips to the opposite  
edge of the dish. Put one or two drops of iodine next to this  
long drip mark and tilt til they run together. Your dark liquor  
spread out across a dish will essential be clear so you can see  
the reaction with the iodine.

From: Domenick Venezia <venezia@ZGI.COM>  
Subject: Harsh bitterness/Haze/Extractf

I tend to do the same recipe until I get it right. Before I commit to the third attempt I thought I'd run some things by the community and see what you-all think. So my second Fullers ESB clone is now four weeks old and still hazy with a harsh note to the bitterness. Here's my guess as to what is going on, correct me if I speak nonsense or drivel.

I think the harsh bitterness, which is slowly mellowing, is from the high alpha hops (Cluster) that I used to bitter (about 80% of the IBUs are from Clusters, the rest Kent Goldings). My guess is that my high sulfate (400ppm) water treatment and the humulone analogs from the Clusters (a la G.J.Fix in HBD #1264) combined to to give this harshness.

The first batch had the same harshness which faded in time, and it also cleared very nicely. In the latest I ... (small embarrassed cough) ... forgot to take into account the water retained by the grist so came up about a gallon short on my sparge. It gets worse. I drained the grain bed dry, then sparged again with an additional 1.5 gallons @ 180F.

Whereas the original 7 gallons of sparge water had been "burtonized", the last 1.5 gallons had not. The burtonized sparge water had enough buffering potential to keep the pH low during that part of the sparge, but the last 1.5 gallons had no buffering potential at all. Also the grain bed was dry, but kept in a warmbox where it stayed above 150F, then I hit it with 1.5 gallons of pH 7+ water at 180F and I think I pulled out just enough tannins to create a persistent haze but no noticable astringency, though I must admit the harsh bitterness may well be masking it.

After 4 weeks of bottle conditioning the haze has cleared from only the top inch of the brew, and a very definite line of demarcation has formed between the cleared brew and the hazy brew. If you've ever seen an aerogel, it kind of looks like that. There's no ring around the collar and no off flavors and I am meticulous in my sanitation, so I doubt that it's an infection.

The recipe was 80% Maris Otter 2-row pale malt, 10% crystal and cara-pils, and 10% flaked maize. Everything was mashed because I find steeping a pain. And of course I do no mash out. So now that half of you are convinced this explains the haze, what about the other half?

Also, if anyone remembers EXTRACTF, a small program for calculating extraction efficiencies, it was finally uncompressed, detarred, and put

Lastly, no one has yet responded to my request (now I'm begging) for a Samuel Smith Oatmeal Stout clone. A number of people have queued up for the results, but no one has come through with the goods.

Thanks in advance,

> I know he's only baiting us, but I feel like a sucker this morning. The mash has a buffering effect, yes. As the goodies are drawn off, however, the pH does rise. This is quite variable....

Indeed it is and makes it clear that I wasn't baiting anyone and the rest of your response makes a mockery of all the absolute dogma that has been pronounced on the subject. Every situation is different and brewers must either know exactly what conditions prevail or experiment to find out what works best.

>It does indicate, however, that your pH is rising, and soon will reach a level that will extract noticeable quantities of tannins from the husks.

Rising, yes.. but "soon"? How can you possibly know that without knowing the water chemistry and that of the mash? And what magic level "extracts noticeable quantities of tannins"? What if I don't reach that level till the last pint of sparge water?

> In the decoction mash, you have a thick mash which has not had the sugars and acids removed, so the pH stays low. Where's the problem?

I believe I was the one who suggested that there is no problem.

>From: prf@cherry-semi.com (Paul Ferrara)  
>Subject: Stepping up to a 5 gallon boil

>Or should I really spend many \$\$ and buy a stainless steel pot, propane cooker, picnic cooler mash tun, sparging manifold, etc, etc, etc ....

I may be biased but I think you should buy a 32 qt enamel kettle and put an easymasher in it. (total cost about \$50) That is all you need for mashing, lautering, boiling and fermenting. One piece of equipment does everything including a super boiler for extract beer till you are ready to move on to all grain. What you save on enamel over ss will pay for the propane cooker if you need one.

If you do go stainless, do not compromise on anything less than 10 gallons (not dogma, just experience) and sooner or later, that will be too small for boiling but will still make a great mash tun.

Date: 23 Nov 93 00:39:15 MST (Tue)  
From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: twist-offs, and bottlestuff

I don't think there's any particular trend to twist-off caps. Brewers just choose one or the other when they get going.

Sierra Nevada has *\*always\** used twist-offs, as far as I remember. I can't verify that all the way back to the beginning, but I've got an '83 Celebration Ale here, and one of the original Bigfoot with the line-drawing (no color) label, both of which are twist-off. [BTW, anybody know when that first Bigfoot was brewed? I'm sure it's 86 or earlier. Is it time to drink it yet?:-]

As for re-capping twistoffs, it's probably a good-news/bad-news situation. The good news is that the "threads" on the bottle are pretty fragile, so if a bottle is getting old, that might be the first place that fails. The bad news is that you find out the bottle is getting old *\*after\** you've filled it and tried to cap it.

In this area, there seems to be a microbrewery preference for the 22 oz (US arcane measure) longnecks. They seem to be reasonably sturdy, and the packing density on storage shelves is pretty good. I used to like the 25 oz Tooth's Sheaf Stout bottles, but they've changed the bottle (phoo on the silly CUB stamped label) and it's a lot easier to get bottles from the variety of products from 4 local breweries plus various west-coast micros than from one brew shipped half way 'round the world. 5 gal, even with carboy headspace and sediment, is still more than 2 cases of 22 oz, but I bottle the rest in 12 oz for taste checks, solo drinking, etc.

From: Lee=A.=Menegoni@nectech.com  
Subject: chiller break in

Assuming you made an Immersion chiller:

The only thing you need to do is ensure there are no machine oils on the out side. When I made an immersion chiller. I soaked it in a bucket full of hot water and lots of dish soap, dish soap cuts through oil. I rinsed it off and then soaked it in a bucket that I added vinegar to. The thing came out looking like a new penny.

When I brew:

After completing my sparge I drain my mash tun into a food grade bucket and add any extra acidified sparge water. I soak the chiller in this the low PH cleans off the metal. I then put it in the boiling wort, this cause the boil to subside, when the boil commences again I wait 3-5 minutes before running the water. I also capture run off water in the base to my shop vac, in which I have put my brew pot sitting on top of a couple bricks. This reduces water use and reduces cooling time.

Subject: sam and wasted wort

\* Chris>Your loss. Although Koch may be a slime bag, he makes a decent  
\* Chris>product.  
\*  
\*Yes, he makes decent beer. But so do literally hundreds of good, decent  
people  
\* who avoid using the strong-arm tactics of the neighborhood bully to  
sell their  
\*product. Of the hundreds of brewers attending this year's GABF, the BBC  
tmtmtm  
\* was the only one in violation of GABF marketing rules. They were only  
allowed  
\* to attend because the GABF feared the threat of a lawsuit, which it  
certainly  
\* does not need. So, why would you want to buy beer from these people?  
You can  
\* buy good beer, better than Koch's, from good people. I'm with Al on  
this one:  
\*  
\* BOYCOTT SAM ADAMS PRODUCTS!!!

Please elucidate on the GABF situation. I always wondered how you could  
have  
the "best beer", since I assumed there were about 500 zillion categories.  
What exactly does it win?

Also, I see this thread an awful lot in music--ie, so and so "sold out."  
The implication becomes that if you can get it anywhere, it must not be  
very  
good, and the only thing that saves your own beer drinking ego is if you  
can  
prove you know of some great obscure beer produced in a chicken shack by  
two  
dwarf gypsy albino seamstresses with no arms that you can only get three  
days  
of the year cause that's the only time they come to market with it.

Until I see evidence of slave labor, rats in the bottles, or use of a  
counterflow chiller (just kidding Mr. Schmid), I need more proof before I  
eschew dollar draft Sam's at my local pub.

\*  
\* >Would you eat a sandwich you dropped on the garage floor?  
\*  
why would anyone want to ferment a sandwich??

:-)

\*When I was ready to take the plunge to all-grain,  
\*several friends talked me into going with the picnic  
\*cooler setup. I'm glad they did; it's the closest you can  
\*get to unattended brewing. There is no worry about scorched  
\*grain, stirring, etc.  
\*

Can you describe this method further??

\* Subject: Boiler siphoning

\*

\*

\* I am leaving too much wort behind in my boiler after siphoning to  
\* primary fermenter. I leave about .75 gal as a combination of what is  
\* held in the hops and what is left because the hop bed causes my siphon  
\* to "break". I use a Sankey keg as a boiler. It has a 1/2" pipe  
\* nipple coming in from the side and an elbow and nipple going down into  
\* the botto. Over the nipple is a screen (1/8" grid) to keep out the  
\* whole hops. When I let liquid out and there is no hops, then all but  
\* about 1/2 cup of liquid is removed.

\*

\* 1) How much liquid do you leave in your boiler including  
\* in the hop bed.  
\* 2) Any suggestions, or do I just figure in the excess wort  
\* needed to be left behind?

Not to once again discount the folks who like to build stuff for their  
brewing (not at all, really), but here's what we do:

1. Boil.
2. grab sanitized saucepan and sanitized strainer, common household kind.
3. fill saucepan with wort and lots of hops, pour into strainer.
4. fill saucepan with wort and as little hops as possible, pour into strainer.
5. when strainer is full of hops, dump and repeat from #3 until pot is empty.

The whole hops do a really good job of straining everything else, like  
pieces of whole hops, pellets from perhaps a finishing, and some of your  
specialty malt grains. Just don't set either the saucepan or the strainer  
down, to keep things clean.

I'd say we waste about 6 oz of concentrated wort with this method. It  
takes  
two people to work best, though. Maybe some of these machines are to help  
you  
better brew alone, to which I say shame on you--find a friend to help.  
Cuts  
costs, passes time better, spurs a perhaps previously unknown bond  
between  
you. Or (gasp) maybe even try to involve your spouse! Brewing beer alone  
I  
fear would make me pretty much a drunk.

According to the instructions from the manufacturer, the caps are moisture activated. They should not be boiled, but rather rinsed with sanitizing solution and used immediately. If you're real gutsy you can just use them without sanitizing and give your bottle one quick shake after capping to let the beer do the activation.

till the  
> last pint of sparge water?

Excuse my brevity. Read: "Tannins are extracted to a greater  
degree the more the pH of the mash rises above 5.3, and if unchecked this  
rise will lead to astringent flavours. This rise is dependant on water  
chemistry, ingredients and techniques." There is no "Magic level". It  
is  
a gradual process, but cumulative.

> > In the decoction mash, you have a thick mash which has not had  
> the sugars and acids removed, so the pH stays low. Where's the  
problem?

>  
> I believe I was the one who suggested that there is no problem.

You suggested there was no problem with the sparge, and argued it  
by asking why tannins were not extracted during a decoction.

Subject: yeast wash

Can someone clarify for me:

The "yeast.faq" describes the process of washing yeast. You pour the sterile water into the carboy, slosh, and pour it back into the jar. Then you "agitate the jar to allow separation of the components. Continue to agitate periodically until obvious separation is noticeable."

This step doesn't seem to work. The more I agitate, the more homogeneous the stuff becomes. Can someone elaborate. Does the yeast stay in suspension and everything that settles is trub? (It looks like the yeast settles too, no? Or did I just wait too long?) I was doing lager yeast--is that maybe different from ale yeast? Is the sterile water separate from the yeast?

From: gelinas@ekman.unh.edu (Russell Gelinas)  
Subject: new chiller, SA

A great way to clean a new immersion chiller is to boil it in a solution of vinegar and water. About '\*this much\*' vinegar should do it :-). The chiller will come out shiny.

As for Jim Koch/Sam Adams, we boycotters realize he makes a good beer, that he's allowed some credit for the microbrewing boom, and he personally is probably not really a slimeball. But his marketing tactics are obnoxious, harmful to the Boston brewing climate, and ultimately unnecessary. Personally, I don't much care if he wants to spend his money on advertising, though I would appreciate a little more truthfulness. What irks me is when he uses his money to hire lawyers for copywrite lawsuits, etc., forcing other breweries to use \*their\* money to fend him off. He would have my \$\$ to brew and advertise, he won't get it to run down other breweries.

>whether these long lasting beers were primed or forced and other  
>necessary specifics.

> Thanks In Advance-

> Glen

>P.S. Thanks for the catalog, are the '93 whole hops in yet?

I don't know how the original Liberty/Christmas Ales were carbonated, but all of Anchor's current products are "naturally carbonated" which they do by sealing their secondary fermentation stage so the CO2 goes into solution instead of escaping to the atmosphere. I don't believe they are "krausened" with gyle, just sealed up at the appropriate time in fermentation. The beers are all centrifuged to remove the yeast and then flash pasteurized on the way to bottling. BTW, the very first, and only, Liberty/Christmas/Anchor Ale was made with sugar as well as malt, because "that's the way the Brits did it."

I have heard that the presence of yeast in the bottle also tends to help the beer keep. I have some one-year old SNPA that is still fine.

We are shipping some '93 now and will have it all available in a few weeks. Please call for details as this is not the politically correct place to post details.

From: Patrick\_Waara.WBST129@xerox.com  
Subject: Metallic/Mineral Flavor

Hi,

The last two batches of beer I've made have had an unpleasant (but not undrinkable) metallic/mineral flavor. You can taste it on the back of your tongue and on the roof of your mouth. Both of these beers are a darker variety (a brown ale and a stout). I have only had this happen two other times in the nearly 100 or so batches I have made, and I cannot figure out what could have caused it. The first two times it happened (over two years ago), I blamed it on adding Bourton Salts or Gypsum to my water. I stopped adding anything to my water and the flavor did not reappear until now. The only difference in these batches and identical successful batches is that I used Wyeast liquid ale yeast instead of Whitbread dry ale yeast. I used the Irish ale yeast for the stout and London Ale yeast for the brown ale. I have used other Wyeast varieties with no problems whatsoever.

Can anyone tell me what may have caused this metallic/mineral flavor in these batches? Is there some specific thing that can cause this flavor? It isn't just a characteristic of these yeasts, is it?

If possible, please respond by mail to Waara.wbst129@xerox.com. I have been having difficulty keeping up with the digests lately, so please excuse me if this has been discussed recently.

~Pat

From: rowan@landfill.rutgers.edu (Andy Rowan)  
Subject: howto siphon hot wort

OK, first the preliminaries. I'm talking about extract brewing, so keep in mind the restrictions: lazy, uninformed, etc.

Having heard all the hullabaloo about hot side aeration, I want to avoid it. Up until now I pour from the kettle, through a funnel, into the carboy which has 3gal cold water in it. So siphoning instead of pouring seemed like a simple solution. So I tried a couple of stupid ideas, which didn't work, and now I'm looking for better ideas.

I did my last batch with pellet hops, so I wanted to keep the crud from going into the carboy. So I stuck some cheesecloth over the end of the hose but it slowed the flow so much that I couldn't keep the siphon going. I guess the pot scrubber idea is worth trying, but will the hop crudge pass through it? And how do you keep it on there?

Has anyone come up with a nifty-neato design for something to do this? Something like a metal tube with a little screen doohickey on the end?

Not being a welder, I don't really want to make a hole in my kettle and install a spigot so I don't have to siphon...

From: Trever Miller <amby@wooga.cuc.ab.ca>  
Subject: Tarpit Stout && Can we repitch with champagne yeast in secondary?

Here's something we started the other day... questions follow at the end.... -- BUG

=====

Ye Olde Tarpit Stout

(Brewed on November 21 1993 by Ambush Bug and Satanic Garden Rake)

Ingredients:

Munton & Fison Dark-hopped Malt Extract (3.3 pounds)  
Munton & Fison 3 pound Stout Kit  
4.5 pounds blackstrap molasses (About 60% sucrose and 40% flavoring extracts)  
25 grams of Fuggles leaf hops  
a pinch of cinnamon (Just a pinch! Or, Mr. Bug's idea of a "pinch". Ie., a small handful)

Destructions:

Over a period of about an hour's worth of boiling, the following were added:

Brew pot 1: (Bug's pot)  
Bring 2.5 gallons water to boil  
dump in stout kit  
stir  
dump in 5 grams leaf hops  
stir  
dump in dark malt (15 min into boil)  
stir  
dump in 1/2 the rest leaf hops(35 min into boil)  
stir

Brew pot 2: (SGR's pot)  
Bring 1.5 gallon water to boil  
dump in 4.5 pounds molasses. (NOTE: Not all at once. Spread this out over about the first 1/2 hour of the boil.)  
stir  
dump in 5 grams leaf hops  
stir  
dump in 2 cups corn sugar (40 min into boil)  
stir  
dump in remaining hops(45 min into boil)  
stir

BOIL THE HELL OUT OF IT! (Specifically, about an hour or so.)

Dump contents of brew pots into primary fermenter. Stir. Pad volume with boiling water to 5 gallons. Cool down. Pitch. GO YEASTIES!!

NOTES:

November 22, 1993

4 1/2 pounds of blackstrap molasses may actually have been a tad excessive. (This was the thickest, darkest wort I've ever seen on ANY homebrew.) That actually makes quite a hefty portion of the total fermentables, like about 35% or so. That in itself wouldn't be bad, but the molasses in that quantity may prove to have a really overpowering flavor. You can smell the wort from outside the door of our apartment. It may have been better to go with lighter molasses, or less of it.

(Mind you, that may turn out to be a good thing. I dunno. I'll have to sample some when we transfer it to the carboy. I have a feeling that once the yeasties finish munching on this one, we may be kicking on some barley wines for strength.) -- SGR

[Also, we didn't bother to borrow a hydrometer... My guess is we can eyeball it for when it's time to transfer to secondary etc. -- BUG]

November 23, 1993

We have a good fermentation going... approx a 6" head of nice brown foam and the hop leaves. -- BUG

=====

Query : We pitched the dry yeast that came with the stout kit. We were wondering how one would go about pitching some sort of champagne yeast upon transfer to the secondary. We've already got just over 23 litres in the primary, and don't want to add any more volume than necessary (won't fit in secondary....).

If we just pitched in one or two packets of dry champagne yeast into it upon transfer to secondary, what's going to happen? Will the original yeast be too numerous for the new ones to get a foothold? -- BUG

Subject: Mail Order

A public thanks to everyone that took the time to send me info on mail order supplies. I guess the picture of a fellow brewer going dry was a scary thought. I've put the replies together into a list if anyone else is interested, though it would be nice if it got into an FAQ (hint).

Also, one of the most recommended places was St. Patrick's of Texas in Austin. While talking to Lynne she said she could read e-mail but not get anything out, so if there are any volunteers in that region.... I would offer but it's kind of hard to trouble shoot from S. Cal. I will offer any advice I can.

Again thanks.

Subject: Kegging FAQ

I have begun work on a kegging FAQ and I will need a few knowledgeable contributors and reviewers to help me. I mean to cover a pretty wide range of topics that will include bottle conditioning. I am especially looking for chemists, physicists, cellarmen, and biologists to contribute

to and review certain parts of the FAQ. I plan to develop the FAQ over a

period of several weeks, but I do expect to make progress. I am also interested in submitting the FAQ to Brewing Techniques for publication.

I do not plan to post every iteration of the FAQ to the two Internet Digests.

A proposed outline is below.

From: Larry Atkinson <atkinson@cae33.Mitel.COM>  
**Subject: Kegging FAQ**  
Subject: Used Brewery Kegs

I was walking around the local flea market last weekend and came across an old Labatts brewery keg (labelled 1987). The size looked like the standard 66L (15.5 gal) keg, but instead of a single fitting on top for both CO2 and beer tap, this one had two circular fittings, one on the top, presumably for CO2 and another on the side near the bottom probably for a tap. On the side about halfway up was a bung. Here's the catch. Neither CO2 or tap connection had any hardware connected to it.

Does anyone out there in homebrew land know anything about this type of keg especially if and where you can buy the attachments?

I am presently kegging with one 5 gal. pop keg, but up here in Canada even the used Cornelius kegs go for \$80 Cdn (\$65 US), so I would hate to pass up a bargain if the Labatts keg is useable. Any thoughts or comments are welcomed.

On a related note, I tried calling Defalcos in Texas about kegs, but got the same response as another recent poster, that they will not ship these anymore. Seems that UPS is just too much of a pain for them. Does anyone know of an alternate source in the Northern New York area. Ottawa is only 1 hr from the New York border (and ~3 hrs from Syracuse) so I figure that a Saturday day trip is not out of the question.

Thanks,

Larry Atkinson

From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)  
Subject: kegging pressures

Last week, there was a kegging question, that I fired a from-the-hip answer to. The concepts were OK, but I got a constant wrong. Here is the table of values I really used when designing my dispensing system. This will end-up in the kegging FAQ, but I promised it sooner than that 8-)

t

Resistance Data - Source: Standard-Keil Catalog

inside diameter	pounds of resistance per running foot		
	Vinyl	Polyethylene	Stainless Steel
3/16"	2.20	2.20	-----
1/4"	.60	.60	2.00
5/16"	.20	.20	.50
3/8"	.10	.064	.20

Two feet of vertical lift provides 1 pound of resistance  
Two feet of vertical drop adds 1 pound of apparent pressure,  
ie: requires 1 pound additional resistance  
Proper flow-rate is two ounces/second at the faucet

The goal: match the resistance of the dispensing line to the pressure in the keg. Pressure at the faucet should be very nearly zero. So, if your beer is stored under 14 PSIG, and your faucet is 18" above the center of your keg:

3/4# resistance due to vertical rise  
1# resistance due to miscellaneous fittings  
12-1/4# resistance due to 5'7" 3/16" vinyl beer line  
-----  
14 PSI

From: WESTEMEIER@delphi.com

Subject: Rauchbier aroma

My personal specialty is a Bamberg-style rauchbier. The smoke flavor is something I really enjoy and I always get great comments on it whenever I make a batch. My technique is very simple. I use an ordinary backyard smoker. I get the grain slightly damp, smoke it over wood chips for an hour or so, then let it dry for a few days. After that, I mash and brew normally. Experimentation has shown that the Wyeast Bavarian Lager yeast works best, and smoking between one-half and three-quarters of the grain provides the right level of smokiness.

My problem is that although the smoke comes through wonderfully well in the flavor, my beer is always eliminated in competitions because the smoke is so subtle in the aroma that it's not in the same league with the winners.

I have tasted some of the winners at competitions in this category, and they generally smell and taste like the brewery was burning down around the batch as it was brewed. What am I not doing right?

Short of using some sort of "liquid smoke" solution (which I absolutely refuse to try), is there some trick to get the smoke aroma to express itself more strongly?

Any suggestions would be welcome.

Subject: Hops as preservatives/Dryhopping problem/Brown Ale yeast/dark mash

Mark writes:

>Actually there are studies that show that hop oils (responsible for the  
>aroma) do have a preservative effect and do inhibit the growth of  
>bacteria.

Interesting.

>And for an informal opinion, Fritz Maytag strongly believes  
>that dry-hopped beers last much longer (like 10-20 years) than beers  
>that  
>are not dry hopped. He bases this on tasting his Christmas Ales from  
>many years ago (that he has in his own collection and that people send  
>to him). He claims that a 17 year old Christmas Ale he tasted was still  
>quite good, but he admits it is not exactly the same as when it was  
>brewed,  
>but certainly not spoiled.

I don't believe this is a valid datapoint. I contend that Christmas Ales  
are often much higher in alcohol and that may skew this data.

>Also historical data shows that IPAs (the  
>real ones destined for India by boat) were called for (by contract) to  
have  
>a high dry hopping level ("2 lbs of Kent hops per hogshead" which  
translates  
>to 2.47 ozs per five gallons).

You fail to mention that they had bittering hop rates that would  
translate  
to IBUs in the vicinity of 200. High dryhopping levels may just have  
been required so that there is some hop nose in the final product. Recall  
that these were wooden kegs and that oxygen is known to kill hop nose.

I don't disagree with the initial premise, but the last two examples I  
feel  
are not good supporting arguments.

>  
>1) unclean equipment used in the dry hopped sub batch - Very Unlikely  
>  
>2) bacteria carried on hops into the beer - ???  
>  
>3) Excessive handling with bare hands introduced bacteria into dry  
> hopped batch - very likely

I think it may have been 1, 2 or 3, but more likely not bacterial, but  
rather wild yeast, and most likely (IMO) the mesh bag. I, personally,  
feel that they are difficult to sanitize well and difficult to clean well  
after use.

\*\*\*\*\*

George L writes:

>Does anyone know whether British Ale Yeast is the most appropriate liquid yeast for brewing Northern style Brown Ales?

It would be appropriate, but if you like diacetyl (butterscotch) you may want to consider using Wyeast Irish (#1084). The British is reportedly the Whitbread triple-strain yeast (with nice, tart overtones), whereas the Irish Ale is allegedly the Guinness yeast. I think that either of these yeasts are a good choice for a Northern-style Brown Ale.

\*\*\*\*\*

Mark A writes:

1) I brewed a porter because my water is high in bicarbs and I didn't want to worry about messing around with my water too much. Since Noonan and Miller and just about everyone else says that a dark mash has a higher p.h. I assume that they mean that I should add the dark grains to the mash at mash in. Otherwise, I will have a mash which is the same as a pale ale mash and will have p.h. problems. Is this not correct?

You got everything right except switched the high-low pH deal. Dark grains acidify your mash, i.e. LOWER pH, so if you have high carbonate water, you do want to add the dark grains in the mash.

> gotten conversion. So, how do you check for conversion of a dark mash?

You place a drop of mash liquid and a drop of iodine next to each other on a white plate and then carefully watch as you run one into the other. It's not easy to spot color change due to starch/dextrins, but you'll get the hang of it.

> according to miller it seems that I should do the following:

>  
> Degrees =  $(1.061 * 4.25)/10 = .45$

>  
> since my total grain bill came to 10 lbs (8 lbs pale malt) and I was only left with 4.25 gal.

You should leave off the water (1.000) when you do this:

Points =  $(61 * 4.25)/10 = 25.92$

Basically, 26 points/lb/gal. Not bad -- I would say a decent extraction is between 25 and 30.

From: korz@iepubj.att.com  
Subject: Crabtree/sterols/peroxide

Ulick writes:

>I have one question. Al mentioned that the Crabtree effect will occur if  
>monosaccharides predominate. Is this true for fructose, and if so what

Yes. If fructose + glucose levels are above a certain level (0.5% I believe)

the yeast will have a tendency to go into anaerobic fermentation (Crabtree effect) also. Note that if Oxygen levels are VERY high (sorry, don't have

my books here) the Pasteur effect can force the yeast to go into respiration.

It is my understanding (from discussions with George Fix) that in a high monosaccharide, high-O2 environment, the Crabtree and Pasteur effects are in contention -- I must admit I don't really know all there is to know about this.

>happens when sucrose is present? Would the sucrose become invert (fructose  
>and glucose) if added to the slightly acid beer as a bottling sugar, or  
>would the respiration phase be initiated as in the case of maltose or

Sucrose is converted to a glucose and a fructose pair by the enzyme invertase which is excreted by the yeast.

BTW, I read somewhere, that sucrose has twice the carbonating potential of corn sugar (dextrose, glucose), but have never seen it anywhere else. I don't think this is true. Anyone know for sure?

\*\*\*\*\*

Somone (sorry) asked about sterol synthesis.

I believe the sterols are used in building the cell walls. Poorly oxygenated wort is said to reduce the yeast's alcohol tolerance and this may be related to the sterol synthesis.

\*\*\*\*\*

Fisher writes:

>A good friend of mine works in the food processing industry, and he  
>says that I should use hydrogen peroxide to sanitize, like the food  
>pros do. Is this a good idea? I am not motivated to change, but he  
>won't leave me alone without a rebuttal.

You can use B-Brite or One-Step Sanitizer. They are peroxide-based. The active ingredient in both is Sodium Percarbonate, which (if I understand correctly) is sort of like Sodium Carbonate (washing soda) and Hydrogen Peroxide when it is mixed with water.

Subject: Hello Everyone

Hello everyone, I'm new to homebrewing and I'm new to HBD but I like what I see. I do have 2 questions:

1- I've read that Aluminum should not be used as a brewpot, and that cast iron is bad also, because both can impart a metallic taste to the beer. If I can't use cast iron or aluminum, what am I supposed to use?

2- What do the readers of HBD think of using Grolsch flip top bottles to bottle beer. I know homebrew shops carry gaskets for these bottles, but I've never seen anyone buy them. Any help would be greatly appreciated.

3- And, if you live in Northeast PA, 1-Quart A-Treat soda bottles are wonderful for brewing. They cap nicely, and you can bottle one quart at a time. Makes filling less tedious(sp?)

Yow! I don't know where you heard that, but it is actually the reverse,  
if  
anything. While there are many factors affecting beer stability in the  
bottle, the presence of live yeast means that the beer will last \*much  
longer\*  
in the bottle.

Subject: ATTN: BEER HUNTERS

Howdy,

Disclaimer: I'm not interested in SA "politics", so please don't include this posting in any "Koch bashing".

I have a 6-pack of Noche Buena at home, & am interested in trading 2 bottles of it for 2 bottles of Sam Adams Cranberry "Lambic". I figure that someone out there on the east coast might think this is a fair deal. For those who don't know, Noche Buena is brewed by the Cervezaria Moctezuma in Mexico. It's a deep amber lager, full bodied & mild. Very good, & it hasn't been on the American market for a few years now. It's brewed especially for Christmas. This is the beer that George Fix referred to in a recent HBD posting. He would refer to this beer as a Vienna style, I believe (but I don't want to stick words into his mouth for him). Anyway, e-mail me directly if you are interested. First come, first serve. I'm also willing to trade a couple of bottles of homebrew in the deal, if you are! BTW, 'cuz of Thanksgiving, it may be Monday before I respond to any responses.

Peace,

Alan, Austin

Subject: Beer adverts. and new yeast in secondary  
James Clark writes about his displeasure with megabrew adds:  
And, I must make a loud second to his complaints. I suppose  
this is flame bait, but here goes. The mega brews and their  
adverts. do all responsible drinkers and homebrewers a great  
diservice. Maybe James is right and it is not enough to simply  
not buy their swill. "Budmiller" is dangerous to our rights.  
It offers no sensation of fullness or gustatory (\$5 word)  
satisfaction until you have drank a lake of it. These beers  
are intended to be and are soda pop for adults. They are  
nothing more than an alcohol delivery system. They have only  
a limited usefulness in our society. They encourage abuse  
by their very characteristics. I bet the neo-pro's love it.  
The "joe/jane six pack" culture plays right into their hands.  
There, have I raved enough? Say yes already.

Trever Miller on adding yeast to the secondary.  
Oxygen will be depleted by racking time and yeast added to the secondary  
will not respire much. That is, they will not increase in number  
from what you pitch. So, pitch a vast quantity of yeast slurry.  
In order to have enough O2 to start respiration again without  
oxidizing the beer you would need to add 2 1/2 to 3 gallons  
of fresh wort with the new yeast. Your fermenter probably will  
not handle that!

Hoppy Turkey Day to All

Well I'll get up on my soap box and suggest there are two Rauch beers  
here.

The ones that are drinkable and ones that win competitions! I have had  
several very well made Rauch beers and personally enjoy the subtle play  
of  
smoke and malt flavors and aromas. Now I had the smoked ale at the AHA  
nationals that won Paddy Giffen homebrewer of the year. IMNSHO it was too  
smokey! We're talken rip your lips off with smoke! There is this numbing  
phenomena that goes on at competition judging that desensitizes all  
judges  
palates. So you need to decide if your brewing your Rauch beers to your  
taste or for competitions.

Maybe Tom Altenbach would jump in here and tell us a few tales about his  
great Rauch beers and his mixed success in putting them in competitions.

Subject: Beer ads

May I suggest to Mr. Clark that he take his television and throw it out the window, much as they once did at the beginning of SCTV (way back when). I agree wholeheartedly with him regarding beer advertising, which is merely the worst aspect of television advertising (or television itself, for that matter). It's been several years now since I threw out my television so as not to turn into a quivering blob of mindless animal matter, and the few occasions I get to see tv remind me all over again why I did it.

Frankly, I'd much rather kill brain cells hoisting homebrews than watching tv.

Subject: Rauchbier

Ed Westemeier asks about smoke aroma...

I think your problem is that you're losing the aromatic smoke oils during your boil.

I suggest "dry smoking" your beer. Add a few handfuls of smoke in the secondary and let it really soak in. Or, you could use an EasySmoker(tm) (sorry Jack, I beat you to it) made of charred sticks tied around the end of a copper pipe. You can make your own easily or buy one from me (not an advertisement).

Date-Warning: Date header was inserted by HELIX.MGH.HARVARD.EDU  
From: "John J. Magee" <magee@HELIX.MGH.HARVARD.EDU>  
Subject: Iodine Test: Use or Not?

Last night, for my 3rd all-grain attempt I brewed up 4 gallons of a strong Scotch Ale, and managed to achieve only about 20 points extraction. This obviously hurt the necessary beefiness of a Scotch Ale wort; going into the fermenter the gravity was 56-57 rather than the target 80. Oh well.

Since I've achieved rates of about 25 on my last two batches ( I was counting on 27+ this time due to practice & better technique), I think here the problem might be traceable to incomplete starch conversion. Why? 'Cause there were traces of black in my iodine test when I decided to sparge.

'Why decide to sparge when your iodine test showed some black?', you ask. Well, the mash had been happening for about 1.5 hours (single temp; 152-156 deg.), and a previous test had shown rampant black. Now the blackness appeared granular- there were lots of little tiny dots of black rather than a true black color. I've read Miller, and he says that the iodine test is useless because cellulose particles react like starch. I decided that those little tiny dots were probably cellulose particles. I sparged. This was probably stupid. I have a Wee rather than a Wee Heavy :).

Did I mess up? Are iodine tests useful? It was depressing to be counting on (and needing for style) my highest extraction rate yet and to end up with a pathetic

one. But the best thing about homebrew is that within broad limits it's  
always  
tasty as long as it's not infected.

Subject: sterilizing bottle caps and Rauchbier

Chuck Wettergreen suggest sanitizing Pureseal caps prior to use with a sanitizing solution. This comment got me wondering. I never sterilize my caps by boiling or anything prior to use because of laziness and a fear that heat may deform the plastic lining. Are caps a risk? Has anyone

taking a slant of packaged caps to see what may live on them, or noticed contamination that could be blamed on unsterilized caps?

Ed Westmeier wants very smoky beer - why not bubble smoke through the secondary (dry-smoking?)? Seriously, apart from competition reasons, why do you want smokier beer? I personally think Rauchbier, or at least the commercial stuff, is one of the foulest tasting beers on the market (acquired taste, maybe?). I had the stuff at Zekes, a bar in Dowagiac in Southwestern Michigan with over 150 imports, and was informed by my homebrewsuppliessupplier that once when he and a group of friends were there one of them asked for their foulest beer, and without hesitation the barmaid got a Rauchbier. I remember that the giggest problem, IMHO, was an overbearing sweetness.

From: Lee=A.=Menegoni@nectech.com  
Subject: Crabcake Effect / Sam Adams beers

RE: The CrabCake effect.

Recent studies have shown that moderate to heavy bodied beers, when consumed in moderation, can lead to the CrabCake Effect in humans. Stated briefly the precursors to the CrabCake effect are low quality crabcakes, usually found in frozen food sections, that contain a high fraction of bread, flour or other grain based filler. These cakes when consumed in conjunction with small amounts of beers higher in Final Gravity than most American Premiums and Light cause an apparent recombination in the stomach with the consumer suffering from a feeling that one is filled with a giant CrabCake. The most obvious outward symptom is the inability to consume more beer. Found particularly capable of producing the CrabCake effect were products produced by the Boston Beer Company, brewers of Sam Adams beers. Additional research is being conducted to determine if the method of chilling the prefermentation product has an impact on this effect. Noted Italian chefs have indicated that a similar phenomenon, The Gnochì Syndrome, can be avoided by the consumption of Red Wine. Though red wine with fish is anathema with wine lovers research is under way as to the effect of white and blush wines on the Crab Cake Effect.

korz@iepubj.att.com writes:

> BTW, I read somewhere, that sucrose has twice the carbonating  
potential of  
> corn sugar (dextrose, glucose), but have never seen it anywhere else.  
I  
> don't think this is true. Anyone know for sure?

Per molecule, maybe. Per weight, no way. Just count carbons.  
1 mole of monosaccharide makes 2 moles ethanol and 2 moles CO<sub>2</sub>:  
C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> -> 2 C<sub>2</sub>H<sub>5</sub>OH + 2 CO<sub>2</sub>  
1 mole of sucrose (disaccharide) makes 2 moles of monosaccharide:  
C<sub>12</sub>H<sub>22</sub>O<sub>11</sub> + H<sub>2</sub>O -> 2 C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>

but they weigh almost the same (1 mole of sucrose (342 grams) is 18  
grams lighter than 1 mole each glucose & fructose (360 g total)).

Alternatively, 1 g of glucose makes .489 g CO<sub>2</sub> and .511 g ethanol. 1g  
of sucrose would make .515g CO<sub>2</sub> and .538g ethanol. So, yes, the  
carbonating potential of sucrose is slightly higher (5%) than that of  
glucose.

From: lyons%adcl@swlvx2.msd.ray.com  
Subject: Imprtnce of competing chemical reactions?

In HBD #1279 Todd gave the following reactions:

>eq 1: fermentation of glucose  
>  
>C6H12O6 -----> 2 C2H5OH + 2 CO2  
> (ethanol)  
>  
>eq 2: respiration of glucose  
>  
>C6H12O6 + 6 O2 -----> 6 CO2 + 6 H2O

One reaction converts sugar to water, while the other converts sugar to alcohol. Does this imply that two different batches of beer, with identical OGs & FGs, could have significantly different alcohol concentrations based on the initial oxygen content prior to fermentation? Would this imply that pitching a large yeast starter (maybe using the dreggs of the previous batch) and not aerating the wort would result in a more potent product? I'm wondering why the homebrew in which I attempt to match the OG & FG of some commercial products always seems to have more of a kick too it?

Chris

Subject: PET Bottles

I recently posted asking about PET bottles. The responses have been very positive, that is, there don't seem to be any Major problems with using them. A few of the key comments are shown below. Thanks to all who responded.

>From: John Mare <cjohnm@ccit.arizona.edu>  
Notes that "Several high-quality British brewers are marketing "real ales" in PET bottles (eg. Sam Smith). I have also encountered a South African (Mitchells) and Canadian (Wellington) who successfully use these plastic bottles."

>From: Drew Lynch <drew@chronologic.com>  
Notes that the bottles are clear and so one must consider UV degradation of the beer, which "can give it a skunky smell... so you may want to keep them covered."

>From: John DeCarlo <jdecarlo@homebrew.mitre.org>  
>1) They may be oxygen permeable--I wouldn't store in them over a year.  
>2) People have reported that some versions (Dr. Pepper?) of soda leave a  
> lingering taste--I use the Seltzer ones primarily.  
>3) You can squeeze them to tell if carbonation is complete.  
>4) They can stand higher pressures than regular glass bottles, in case  
you  
> worry. [Heaven Forbid!]  
>5) They are perfect for parties--you don't care if you don't bring the  
bottle  
> back home with you.

Overall the use of PET bottles seems perfectly reasonable. Just pour your beer into a nice looking glass before you let your friends see it! ;-)

\*\*\*

>  
> Dan (?) pickerel@micom.com had a list of Mail order supplies:  
>  
\* I just typed up a list of suppliers from Brewtechniques Vol 1. No. 4  
and some from the southwest brewing news. I could e-mail it to anyone  
who asks. Most of the ones I gathered had 800 numbers and free catalogs.

I do have an extensive list (hard copy) , but never had the motivation to  
TYPE it into a database, but BOY that would be nice to have! NationWide!  
\*\*\*

Larry Atkinson was looking for fitting for kegs- real bar type kegs.

\* I don't know what type the Labatts counts as- but here is a supplier  
for bar equipment, including all kinds of fittings and pieces for kegs-  
some are useful for soda keg usage too. Things like shanks and taps.

Oliver D. Ennis 4151-53 Sepulveda Blvd, Culver City, CA. 90230  
800-843-6647

Foxx Equip. 421 SW Blvd, Kansas City, MO.  
800-821-2254/  
Have some stuff for big kegs. They might be able to tell you what you  
need.

\* No connection, just have their catalogs! Bonk Bonk! Tell 'em Jim!

\*\*\*\*\* QUESTIONS \*\*\*\*\*  
\*\*\*

1. Hey- Anyone know of a source for nice taps handles. You know the  
tall  
kind of pull taps, to go on a fridge shank, not onto a bar...  
good beer brands would be preferable to shmits (- the l ) Hep' me!?

2. Anyone have any good beer/brewing related clip art. Prefereably MAC  
format. PICT is good. I am especially looking for pictures of HOPS,  
BARLEY, KEGS, CASKS, GLASSES, MUGS, But especially decorative hops and  
barley vines, and sheafs. I have various animals, and some mugs, but  
not much to make BEER labels from.

ALSO: I'd really like to find a GOOD picture of a....C O Y O T E..what  
else!  
Ideal would be a COYOTE howling, maybe even a cactus nearby, or a moon.  
..

If you haven't figured out...trying to get a LOGO together for my "brewery".

I will gladly send homebrew or mead to anyone able to help me sufficiently!

\*\*\*\*\*  
Today is SCOTCH ALE day. Oh yum. Gotta go grind! I get to try my new belgian malts for the first time! (Thanx Lynne!)

So many beers to brew, so many beers to sample...whats a guy to do but brew.

Chow for Now.

From: Keith MacNeal 24-Nov-1993 1323 <macneal@pate.enet.dec.com>  
Subject: getting wort into primary/chiller cleaning/changing yeast midstream

JC Ferguson asked about cleaning immersion wort chillers prior to use. I soaked mine in a solution of TSP, bleach, and water (the same solution I use to clean bottles and remove the labels). It worked great in getting the grease and grime off. The only thing I do now to get it ready for use is to put it in the boiling wort 15 minutes or so before removing it from the heat. The copper tubing does get a bit brighter after use, but I don't think a little copper oxide is going to hurt anything in the beer (if it did, we'd have to scrap all of our copper plumbing).

To get my wort into the primary after chilling, I use the same approach Mark Bunster outlines in Homebrew Digest #1280 (November 24, 1993). And if by chance some of the break material and hop pellets work their way through the strainer into the fermenter, I relax and have a homebrew. I know Dave Miller likes to get the beer off the trub as soon as possible but I really haven't seen any compelling information that makes me want to start whirlpools and siphons, drill holes in my brewpot, worry about filters, or add another racking step (and all its complications) to my process.

In Homebrew Digest #1280 Tever Miller asks about repitching his Tarpit Stout with champagne yeast. My response is why? I brewed an Imperial Stout using only Irish Ale yeast from Wyeast. I didn't have any problems with it fermenting out.

Subject: rauchbier

\* My problem is that although the smoke comes through wonderfully well in  
\* the flavor, my beer is always eliminated in competitions because the  
\* smoke is so subtle in the aroma that it's not in the same league with  
\* the winners.

\*

\* Short of using some sort of "liquid smoke" solution (which I absolutely  
\* refuse to try), is there some trick to get the smoke aroma to express  
\* itself more strongly?

\*

This is just a thought--no idea whether it will work:

try rigging up some way to smoke your hops. Not necessarily the bittering  
hops

(although you can try that too), but the finishing hops, the ones that do  
much to give aroma. If you don't use finishing hops, maybe try.

Ah, rauchbiers. I remember being treated to one as a 17 year old in  
Nuernberg

Germany, in a bar near the medieval castle downtown. My grandfather  
explained

its origins (it's known as a Schlaenkerla there) and handed me a half-  
litre.

The smell about knocked me down, and I remember the omnipresent feeling  
that

I was drinking a beer and bacon fat solution. It grew on me, though, and  
by

the bottom of the glass I was ready for another. My grandfather wisely  
demured--when we stood to go I was pretty wobbly.

Subject: wyeast types

I was fortunate enough to get a copy of the following Wyeast Yeast Profiles from Wyeast Labs (1-503-354-1335) courtesy of our good friends at Evergreen Brewing Supply in Bellevue, Wa. (1-800-789-BREW). BTW, they (EBS) have an impressive list of Belgian malts which, as far as I know, no one else in town carries (and I've been in them all).

WYEAST LABORATORIES YEAST PROFILES

Ales    Saccharomyces cerevisiae  
-----

1007 Our original Ale Yeast of German origin. Ferments dry and crisp leaving a complex yet mild flavor. Produces an extremely rocky head and ferments well down to 55xF. Flocculation is high and apparent attenuation is 73-77%.

1084 Irish-style Ale Yeast. Slight residual diacetyl and fruitiness is great for stouts. It is clean, smooth, soft and full-bodied. Medium flocculation and apparent attenuation of 71-75%.

1338 European yeast from Wissenschaftliche in Munich. A full-bodied complex strain, finishes very malty. Produces a dense, rocky head during fermentation. High flocculation, apparent attenuation of 67-71%.

1098 British Ale Yeast from Whitbread. Ferments dry and crisp, slightly tart and well balanced. Ferments well down to 65xF. Medium flocculation, apparent attenuation 73-75%.

1056 American Ale Yeast. Ferments dry, finishes soft, smooth and clean, and is very well balanced. Flocculation is low to medium. Apparent attenuation of 73-77%.

1028 London Ale Yeast. Rich mineral profile, bold crisp slight diacetyl production. Medium flocculation. Apparent attenuation 73-77%.

1214 Belgian Ale Yeast. Abbey-style top fermenting yeast suitable for high gravity beers, doubles, triples, and barley wines. Medium flocculant strain which clears well. Apparent attenuation 71-75%.

Lager    Saccharomyces uvarum  
-----

2007 Our original Lager Yeast Strain. Specific for pilsner-style beers.

Known as many things, we call it Pilsen. Ferments dry, crisp, clean and light. Medium flocculation. Apparent attenuation 71-75%.

2308 Munich Yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American homebrewers. Sometimes unstable, but smooth, soft, well-rounded and full-bodied. Medium flocculation, apparent attenuation 73-77%.

2042 Danish Yeast Strain. Rich, yet crisp and dry. Soft, light profile which accentuates hop characteristics. Flocculation is low, apparent attenuation is 73-77%.

2206 Bavarian Yeast Strain used by many German breweries. Rich flavor, full-bodied, malty and clean. Medium flocculation, apparent attenuation of 73-77%.

2035 American Lager Yeast. Unlike American pilsner styles. It is bold and complex and woody, produces slight diacetyl. Medium flocculation, apparent attenuation of 73-77%.

2124 Bohemian Lager Yeast. The traditional Saaz yeast from Czechoslovakia. ferments clean and malty, rich residual maltiness in high gravity pilsners, medium flocculation, apparent attenuation of 69-73%.

2112 California Lager Yeast. Warm fermenting bottom cropping strain, ferments well to 62xF while keeping lager characteristics. Malty profile, highly flocculant, clears brilliantly. Apparent attenuation of 72-76%.

YEAST and BACTERIA CULTURE PROFILES      *Saccharomyces delbrueckii*, s. *cerevisiae*

3056 Bavarian Weissen. A blend of s. *cerevisiae* and *delbrueckii* to produce a south german style wheat beer with a cloying sweetness, when the beer is fresh. Medium flocculation, apparent attenuation of 73-77%.

Wine Yeast  
- - - - -

3021 Prise de mousse, Institute Pasteur champagne yeast race bayanus. Crisp and dry, ideal for sparkling and still wine and fruit wines. Low foaming, excellent barrel fermentation, good flocculating characteristics. Ferments well at low (55xF) temperatures. Also can be used for Barley wines.

3028 French (bordeaux) wine yeast ideally suited for red and white wines which mature rapidly or reds requiring aging. Moderate foaming, low sulphur production over a wide temperature range. Enhances the fruity characteristics of most wines.

Sake Yeast      *Saccharomyces sake*  
- - - - -

3134 Japanese Rice Beer Yeast Strain for use in conjunction with Koji (Aspergillus oryzae) for making a variety of sake styles. Full-bodied profile with true sake character.

Malo-lactic Bateria

-----  
Leuconostoc oenos

4007 Malo-lactic culture blend isolated from western Oregon wineries. Includes strains Ey2d and Erla. Excellent for high acid wines and low pH. Softens wines by converting harsh malic acid to milder lactic acid. Can be added to juice any time after the onset of yeast fermentation when sulphur dioxide is less than 15 ppm.

BRAND NEW ALE, LAGER, AND LAMBIC YEAST STRAINS (as of 11-18-93)

1968 Special London Ale Yeast. Highly flocculant ale yeast with rich malty character and balanced fruitiness. High degree of flocculation makes this an excellent strain for cask conditioned ales.

1728 Scottish Ale Yeast. Rich smokey, peaty character ideally suited for Scottish style ales, smoked beers and high gravity beers.

2565 Kolsh Yeast. A hybrid of Ale and Lager characteristics. This strain develops excellent maltiness with subdued fruitiness, and a crisp finish. Ferments well at moderate temperatures.

2278 Czech Pils Yeast. Classic dry finish with rich maltiness. Good choice for pilsners and bock beers. Sulphur produced during frementation dissapates with conditioning.

3068 Wheinstephen Wheat Yeast. Saccharomyces delbrueckii single strain culture for German wheat beers.

3944 Belgian White Beer Yeast. Rich, phenolic character for classic Belgian styles, including Grand Cru.

3273 Brettanomyces bruxellensis. Belgian lambic style yeast with rich, earthy, odiferous character and acidic finish.

Vic Keranen

just in case you are wondering, I don't work for either co. Just a homebrewer who figured I should pass this on since I haven't seen this info anywhere else.

From: "Moore, Brian" <Moorebw@hvsmtpl.mdc.com>  
Subject: Grains/Easymashing

Hello All,

Just a few general grain questions:

First of all, I've been looking at a lot of recipes lately to find some tasty pale ales and such. Many of these recipes call for something on the order of 1/2 # 30 (L) Crystal, and 1/2 # 90 (L) Crystal. Would this not be the same as 1 whole pound of 60 (L) Crystal? Would there be any difference in the flavors either way?

Secondly, I've been considering buying one or two fifty pound sacks of 2-Row malt (There's a place in Orlando where you can get a fifty pound sack for \$19.95). Since I don't have a mill, I'm going to buy the grains pre-crushed (Free crushing). I will probably use them all within a couple of months. I've heard talk that crushing grains and then keeping them around for a while will cause the grains to "go stale/bad". What exactly does this mean? Will the stale/bad grains not give me as much goodness? Will my beer taste stale? Should I even be concerned or is this more of the boogy/bogyman talking?

Now on to easymashing ...

Sorry Jack, this isn't about an E(e)asymasher (I'm a cooler man myself). Here is a technique John Goodman and myself have used to cut our all-grain brewing time in half. Hopefully this will help some of you out there who are afraid of the extra time all-graining takes. Since my house is only about 5 miles from work, I go home for lunch (about 10 minute trip). Immediately upon arrival, I put about 2.5 gallons of water on my propane burner to heat to about 175 F. In the seven minutes this takes, I put all of my premeasured grains in the cooler (slotted copper manifold, etc. etc.). Once the water is heated, I mash-in and put the lid on the cooler (The mash temperature stabilized at about 158-160). Now I grab a quick sandwich (not necessarily off the garage floor) and return to work. Total time: about 45 minutes.

Once back in the office, I work for about 2 to 2.5 hours (this technique does call for leaving early, although I guess a 3 or 4 hour mash isn't out of the question). When I get back home, the mash temperature is down to about 145 F. Next, I heat the sparge water (10 minutes), sparge (30 minutes), begin heating runnings immediately after recirculation, bring to

boil (20 minutes), boil (90 minutes), cool/aerate/pitch yeast (30 minutes).

Total time after work: 3 hours. Done by dinnertime! If only I could find a way to sparge while I'm at work.

Subject: Thanksgiving

Good afternoon fellow brewophiles,

Came upon a copy of "Early American Beverages" (John H. Brown, Bonanza Books, 1966) the other day. This delightful history is full of recipes for beers, wines, mixed, "temperance", and medicinal drinks from early colonial times to about the Civil War. In the spirit of Thanksgiving, I offer this excerpt:

"Common Beer: Two gallons of water to a large handful of hops is the rule. A little fresh-gathered spruce or sweet fern makes the beer more agreeable, and you may allow a quart of wheat bran to the mixture; then boil it two or three hours. Strain it through a seive, and stir in, while the liquor is hot, a teacup of molasses to every gallon. Let it stand till lukewarm, pour it into a clean barrel and add good yeast, a pint, if the barrel is nearly full; shake it well together; it will be fit for use the next day.

The Way To Live Well, 1849"

How's that for turnaround time! of course there were better brewers around too:

"English Beer, Strong: Malt 1 peck; coarse brown sugar 6 lbs.; hops 4 oz. ;  
good yeast 1 tea-cup; if you have not malt, take a little over 1 peck of barley, (twice the amount of oats will do, but are not as good,) and put into an oven after the bread is drawn, or into a stove oven. and steam the moisture from them. Grind coarsely.

Now pour upon the ground malt 3 1/2 gals. of water at 170 or 172 degrees of heat. The tub in which you scald the malt should have a false bottom... bored with gimlet holes... to hold back the malt meal. When the water is poured on, stir them well, and let it stand 3 hours, and draw off by a faucet; put in 7 gals. more of water at 180 to 182 degrees ; stir it well, and let it stand two hours and draw it off. Then put in a gallon or two more of cold water, stir it well and draw it off; you should have 5 or 6 gals. (sic) Put the 6 lbs. of coarse brown sugar in an equal amount of water; mix with the wort and boil 1 1/2 to 2 hours with the hops; you should have eight gals. when boiled. When cooled to 80 degrees put in the yeast, and let work 18 to 20 hours, covered with a sack; use sound iron hooped kegs or porter bottles, bung or cork tight, and in two weeks it will be good sound beer, and will keep a long time; and for persons of a weak habit of body, and especially females, 1 glass of this with their meals is far better than tea or coffee, or of all the ardent spirits in the universe."

I'll Bet! Happy Thanksgiving Y'all.

Subject: Box crates, Lids, G.L.V.M., AND Smoke

Hoppy Thanksgiving All you Brew Dudes and Gals,  
A few ago one person asked about crates for beer bottles, I contacted  
a local dairy and was told that the plastic crates are not for sale, I  
lack blocked grey matter to steal, so I made some out of 1x8 and 1x3 pine,  
cost was about \$11 for material and produced 4 stout clean boxes, much  
cheaper than a \$15 plastic crate and a whole lot cheaper than jail. Size for  
30 bottles, 12oz is 12 1/2"x 15" I.D. If any need plans, just hollar.

After fighting the lids on my plastic fermenter and disturbing the  
sediment, I bought some lids from a paint store, they are NEW, HDPE,  
and they hav an airtight 2 1/2" bung that is handy for checking progress  
and access for racking. The lid has skirts on the side for easy removal  
and installation. Cost: \$2

Has anyone out there tried using the cousin of hops for flavoring or  
any other value? I refer to Green Leafy Vegetable Matter, its a sick bird,  
[ill-eagle] Results? I am just curious...

In HBD #1280 Ed asks about Rauchbier, hey Ed I am going to try this;  
Take some apple wood from my pruning, let dry and "charcoal" in my  
smoker, then add to the primary and let it perk away, just a few  
briquets should have some good clean flavor to it. Any other ideas?

Subject: Partial Mash

#### Partial Mash for Extract Brewers

To do a partial mash, the extract brewer has to do a small amount of tinkering, and invest in a small amount of additional equipment. By doing this, the brewer can learn the methods of mashing, get an idea of the time involved, and see a difference in the beer, without having to make large investments in lots of equipment. This procedure can be used to modify all-grain recipes which include uniquely flavored grains, but that require mashing, including but not limited to Belgian 2-row pale malt, vienna malt, munich malt, biscuit malt, and victory malt. It also treats specialty grains such as crystal, chocolate, etc. in a manner similar to the all-grain setup. The extract brewer can substitute pale malt extract for most or all of the relatively large amount of base pale malt (usually 2-row) and mash the rest of the grains, without building or buying a large kettle, etc.

An easy setup involves a small (3-6 gallon) cooler of any shape. These are found in almost any home and serve nicely as a small mash tun which will hold liquid and grains at temperatures up to about 170F. An occasional use in this manner will not harm it for later use as a cooler. In order to reclaim the liquid in it, a simple manifold can be made from two feet of 3/8" soft copper tubing. You can crimp the end of the tubing and drill some small holes in it or cut a few notches in it with a hacksaw. The openings in the manifold should face downward so that grain will not plug them up. Another choice would be to clamp a small piece of stainless steel screening onto the end of the uncrimped pipe. The type of manifold isn't critical, as it is the grain that actually does the filtering. This lautering mechanism will pull the liquid out of the grain using a siphon.

Remember that during mashing/sparging sanitation is unnecessary (although general cleanliness is always a good idea) because the hot liquor goes immediately into the kettle for boiling. The following equipment is necessary; much of it is probably already used by the extract brewer:

Usually these are the only two items needed to purchase:  
2' of soft copper tubing  
tincture of iodine (optional)

Most extract brewers have these items around the house:  
Small cooler

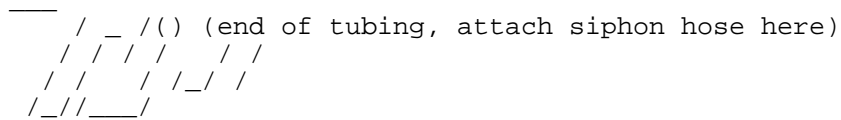

siphon hose  
 white plate (optional)  
 hydrometer  
 thermometer  
 kettle  
 fermenter  
 etc.

Diagrams:

SIMPLE MASHING SETUP

SIMPLE COPPER TUBING MANIFOLD

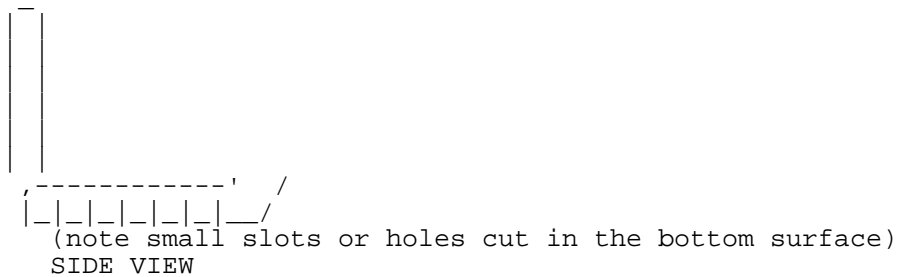

TOP VIEW

BOTTOM VIEW

(end of tubing, attach siphon hose here)

Up-front work:

Bend the copper tubing (be careful not to kink it) into a shape similar to the

one shown above, keep the up-pipe below the cooler lid level so the lid will close. The only reason for the funny bends are to allow the tubing to stand up by itself while dumping in the grains, etc. You can do your own versions of it and probably come up with something better (a partial loop comes to mind).

Put the copper tubing in the cooler to check the fit.

The mash:

Dump the crushed grains (have the homebrew shop crush them for you) on top of the manifold. Add hot water per the recipe and "dough-in" the grain. This involves making sure that all the big chunks of grain are all moistened. Check the temperature and adjust with hot or cold water to get to the proper mash temperature (usually 150-156F). The enzymes in the barley will handle short durations of temperature extremes with no problems, so don't worry. Just make sure you have a couple quarts of near boiling water and tap water ready to adjust the temperature. When you hit your mash temperature, close the lid and wait 30 minutes. Recheck the temperature (it is best to just leave the thermometer in the mash) and adjust back up with hot water if it has dropped more than 4 degrees. Wait another 30-60 minutes and do the iodine test if desired. During the mash, you can be heating the sparge water so it will be ready at the end of the mash.

The iodine test (optional):

With a clean spoon, stir the mash a bit and let settle for 5-10 minutes. Dip some liquid (a spoonful is plenty) off the top of the mash and pour it onto a clean white plate. Drop a drop of the iodine onto the mash liquor. If the iodine changes black in any part, there is starch remaining and you should continue the mash. If it remains the same red/brown color, starch conversion is complete and you can continue. It is probably good to do this test at the very beginning of the mash, just to see a positive starch test as a reference. Then do it again after mashing; the starch test should be negative.

The mash-out / sparge:

Dump the ground specialty grains into the cooler. Then dump all the sparge water at once into the cooler and stir the mash. Close the lid for a few minutes to allow settling. Note that this is not a true mash-out because the

overall temperature of the mash doesn't rise very much due to the thermal mass of the goods already in the cooler. Mash-out for the homebrewer is debatable at best and it is not important for the beginning masher. Next open the cooler, attach the siphon hose, and start a siphon by sucking on the hose or any other convenient method. Remember, sanitation is not an issue at this point because this liquid is heading for the boiling kettle. Drain off all the liquid into your kettle. Note that it is best to have the kettle 2-3 feet below the mash/lauter tun (cooler) so you can maintain a good strong siphon to drain the liquor from the grains.

The rest is just like an extract brew. Add your extract and boil away. All of these extra steps will take a couple of extra hours but it will give you an idea of what all-grain brewing takes, and should increase the variety of recipes available to brew. Best of all, it is easy and cheap!

>let's get back to brewing.

Pam, seeking advice is fine, but you have to put up with the egos of the advice givers. That's life. Deal with it. This forum is give and take and it really frosts me when the only reason for a post is to flame/counter-flame etc. Give something or take something, but don't whine about it.

\*\*

Tom Leith writes:

> I have begun work on a kegging FAQ and I will need a few knowledgeable contributors and reviewers to help me.

Whoa pardner! You might talk to Dion Hollenbeck and coordinate. He has been doing the same thing for the past several weeks. Also, not to gripe (more information is always welcome), but your FAQ looks more like a book. Sounds great, though.

\*\*

I would add one thing to Mark A's "iodine test on dark mash liquor" problem. I always advise people to do an iodine test at the very beginning of the mash (dark/light doesn't matter), as a reference. Then do it again at the end of the mash. If you know what a positive starch test looks like, it is much easier to determine a negative starch test. I still do this sometimes when I'm bored.

Tell him that there are any number of sanitizers that are perfectly acceptable for homebrewing. Off the top of my head: bleach, iodophor, B-brite, boiling

water/steam, alcohol, many others. I think the Zymurgy Gadgets & Equipment issue has a long article about them, but it has some wholes in it as well. Bleach is probably the cheapest of them all, but they all have different pros/cons.

Subject: Alternative FAQ Formats

I recently downloaded the Yeast FAQ and found that it was chock full of great info. However, I found it difficult to use as is, so I decided to create a booklet out of it with PageMaker. In addition, I also created a Yeast FAQ Windows Help File. The point of this post is to ask if anyone would find either of these formats useful?

The booklet file is a HP Laserjet print file of about 93K compressed. All that is needed to print a booklet on 8.5 X 14 paper (8 sheets) is DOS and a HP Laserjet. It's a great way to distribute FAQ's to your friends and club members.

The Windows Help file is about 60K and runs with Windows 3.1, although it probably would run with 3.0 also. It's loaded with all of the nifty Windows Help stuff.

The idea here is to create a Help File and Booklet for all of the other homebrew FAQ's and then upload them to the archives, if there is enough interest. IS THERE?

If anyone can assist me in getting in touch with the right people to arrange for uploading at sierra.stanford, I would appreciate it.

If you have any comments, email me at b\_regent@holonet.net, or to rec.crafts.brewing. (bob regent)

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: 200 IBUs/Grains of Paradise

Al Korzonas writes in response to my posting of a historical reference that IPAs of the time had IBU ratings of around 200!

My first reaction was that this can't be right! So I went back and checked the reference that gave me the 2.47 ozs number (per five gallons) for dry hopping.

I recalled calculating the IBUs for the "ordinary home ales" and came out with 52 IBUs based on 5% alpha hops and 20% utilization and Rager's gravity adjustment. OG of the ale was 1.080 and hopping rate was 8 lbs/quarter of malt. It took 12 quarters to produce this strength of beer, so 96 lbs of hops was used in 1900 gallons (US) of wort.

But the same reference also states that "20 lbs per quarter of the best hops shall be used" for ales and porters brewed for the India government.

Assuming the same 5% alpha and OG of 1.080, this translates to 203 IBUs at 30% utilization (Rager's formula unmodified). Using my more conservative utilization of 20%, we still get a whopping (hopping?) 143 IBUs!

So Al is right (or close anyway). These musta been some beers! Buffalo Bill Owens (who started the first US brewpub and coined the term) brewed an ale called Alimony Ale, "the most bitter brew in the world" but I never tried any (I've had the real alimony, thank you). Has anyone ever brewed or tasted beer this bitter? I think I'm going to add some iso alpha extract to some Anchor Liberty and get it up to 150 IBUs to see what it tastes like. I'll let you know if was actually palatable or not.

BTW, in case anyone's interested, the reference I'm using is The Manual of Brewing: Scientific and Technical by Egbert Grant Hooper, 1891.

\*\*\*\*\*

Now I'll ask a question. In the recent Zymurgy, an article talks about hop substitutes, as does Hooper in the aforementioned book. Here's a quote (talking about hop substitutes): "Narcotic principles are little used now except in very low neighborhoods. We have, however, reason to fear that grains of paradise are still sometimes employed with the object of increasing the intoxicating character of the beer, and imparting a fictitious sense of strength."

What is (are) grains of paradise? I would have assumed opium of some sort, but a previous sentence reads: "the substances which at various times have been used to wholly or partially replace hops or intensify the bitter or narcotic character of the beer are very numerous, and include gentian, quassia, aloes, marsh trefoil, broom, wormwood, cocculus indicas, grains of paradise, opium, tobacco, picric acid and strychnine."

Note that grains of paradise is listed separately from opium.

Clues anybody?

(Yes. Strychnine and picric acid. Don't try this at home kids.)

**Subject: brew belt problem**

I am a very careful brewer and have been brewing successfully for the last two years without incident. However, my last six batches have been flops due to contamination. I have exhausted all avenues and am getting very disgusted. I even sought advice on the net to ensure my bottle washer is germ free.

I consulted a friend who is a microbiology lab technician and she has the following theory about the use of brew belts. I have purchased a brew belt 6 batches ago and coincidentally never had a good batch since. I consulted a few brewers on the use of brew belts and they said no problem and to look elsewhere for the contamination source. I only use the brew belt for 12 to 24 hours to start the fermentation since by basement is 60 degrees. She claims that 75 degree wort is a good environment to permit yeast to grow and overpower the small amount of nasties present in initial wort. She claims all initial wort has a certain amount of nasties due to the fact that it is next to impossible to be 100% sterile in a home environment. She believes that the surface temperature of the brew belt (100 degrees +/- 5) kills the yeast which is in the general vicinity of the belt (1 to 2 inches). She claims that this area which is void (or almost) of yeast is a natural incubator for nasties which can grow rapidly at 100 degrees with little or no yeast to worry about.

Any thoughts?

Ed

valve,  
>close gas line, open beer line. Wait for beer to fill bottle under  
>pressure. Remove contraption and cap immediately.

O.K. as I understand what you are doing, you are missing a step. Here  
is the procedure as I am told. (Keep in mind that I have never done  
this, only read about it--story of my life :)

- 1) open valve to CO2 to presurize bottle.
- 2) open bleed valve to purge bottle of air.
- 3) close bleed valve and repressurize bottle.
- 4) close valve to CO2 5) open liquid valve -- beer will not flow at  
this point since the pressures are equal
- 5) slowly open bleed valve. This will reduce the pressure in the bottle  
and allow the beer to fill it up.
- 6) When bottle is full: close liquid valve and remove counterflow
- 7) cap.

That should do it.

From: Jim Cave <CAVE@PSC.ORG>

Subject: Error in Zymergy

When reading Ed Westemeier's article in zymergy about the old (as in historical) English recipes, I noted that the extraction/efficiency rates for these recipes are out of line. These are for 6 U.S. gal recipes. For example, the Usher Stout:

18 oz pale malt.  
6.5 oz carapils  
4 oz black xstal  
2 oz xstal  
2 oz Amber  
2 oz Brown

...This to produce 6 gals at 1.056 O.G. In this instance, I figure the recipe is out by about a factor of 6 (i.e. the recipe is for 1 U.S. gallon). The extraction rate would be about 32 points per pound per gal, which in itself might be optimistic for yields of only 6 gal. I'm not sure about the hopping but that might also be out by a factor of 6.

This logic does not seem to follow for the Whitbread porter:

2.5 lbs pale malt  
7 oz brown  
2.5 oz Black --- 1.060 O.G. 6 gallons

When I follow the logic for the Usher stout in this situation, I get 1.100+,  
So....what gives?

I think Ed is on the digest so perhaps he could comment?

Subject: Jim Koch

I find it strange that there are people in this forum that judge a man by the beer that he makes. Unfortunately, that's not how it's supposed to work. You judge a man by his actions, deeds and the way he treats others. Jim Koch is no exception. He should be judged by his actions and not the beer that his company makes.

I think there are currently enough people out there who have been sued or threatened with lawsuit by Koch to start a new forum. Call it the lit.koch.sued.digest or something like that. This man is a monster but unfortunately since I'm an atheist there is no hell for him to burn in.

I remember years ago when the gay community waged their campaign against Anita Bryant and her homophobic preachings. Remember? Every time she went to speak in a public forum she would get a cream pie in the face. Pictures of her with pie on her face got more media attention than her message. Eventually she gave up. A fiendishly effective tactic if you ask me.

>with champagne yeast. My response is why? I brewed an Imperial Stout using  
>only Irish Ale yeast from Wyeast. I didn't have any problems with it  
>fermenting out.

My line of thinking was that there's a large amount of fermentables in this batch, and I used the dry yeast packet that came with the kit.

I'm not sure if they'll be able to make full use of all the goodies...

I have had batches where the provided dry yeast didn't ferment anywhere past approx 4%/vol, even though there was ample fermentables, and was hoping to get somewhere between 8% and 10% with this batch.

Perhaps my paranoia is unwarranted, as for the past day or day and a half the sounds coming from the primary are akin to a LARGE bowl of rice crispies... I guess the yeast really likes it :-)

Yes. There are references to hopping rates of 20 lbs per quarter, and yes the formula does equate this to 200 IBUs (but how accurate is the formula when extrapolated to these extremes?) Rather than adding hop extract to get some theoretical level of IBU, why not try brewing a beer with this hop rate?

>So Al is right (or close anyway). These musta been some beers!

They are, I can assure you!

> Has anyone ever brewed or tasted beer this  
>bitter?

Yes. A number of times. The Durden Park Old British Beers book gives the following recipe for one Imperial gallon (1.2 US gal):

Original India Pale Ale   OG 70  
    3lb Pale Malt  
    2.5 oz Goldings Hops

An infusion mash and 90 min boil - I leave the detail to you. The recipe corresponds to the heaviest IPA shipped from Burton-on-Trent in the 1830s according to the reference. Simmond's of Reading were shipping an almost identical formulation (2.9lb pale malt plus 2.25oz hops) in 1880.

It should be matured for \*at least\* eight months (it was a long way to India)

Give it a go Mark

>BTW, in case anyone's interested, the reference I'm using is

Subject: re: almost there

James,

congratulations on getting set up!

As to your questions,

yes, 5 grams of dry yeast should be plenty. Some people want to pitch the larger packets, or two small ones, and the more you get in there, the better, but 5 is enough. Be sure to aerate *\*very\** well. Doesn't matter how much yeast you put in if there's no oxygen for it to use...

no, there should be no problems using the liquid extract instead of dry.

I have heard arguments that syrup is better, because it has not been as highly refined as the dry, and I've heard counterarguments that syrup is just dry with water added back. In either case, you don't do *\*worse\** by using syrup. One caveat: syrup is equivalent to dry plus 20% water, so, if your recipe calls for 5 lbs dry, you need 6 lbs syrup.

I've never used one of these gadgets, but I'd say your friend is right.

Beer yeast \*does\* thrive at 75, and anything over 90 is not good for it.  
On  
the other hand, ~100F is perfect for the nasties to breed in.

Why do you bother with the setup? Even tho your basement may be at 60, if  
your wort is at 75 when you pitch, it will take hours if not a couple of  
days to equilibrate down to 60. Why not just put a jacket of glass wool  
around the carboy/fermenter? When it eventually reaches 60F, it's still  
(barely) warm enough to ferment ales.

You might also be able to put some insulation between the brewbelt and  
the  
fermenter, so it doesn't come in direct contact with the wort, or even a  
second waterbath that you keep warm, and put the fermenter in that.

One thing's for sure: I'd brew my next batch without the belt, and see  
what  
happens.

From: WESTEMEIER@delphi.com  
Subject: Rauchbier replies & Zymurgy recipe correction

Many good ideas about my rauchbier aroma question:

Bob Jones suggests that Rauchbiers can be divided into the ones that are drinkable and ones that win competitions. He also advises me to decide if I'm brewing them to my taste or for competitions.

I agree completely. As a Certified judge myself, I can appreciate the problem of the jaded palate after a half dozen score sheets. I think I'll forget the competition aspects of it and just brew the beer I enjoy.

By the way, I was surprised that so many people asked why I would bother with the style. The fact is that the only commercial example I know of in this country (Kaiserdome) is pure swill. I don't know if it's a shelf life problem or what, but if that's your only experience with the style, you're right to question my sanity. It's nothing at all like what you'll find in Franconia. Brew some yourself (or come to Cincinnati and try mine) to see what it's really like. A fine Oktoberfest with a subtle smokiness that adds to the flavor and doesn't compete with it. THAT'S Rauchbier!

Mike Schrempp suggests "dry smoking" by adding a few handfuls of smoke in the secondary. This is a marvelous idea, and I'll give it a try, but I use pretty thick smoke and I don't know if I can force it through the narrow neck of a carboy. His other suggestion sounds more practical. I've already sent off my \$29.95 for an EasySmoker (tm).

Ulick Stafford's idea of bubbling smoke through the secondary is probably more practical, but I don't feel comfortable with the infection risk in such an arrangement. Intriguing thought, though!

Mark Bunster's idea of smoking the finishing hops is also very intriguing. It may not have a large effect, but if the smoke is kept fairly cool, it might work.

Ed Quier's idea of putting apple wood charcoal in the primary is interesting, but I guess it won't impart much smoke flavor or aroma. I'm very curious to hear the results of the attempt, however!

Thanks to all for the suggestions and interest.

+++++

ZYMURGY RECIPE ERROR

Jim Cave asks about the (obvious) error in the recipe quantities in my Zymurgy article. Others also probably missed the correction so here it is again:

The quantities shown are for ONE Imperial gallon, NOT 6 US gallons.

To convert to 5 US gallons, multiply everything by 4.2

To convert to 6 US gallons, multiply everything by 5.0

The Zymurgy editor has promised me that a correction will appear in the next issue. No one is really sure how it happened, but it is clear that it would not have occurred if they had sent out proofs for review prior to printing. Ah, deadline pressures!

Again, apologies to all for the recipe errors.

Subject: Cider Problems

Well, I opened up my first bottle of cider last night and I was very disappointed. It was well carbonated, crystal clear, and altogether okay but for one thing: it had an overpowering sulfur flavor. The good cider flavor was there, and the added cinnamon was as well, but the sulfur was the dominant flavor. Yuck.

My guess is that I overdid the campden tablets. Outside of adding them and sterilizing with a weak (as advised in a winemaking book) solution of metabisulfite, I don't know how else I could have gotten the sulfur flavor in there. Anybody have any other ideas? I took sweet cider (read:unfermented) added some cane sugar to raise the S.G., some tannin, acid blend, yeast nutrient, and champagne yeast. It fermented in primary for one week, and in secondary for about one month. I bottled and it has set for about one month.

Any ideas on what went wrong?  
Does it just need to age longer?  
Can I salvage this stuff?

Thanks for any advice,

Sean V. Taylor

Subject: very low s.g.

my friend and i tried to make our first batch of beer today (try being the operating word). it was a semi-disaster, but between a cracked carboy and burnt malt extract on the bottom of the pan (dude, are we supposed to stir this?) we got the stuff racked. here's the problem: we weren't really that exact with our water. we just cooled the wort, dumped it in with some cool water and topped off the carboy (good thing we had three of them available) so that there was about three or four inches of air space left. we thought we had it, but the starting gravity was way too low. the recipie says o.g. should be about 1.036 and ours was 1.014. so, should we just throw it out and start over, or can we introduce some super- concentrated wort, or should we even worry about it? or should we just call it "unintentional light beer"?

You have 5 gallons of this stuff? Does it smell/taste burnt? (you did mention burnt malt at the bottom of the pot.)

I guess I would say I'd need more info before I can tell you what to do with it... what's your setup? I.e., how big a batch of wort can you make at one shot? What was the recipe? I.e., did you hop this stuff 'appropriately'?

If the proportions are right, you could just brew another batch of wort and thicken it up a little. If they're all out of whack, or it tastes burnt, toss it.

On the other hand, if you can make a decent beer out of OG 14 wort, Anhaeuser Busch will pay you millions for the recipe. :)

>i'm not really able to contribute to the HBD in a positive way (yet).

Heh... just share that super recipe with us so we can share in the wealth. ;)

From: eurquhar@sfu.ca  
Subject: golden syrup - the last chapter

Enough with the golden syrup and treacle. In an attempt to settle this here is how it's made and what it's made from.

Golden Syrup is a british style sugar product. It is made by a controlled hydrolysis (breakdown) of concentrated (read saturated solution 67% w/v) cane sugar syrup with a strong acid usually hydrochloric acid. The reaction is terminated after approx. 1 minute by neutralizing the acid with a strong base usually sodium hydroxide. This gives the finished syrup a dark golden colour and caramel flavour with a very slight salty taste as table salt (sodium chloride) is produced during the reaction. Treacle is produced in a similar way just a requires a longer conversion time. Invert syrup is produced similarly with an acid such as citric acid or by enzymatic means. Both reactions take place in hot syrup to speed the reaction. Chuck Wettergreen's recipe is a good example of how invert syrup is made as it is often not neutralized after the reaction is finished to your satisfaction ie. is a lvely rich golden colour. Heed his words about boilover and make sure that all the sugar and acid is dissolved fully at low heat before starting the conversion step. The reaction would work as well just below boiling except maybe take a little longer.

Golden syrup but not treacle is made in Vancouver, British Columbia by Roger's Sugar by the exact same processes as Tate & Lyle in Great Britain from usually Australian raw sugar. Tate & Lyle was asked by Roger's Sugar to setup their plant in British Columbia before the turn of the century. No I won't ship any to anyone but ask your major supplier to call them and inquire. They are STRICTLY WHOLESALE. While your at it inquire about their demerara sugar. Makes american brown sugar look like ordinary granulated white sugar. Once you taste it you'll never go back.

For what it's worth, before heading back to university I worked as a quality control technician in the B.C food industry and am quite certain of my facts.

Subject: Gravity

for anyone who got a good laugh at my last post, you'll like this one  
(i'm  
only writing this to redeem my reputation):

i realized that an original gravity of 14 was damn near impossible  
barring  
any major disasters in the brewing process, so thought about it for a  
while and then it hit me: we had poured the 3 1/2 gal. wort into about a  
gallon of cold water and then topped the carboy off with cold water. this  
mixed with the wort just enough so we couldn't see the inversion layer we  
had created.  
sure enough, today we carefully stirred it up with a sterilized coat  
hanger  
and took a reading and it was up to 28. i guess that's still pretty low,  
but our yeast has been going like crazy for the last 18 hours, accounting  
for at least a few points.  
by the way, (when) will the fermenting beer clear up?

From: TiM@world.std.com  
Subject: "Falstaff Tappers"

At my not-so-local homebrew haunt, I encountered a person who had several old "1-case capacity" Falstaff Tappers. They looked like mini-stainless kegs with a tap on one end. It appeared the keg was intended to lie on its side. The kegs looked like they would make great homebrew "travel-kegs" much like the new "party-keg" CO2 cartridge taps. The mini-kegs looked about 15 years old, but who knows, they were found in an attic.

Does anyone know how to care for these mini-kegs? Can they be re-used as "travel-kegs" for homebrew? We spent about 15 minutes looking at the keg, and couldn't figure out exactly how to get the mechanism on the bottom of the keg unlocked, or how to pressurize the keg if we did.

There must have been quite some expense in setting up to produce all these "Falstaff Tappers".

Thanks for any responses.t(

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>  
Subject: Durden Park address, hopping rates

Hello all,

It seems the Zymurgy issue on Old English Beers has caught the attention of quite a lot of us (not least because of the unfortunate mistake concerning volumes). Well, first some questions: I don't subscribe (and suspect the sub is astanomical to Switzerland), but have read here various opinions on the publication, ranging from good to a complete waste of money..... Well, should I ask Santa Claus for yet another present? Secondly, has anyone got Harrisons (sp?) address, or alternatively that of the Durden Park club? (Sorry to whoever supplied me with it before, our mail server choked and died YET AGAIN recently and I lost all my saved messages).

Finally, a comment on the hop rates in the Zymurgy issue: I've brewed a 1055 Pale ale with 3 oz Fuggles and 2 oz Goldings. At bottling time I regretted it considerably, since it tore the roof of my mouth off. However, about half a year later (sorry no notes here) it was wonderful. The hop flavour was unlike what I get by any other means.

On the same subject, Clive LaPense (sp?) who also write a book on historical beers, has commented on his recipes in a freebee Brewing and wine making magazine in Britain. His detractors all questioned the "ridiculous" hopping rates he gave. His answers were:

1. Let it mature long enough, and
2. Try it.

I would definately agree.

Rob. Thomas.

I have used Demerara sugar by Tate & Lyle and have also used domestic  
light  
and dark brown sugar in homebrewing. While I found the imported Demerara  
sugar  
interesting, IMO it is not vastly superior to domestic brown sugar. T&L  
Demerara sugar has a smooth, pleasant flavor of molasses. This character  
is  
easily emulated with a quality domestic light brown sugar or light  
molasses.

Relax mon. Everything sounds like it is going in a normal way.  
If you want, you can rack it off to a secondary container, but this  
isn't necessary.

>also, we have a brown ring around the neck of our container from the

From: btalk@aol.com  
Subject: which yeast?

I have a doppelbock recipe that has performed well in contests, and in the quest for the best( also known as the never ending tweak), I started thinking about choice of yeast. I've used Wyeast 2308 Munich, made into a starter. Fermented @47 f for 3 weeks, 55f for 1week,back to 47 f for 1 week, then lager at 32f for 3 -4 weeks. Does anyone have experience with (or contrast/compare) Wyeast 2308 munich vs. Wyeast 2206 Bavarian?

The 2206 Bavarian description seems to stress the smooth maltiness that a doppelbock should have.

I have a fridge to use for lagering, so low temp ferments aren't a problem for me.

Any thoughts here would be appreciated.

THANKS MUCH.

From: Mark A. Stevens <stevens@stsci.edu>  
Subject: Alternative FAQ Formats

In Homebrew Digest #1282, Bob Regent (b\_regent@holonet.net) mentioned that he was creating a PageMaker layout and Windows help file of the Yeast FAQ and asked if these were useful.

My feeling on this is "No---not the way they are."

While a nicely laid out booklet format for the FAQ might be useful, putting it up on the net in a vendor-specific format requiring a specific brand and model of printer is decidedly net-user-hostile. Generally Bob, people put things up in a format that is NOT limited to one software and/or hardware vendor's products so that as many people as possible can make use of your hard work and so when the specific product you geared your work toward is phased out your work doesn't become a useless disk-space waster.

For most information, ASCII text is the most useful format, so you'll find that no matter how great a job you do, the ASCII format will still probably be more often used because EVERY platform and software can handle an ASCII file. For a layout, PostScript is the most intelligent choice because it is supported by a wide range of different vendors and because PostScript file viewers are available for most platforms and because LOTS of different software can import PostScript. (DVI or TeX are not unreasonable choices, but not as many people know how to handle DVI or TeX files so these aren't optimal choices).

For the Windows help files, I'd say these are pretty much useless for two reasons:

- 1) Form doesn't follow function. When I'm brewing or culturing yeast, I'm doing so in my kitchen, not at my computer. A document like the layout can be printed out and taken to the kitchen with me to look at as I perform whatever process is being described, a help file is totally useless because I don't keep my computer in my kitchen. Simply a mis-application of technology.
- 2) Vendor-specific again. Not EVERYBODY uses or wants to use MS-Windows.

If you really are enamored of hypertext help, then a generically useful format that allows for information discovery might have some utility. This means investigating tools like HTML and WWW to put up a net-based hypertext that anyone anywhere in the world can access with a click of the mouse. This might require some work, but would be a useful tool.

In any case, stay away from vendor-specific formats if you want to be a good net citizen.

Salut!

In the NCJOHB it says there is an advantage to the removal of the very bitter and brown resinous scum on top of the kraeusen (less of a "bite" and the "fusel" oils are removed which contribute to what is referred to as "beer headaches"). A "closed" fermentation system (5 gal carboy with a overflow tube) facilitates this. I use a 6 gal carboy with an airlock ("open" fermentation system). Should I switch to a "closed" system and is there really a noticeable improvement in the flavor of the brew?

From: Ed Hitchcock <ECH@ac.dal.ca>

Subject: HSA again...

In Austin + Pugsley's article in the special issue Zymurgy they describe the technique for a good infusion mash. They say to use enough hot water to cover the false bottom, then run a stream of strike water and a stream of crushed malt together, so the malt is thoroughly covered with water when

it gets to the bottom. Once the mash lands, leave it. They also say that

the streaming process traps air in the mash, making it more buoyant, so that it does not jam up the false bottom. This mention of trapping air in

the mash set off little alarm bells. Can it be that less air contact is made this way than gently stirring? Or is this just the case for large scale mashes, where "gently" stirring is next to impossible?

From: Jason Goldman <jason@bluestar.cnd.hp.com>  
Subject: Re: Rauchbier

This last May, I took a beer trip to Germany and one of my stops was in Bamberg, home of Rauchbier. My only previous experience with this style was Kaiserdom Rauchbier, which I found to be totally undrinkable. However, when we were in Germany, a friend of mine (who is not known for drinking 'weird' beer) recommended Spezial from Bamberg. Also, Michael Jackson recommends Schlenkerla in his world guide to beer. So, we stopped in at Spezial first. I was amazed at how good the beer was. The smoky flavor was clearly there, but balanced perfectly with a wonderful malty sweetness. While the smoke was assertive, it wasn't a sharp, harsh, or chemical-like flavor. I was talking to my table-mates (who were all local) about America and beer. They asked me how I liked my beer. I told them that I liked it alot and that I had only had Rauchbier once before I came to Bamberg and that it had been Kaiserdom. Before I could say that I hadn't cared for the Kaiserdom, my table-mates spit on the floor and told me, "Peh!! That is awful beer. No, Spezial is the real Rauchbier." Then they leaned forward to impart a great secret: that the \*best\* Rauchbier is Schlenkerla. They proceeded to draw me a map to get to the place. One fellow explained that I would have to have 3 beers when I went there. He said I might find the first one a little bit strong. He wasn't able to tell me if it was strong with smoke or alcohol. Anyway, by the time I finished the first one, I'd be accustomed to the beer and be ready to have a second, where I could really appreciate the taste. I asked him why I should drink a third. He looked at me as if I were crazy, "Because it is so good, of course."

We made it to Schlenkerla the next day. This beer was also very malty. The smoke flavor was slightly heavier and the beer was more alcoholic. I liked it from the first sip (no need to get acclimated), but my wife preferred the Spezial because it was mellower.

I judged Smoked beers in the first round of the AHA nationals (in Denver). The style includes rauchbiers as well as other styles. I was warned that many of the entries would be likely to rip our heads off with smoke flavor. Actually, I found two or three good examples of rauchbier which had assertive yet complementary smoke flavor. I also learned that peat smoked beers (like at least one smoked porter and some smoked Scotch ales) can have a very harsh, phenolic character. There were also a couple of entries that had very little smoke character at all. One of the other judges was familiar with Bamberg style rauchbiers and both the other were experienced with other smoked beers. I think that we passed on some good beer, none of which were overwhelmingly smokey. However, I do believe that this is a style where one person's evaluation of overwhelming corresponds to another's evaluation as perfect.

Mark Alston wrote:

> This dark color brought out another problem. There would be no way  
> to tell if iodine went black or not. The mash was black on it's own.  
> Thus, I could not test for conversion.

One way to avoid this problem is to wait to add the dark malts until  
mash-out (or until after conversion). I do this with my porters,  
and have achieved excellent results. You still get all the color  
and roastiness out of the malt, and perhaps get less harsh tannins &c.  
out of the black grains.

I've got a question of my own regarding apple cider. I made my first  
batch this fall, using apples from the tree in my back yard. Boy howdy,  
pressing apples is a pain! Next year I'll probably use fresh,  
unpreserved juice to start off with. However, you see both "apple  
juice" and "apple cider" in the stores. Is there a difference? If so,  
is it chemical, biological, or just legal/regulatory? And of course,  
which will make better hard cider?

From: gjfix@utamat.uta.edu (George J Fix)  
Subject: Caustic washing

Glenn Anderson asks in HBD#1281 about residuals from caustic (NaOH) detergents.

First, let me say that a 2% sodium hydroxide (NaOH) solution is the most effective detergent known to me for removing heavy organic soils. This, however, is not play stuff. Protective gloves and glasses are definitely required to prevent severe burns.

Pure reaction quality NaOH can be obtained in grocery stores under various product names. The one most widely available in the Southwest is called Red Devil. Analysis has shown that it is indeed 100% NaOH, and contains no impurities. You can get the same stuff from Fisher Scientific, but at an outrageous price.

Caustics are strong surfactants, and will definitely leave an inorganic film. Vigorous hot water rinsing may or may not completely remove this film.

Thus in commercial practice a caustic wash is followed by a rinse with a sequestering agent to remove inorganic residuals. The most popular such agent by far is phosphoric acid. The main reason for this is that it is a weak acid that is natural to beer. A widely used sequence goes as follows:

- a. Hot water pre-rinse
- b. Caustic wash
- c. Hot water rinse
- d. Phosphoric acid wash
- e. Hot water rinse

This is generally all that is required of brewing equipment. Cooling apparatus, fermenters, et al need an additional sanitation sequence.

Misc. Notes:

1. Large industrial brewers apply the caustic solution at 180-195F. I have personally found that a solution at 120-140F is almost as effective, and a good deal more practical for hand operations. We are now recommending that even small micros and brewpubs use the lower temperatures. This has proved to be adequate. See e.g. Dave Miller's column in Brewing Techniques.
2. If you have any doubt about inorganic residuals, apply a standard iodophor solution. The former will turn the latter as white as snow.
3. The most widely used iodophor in commercial practice is the version which has iodine and phosphoric acid as the only active ingredients. This provides some sequestering action to counteract surfactants, however the sequestering step (step d above) is still used in the wash cycle.
4. Industrial brewers typically use a 5% phosphoric solution for sequestering. I have personally found that a 1% solution is adequate for all but extreme cases. While this solution is only weakly acidic, gloves are still recommended. The sequestering solution

can be added at ambient temperature.

Subject: Re: very low s.g.

I think I know why you may have your very low gravity. If you only boiled a gallon or so, it has a very high density (gravity) and hence will sink to the bottom of the carboy. I literally saw this happen with some of my first batches. Eventually, the temperature differential will cause some mixing, but you will be better off mixing it immediately after pouring. Actually, you will be really better off getting a larger pot and a wort chiller. Get some mail-order brewing supply catalogs for ideas, see the Zymurgy magazine special issue on gadgets, and beg, buy, or borrow some books on the subject. A stitch in time etc. :<)

From: sdlsb.dnet!73410%sdllcc@swlvx2.msdl.ray.com (Carl Howes)  
Subject: Guinness clone?

I will be brewing a stout this weekend with which I hope to emulate Guinness. I looked at Papazian, Miller, and Cat's Meow over the weekend and developed the following extract/specialty recipe:

7 lbs. M&F light DME  
1 lbs. flaked barley  
1 lbs. roasted barley  
0.75 lbs. crystal malt  
1.66 oz Chinook hops (12.6%) at 60 min.

A note on my current limitations. Brewpot: 16qt size, effective maximum capacity 12qts. This is why the hopping is so heavy, to compensate for the very high SG in the pot. Scaling is based on Papazians' table with the goal of coming out equivalent to 15AAU in a full volume boil. The questions: some sources call for rolled barley, some for flaked. My local supplier had never heard of rolled. Are they the same thing? Papazian and Miller both simply specify "high alpha" hops in their "Toad Spit" and "Dry" stout recipes. In scanning the back HBDS I have on hand, I find Goldings (I assume Kent) recommended by Brian Bliss in #1145, and Geoff Cooper in #1150 states that Guinness uses Target. Where all the hops are for bittering, does the variety really matter? Several sources call for an addition of soured ale for a Guinness clone. I assume a lactobacillus souring, or is this a momily? TIA.

>to be a problem. (They all taste great!) I know the WYEAST is  
>underpitching, but... Which is better, all around for the entry-  
>level brewer, liquid or dry?

With the recent arrival of much better dry yeasts, I'd say that perhaps dry yeast might be better for beginners because it is easier to use. The slow, long ferment with Wyeast is probably due to under-oxygenation. A package of dry yeast contains much more yeast than a package of Wyeast and since the yeast is oxygenated just before drying, dry yeast can cope better with under-oxygenated wort. This is a common occurrence for dry yeast users when they first switch to liquid yeast. A starter will also help shorten lag time and reduce fermentation time quite a bit.

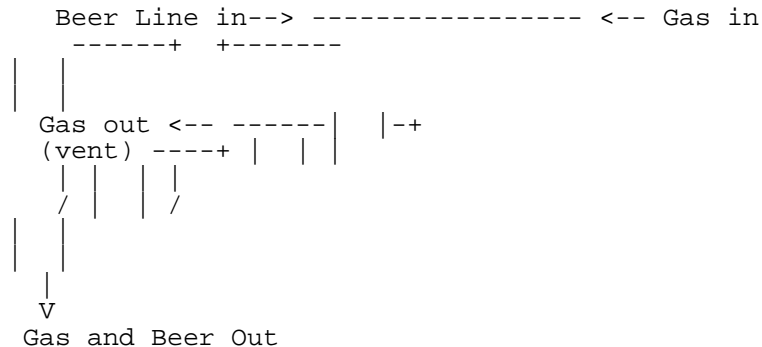

Did anyone else notice that two first-place winners in the AHA National Competition were made with EDME dry yeast?!?! I also happen to know that the Best of Show winner at the 1993 Chicago Beer Society Spooky Brew Review was brewed with Red Star Ale Yeast!

\*\*\*\*\*

Dave writes:

I recently recieved a counterpressure bottler as a gift. Yesterday I got the assorted hoses and connectors that I need to run the thing, and it didn't take long to find out that I don't really know how to work it. There are two general possibilities: I'm hooking it up wrong, or I'm using it wrong. So, first, this is how I hooked it up:

<I've modified Dave's drawing to be hooked up properly>

The way it should work is to first let CO2 through the "Gas in" leg, with the "Gas out" valve opened to purge the O2 from the bottle.

Then, close the "Gas out" vent valve to pressurize the bottle.

Next, close the "Gas in" valve and open the "Beer Line in" valve.

Gently open the "Gas out" valve to fill the bottle.

Once the bottle is full, close the "Beer Line in" valve and remove the device.

RE: commercials and commercial beer:  
>These beers are intended to be and are soda pop for adults.  
They are nothing more than an alcohol delivery system. They  
have only a limited usefulness in our society. They encourage  
abuse by their very characteristics.

\* E.G.: Ice Beer by Miloooooor. Ads say it's "ice brewed, till  
xtals form, then cold filtered" makes it "easier to drink"...  
implied: Lots and Lots of it! Right?

So what the %&\$ is the deal here. Ice brewed? Now they got a  
special yeast which ferments at FREEZING temps or something?  
And what's the point of the xtals. Do they filter them OUT so the  
beer is "stronger", then water it down again so it's suitable as  
Utah 3.2 near-beer?

I intend to distill, ugh...uh...ummm.....I mean- "enhance" a brew  
this winter, by doing the ice beer thing. Concentrate, yes that's it!

Plastic bucket, outside after fully fermented, then rack away from  
the ice. Keg, and carbonate. Anyone ever tried it? I would think  
that with the colds we've had already, getting it frozen shouldn't pose  
a problem. Hope no cops see it sitting outside! (or high schoolers for  
that matter!)

But what does Miller think their process is? Anyone REALLY know, or  
is it what I presume, another advertising ploy to impress the ignorant  
mindless masses who don't have a clue what REAL brewing is all about?!!!

\*\*\*

> Dave Rose. asks bout cp filling  
>close gas line, open beer line. Wait for beer to fill bottle under  
pressure. Remove contraption and cap immediately.  
The problem: Well, if I thought about it i would have figured out  
that since the keg and the bottle are under the same pressure, there is  
no  
reason at all for the beer to move from the keg into the bottle. In  
fact,  
this is exactly what happens: nothing. Or at least very little.

...responded to by Mark

- 1) open valve to CO2 to presurize bottle.
- 2) open bleed valve to purge bottle of air.
- 3) close bleed valve and repressurize bottle.
- 4) close valve to CO2
  - \* Be sure to do this!
- 5) open liquid valve -- beer will not flow at  
this point since the pressures are equal
- 5) slowly open bleed valve. This will reduce the pressure in the bottle  
and allow the beer to fill it up.
- 6) When bottle is full:
  - \* You might want to first close exit valve, then  
... close liquid valve and remove counterflow
  - \* Even more important. REMEMBER THIS! Unless you want beer  
flying everywhere!
- 7) cap.

\* Have your cap ready in capper (magnet! :) and a towel underfoot, I've understood this to be a gushing experience.

- \* Make the kegs be as cold as possible to reduce foaming. Chilling the bottles after sterilization if a good thing too. You may want to have another set of hands attached to you, or someone else near by for this. I've heard it takes an octopus!

NOW... "That should do it.... Sounds good."

RE: Setup of lines: Miller shows two alternatives (BWGB):  
the one you had

```
gas in---|____|-- Beer in
|
|_|-- Gas out/purge
Bottle
```

and

```
gas in---|____|-- Purge, gas out
|
|_|--Beer in
Bottle
```

Both have a T connector splitting the gas line between cp-filler and keg. Therefore they stay under the same pressure.

BTW: I've haven't done this yet- so yes I'm blowing out my \_\_\_\_\_  
BUT: I've read, discussed, and thought about it a fair bit! So nyah.  
\*\*\*

Sean V. Taylor has <<<sulfer cider>>>:

Any ideas on what went wrong?  
Does it just need to age longer? \* BINGO!!!  
Can I salvage this stuff?

\* Patience grasshopper. When you can snatch this pebble from my palm you will be ready to quaff that cider!

\* The ciders I've done and tried were sulfury when young (as with some wines/fruit meads) and the sulfur aroma dissipated with age.

You could let the bottle breath for a time before drinking too. Pour it fairly roughly. But really- age is the best solution. Mine have set for half a year, to a year, then were wonderful!

\*\*\*

A friend is starting to brew, and has access to filter equpt, but does not keg. He does have a pump, so it could be done.

But why? My thoughts on filtering leave me in the 2-3 micron range, big enough for yeast to pass, w/o losing body. (too much) But not sterile filtering. If he's gonna bottle he has to be sure to leave yeast for carbonation, or repitch. Either way there will be sediment in the bottles.

Question is: Is there any advantage to be gained by filtering that wouldn't be better served by fining with ---something, anything!--- rather than hassle with filtering. It just seems so simple a step to add for a kegger (ya sure, you betcha it's on my x-mas wish list!) but for a bottler?

ANYONE FILTER WHO DOESN'T KEG? HOW / WHY / WHEN / WHERE / WHO...what?  
\*\*\*

>Many of these recipes call for something on the order of 1/2 # 30 (L) Crystal, and 1/2 # 90 (L) Crystal. Would this not be the same as 1 whole pound of 60 (L) Crystal? Would there be any difference in the flavo2s;either way?

\* Uh,,, no. Sorry but it doesn't work that way. The kilning process darkens the malt to different degrees. Along with this are changes in the quality of starches, sugars, and colors of the malt. Each crystal is considered separately in estimating color.

Lighter crystals will give a sweeter note to beers. Darker crystals will give less sweetness, more body, and a "toasty" quality. Using some from either end gives you the best of both worlds and using twice from in between gives you some of each...sort of.

Mixing and matching crystals is a favorite pastime in the Coyote grain room. A general rule of thumb is are you staying light, or leaning into ambers, or yet darker. Stick below 60 (or 80) if you're working in pale territory, and go higher if you want RED amber beer, or are into the roastier nut browns.

...snip...

>(There's a place in Orlando where you can get a fifty pound sack for \$19.95). Since I don't have a mill, I'm going to buy the grains pre-crushed (Free crushing).

\* Say what? \$20 for 50# ! I've seen \$30 for 6 row, but that's the best. What a deal. Send me their address/phone! Shipping will kill it tho. What kind of malt is it? Belgian NOT I'm sure!

>I've heard talk that crushing grains and then keeping them around for a while will cause the grains to "go stale/bad". What exactly does this mean? Will the stale/bad grains not give me as much goodness? Will my beer taste

\* If you store it in a dry, fairly cool location it should be ok. Some of the enzyme/substrate quality of the grain will decrease. You can expect lower extraction rates. Just UP YOUR GRAIN BILL. If you use the malt within a reasonable amount of time and store it well (metal cans/plastic buckets...fairly airtight.) and concede to use more (which at \$20/50# = .40 \$/# isn't a problem!) you will be fine. Some people may encourage you purchase their grain mill, or you may come across a cheap... cor---onet!! or something. And that's handy! I'd say use within 6 months, and you're alright. Longer than that...

Brew More OFTEN. Brew MORE...often. a BREW more often.

From: Mark Garetz <mgaretz@hoptech.com>
Subject: Sierra Nevada and the Hop Back/Yeast

A long while ago I promised some info on Sierra Nevada's use of the hop back. I was supposed to take a tour with my homebrew club a few weeks ago, but illness prevented me from attending. I did finally talk to one of the guys who went, and here's the deal:

Sierra Nevada no longer uses the hop back in production of any of their beers. Instead, they have switched to dry hopping. The rate of hops was disclosed, but the person I spoke with couldn't remember, so I'm going to have to ask someone else. They use whole hops (everywhere) and put the hops in a hop bag for dry hopping. BTW, the reason given for discontinuing the use of the hop back was that it was too much of a hassle to clean and sterilize.

Other interesting tidbits: The question was asked if Wyeast 1056 (aka American and/or Chico) was the same strain as they used. The answer was to that they had no idea, but wondered why it would matter since "you can get our yeast from a bottle of our beer." Their yeast came from Siebel, and is banked there, so maybe someone with a connection at Siebel could tell us more. Also, they claim never to wash their yeast, and they repitch it about 20 generations before starting with a fresh culture.

I'll report again when I've had a chance to debrief more of the club members.

of
> days to equilibrate down to 60. Why not just put a jacket of glass wool
> around the carboy/fermenter? When it eventually reaches 60F, it's still
> (barely) warm enough to ferment ales.

My recent experience with Wyeast 1056 is that 60 is indeed barely warm
enough to ferment. The beer fermented out pretty well but it was mild.
Does anyone have any recommendations for yeasts that work well at that
temp?

Should I think about using lager yeasts? Maybe a lager/ale combination?

Someone asked a couple weeks ago about mixing yeasts in a batch, a
question

I've wanted to ask the HBD community for several years since in making
one

of my first beers, a pack of dry lager yeast was purchased by mistake and
used along with a dry ale yeast. This was one of my better beers of that
era. I don't recall seeing any responses to the question of blending
yeasts.

Its often said that yeast is one of the major factors in the flavor of
beer - seems like this must have been tried at least a few times?

Subject: yeast, cowboy beer

Homebrewers,

In response to the liquid/dry yeast question, I vote for liquid yeast only. The only batch in which I ever used dry yeast (EDME) came out tasting very metallic. I tried a bottle that had aged for six months and it was better, but still only barely drinkable, and this from a guy who sometimes enjoys mega brews. The last time I was at the homebrew store, the proprietor was testing the Doric, Windsor, and Nottingham (sp?) dried yeasts in side by side comparisons. He judged the Winsor and Doric better than the Nottingham, but said he would not use dry yeast in anything he brews personally.

On the subject of historical beer, I saw "High Plains Drifter" the other night and wondered to my self, "Self, what kind of beer is that saloon serving?" It came from the tap under pressure, the glass was half full of head, and it was light golden. I guess it came from a wooden keg and was pretty harsh. Anyone know?

Subject: Whitbread update

A month or so ago, Chris Lyons asked about the new Whitbread.

The new Whitbread dry yeast has never been distributed due to the inability of the processor to produce a clean product. Repeated attempts have failed. Crosby and Baker states that the new Whitbread will not be available for at least another 6 months and they are not terribly optimistic about that given the recent history of contaminated Whitbread.

George Fix has claimed, on the digest and in Zymurgy, that the new Whitbread is available and that it is clean. Moreover George claimed to have received very good scores at homebrew competitions for beers made with the new Whitbread. George claimed that new production procedures are the reason for the new and improved Whitbread. It's now glaringly obvious that all of these reports were in error. I advised digest readers months ago to view the reports as wishful dreaming lacking any sound scientific basis because of the patently obvious flaws in George's methods.

For those who still put credence in George's earlier reports, just ask him where to buy a pack of the new Whitbread.

For those who are still purchasing Whitbread, please note that Crosby and Baker, the U.S. distributor, states it was produced well over a year ago.

Subject: Aluminum Brewpots?

I am relatively new to homebrewing, having made just two extract batches. However I am starting to scrounge up the hardware for mashing. My wife has a canning setup she has had almost forever. It has a 2-gallong pot and a 6 gallon pot, both made of aluminum.

Should I use them for boiling my brew? I know back in the '80s there was talk of a link between aluminum and Alzheimer's Disease. I thought that had been downplayed or disproven, yet I never see aluminum listed in the brewing books as an alternative. If safety is not the issue, why can't I use these? I would point out that a LOT of jams and jellies have been made in them, without apparent ill effects. <At least I don't REMEMBER any loss of memory! ;^) > They haven't dissolved or corroded. Why would wort be any different?

Any feedback will be appreciated. I really don't relish shelling out bucks for a new pot when these are already here.

>souring, or is this a momily? TIA.

first of all, omit the crystal malt. guinness is a very dry beer,
regardless of first impressions, and if you brew extract/partial biol,
the beer will probably be too sweet anyway (caramelization).

1.66 oz of chinook may not be enough if you only do a partial boil.
I've tried and tried to dup guinness, but keep underestimating its
bitterness. I now agree that it doesn't matter what kind of hops
you use if you boil long enough to drive off ALL flavor and leave only
bitterness. I'm an anti-american/high alpha* hop fanatic myself, and if
I
do taste any hop flavor (which you will if you use fresh morris-handbury
hop plugs even after a 60 min boil) in my stout, I like golding best.
(I mean kent goldings - I've haven't used much styrian goldings).

* => N Brewer is a notable exception.

If you use target hops, boil for 90 min. My long boils, however, may
be producing too clear of a beer for guinness (draft, at least -
guinness extra stout is actually quite clear, albeit dark). Don't
use any irish moss.

I've had good luck adding soured beer to the boil (but other flavors
and high hopping rates in those batches may be more the reason), and
bad luck adding lactic acid to the finished product, in varying amounts.
Does the boil drive off most of the lactic acid? No soured beer is
added to extra stout, only the draft version, to the best of my
knowledge.

Guinness has a lot of roasted barley flavor, and 1 lb is not enough, IMHO, for a "normal mash". people who add the dark grains at mashout may differ.

- brian_13 tries and still hasn't quite imitated guinness_bliss

yeah, but I find it safer than needles, and much more pleasant than everclear :-)

>So what the %&\$ is the deal here. Ice brewed? Now they got a
>special yeast which ferments at FREEZING temps or something?

...

>I intend to distill, ugh...uh...ummm.....I mean- "enhance" a brew

>this winter, by doing the ice beer thing. Concentrate, yes that's it!

I thought that they were freeze-distilled. What IS the deal?

I thought freeze-distilled meant that they had to be sold as hard alcohol? But then again, sherry and port wine have brandy added, but aren't sold as hard alcohol. Are they trying to force legal precedent?

>But what does Miller think their process is? Anyone REALLY know, or

>is it what I presume, another advertising ploy to impress the ignorant

>mindless masses who don't have a clue what REAL brewing is all about?!!

!

Well, they seem to have pulled zima off. Seriously, if they like it (and I've tried it, but much prefer a good gin & tonic), let the yuppies have it. Just don't call it "beer" (and they don't).

>inability of the processor to produce a clean product.

...

>For those who are still purchasing Whitbread, please note that Crosby
and

>Baker, the U.S. distributor, states it was produced well over a year ago.

I've seen it distributed by GW Kent, and more recently by C&B. I thought the C&B stuff was the "new, improved" whitbread. Nevermind, they both worked, I've never had a sour batch from either, and many a good batch.

(what do a few impurities matter if it takes off quikly enough to
overpower
them?) Sadly, the supply seems to be drying up again.

From: paul.beard@gatekeeper.mis.tridom.com (Paul Beard)
Subject: Cider requirements

Down here in the mountainous South, we can get a thick, brown apple
cider
(nothing like the pale sweet stuff foisted on kids). Being a big fan of
Westcountry (England) cider (again, nothing like Woodpecker or Strongbow
--
more like Silas's secret recipe), I'd like to make some of it. Since I
would guess this is as close as I can get to pressing my own, what steps
would have to take to get it fermenting? The stuff seems to ferment by
itself, even
in the refrigerator, so I'm guessing I really just need to control the
natural process.

Any suggestions/firsthand experience??

Subject: Whitbread Report

I started not to reply to O'Conner's flame in HBD#1285, however he has been responsible for so much misinformation on HBD I could not let this one pass.

The new Whitbread yeast was initially distributed to various commercial operations. It proved to be a poor flocculating yeast in unitanks, and the ADF achieved was lower than desirable (68-72%) in these tanks. Crosby+Baker decided not to distribute the yeast because of this. There were absolutely no complaints about the yeast not being clean. The bacterial and wild yeast counts were exceptionally low. O'Conner is blatantly lying about that point.

Don writes:

>George Fix has claimed, on the digest and in Zymurgy, that the new
>Whitbread is available and that it is clean. Moreover George claimed to
>have received very good scores at homebrew competitions for beers
>made with the new Whitbread. George claimed that new production
>procedures are the reason for the new and improved Whitbread. It's
>now glaringly obvious that all of these reports were in error. I
advised
>digest readers months ago to view the reports as wishful dreaming
>lacking any sound scientific basis because of the patently obvious flaws
>in George's methods.

The score sheets of the competitions entered are on file with Crosby+Baker.
O'Conner has never asked to see these and check them out. The names of the judges are on the sheets, and given that many are on HBD I am deeply offended by O'Conner's wild assertions.

Another reason C+B decided not to distribute the new Whitbread is that they have been getting good reports on the Mauri and Red Star strains. I recently entered a bitter in the Spooky competition that was fermented with the Red Star yeast. It took BOS. I have not received the score sheets (can someone in Chicago help me here), but copies of these will be sent to Crosby+Baker when I get them. Those and all the others can be obtained from C+B for those that are interested.

>top. Any recommendations on how to move that little freezer compartment
>out of the way. The freon lines run through it, so it will be kind of
>tricky. Also, what equipment will I need for the tap? Thanks
>
>Harry Covert

When dealing with freon, caution is warranted. The most important thing
in relocating the freezer compartment is not to crack the freon lines.
The lines are usually constructed of fairly pliable metals than can allow
some freedom of relocation. You might try dropping the front of the
freezer compartment down to give you access for your tap line/s in the
front.

The freon lines are most likely attached to the box in the back, but if
you have connections in the back and the front you may have some
problems.

There will also be some kind of thermostat control attached to the box
that may need to be detached from the box to regain temperature control.
Remember when you alter the unit, the cooling capacity is also altered.
Since older units are less likely to be frost free (that's good for
temp control) moving the freezer may cause heavy frosting. An Air Stat
or similar temperature control device will be helpful. In older,
single door fridges the freezer unit is often the cooling unit
for the entire fridge.

As far as equipment needed to install a tap, you will need a
Beer Faucet & Shank (Available from some Homebrew shops and mail order).
The shank should come with a Hose Tail Piece and Coupling Nut.
Make sure the hose tail piece is the same diameter as your dispensing
lines from your keging system. Since you wish to install the faucet on
the
top of the fridge you will need a dispensing tower on which to attach
the faucet. The most recent copy of Zymurgy advertises such a device on
the inside back cover. Bar supply stores will also carry the tower
as well as the faucets and hardware.

It might be easier to install through the door rather than on the top of
the
fridge. It would avoid the hassle of moving the freezer and the added
cost of the dispensing tower.

I have used Demerara sugar by Tate & Lyle and have also used domestic
light
and dark brown sugar in homebrewing. While I found the imported Demerara
sugar
interesting, IMO it is not vastly superior to domestic brown sugar. T&L
Demerara sugar has a smooth, pleasant flavor of molasses. This character
is
easily emulated with a quality domestic light brown sugar or light
molasses.

Subject: Leinenkugel, Weizenbock and H2O ph.

In HBD 1285 Tom Vodacek writes:

From: THOMAS VODACEK <VODACEK@uwplatt.edu>
Subject: Leinenkugel's Winter

I have heard that one of the megabrewers bought up Leinenkugel's last year and that regular Leinie's is no longer brewed in Chippewa Falls, just specialty seasonal beers. Can anyone tell me the true story?

I attended a Pennsylvania Beer Festival recently and, along with a bunch of micro breweries, Miller and Strohs were present. Miller had their two all barley malt beers (I liked the ale) and two Leinenkugel beers (one with a red label and the other with a black label). Miller said they now own Leinie's but still brew it @ Chippewa Falls. Strohs had three different lines of beers. One called Augsberger included a "dopplebock" that had little or no aroma and could not have possibly been a true dopplebock. There was also a Signature series and a Cream Ale made by a company in Canada (starts with an "S") that had no label on the bottle, just raised glass lettering. Nice bottle, okay beer. The best beer was probably Red Feather Ale made in Chambersburg, Pa.

Just recently returned from Munich and the best beer I had was a weizenbock from Schneider called Avintinus. It is served in a very unique wheat beer glass at their beer hall near Marienplatz.

Here's my homebrew related question: I have been brewing for three years now (all grain for 2 1/2 years) and have not had too many problems. I and my friends think the beer tastes fine (I also took first place in a LOCAL contest in the pale beer category in '92 with a Dortmunder Export)

However, I usually taste a slight metallic off-flavor. I think it might be related to my water ph. Basically my water ain't base, in fact its acidic. I have a spring feed house and the ph is in the 4.0-5.0 range. As a result I usually have to add Calcium Carbonate to RAISE me mash ph rather than gypsum to lower it! Is this really strange? My shower has a tendency to turn copper blue every several months! This my be a question for the plumber's digest but its the acidic water slowly eating away at my copper pipes? I haven't splurged for a complete water analysis yet but I'm certain the water is soft (I boil it and get no white residue). Any advice? TIA.

From: Paul Sovcik <U18183%UICVM@UICVM.UIC.EDU>
Subject: Bottling Sanitation Experiment

Well, after a year of "taking" from the HBD, I will "give" a little back. In the spirit of Jack Schmidling and true science, I decided to conduct an experiment that would help me decide on the value of sanitizing my bottles in terms of homebrew taste.

MATERIALS AND METHODS: One five gallon batch of porter was prepared using standard homebrew procedures. At bottling time the bottles were divided into three groups. Group one was unsanitized bottles that were only rinsed out after the last homebrew was emptied from them. Group two was santized with a weak bleach solution with a contact time under 3 minutes and rinsed with tap water, the bottles in this group were actually filled with about 3 oz. of solution and this was swirled about once. Group 3 was anally sanitized with a full soak for 30 min in a weak bleach solution, and then rinsed with tap H2O. The bottles were then separated and stored under similar aging conditions.

RESULTS: The anally sanitized batch and the "casually" sanitized batch (groups 3 and 2, respectively) did not differ in terms of taste. The unsanitized batch of bottles (Group 1), however, had a noticable off flavor. This was confirmed in both an unblinded way (I tasted the marked bottles) and in a blinded way (I poured for a friend without telling him that one was bad!)

DISCUSSION: I conclude from my results that sanitation is necessary, but anal retentive sanitation is not. Actually, I expected to find that sanitization was not necessary, and that the unsanitized group would be fine. I also was surprised that the off-flavor (which I cant identify...it was kind of a cidery taste most promenant in the aftertaste...a "thinness", if you will) was prominent in many of my early attempts (about 5 yrs. ago) at brewing.

Well, just my futile attempt to try an actual (gasp) experiment here, instead of relying on the contradictory opinions of "expert" authors.

Subject: cleaning Easymasher, big tuns

Hello Homebrewers,

I have been using Mr. Schmidling's Easymasher system for about 5 batches now, and have found it to perform as advertised, that is, very well and very easy. I have run into one small problem, which is that it seems to be getting a little clogged after multiple uses, leading to stuck or slow sparges. Examination shows some of the screen holes plugged. I have gone after it with needles and a toothbrush, but does anyone else have a good method for cleaning? Also, I could replace the screen every 5 batches or so. Hints?

My other question has to do with setting up my own pico-brewery, for 10-15 gallon batches. I would like to set up a large mash tun, made out of some good metal material, like a half barrel or something. Questions are, what is good way to set up sparge (would Easymasher work?) or false bottom the diameter of the tun with holes. Also, every commercial brewery I have seen has two tuns, one for mashing, one for boiling. Is there a good way to use the one vessel for both (ala Easymasher)? I have liked the time savings coming from starting to boil immediately with the sparge, but I wouldn't want to be hiking from my garage to stove 2 cups-at-a-time with sparge output. What do others do? Lastly, would you recommend getting a propane burner, or using natural gas, tapped in from house supply (assuming I could do this or have this done without turning my house into a Hindenburg.) Any suggestions would be appreciated.

Thanks,

Tim Sasseen

From: Drew Lynch <drew@chronologic.com>
Subject: Re: Counterpressure filler

Al (and net-folk),

I also have one of the CP fillers like the one you describe. I found that one additional step helps keep down foaming: Before I close the beer flow, I close the gas out valve. I then close the beer flow, and reopen the gas out valve slowly. It adds a little time, but I've found it reduces the likely hood of last second foam buildup.

I was curious about a couple of things...

- 1) What pressure do you run the system at?
- 2) I was considering replacing the gas in and beer in valves with ball valves, and adding a ball valve to the gas out line. It seems to me that this would save a lot of finger wear and tear. Has anyone else tried this?

> of my last few batches of oktoberfest that ended up much too dark.

The chocolate malt is really emphasized by the brewery-- very distinct, and the slight boost in alcohol content seems appropriate for a wintertime beer. It's a specialty beer, available for only two months: Nov - Dec '93.

> I have heard that one of the megabrewers bought up Leinenkugel's
> last year and that regular Leinie's is no longer brewed in
> Chippewa Falls, just specialty seasonal beers. Can anyone tell me
> the true story?

Jacob Leinenkugel Brewery of Chippewa Falls was purchased by Miller Brewing Co. in 1988. Apparently Miller was very interested in acquiring an established beer with a regionally popular label while the Chippewa Falls brewery needed capital and increased brewing capacity to service the heavy beer markets in the Milwaukee-Chicago corridor. The acquisition finally broke the 120 or so years of Leinenkugel family ownership although the family still runs the brewery. A friendly arrangement as far as it goes; the expected outcries from loyal drinkers.

The first year, Miller did nothing to affect the product. A year or so later they started using the Leinenkugel label on beer made in Milwaukee using the Leinenkugel recipe. To the exception of the water that is, as Chippewa Falls has a world-class pure water spring that the brewery draws from. Leinie's regular is made in both locations-- it depends on distributorship which location your local supply comes from.

Thus far, what you've heard is correct. Each specialty beer (Leinenkugel's Limited, Red Lager, Bock, the Dark Lager from last year, and the Winter Lager from this year) are made exclusively at the Chippewa Falls brewery. There are no immediate plans to change this as the brewing practices of the specialty beers will keep it mostly regionally successful while Miller continues to probe the mega-market with its own speciality products for now (e.g. Miller Amber, Reserve, Clear, etc.).

Subject: A Wedding, Homebrew, and Texas

Hello Fellow Homebrewers,

I have made a great decision in my life. No, it does not concern whether I will use a counter-flow chiller over a immersion chiller (definitely the counter-flow). I have asked a wonderful girl in Texas to be my wife. The wedding has been set for July 2, 1994 in Fort Worth, TX.

I want to provide a substantial amount of the beer for the reception. I am going to try the logistical equivalent of the Desert Storm in homebrewing by brewing 50 gallons beer, 10-15 gallons of mead, and 15 gallons of hard cider. All of the beverages will be in the 5 gallon kegs to allow for easy storage, transporation, and serving. It will be a sizable reception of about 400 guests. This may not be enough beer but with the Coors Light (ughhh!) kegs for the Mother-in-Law, this should be a good start.

Here is my dilemma, I live in Los Angeles, CA and either have to brew here and transport there or brew in Texas on the few weekends that I go back. Either way, I will need a place to store the beer out of the Texas heat. If anyone can help me by suggesting a storage place or allowing me to brew with their equipment, I would be most grateful (even compensational with the beer that is brewed). Please respond at the E-mail below.

Brewing for a Better Tomorrow,

Michael Froehlich

Subject: Turkey Leftovers & Scrumpy

(sent to Home Brew Digest)

I was telling a friend of mine about recent efforts to create a cherry mead, and we started talking about brewing in general.

Amidst our discussion, my friend mentioned "scrumpy".

"Scrumpy" is a British brew, usually beer (although it can be cider) to which has been added, in addition to the more conventional fermentable materials, some sort of meat.

The concept apparently extends back through antiquity. Naturally, the question of "why" arose.

My friend asserted that the addition of meat to the ferment created a better head ... foamier, longer-lasting. This, he confided, was straight from a friend of his, whom brewed at 20 Tank Brewery, here in San Francisco. (Said friend added turkey to his home brews, not to 20 Tanks' professional products, I hasten to add.)

I speculate that there might be an element of truth to this - perhaps the addition of meat, after decomposition in an environment otherwise devoid of the usual corrupting bacteriological agents, results in free colloids in the solution, which not only change the taste in a subtle way, but have the valuable and primary additional consequence of changing the characteristics of the brew's resulting foam, when poured.

So, if you were wondering what to do with those turkey leftovers, now, you have a way to get rid of that chunk of breast meat, and contribute to the cause of brewing science, simultaneously ... (-:

Subject: cool ferment temps

Ed talks about having a cold basement and the use of the Brewbelt.

I too have a basement that gets down to around 60 F or below in the winter and had a slow start on an ale last January. After 3 days I figured I had to do something. My solution was to waterbath the carboy in a 20 gal plastic trash can.

Total cost: 0\$ The trash can was holding Al cans for recycling, and my neighbor had a `gerbol from hell' that chewed up their fish tank - so he donated an aquarium heater to the cause.

There was a circumferential temperature gradient in the trash can, so I will use 2 heaters next time. I will also use some bleach in the water during the secondary fermentation. But overall it worked pretty well.

The waterbath with aquarium heater is also an effective way to maintain temperature while growing up yeast starters during the winter.

Ed, thanks for telling us about the Brewbelt problems.

Subject: Ice beer/Mixing yeast

Coyote, where have you been? Ice Beer is getting alot of hype in the Northeast US and in Canda. Molson, Labatts, and Genessee are all offering Ice Beer. They talk about brewing at ice cold temperatures, not fermenting (I considering brewing to be the entire process from mashing to bottling) so I don't get too worked up about the advertising terminology (for this and any other product). I believe Ice Beer has been discussed a few times in here and I'm pretty sure someone even verified that "freeze distillation" is not regulated/prohibited the same way as regular distillation.

Someone asked about mixing yeasts in beer. I've read that American Cream Ale and Kolsch styles of beer used both ale and lager yeasts. The recent posting about Wyeast strains listed a new Kolsch yeast which has both lager and ale characteristics.

Subject: Soda Ash Residue

I threw some labeled bottles in a sink of hot water last night and sprinkled some soda ash on top. In the morning the labels slipped off nicely but there was a thin opaque film that I rubbed off the outside of the bottles with hot water. The film is also on the inside. A bottle brush will get some out, but there are still patches with brush streaks. Running them through the dishwasher rinse cycle didn't remove more.

Is the film from the soda ash, the glue on the labels, or water chemicals?

I've usually used chlorinated TSP in the past, and will go back to that if soda ash is a problem. Also what is the chemical name for soda ash?

Thanks for your help.

Subject: Noche Buena y Leon/Guinness error/FAQ format

All this talk of Noche Buena (anyone know where I can get it in southern CA?) reminds me of one of the best bottled beers I've ever had. It's called Leon and it's brewed in the Mexican state of Yucatan. Some buddies and I were out cruising around the jungle and climbing the odd pyramid or two when we ran across this stuff at a cervceria in some town I never knew the name of. They had Corona and Leon (?caliente o frio?). Being familiar with Corona, the only choice was Leon, whatever that might be. Well, as it turned out, Leon was a very tasty dark red Vienna lager. Yar! My favorite style! I KNEW all that chanting "malted beverage malted beverage malted beverage malted beverage" on the airplane on the way down would please the Maya beer gods. Very well-balanced, not very sweet but with lots of body, and almost no hop aroma. A little like Spaten Oktoberfest in taste, only a little drier. A case of these babies on the veranda at Uxmal in the rain, jungle all around, a belly full of pollo pibil, and a real Havana cigar (I know, ruins the taste. Wait 'til Leon numero cinco before lighting up.) is heaven indeed. Stupid guy tricks. !Muy fabuloso!

As I remember it was about \$8US a case to begin with, \$3 if you brought all your empties back (!). They reuse rather than recycle their bottles. Either one helluva ("Oh, sorry" -- T. Jones 'A Fairy Tale') bottle-washer or the worst job in the Beer World. We looked around in Merida on our return from deepest darkest Mexico and couldn't find it. As Merida is the only thing that even resembles a city in the area, you'd think it'd be a good market. I really gotta wonder where this stuff is brewed. 'Course, we could have missed it... We also hunted a LOT for precious bottles of Leon upon our return to Cancun (having been unable to refrain from quaffing them within minutes of having said "let's save these"), but to no avail. Next trip I will make a serious effort to hunt this brewery down. I guarantee a case of this stuff will be one of my carry-ons when we come back from Cancun this September. Anyone care to trade for some Cranberry Lambic? ;-).

While I'm not working, I had an interesting (embrassing, really) experience the other night at the house of some buddies'. These guys have a keg fridge that is always well-appointed. They've had SA, Spaten Okt, Anchor, Newcastle, etc. you get the idea (They live in Costa Mesa, CA. Address avail on request). Well, I went over, helped myself to a free whatever was on tap, and thought to myself "that's the darkest beer they've ever had here." Looked, smelled, and tasted like a porter. My first thought was SN Porter (way off!), but it wasn't sweet enough. This went on for a while and I finally had to ask. The answer was Guinness. I really felt dumb. You'd think that somebody who drinks as much of the stuff as I do (my cat's name is Guinness) could pick out at least the tanginess of a Guinness.

There are two things that I can think of that might explain/excuse me: 1) the keg was at the proper temperature ('bout 55?) so what little sweetness there is may have come through and 2) while the keg may have been conditioned at one point with nitrogen (or is it CO2 & nitrogen?), it was about half gone and was being dispensed with CO2 only. It definitely did not have a typical Guinness head (big bubbles that didn't last very long). At no time did it really taste like Guinness to me. Thoughts? Ridicule?

And finally (finally!), a comment or two on Mark Steven's comments

on special-format FAQs. I think that while a rearranged or different format FAQ IS of limited usefulness (I rearrange my own), this would mean that much of the stuff already in the archives is of similar low worth (eg, brfware, brewsheets, images, co2.c, etc.). I work with 1974 technology (VMS, VT330) and do not have access to even PostScript (Though I'm not sure. Hard to tell with the hindrance called "VMS".) I think it's a mistake to say "let's use something everybody has" because that is the case, as Mark says, only with flat files. I'd still like to see what the brewsheet looks like. If there's enough interest, and it's acceptable to the good folks at Stanford, then Bob should get to post his reformatted FAQ. I think we have a little pride in having accomplished something here. Bob spent his own time on something he thought he himself might find useful. Having accomplished this and, in fact, finding it useful, he simply wants to know if anyone else MIGHT ('s'free, you know) also find it useful. Nada mas.

Dos mas cervezas rapido, por favor. Gracias y buenos noches.

Subject: Used Kegs?

Now that it appears DeFalco's won't ship used soda kegs anymore, does anyone have a good source that will ship small quantities at reasonable prices? My local shop wants \$35 each for them, which appears pretty high when compared to DeFalco's \$15 + shipping. Maybe part of the difference is made up in the fact that the homebrew shop has already replaced the o-rings, etc. and maybe DeFalco's hasn't (hadn't). This is no rush, I have two kegs on loan, but it would be nice to find a good price sometime so I can own my own.

As long as I'm talking kegs, I have a question. When you shake a keg to carbonate it, it is inevitable that some of the liquid will be forced into the gas inlet hose. I've seen check valves advertised in some magazines, but they are designed to keep the liquid out of your regulator (a good idea). They don't appear to address the issue of contamination via a dirty gas hose. Do you sanitize your gas hose? How? I don't particularly like the idea of disassembling the gas hose every time I do a batch, but if that's what it takes...

Subject: no subject (file transmission)

I have been sitting on the sidelines, reading HBD for a good part of a year, building up energy to actually ... you know, BREW BEER! The continued encouragement, support and lent equipment from my local brewer/engineer friends made it possible to spill wort on my sneakers this past Saturday. Other than fumbling around with a clogged strainer as I poured the wort into the primary carboy, it wasn't as difficult as I had imagined. My steam beer knock off is merrily bubbling in the basement (57 degrees F). Of course, it may be foreign beastie city in there - only time will tell. I think I'm hooked on this brewing thing and hope to contribute some wildly passionate, learned treatise on some important beer topic such as the whether to use stick or book matches to light the cooking stove (just kidding, I love fanatics). Anyway, all you almost-brewers out there, it is not (so far) as mysterious as it sounds!

P.S. A good word for St. Patrick's of Texas for prompt and courteous service in correcting a minor order problem.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: Golden Syrup

I've been catching up on some older HBD's and notice a thread on golden syrup. There were a few posts indicating that it was a single substance that could be approximated by creating invert sugar, or caramelising and so on. In fact, it's a rather special combination of sugars. Here's the information I got out of a book some time ago

It's composition is:

| | |
|-----------------|-------|
| sucrose | 27% |
| reducing sugars | 47.4% |
| other organics | 4.4% |
| ash | 3.2% |
| water | 18% |

I've seen reference to it in an American book as "golden invert syrup", as one form of liquid sugar. At any rate, the sugars make up 74.4% by weight of the stuff. If this was in the form of sucrose alone, it would crystallize out, likewise if it were reducing sugars, glucose would crystallize. The proportion (1.75 reducing sugars to 1 of sucrose) produces a stable liquid. In the refining process, none of the syrups in process have a high enough reducing sugar content, so special batches of "invert syrup" are made (sucrose solution heated in acid environment -> equal quantities of glucose + fructose). This is added to other syrups to obtain the right proportions.

From: Allan Rubinoff <rubinoff@BBN.COM>
Subject: hop utilization

I brew from malt extract, boiling only about half the wort and then adding it (after chilling in a water bath) to cold water in the carboy. I know that one of the problems with this approach is that hop utilization is less than optimal due to the high gravity of the boil.

It occurs to me that there may be a simple solution to this problem: boil the hops in plain water for an hour, and then just add the extract and boil for another 15 minutes to sterilize it. This should maximize hop utilization without compromising sanitation.

This seems like such a simple (and obvious) solution, that I wonder why I've never seen it mentioned anywhere. Does anybody know of any reason not to do this?

Thanks in advance,

Allan Rubinoff

From: troy@scubed.scubed.com (Troy Howard)
Subject: cool ferment temps

Rick Magnan asks about an appropriate yeast for fermenting at around 60F. Try Wyeast 2112 (California Lager). It is quoted as fermenting well up to 62F while keeping its lager characteristics. I, myself, have used it for ales (a couple of steam beers and a brown ale), and it has performed well even at 65F. Since it is a lager yeast it should not have any problem at 60F. I have a brown ale made with this yeast ('cause its what I had on hand) which has been raging at 63F.

From: lyons%adc3@swlvx2.msdl.ray.com
Subject: New red star yeast

I have experimented (tried) the new red star yeast on two different batches and would like to compare notes with anyone else who has tried it.

My notes include:

Lag time: slow (approx. 1 day).
Attenuation: 78% for all malt extract recipes (using 100% M&F light).
After taste: Thought it gave the beer a somewhat phenolic flavor, but this faded after 2 months in the bottle.
Fermentation: Very strange primary ferment ... a thick (1") head of yeast (I think this is what it was?) remained on top of the beer after the end of the primary ferment. Had to siphon below the yeast cake(?) when racking to the secondary. Never observed this with any other yeast?

Does anyone else have any comments on this particular yeast?

Thanks in advance,
Chris Lyons

From: Tom Clifton <0002419419@mcimail.com>
Subject: RE: Questions from COYOTE <SLK6P@cc.usu.edu> on filtering

My thoughts on filtering.... Why bother! According to Papazian a bit of yeast helps add to the stability of the brew. If you have followed the basics of good wholesome brewing (sanitation) there won't be any bacteria you need to filter out. Best of all, if you want good clear beer with no chill haze problems once you have carbonated your brew (primed and waited 7-10 days) all you have to do is to put the bottles in your 'fridge for two weeks or so at 34-36 degrees and the chill haze and "stuff" will precipitate out and you will have sparkling clear brew. Besides that, if you are brewing with a lager yeast this will give you a reason to wait another couple of weeks before drinking all your brew!

Subject: aeration/recipe/smaller batch?

to don biszek, who writes
>If you are reading Papazian, then why don't you follow his strongest
advice,
>and Relax!! Your beer will be the same whether or not you worry and post
>20 questions about each bubble that perks up!
>don

don,
i assure you that i am not stressed out about our beer, i am merely
asking
questions so that i don't make the same mistake twice. i'm sorry that
all
these questions are bothering you, but i will stop asking questions when
a) i run out of them
b) people stop responding because i am bugging them
i guess the answers to these are obvious, but remember that i really have
no clue as to the proper brewing procedure.
BTW: i have found that a good way to relax is to drink a few sierra
celebration ales (anybody know the % alcohol in those things? they sure
are
strong. i also couldn't quite place the flavors. anyone know what they
add?)

now for the real questions:

1) is it okay (or even advisable) to shake up and thus aerate the beer in
the middle of fermentation?

2) for our next recipe we plan on just improving on the righteous real
ale.

i thought a good recipe for 5 gallons would be:

- 6.6 lbs John Bull amber malt extract syrup
- 3/4 lb. cracked crystal malt
- 2 oz. cascade hop leaves (boiling)
- 1 oz. willamette hop leaves (aroma)
- 1/2 oz. willamette hop leaves (finishing)
- 2 pkgs. (10 oz.) Windsor dry English ale yeast
- 3/4 cup corn sugar (bottling)

does anyone know if these proportions are okay? i just kinda thought them
up, so i don't really know if it will work.

3) i want to try a batch without using the blowoff method, but i still
want
to use a 5 gallon carboy. if i make 4 gallons will the kreusen still
reach
the top of the carboy or would i be safe to just put the fermentation
lock
on?

thanks for all the help so far. if everyone gets sick of me just stop
answering my questions and i'll take the hint.

Subject: Kirschenbier and stream of consciousness

Whenever I can find cherrys again, I plan to try adding them to my standard bock. It seems reasonable (to me) to wash the whole fruit in a mild bleach solution, rinse, dry, smash (how?), force into a carboy (how?), then siphon from the primary onto them. I'm thinking about 10 pounds of cherries to a 5 gallon batch. Maybe freezing/thawing before smashing? Do the pits matter? Any comments appreciated, I'm flying blind.

Many thanks to the person who suggested that hops have no place in melomel. I'm eagerly anticipating the next batch without that "something's not quite right" effect.

Some beginner's advice on eliminating that pesky air bubble from a racking cane: if the wort's flowing at a good rate, a flick (thwack?) (like you'd deliver to a dog nose encroaching on your pizza) where the bubble is will cause the air to "break up" and flow down the siphon hose. As with a dog nose, it may take several strikes to be fully effective.

Finally, on megabrew advertising: I'd much rather see large-breasted, presumably buzzed young women cavort on the beach than Santa Claus shopping at K-Mart. For an extended slow-motion-bikini-volleyball scene, I might even buy a sixpack to give to visitors I wouldn't waste homebrew on :-)

Subject: hopping bracket?

Should bracket be hopped at all?

If so, what's a reasonable basis for the hopping rate? I can think of two references--the potential alcohol and the malt content--which suggest values that differ by roughly a factor of two. That is, if you do hop it, are you aiming to balance against the residual character of the malt, or the eventual alcohol, or somewhere in between?

I'd be interested to hear from either folks who have made (what they consider to be) a successful bracket, or anyone who has historical information on how bracket was really made. Since it was a fairly old style, was it really before hopping ale was common?

Mind you, I'm not tied to historical precedent, but I'd like to know what folks did with it.

Subject: Scrumpy!!

hello all,
having just finished reading hbd 1286, I have to pick up the bait.
Richard Childers mentioned Scrumpy, and the fact that it contained
meat. Well, Scrumpy is always Cider (ie never beer, as said in hbd1286).
It also does not by definition or tradition contain any form of meat.
SOME scrumpy contains meat (often beef due to sanitation laws). This
arose historically because often rats or even mice fell into the open
fermentors
quite regularly. The benefits of the extra meat were noted, and people
started
throwing stuff in to simulate the effect. What the effect is, I'm not
sure. Scrumpy is live (ie contains yeast), often unclear (due to lumps
of apple), and more often than not strong. I don't think it is GENERALLY
more fizzy, or with better head. But I will stand down on that if I
get a flame from a producer of such a product.

Oh my, and I said I'd never flame..... well, it's only a little spark.
Rob. Thomas.

From: ANDY PHILLIPS <"/G=andy/S=phillips/OU=cell biology/OU=lars/OU=i a c
r/"@AFRC.ac.uk>
Subject: Old British Ales

On the subject of high hopping rates in the "Old British Beers"
booklet (Durden Park Brewing Club), I recently brewed a barley
wine in a similar style to those in the book.

Ingredients (UK units and malts throughout):

7lb crushed pale malt
7lb " lager malt
2lb " wheat malt
1lb flaked rice

Mashed with 3.5 gal treated water at final temperature of 65-66C for 90
min in

picnic cooler. Sparged slowly to 3 gal total wort (I sparged a further
4 gal for a second beer). Boiled 90 min with 5 oz Goldings and 2 tsp
Irish

Moss. Final yield 2.3 gal at 1.112. Pitched with 500ml starter from Edme
dried yeast. Fermented 6 days, then racked into 2 gallon jars with
airlocks.

Fermented a further 21 days, then racked again into jars. Gravity when
last
taken was 1.035.

Despite the high hopping rate - I can't remember the IBU rating from BRF,
but it was well over 100 - this is not noticeable bitter. I suspect that
this is partly because the flavour is overwhelmingly malty, and the hop
taste can't get through, and partly because of the lower hop utilization
at high SGs. I don't know whether BRF is capable of an accurate
calculation
in the high SG range - the formula used may not be valid.

Moral - don't be frightened to overhop, especially at high SGs. Even if
the beer
tastes disgusting at first, it will mellow with age.

Cheers,
Andy Phillips

From: paul.beard@gatekeeper.mis.tridom.com
Subject: Turkey Leftovers & Scrumpy

I mentioned something this on either r.c.b or alt.beer. The scrumpy my family knows from the southwest of England is a strong cider, guaranteed to get you legless in one glass or less. It is not a commercial product, more like a farmbrew and I was told that the addition of a dead rat in a sock (like a teabag and for a similar reasons) was used advocates by some older practitioners.

In that region, scrumpy is hard cider and is not for the fainthearted. There's enough beer down there as it is and they call it beer, nothing else.

Has anyone else heard anything about this meaty concept? As a vegetarian, I could never drink the stuff, but I'm not sure I'd want to.

From: "Robert H. Reed" <rhreed@icdc.delcoelect.com>
Subject: ICE BEER

There has been some discussion regarding ice beer in the last few digests:

My information on the recently in-vogue ice beers is that that these beers are fermented like their non-ice beer brethren, and then aged at below freezing temperatures. While ice crystals are indeed formed, I think another important effect is the flocculation of certain substances that could make the beer less than "smooth". I know that LaBatt's, Molsen, and AB are making ice beers, but *not all* ice beer brewers filter out the ice particles that form during aging. Thus, some ice beers are normal strength and others have higher than "normal" alcohol content. Now if we could convince them to leave out the corn, rice, and heading agents...

Subject: Turkey Leftovers & Scrumpy

I read the entry on HomeBrew Digest regarding Scrumpy, and I happen to have a lot of turkey sitting around . . .

Does anyone have a "good" recipe for scrumpy?

I am at least curious about when the bird goes in the brew - --during the boil or mash?

I suppose the feathers would help strain out the trub :))

Reply to me, and I will summarize to the digest

Also appreciated would be some pointers to document how far in antiquity the scrumpy practice goes.

From: Jim Busch <busch@daacdev1.stx.com>
Subject: Re: Ice Beer & Witbread bashing

RE: Ice Beer

I believe the process used to mass produce ice beer is as follows:

1. Regular wort fermented (lower initial OG??, Same OG??)
2. Still beer passed through chilled line, forming ice crystals in suspension.
3. Ice crystals filtered out, along with yeast, proteins, and anything else that would give residual flavor to the product.
4. Deaeriated water *added* back in to the finished bright beer tank.

Obvious questions arise over the value of adding back in water that was just iced out. I have yet to sample one, but the brewers feedback is that it does taste different, and somewhat better. Yet another variation on the mass market products.

RE: Whitbread & flame baiting

First of all, I could care less about any dry yeast, even though I find the discussions interesting. I do care about intelligent debate on the forum, and hope that we rise above the flame mode. As I discussed with Dr. O'conner via private email, I have no problem with different opinion, provided that the opinions are presented with some technical issues/merits /procedures, just some supporting evidence. To just come to the opinion that so and so is plain wrong without presenting any supporting data is an example of poor scientific method. I certainly hope that most of us in the scientific community approach issues with an open mind, perform tests/experiments, and then analyze the results. Maybe Dr. O'Conner has done this, and has supporting evidence to back up his claims, it is quite difficult to ascertain this by his posts.

Good brewing,

From: dturner@ganymede.sca.com (David Turner)
Subject: TSP Disposal

Greetings!

As a new homeowner, I suddenly find myself concerned for the welfare of my septic tank and well in the presence of my brewing activities. I have been convinced that the chlorine I use for sanitizing is dilute enough so as not to cause problems with my septic tank (and it can only improve the health of my groundwater well), but I am worried about the Tri-Sodium Phosphate (TSP) that I occasionally use to clean grungy bottles. The package has a great many warnings about eye protection, rubber gloves, etc., leading me to believe that it is rather toxic (or at least caustic). I'm not sure I want to be pouring it down my drain, killing valuable bacteria in my septic system. Nor do I want to contaminate my (or my neighbor's) well by dumping it on the ground in a corner of my property.

So, what's the collected wisdom on this issue? Is TSP environmentally hostile? How do fellow homebrewers dispose of this stuff?

Please e-mail me directly (dturner@sca.com) if possible; I need the information soon! Eagerly awaiting your replies...DT

Soda ash is (if I remember right) Sodium Carbonate, also called washing
soda. It is alkaline enough to very slightly etch glass. When you are
washing off the "film" you are probably rubbing off and/or polishing
the etched glass on the surface. Glass is not as insoluble as people
think, and you shouldn't use really alkaline cleaners on glass. Read
the labels on some of the harsher spray cleaners sometime, they almost
all say to not use on glass. Next time, you might use ammonia, which
isn't harmful to glass. Of course, you need to use it outside.

Subject: Copper in a boil/Wheat Yeast Stains

Folks-

I've brewed two batches of wheat beer so far, both of which have been using extracts and both with Wyeast 3056 Bavarian Weissen liquid yeast. I've made 1 qrt. starters with the same composition as the main ferment before pitching and have had good quick startup's to fermentation. I really like the weissen taste, and I'm wondering if the 3056 is the best strain for this flavor. I've seen talk of both Red Star Ale Yeast (dry) and a new "Wheinstephen Wheat yeast (3068?). What's the opinion out there as to which is the best?

The second question I've got (thanks for bearing with me!) is whether or not it would be adviseable to use copper fittings in a boiler. I've obtained a SS half keg, ala budweiser (legally) and I want to use a copper double sided male connector through a hole in the side of the keg. This is the kind used for joining two flare fittings. One side would connect to 1/2 inch copper tubing going to a wort chiller, and the other would be slightly inside the boil. A cut down nut (also copper) would compress two gaskets (teflon) to provide a seal. Would there be any problems with: toxicity or taste degradation? Corrosion? Or would it be better to spring for a SS fitting?

Thanks In Advance-

Glen

According to an article I read on cider, the reason for adding meat to the fermenting brew was to prevent a stuck fermentation over the winter months. The meat provided nitrogen and other nutrients to help the yeast survive the colder temps. Today, you can probably get the same effect by adding some store-bought yeast nutrient (unless, of course, you actually *like* scrumpy :-).

Siebel's BRY-96 is the same as Wyeast #1056 American Ale.

Michael writes:

>a batch of Samual Smith's Nut Brown Ale. Does anyone have
>a tried-and-true all-grain recipe for this delicious ale?
>Any suggestion as to what an appropriate yeast would be?

I'm afraid I can only offer speculation on this, and what I
propose is a bit risky, so take these comments with a grain
of salt. What you want is a high-diacetyl beer. One of the
biggest diacetyl producers is Wyeast #1084 Irish Ale. Here's
the risky part: try aerating the beer *during* fermentation.
It's basically what they do at the Tadcaster brewery when they
make Sam Smith's beers. I've read that the reason they do this
is because their yeast is highly-flocculent (too flocculent)
and they need to get it back into suspension. What this
aeration has a tendency to do is to increase diacetyl production.
Another risky proposition: when the beer is pretty much fermented-
out, chill it abruptly to drop the yeast. Alternatively, you could
use finings, such as Isinglass, to drop the yeast so they have
less opportunity to re-ingest the diacetyl.

Granted, I'm not speaking from experience here, only passing on
information gathered from various sources, so I would be
very interested in any personal experiences with either of the
two "risky" propositions I've put forth here.

Subject: London supplies

I'll be passing through London next month. I'd like to bring home some hard to find supplies. Does anyone have suggestions for good homebrew supply stores, particularly in the south Thames (Balham, Brixton, Clapham, Battersea, etc.) area ?

Last night. I dunked my immersion chiller and monitored the temperature. It seemed to stall about 100F. The reason ? I forgot to turn the burner off.
Duh !

For those immersion chiller users out there concerned with conserving water, consider gradually reducing the cold water flow as the wort chills. At 212F, a high flow can really transport a lot of heat. However, by the time the wort is below 100F, you really don't need any more than a trickle.

My time vs. temp, flow curve looks like :

Where the "#" curve represents both the temp falling from 212-70F and the water flow rate dropping from 4 to 0.1 gallons per minute. The "w-w" curve represents the "wasteful" method of leaving the water on full blast for the whole cooling cycle. Of course, the wort will cool a little faster with the full blast method, but not by much. As you can see, the water savings are tremendous and is well worth the extra minute or two (at 0.1 gpm no less !) of cooling time. But you probably already knew this.

This reasoning applies only if the outflow is not re-used. I've seen many clever posts by frugal brewers saving the clear water to wash clothes, etc. My method is to run the outflow hose outside so it waters my trees, but that doesn't apply now that the rainy season has come to San Jose.

Cheers,
Bart

> file formats, I concur; I am all for PostScript file dumps. I assume
most
> of us have access to a PostScript laser printer and as long as we keep
> things at Level I PS for awhile, it should work great.
```

Bad assumption. There are still lots of non-PostScript printers out there, and there are, I'm sure, a lot more folks other than myself who don't have access to a PS printer.

And before anyone suggests GS, remember that it's output isn't always all that great (e.g., I have a 24-pin printer that I can drive at 360x360 dpi, but GS insists on 180x180 dpi ... and when I force the issue, GS forgets important details, such as the size of the paper, and so on)...besides, some of us don't have it (I have it archived somewhere, but can't afford to waste badly-needed disk space on it when I'd never use it anyways).

So, I have a suggestion that might make things a lot easier. If you're going to do PS documents, please include an ASCII version. Yes, some of the graphics may have to be left out. Perhaps they could be converted to GIF files? I don't know.... I know very little about converting from one graphics format to another. But at least the text portion would be available, where it wouldn't be otherwise.

I would suggest that another alternative format might be TeX. I could help in that area, if people are interested. From TeX's DVI output, you can go to just about any format you want. Then you just distribute the TeX source, and people can do whatever they want with it (including convert it to other formats, if desired).

Just a thought....

Later,

Subject: Scrumpy, Colloids & Foam

Got a little flack from one or two people (whom apparently missed the very explicit request at the end for mail to be sent to me here at pascal@netcom.com) suggesting I didn't know what I was talking about.

Let's step through the sequence of thought here ... take small steps.

'collegen' is a term which refers to "fibrous protein which occurs in vertebrates", according to Webster's 9th New Collegiate Dictionary.

'colloids' are defined as "gelatinous or mucinous substance found in tissues in disease or normally". Perhaps I selected the wrong word here, as what I was referring to were the threads of protein of which muscle and meat are composed ... which I understood to be colloids.

I'm not sure what agents exist within a wort or cider or other solution (yes, I include beer in the 'scrumpy' category, as well as cider) of fermenting fermentables, but it is undeniable that they exist, since meat placed in cider and other fermenting solutions undergoes change and dissolution.

Such an action must inevitably result in the tissue being teased into either shorter threads of protein (muscle is made up of longer threads) ... or component molecules.

Such threads as may exist might prove a tangible explanation for better head (which is so far strictly hearsay, and I haven't the slightest wish to test this hypothesis on a perfectly good batch of cider) on one's brew. This is strictly a theory, propogated for the interest of those of you with a scientific bent. (Jack, maybe a few others. [flamebait :-])

Surely people have been putting meat into their fermenting solutions for some reason over these many centuries. "Why" remains to be answered ..
.

From: STROUD%GAIA@leia.polaroid.com
Subject: Wort Processor Krush-Off: Part II

As a followup to the Worts successful Klub Krush-Off in September, the club held a second Krush-Off at the November meeting. Several Worts had recently received 'improved' grain mills and we wanted to see for ourselves how good the new mills really were.

Bob Gorman brought an 'improved' Glatt mill in which the rollers had been redesigned with a fine knurled covering as opposed to the long grooves in previous models. And Dan Listerman sent the club an improved PhilMill for testing. The knurl was much coarser than in the previous model. The malt used for this Krush-off was again pale 2-row. Each mill was adjusted for crush quality, then 2 lbs. of malt were run through in a time trial. Results and comments are shown below:

The Time Trials:

1) The Knurly GlattMill - Powered by a normal household drill, this mill crushed the malt in an impressive 26 sec., nearly as fast as the Schmidling MaltMill (21 sec) in our original Krush-Off.

2) The original GlattMill - Also powered by a normal household drill, this mill took 1 min. 6 sec. to crush the same amount of grain. [Note: this mill took 45 sec to crush the same amount of grain in the first Krush-Off. Obviously there can be substantial variations in the crush-time depending on how the mills are adjusted and the speed of cranking]

3) The New-Improved Listerman PhilMill - When powered by the normal household drill, this mill refused to budge. Even when the adjustment screw was backed off slightly, the operator was afraid to continue, citing fear of drill burnout. Not to be dissuaded, however, Tim Dalton dragged out a monster industrial 5 amp drill. It didn't hesitate when attached to the mill and crushed the malt in 38 sec.

General Comments:

The Knurly Glatt was much faster than the Slotted Glatt and also threw a bit less grain behind the mill than the Slotted one. But this is still a design bug and can be easily fixed by extending the drop shoot up higher to cover the back of the rollers.

The Slotted Glatt gave a very nice crush as we had previously observed, but

most of the husks were still cut in half width-wise. I assume this was due to the large slot size. The Knurly Glatt also gave a very nice crush, but the adjustment was slightly off, so although the kernels were cracked many of the husks still held together. However a little tweak between the fingers caused them to fall apart nicely. But this did give the appearance of un-crushed kernels and the question was raised as to whether they would open up in the mash or not.

We did a follow up crush on the Knurly Glatt with the rollers a couple of notches tighter. At this point the Knurly Glatt produced a bit more powder than the Slotted Glatt, although still well within acceptable ranges.

The New-Improved Listerman Mill required a lot more torque to crank than the Glatt Mills. It should be noted that the drill used to turn the Glatt mills was very beat and it took a few seconds to get up to full speed when using the Glatts which are extremely easy to turn. However, even if the drill had been in perfect shape it would still have had a very hard time turning the Listerman Mill. The bigger drill was definitely needed and was a whole lot more fun to use. Of course, manual operation of the mill is always an option!

The crush of the Listerman was good. However the adjustment of the rollers was a little on the tight side, so the crush came out a bit more powdery. It's too bad the operators didn't adjust this mill better because we would have liked to have seen how much powder and husk demolition the New-Improved Listerman Mill would have produced if properly adjusted. Nevertheless the crush was still acceptable.

As a followup it would be interesting to see a qualitative analysis of the different mills run at different speeds. It is possible that the slotted roller design might do much better at a slower speed.

Some personal comments:

The 'improved' mills do appear to be real improvements over the models tested in the first Krush-Off. Taking workmanship, ease of use, and quality of crush into account, I would personally rate the new Glatt mill and the Schmidling MaltMill about equally. The MaltMill has faster throughput due to its longer rollers and this could be important if you crush large amounts of grain. I

also think that the MaltMill is a more 'mature' mill. By that, I mean that JS has been constantly making small improvements to the MaltMill over the last few years. Even though the Glatt delivers an excellent crush and is easy to use, there are a few spots where improvements would make it an even better product (like raising the height of the back cover plate, redesigning the handle attachment, and downsizing the cover box that partially obscures one of the adjustment screws). Personally I don't think that most homebrewers would go wrong with either one of these two mills.

Although the new Listerman PhilMill gives a nice crush and is certainly adequate for most homebrewing, I personally am bothered by its lack of bearings, given its price, and its means of attachment to a table via screwhooks is kludgy.

For the money, the Glatt (~\$80) appears to be the big winner, especially given its adjustable rollers. The comparable adjustable MaltMill retails for ~\$129, although the non-adjustable model is only ~\$99. The Listerman retails for ~\$75.

BTW, I am a satisfied MaltMill customer and have no commercial interest in any of the above products.

From: "Steven W. Smith" <SMITH_S@gc.maricopa.edu>
Subject: Barleywine, temp fluctuation

Got a couple of burning questions for the oracle (Jack Oracle, yeah, that's him). First, what's the difference between beer and barleywine? Is it the yeast used, alcohol content, carbonation, whim of the brewer? If it's alcohol content, when does doppelbock cross the line and become barleywine? Are there any commercial barleywines?

Second: someone recently asked if temperature fluctuations would adversely affect a lager. Well? (tap tap tap)... I've had five gallons of doppelbock in my fridge for 2 months and it's still happily fermenting. It finally slowed down a bit; 1 bubble every 18 seconds or so.

3 weeks ago I racked it again and had a taste (ok, a big lager glass). It's still noticeably sweet, and I'm running low on homebrew. If it won't horribly desecrate my first actual lager, I'd like to bring it up to room temperature (about 74F) for a few days to accelerate fermentation. It would also be kinda handy to have the veggie drawers and more than 1 shelf again after all this time. The experience has taught me to shop carefully and stack creatively; also that I'm not as patient as I thought I'd be. TIA

Subject: highly hopped beers

We tasted a bottle of Alimony Ale last night -- Bill Owen's "Bitterest Beer in America". Well, it ain't. It's not a bad beer, but the SN Celebration Ale and the homebrew raspberry stout we tasted before it were definitely more bitter.

ObHB: Raspberry Stout (from Hal Buttermore)

2 cans MtMellick Stout
1 lb crystal malt
1 oz galena
2 oz N Brewer
10 lbs Raspberries ("picked by virgins" :-)

Do the obvious thing. (This is a reduced volume boil recipe. If you want to do a full-volume boil, cut the hops, maybe in half.) Raspberries added to primary. Probably not sanitized in any way.

I think the original was fermented with Doric dry yeast.

Very tasty, beautiful red-brown head, almost opaque, but lovely red color when shining a flashlight through about 1/4inch of it. Raspberries jump into your nose, and follow through in the flavor. At this point (brewed summer 1992) it's balanced towards the tart side, but there's still sufficient sugar to stand up to the hops bitterness & fruit acidity. Yum!

Subject: 60F ferments and Kirschenbeir question

In Homebrew Digest #1287 (December 02, 1993) Troy Howard posts:

>Rick Magnan asks about an appropriate yeast for fermenting at around
60F.
>Try Wyeast 2112 (California Lager). It is quoted as fermenting well up
to
>62F while keeping its lager characteristics.

I have successfully brewed with (gasp!) Whitbread dry yeast at 60F. In
the
winter months my basement is too cool to brew ales and the first floor
goes
through wide temperature fluctuations due to a setback thermostat. So, I
ferment on the second floor where the bedrooms are and the thermostat is
set
at a constant 60F.

Also in HBD #1287, Steven W. Smith <SMITH_S@gc.maricopa.edu> posted:

> Whenever I can find cherries again, I plan to try adding them to my
standard
>bock. It seems reasonable (to me) to wash the whole fruit in a mild
bleach
>solution, rinse, dry, smash (how?), force into a carboy (how?), then
siphon
>from the primary onto them. I'm thinking about 10 pounds of cherries to
a 5
>gallon batch. Maybe freezing/thawing before smashing? Do the pits
matter?
>Any comments appreciated, I'm flying blind.

After reading some suggestions in here and some books, here is what I did
for
a peach ale using fresh peaches. I washed the fruit under running tap
water,
pitted it, put it in large Zip-Loc freezer bags, and put them in the
freezer.
The night before I moved the beer from primary to secondary I took the
fruit
out of the freezer to thaw. When thawed I simply squished them all up by
hand
while they were still in the bag. I then poured them from the bag (with
the
assistance of a sanitized stainless steel spoon) into the secondary and
siphoned the beer on top of it. Next time I would use a sanitized funnel
made
from a gallon plastic milk jug to help with the transfer.

As you noticed I didn't sanitize the peaches and I pitted them. Some
suggest
using camden tablets to sanitize the fruit (I really wouldn't recommend
using
bleach) a couple of days before adding the fruit to the beer. I counted
on
the alcohol content and high yeast population in the beer to prevent
infection

and it worked. I pitted the peaches since the pits are large and I would have had trouble fitting the peaches down the neck of the carboy if I didn't. Personally, I wouldn't pit the cherries -- it would be too much work. Freezing the fruit definitely aided in smashing them up. I've read that freezing ruptures the cell walls and makes the fruit sugars easier for the yeast to get to for fermentation.

Speaking of fermentation, you will get a great deal of activity after adding the fruit. Use a 6 gal. carboy with a blowoff tube for a 5 gal. batch with fruit added. Even with this setup I ended with a clogged blowoff due to a peach that didn't get mashed well.

I've always wanted to make bacon stout, but thought that the oils
would kill the head retention.

A nice fresh bottle of sam smith's oatmeal stout has a very bacony
taste to it, and a little real bacon in the brew might be interesting.

>on?

Taking these in order:

1) In the middle of fermentation there should not be any oxygen to aerate with, and you want to avoid aeration after fermentation begins anyhow.

2) Check the label on that can! The John Bull syrup that I have seen is stretched with corn syrup (can you say ripoff boys and girls?) If you go with 6 lbs of dry extract you will get more fermentables per pound (any syrup also contains water) and your cost may be lower pound for pound (I have found this to be so).

3) It should be fine. I use a 6.5 gallon carboy for 5 gallon batches and just put the airlock on.

Subject: BRF IBU algorithm

Andy Phillips writes:

> I don't know whether BRF is capable of an accurate calculation
> in the high SG range - the formula used may not be valid.

The BRF's IBU calculation accomodates high gravities. The algorithm is Jackie Rager's. Is it accurate? I think it's fairly accurate. Can the forumla be improved? Probably.

Whether you agree or disagree with Rager's algorithm, the fact remains that it's the only formula around. If someone has a better formula, I'm all ears.

Having brewed a couple of barleywines and just a few :) Imperial Stouts, I agree that high gravity worts need truckloads of hops just to make the bitterness discernable.

Numerically speaking, if you're getting an IBU value as high as 100, dollars to donuts says the bitterness "retardation" value in the algorithm is not adequate. Anyone care to take a stab at updating the algorithm?

Subject: Red Star Ale Yeast

Dave Lyons wrote:

I have experimented (tried) the new red star yeast on two different batches and would like to compare notes with anyone else who has tried it.

(His) notes include:

Lag time: slow (approx. 1 day).
Attenuation: 78% for all malt extract recipes (using 100% M&F light).
After taste: Thought it gave the beer a somewhat phenolic flavor, but this faded after 2 months in the bottle.
Fermentation: Very strange primary ferment ... a thick (1") head of yeast (I think this is what it was?) remained on top of the beer after the end of the primary ferment. Had to siphon below the yeast cake(?) when racking to the secondary. Never observed this with any other yeast?

I have also used Red Star a few times and I like it. I have had very clean tasting beers using it. My statistics are:

Lag time: Good, Within 12 hours, often within 6. (I use a Starter)
Attenuation: 70-ish%, haven't really been concerned with it.
Primary Ferment: Big Krausen that does stick around, I rack out from underneath it as standard practice. Primary time is usually one week for the IPAs I've been brewing.

Subject: Re: hop utilization

I brew from malt extract, boiling only about half the wort and then adding it (after chilling in a water bath) to cold water in the carboy.

I know that one of the problems with this approach is that hop utilization is less than optimal due to the high gravity of the boil.

I believe that the high gravity is only one factor limiting hop utilization. The simple fact that you are boiling the hops in less than 5 gal of H2O is the main problem. It seems that as the amount of alpha acids in the wort increases it reduces the gradient between the hops and the wort. Thus, extraction slows down. Now to mentally check this idea at the limit points think about boiling your hops in one or two cups of water. I imagine that quite quickly you would reach a maximum bitterness at which you leave quite a lot of alpha acids in the hops themselves.

This hypothesis would be easily testable by simply boiling a few ounces of hops in 1 gal of water and diluting this to 5 gal. and comparing this to the same amount of hops boiled in 5 gal. I imagine that there would be an appreciable difference.

It occurs to me that there may be a simple solution to this problem: boil the hops in plain water for an hour, and then just add the extract and boil for another 15 minutes to sterilize it. This should maximize hop utilization without compromising sanitation.

As stated above, I don't think that this eliminates the problem of reduced efficiency.

Allan Rubinoff writes:

>>I brew from malt extract, boiling only about half the wort and then adding it (after chilling in a water bath) to cold water in the carboy. I know that one of the problems with this approach is that hop utilization is less than optimal due to the high gravity of the boil.

The gravity of the boil is not the culprit. It is the reduced boil volume. (I don't want to start another flame fest here. Let's be very clear: In no way am I saying that as beers get higher in gravity, the utilization doesn't suffer. It does, and this is well documented. *BUT* it is an effect produced by fermentation, not the gravity of the boil. Allan is diluting his wort back to a lower gravity before fermentation begins.)

>>It occurs to me that there may be a simple solution to this problem: boil the hops in plain water for an hour, and then just add the extract and boil for another 15 minutes to sterilize it. This should maximize hop utilization without compromising sanitation.

This will work, but again we have the same problem of lower boil volume. You will get higher extraction rates for two reasons: None of the bittering compounds will be lost on the break (around 7-10%) and the pH of the plain water should be higher than that of wort. A higher pH will improve the isomerization reaction. (Before you all try to boost the pH of worts to get better extraction, be forewarned that this has been tried many times throughout history - it results in awful beer!) Whether the pH of the water will also have this effect, I dunno. I suspect not, since it's not all that higher than wort.

Now, what *will* work is to divide the hops 50/50 between the two boils. This will maximize the extractions from both. (This is assuming equal boil volumes, otherwise divide the hops proportionately to the volume). The other advantage to this is that you *should* have some hops in your wort boil to help promote good breaks.

>>This seems like such a simple (and obvious) solution, that I wonder why I've never seen it mentioned anywhere. Does anybody know of any reason not to do this?

Probably because it's really a *lot* simpler to just put in extra hops to compensate. All the extra boiling and time isn't worth it (IMHO) to save a very small amount of money on the extra hops.

Mark

Subject: Pete's recipe and miscelaneous

I would like to emulate Pete's Wicked Ale. I plan a batch of 8lb brewers malt, 1lb crystal, 1/2 lb cocolate and 2oz. blackpatent, hopped with 11 AAU high alpha (Nugget) bittering, and finished and dry hopped with Cascade. I plan to use German Ale yeast. Comments? Suggestions?

In hbd 1287 Chris Lyons worries that flaked barley adds nothing to an extract recipe. He is probably right - certainly no starch could be converted, and haze may even form, but perhaps some proteins would be extracted that would add to head retention.

David Turner worries about TSP in his septic tank. The reason TSP and other phosphates are considered pollutants (so much so that their use in laundry detergents is outlawed in many states, even including Indiana) is because they are nutrients and help bacteria and algae grow much better in surafce waters thus depriving fish of oxygen by night. This is probably what you want in your septic system, so moderate use should not be a problem. Worry more about the chlorine.

Bill Kitch wants to know where George Fix' famous Michelob dark figure is.

I have seen it in many place includng recently in a Zymurgy. I am sure it is in Fix' Vienna book, but he can comment on that. However, if you have access to a spectrophotometer you could use the ASBC method. Simply, measure the absorbance of a clear (not turbid) sample of beer at 430 nm, convert this absorbance to absorbance by 1/2" (i.e. if you measure in a 1cm cuvette multiply the figure by 1.27), and multiply by 10. For dark beer you may need to dilute or use a smaller cuvette e.g. I meased a brown ale of mine with a mere 1/4 lb of black patent in a 2mm cuvette and got an ABSC reading of 40 - black stuff that. If you prefer to use the EBC scale, it is based on absorbance at 530 nm, but I know no more details about it. Anyone care to fill in the gap?

Subject: James Questions, Copper, First Time Info

Hello Group,

Several Items in #1287 caught my eye, I thought I would do a compiled post.

First, some James Questions. :)

>1) is it okay (or even advisable) to shake up and thus aerate the beer in

>the middle of fermentation?

No. Just leave it alone. 1) you are just aerating with CO2, 2) The yeast are probably done respirating.

>2) for our next repipe we plan on just improving on the righteous real ale.

>i thought a good recipe for 5 gallons would be:

6.6 lbs John Bull amber malt extract syrup

3/4 lb. cracked crystal malt

2 oz. cascade hop leaves (boiling)

1 oz. willamette hop leaves (aroma)

1/2 oz. willamette hop leaves (finishing)

2 pkgs. (10 oz.) Windsor dry English ale yeast

3/4 cup corn sugar (bottling)

That's quite a bit of Hops (don't say Hop Leaves, we'll know you are a Newbie)

Are you sure you want that much? Assuming boil times of 60, 15, and 5. And a

starting gravity of 1.05, but only boiling half, I get a total IBU of 30. Which is not bad, really. I would not recommend the Cascade Hops for the Boil,

though. I like it for the finish, but it is too herbaly for the body, IMHO. Use

the Liberty for Boil and Liberty/Cascade for the finish. Hey, whatever you want.

2 packages of dry Yeast is too much, especially if...

>3) i want to try a batch without using the blowoff method, but i still want

>to use a 5 gallon carboy. if i make 4 gallons will the kreusen still reach

>the top of the carboy or would i be safe to just put the fermentation lock

>on?

If you don't want to use a blowoff, two packages is WAY too much. Use one package and a starter if you want a good fermentation. Even 4 gallons will

probably reach the top with a vigorous fermentation. I would stick with the

blowoff and elevate the outlet hose, so that most of the liquid that get pulled

along with the foam will drain back into the carboy. Or use the higher capacity

plastic buckets for the primary.

Second, Copper in the boil.

>whether or not it would be adviseable to use copper fittings in a

>boiler. I've obtained a SS half keg, ala budweiser (legally) and
>I want to use a copper double sided male connector through a hole
>in the side of the keg. This is the kind used for joining two
>flare fittings. One side would connect to 1/2 inch copper tubing
>going to a wort chiller, and the other would be slightly inside the
>boil. A cut down nut (also copper) would compress two gaskets
>(teflon) to provide a seal. Would there be any problems with:
>toxicity or taste degradation? Corrosion? Or would it be better
>to spring for a SS fitting?

No problem with toxicity, I doubt any problems with taste, after all,
many
breweries use all copper boil kettles. Corrosion of the copper fittings
will
occur but I don't see this as a significant problem. You will only see
your
fittings staying clean. Eventually they will need replacement.
The alternative is Stainless Steel, but I would weigh your costs. Its
your
call.

Instructions for the First Time Brewer:

Over the last couple weeks, I have compiled a basically complete,
annotated
recipe/list of instructions for the First Time Brewer. It is everything
the
first timer needs to know to brew a fool-proof extract ale with dry
yeast. I
discuss Sanitization, Ingredients, Equipment, Boiling and Fermentation
Practices, Do's and Don'ts, What that Mold means, and Recommended
Reading.

If any of you are a first (or second) timer, or have friends about to
take
the plunge, I will be happy to email you a copy. Its 10 pages of ascii
text.

I am interested in possibly putting it on the Sierra server when I get
some

feedback on it. Maybe Patrick Weix can help me here...

Re: Cherry in beer

I made a batch of cherry stout. I only put 5 pounds of cherries in. The head was tinted red and there was a bit of cherry taste but not much.

TNCJOHB recommends at least 10 pounds. I think that should just about do it.

It also says that you should freeze the cherries first and then put them in the wort after the boil. Let that sit for a few minutes to pasturize the cherries and kill the nasties (I'm just quoting from the book here).

I did a primary fermentation in a plastic 5 gallon bucket so that I wouldn't have to worry about getting the damn fruit through the hole.

Of course, this is only IMHO. :-)

From: dweller@GVSU.EDU (RONALD DWELLE)
Subject: ice-beer info

Hi folks--

Just picked the following up off the AP, fyi-----

Labatt suing U.S. brewers over ice beer

The Associated Press

DETROIT -- Canadian brewer John Labatt Ltd. is suing rivals Miller Brewing Co. and Molson Breweries USA in U.S. District Court alleging trademark infringement over ice beer products.

Toronto, Ontario-based Labatt says it filed for trademark protection for the ice brewing process and for the resulting product in November 1992. The application is pending.

"Competitors will not be permitted without challenge to misappropriate Labatt's rights in this area where Labatt has demonstrated clear leadership and innovation," the company said.

In the suit filed Monday in Detroit, Labatt claims that Milwaukee-based Miller and Molson, Breweries USA, a wholly owned subsidiary of Miller, are guilty of; unfair trade practices in the promotion of their ice beer products in the United States.

Labatt began exporting ice beer to the United States in October.

Miller spokeswoman Susan Henderson called the Labatt lawsuit without merit. She said ice beer was developed in Germany in the 19th Century and was known as "Eisbock." Miller began selling Icehouse last summer.

MAYBE I SHOULD TRADEMARK "homebrew," EH?

Cheers,
Ron Dwelle (dweller@gvsu.edu)

From: bret.lanius@ehbbs.com (Bret Lanius)
Subject: Homebrew Digest #1284 (No

I made a batch of Porter based on TNCJOHB's Sparrow hawk porter. While it turned out VERY well I was of course wanting to tweak it before starting the next batch of the same.

Original Recipe:

3.3 lbs Muton Fison Plain Amber Malt
3.3 lbs Muton Fison Plaid Dark Malt
1 lbCrushed Black Patent Malt
1 Oz Northern Brewers Hops
1 oz Tettnang Hops
1 tsp Gypsum
1 Pkg Irish Ale Yeast

I found the Black to be a bit much and thought I'd substitute chocolate for half of that, and I plan to dry hop as well.

What I'd really like is to sweeten this brew a bit.....
Thought maybe Crystal but I don't know if that would do it!
Suggestions appreciated.....

This sounds backwards! (doesn't matter whether Charlie said it or not;-
)
Conventional wisdom [did JS just twitch?] is that you keep more character
by not filtering, but if you're going to keep the beer for a while you're
better off filtering it. Be that as it may, what's the reasoning behind
yeast adding stability.

>...I[[f] you have followed the basics of good
> wholesome brewing (sanitation) there won't be any bacteria you need to
filter
> out...

If only...

No, actually (a) there will be bacteria there regardless of how careful
you've been, and (b) it takes serious filtering to get bacteria out. As
to point (a), Tom's principle is right, that if you're careful the
bacteria
population will be much lower than if you're sloppy. But it's still sub-
stantial. You can't get rid of them all; most of what care and
sanitation
gives you is keeping the bacteria at bay long enough that the yeast get
the available food in early fermentation...keeping the wolf at bay, as it
were. On the other side, for point (b), even if you did filter, would
you
really want to filter that severely?

Subject: Oatmeal Stout & Wyeast 1084

I just made an Oatmeal Stout using Irish Ale yeast. Others have remarked that this yeast ferments rather vigorously. In the words of Miss Lilly von' Stupf, "It's twue! It's twue!"

Ingredients:

6 lb bag of William's Oatmeal Stout extract
2 lb (approx) Laaglander Light Amber Dried Malt Extract
10 oz of chocolate malt

Yeast: "Wyeast Irish Ale 1084"

Total boiling time: 60

Hops added: "Bullion" State:"Pellets 9.0%" Amount: 1.00 oz Boiled for: 60

Hops added: "Hallertau" State:"Old Pellets 3.0%" Amount: 0.50 oz Boiled for: 5

Initial gravity: 1.057

When I poured the cooled wort into the plastic primary, so much foam built up that I had to skim it off before I could close the lid. I used a yeast culture and aerated my wort by vigorous shaking. (IMHO, this is more effective than a pump and airstone) I used a blow-off hose for the first time. (I don't believe in it. Hey, I paid for those hops. I want all the bitterness out of them I can get!) Using a blow-off hose was a problem because of the 1" hole. A 1" i.d. plastic hose was too thick to fit and a 1" o.d. hose was too loose. So I smeared some silicon sealant on the hose the night before. Does anyone know a better way? I put the other end in a 1 gal jug. 5 hours later, it was bubbling.

At 20 hours, it was pushing globs of foam through the hose at the speed of 4 feet per minute! When I switched to an airlock, it had accumulated half a gallon of wort. (I think the toughness of the foam was due to the oatmeal)

I just wanted to warn people to use a blow-off hose when using high-gravity wort, Wyeast 1084 or oatmeal. My uncle had an airlock clog with a Belgian ale. He came home from work to find his plastic primary swelled up like a basketball! When he cracked the lid, it sounded like a gunshot and hurt his ears. I heard about someone who had a glass carboy explode in his closet. It coated his clothes with beer and glass.

From: Mark Stewart <mstewart@scs.unr.edu>
Subject: immersion chiller plans...

Lots of recent discussion on building immersion chillers has prompted me to submit this post. Here's my 'tried-n-true' recipe (for what it's worth):

- 1) buy 50' coil copper tubing, 3/8" outside diameter, (approx. cost for me at this posting is \$13.99...your price(s) may vary).
- 2) buy 20' length of food grade vinyl tubing, (mine comes in that length, you could get by with 16' for this recipe; I save the extra 4' for whatever comes up in life). (approx. cost for me = \$5.99)
- 3) buy 4 hose clamps (diameter should be small/relative to vinyl tubing diameter). (\$2.00 for 4).
- 4) buy 2 female hose adapters/repair ends (make sure you get the swivel kind so you don't have to turn the whole damn chiller to connect to the water source!). (\$1.26 ea.). Also, make sure to toss the clamp portion; you're only going to need the female part cuz you'll be pushing the vinyl tubing (warmed) onto it.

Total cost with tax is no more than \$25.00 (depending on volatility in the copper market!). BTW, this \$25 gives you TWO chillers: one to keep & one to sell to that buddy of yours that doesn't get the HBD.

Process...

- 1) find halfway point of copper coil (25 ft.). Score. Cut with hacksaw. Now you've got two halves of 25' each. Do this enough times and believe me you won't need to measure, you'll know that midpoint!
- 2) here's the special secret: take a Revereware 8 qt. stockpot (the tried-n-true perfect diameter!) and begin winding 25' of coil around its outside. The main reason for this pot is that it gives a perfect diameter for placement into either the kettle OR 5 gal. bucket, depending on your whim. Do the same for the other 25' of copper. When done, you should have two coils of nicely (tightly will come after you do a few) wound copper that resemble oversized SLINKY'S.
- 3) the art comes in straightening the downtube and out-tubes. Put a coil back around the pot and gently straighten first the downtube (this is because you will then determine the out-tube's length after straightening the downtube) and then the out-tube. Uh-oh, just realized that I'm calling one the out and the other the down. This is likely to spark some controversy so I won't say which of these should be for water-in and which will be for water-out (i.e., some might prefer the top tube as water in and some might prefer the bottom tube as water out or vice-versa...I'm just interested in finishing this post!). Anyway, do this for each coil, hack off the extra copper from the longer of the two vertical tubes on each, then use a file to smooth the rough area around the openings. The nice thing about doing things at home is that you can decide yourself how long you want these vertical tubes to be: I've had some people say, "Mark, I'm a big guy and I like big things..make my tubes extra big"...I guess they mean long so I make the tubes long. Others are a bit more retentive and say, "Heh-heh (<Beevus/Butthead noise) I need maximum cooling...make it so my tubes spend all their time in the wort"...their tubes are shortened!

Whatever you do, I find that an ideal length is one that allows for the

juncture where the vinyl meets the copper (haven't quite gotten there yet)
to remain ABOVE the hot wort. This is ideal in that hot wort *COULD* do *SOMETHING* to the vinyl tubing...(note careful choice of terminology...almost neutral in nature, to avoid any threads).
4) is this step 4 yet? Cut vinyl in 5 lengths of 4 ft. each. Keep 5th length.
5) submerge end of one length into HOT water to soften.
6) using elbow grease, work soft end up and onto female hose repair end. (Did I mention that there are often a variety of diameters available and that the best one to get is about 1/2" to 5/8". I forgot exactly which diameter I get but suffice it to say that if you get one that's too big, you'll know soon enough in step #6). Do this for the other chiller's tube also.
7) once you've gotten this up onto the female repair end as far as your heart desires, all that's left to do is clamp the other ends to their respective copper posts...

Well, there you have it...a chiller of your very own, to do with what you want (i.e., *SWIRL* with, *PUMP* up and down, or *DANCE* around with aon your head at the local Burger King..I've no doubt left something out so direct e-mail if necessary with questions/comments. Now that my secrets are out I'll have to look for another way to fund my education!

p.s., guess I should throw in a disclaimer about SLINKY'S and those two idiots from MTV so here it is:
I endorse neither.
M.

Subject: starter gravities revisited

Ok, I know this has been talked about in the past, but I am going to re-open this thread and risk flames and/or a flurry of posts.

Conventional 'wisdom' has it that starter gravities should be about 1.020 in order to maximize cell reproduction and hence cell count. This is of interest to the producers of dry yeast in order to maximize their bulk sales and minimize their costs of production. However, it seems to me that there is another issue being neglected here: health of the cells thus produced.

A close reading of Miller indicates that cells will metabolize sugar in order to build up enough glycogen in their mitochondria (sp?) to reproduce. Miller indicates that in a low gravity wort, the 'first order of business' of the cells is to reproduce...but this leaves the cells with a depleted glycogen content (read: 'they are tired'). I asked the question about a year ago whether a higher starter gravity would produce a more vigorous starter, because after reproduction the yeast would be allowed to process the remaining sugar in the starter in order to increase their glucose supply (read as 'available energy when pitched into a larger volume of wort'). Yes, the cell count would be smaller, but would this be offset by the healthier yeast?

I got no replies or takers.

This issue was first brought to my attention by the brewmaster of Sherlock's home, who says he ALWAYS uses a starter of similar gravity to the wort it is intended to ferment.

Well, I have been trying starters of gravity about 1.040, and volume about 0.75 liters. So far I have had very good results, with vigorous ferments, and lag times on the order of 6-10 hours, whereas I had lag times on the order of 12-15 hours using starters of SG=1.020.

Yes, this is a challenge to the 'net_wisdom': I humbly invite discussion, comments from anyone else using higher SG starters, and ask others to try higher SG starters, and post their findings...

Subject: Ice Beer

I had the chance to taste Molson Ice a couple of days ago. Let me tell you, the beer has no aftertaste whatsoever, but IT HAS NO TASTE EITHER. This baby is made just for the American market where people liek their beers with as little taste as possible. I thought it was awful. Tasted like something severely watered down, and it was so light in color. Probably lighter than any light beer I've ever seen. My initial reaction is unfavorable, obviously. I won't be buying this stuff any time soon. It's 5.6% alcohol, o% taste.

Anyone else had the chance to try any ice beer?

From: Bob W Surratt <Bob_W_Surratt@ccm.hf.intel.com>

Subject: Liquid Yeast Re-Use

Dave,

I've reused Wyeast yeast's many times before with no problem. My method is to sanitize a jar, mayo, mason, etc. and pour in the slurry that is left in the "secondary". You won't want the primary trub as it has all the leftovers from fermentation.

I've kept the yeast for up to 2 months before reuse and it's always worked great. I've also reused it up to 5 times from the initial first time. Just take it out of the fridge when you start your recipe so that it can warm up to room temp before pitching.

Hope this helps.

Bob Surratt Orangevale, CA

From: michael.niemann@mail.trincoll.edu (Michael Niemann)

Subject: Liquid Yeast Re-Use

Here is what I do with Wyeast. I pay \$4.00 per pack and split that into four portions thereby making it \$1.00 per batch.

1. Prepare the Wyeast according to package (burst the nutrient bubble and let it puff up.
2. boil 1 quart of water for 15 min and cool in sanitized bottle (the refrige is best)
3. prepare 1 pint of starter and boil for 15 minutes, add a pellet of hops or so.
4. pour 1 pint of the cold water into a 1.5 liter wine bottle (sanitized of course), add the starter, add the rest of the cold water. This should now be at pitching temperature, so add the Wyeast.
5. ferment for several days until visible fermentation ends.
6. sanitize four bottles and caps. Distribute the starter into these bottles, cap and store in the refrigerator. They should keep for about a half a year.
7. A couple days before you want to brew, make a starter from one of the bottles and ou are ready to go.

It is important to keep everything sanitized.

I have done this for over half a year so far and have had great success. BTW this was posted on r.c.b. earlier this year.

Subject: Help with Noche Buena

We will have our flavor panel meet this weekend. I have done some analysis on samples that have been sent to us, and a preliminary tasting. The alcohol content is ~4.0 (by wt) which is way down from the 5.75% (by wt.) of the version that was in circulation in past years. The color is also down (from 12-13 Lov. to 8 Lov.), and the IBUs are down as well (from high 20s to ~16!). Our initial impression is that it is a respectable version of a "Vienese mild". It could not hold a candle to the top 4 or 5 Viennas we evaluated on the GABF panel. What I have got to do now is to think of a civilized and polite way of communicating this in our review for SW Brewing News. Any ideas? Given the folks on the flavor panel, I fear this beer is in for a rough time this weekend. It is, however, a quite drinkable beer. Some have picked up some diacetyl tones in the beer's sweet finish. This may be due to the caramel malts used. In any case, time will tell, for if it is diacetyl it is going to get raunchy.

There is a rumor that there is an undiluted version out there. Such a version, if it does exist, would surely be available in Mexico. Does anyone know anything about this? It is our impression that Guinness Imports only has the diluted version.

Subject: mead questions

>I've got a coupla mead and fruit mead batches under my belt. I've been kegging my homebrew for about 6 months now, and am wondering about kegging future batches of mead. Is there any reason that I *shouldnt* keg my mead insterad of bottling? What about using stainless vessels for primary or secondary fermentation also, since they take up a fermenter for a coupla months?

* I keg my beer, but bottle my meads. They are easier to store for x months/years that way, for me at least. Plus I like to get quicker turnover of my kegs.

BUT: I have kegged 1/2 a wine once for a party. Sparkling Loganberry Wine. It worked fine. I don't know if the acid levels can become a problem for metals. I know aluminum is bad news, but stainless steel should be ok. There is the possibility of leaching metallic tastes. A friend whose just started kegging beer claims a "keg taste" is perceptable. Could be forced CO2, could be the keg, could be contamination?

BUT, I haven't noticed it, and have been kegging for a year.

There are differences in the "quality" of carbonation between my bottled and kegged beers. But I prefer the fine/small bubble creaminess of the kegs to the bottles. Plus it sure is easier!

Kegging a mead opens up filtering possibilities that could be a benefit. BUT It sure can disappear faster. Why not keg half, bottle half :)

> First hand experience, no urban legends, please. * Who us?! Never...
<huf>

Also, is there a Mead mailing list similar to HBD?

Yes- But it's not kosher to post it, so ask me via e-mail. :)

thanks, You're welcome
jim John.

Barleywine

the yeast used, alcohol content, carbonation, whim of the brewer? If it's

alcohol content, when does doppelbock cross the line and become barleywine?

Are there any commercial barleywines?

* yes. Never tried one (unhappy sigh....yet ;).
Sierra Nevada's Bigfoot. Heard it's heavenly!

Tried a friend's barleywine. Yum. Malty, thick, rich, potent.
I WILL try one ...like real soon.

AHA sez: 1.065-1.120 OG. 6- 12 percent alcohol by volume.
Copper or dark brown. Fruity, bittersweet. Can use strong beer yeast, or champagne/wine yeasts. Aged 6 months to a year.
(but they are not per-se "lagered")

Doppels may overlap in strength, but you're also talking lager yeast vs. ale/wine yeasts. There are differences. It's a matter of style.

*

> 3 weeks ago I racked it again and had a taste (ok, a big lager glass)

.

It's still noticeably sweet, and I'm running low on homebrew. ...

* Get another carboy! :)

horribly desecrate my first actual lager, I'd like to bring it up to room temperature *(about 74F)* for a few days to accelerate fermentation. ...

* Lagers should be warmed at the end of lagering. But not that warm. More like 60. It helps them break down (diacetyl I think? Reference-check)

If you are trying to make a true lager...patience is warranted.

They will benefit from long cold. Clarity, smoothness, balance.

Check the specific gravity. If it is down to say 15 or less (I usually end up between 12 and 8) then- give it a bit of warming (cold closet? or basement handy?) then bottle. You can continue lagering in bottles.

John.

filtering and stuff...

>>...I[f] you have followed the basics of good
>> wholesome brewing (sanitation) there won't be any bacteria you
>> need to filter out...

>No, actually (a) there will be bacteria there regardless of how careful you've been, and (b) it takes serious filtering to get bacteria out. As to point (a), Tom's principle is right, that if you're careful the bacteria population will be much lower than if you're sloppy. But it's still substantial*. You can't get rid of them all; most of what care and sanitation gives you is keeping the bacteria at bay long enough that the yeast get the available food in early fermentation...keeping the wolf at bay, as it were. On the other side, for point (b), even if you did filter, would you really want to filter that severely? Dick Dunn

* I dunno Dick. At the beginning- bact/yeast, then LOTS of yeast, and an un hospitable environment for bacteria. If they are inhibited early on they may be pretty well dormant. Yes I agree it is next to impossible to ELIMINATE bacteria, but it is also not TOO difficult to GREATLY REDUCE their presence. Wild yeasts are also likely floating around.

As for filtering. Filtering bacteria requires less than a 1 micron filter. I don't want to do that to my beer. Filtering DOES present advantages, but also potential disadvantages. Chill haze, protein "colloids", some cellular material, and chunks of anything else still floating around can be filtered out. A level of 2 to 3 microns will do this. 5 microns will let almost all cells pass. as low as .1 micron (bacterial filter- sterilizes) will clean up a beer, but will also CLEAN UP A BEER. Body, head retention and other qualities will be lost. The intermediate levels (2-3) will possibly remove some body, but not too much (I hope).

Much of this clearing can be achieved by adding clarifying agents and such. But time is also a factor. Filtering is instantaneous. Clarification can take time. I keg, and would prefer to have NO sediment if possible. But I haven't yet taken the filter plung (PICTURE: arms outstretched, falling back into body of water). It's the expense at this point. But it may well happen. Someday. But I have looked into it!

The question started because a bottling friend has access to the equipment and wanted to know how and why it could be done. I wouldn't just dismiss the idea as some people do, without first examining the pro's and con's.

From: Larry Richardson <richards@priacc.com>
Subject: Hi there! Request for help.

Greetings to my fellow zymurgists. I am a (very) new subscriber to this forum, although I've been making beer for nearly 7 years.

As I am new to this forum, I hope the following is an acceptable question to post to this list. If not, please excuse the waste of bandwidth and I promise to never, ever do it again.

I have recently restarted producing beer after a two-year hiatus. Before I stopped, I had been obtaining my equipment/malt/hops, etc., from a local beer/wine supply store. Now, unfortunately, the only supply store in the area is a long way away, and geared more to winemaking.

So. I've started using mail-order. The mail order house I'm using only provides the malt in pouches, which I've never used before. To be honest, I'm not sure I like them very much, other than for storage.

My question is, does anyone have a mail-order house they recommend and/or has anyone who does use the pouches discovered an easy/efficient way to get all the stuff out of the pouch.

I look forward to reading everything that comes out in this forum, and I hope to hear from you all about these questions.

Thanks for your time!

Larry

>-- End of excerpt from Dick Dunn

Could it be that it is better to have the yeast consume any free oxygen
than to have it oxidize your beer? Or maybe, if your fermentation is not
complete, any yeast or bacteria still present after the filtration still
has a growth medium. If your filtration was more successful at filtering
out the yeast, the bacteria will have more chance to dominate if you keep
the beer for a while.

This is my first submission to HBD and as I am new to both HBD and Internet,
I hope I am following protocols, etc. If not, please turn down the heat on any flaming you think I deserve. BTW, any information on sources for a Microsoft Windows based utility for exploring Internet would be appreciated. Mail me direct.

There has been a lot of discussion about Hop utilization and hopping rates in the last couple of weeks since I've been eavesdropping on y'all such as the high hopping rates of I.P.A.s of 100 to 200 BU's and much puzzlement expressed over why some beers are not as bitter as expected even though a lot of hops were used:

Example:

Andy Phillips writes in #1287:

>Despite the high hopping rate - I can't remember the IBU rating from BRF,
>but it was well over 100 - this is not noticeable bitter. I suspect that
>this is partly because the flavour is overwhelmingly malty, and the hop
>taste can't get through, and partly because of the lower hop utilization
>at high SGs.

He also indicated that he "Boiled 90 min with 5 oz Goldings"

I'm not picking on you Andy, it was just a good example.

The unpredictability of results when hopping may be due more to the isomerization of the hops than hop utilization. Isomerization is an altering of the molecular structure of the substance in hops that imparts bitterness to beer. It is the isomerized molecules that give the bitterness. Only a fraction of the hops are isomerized during the boil (around 25% max) and the degree of isomerization is directly proportional to the length of time the hops are in the boil. Maximum isomerization occurs at around 45 min. of exposure to the boil. After one hour isomerization actually begins to reverse!
Perhaps this explains why Andy's 90 min. boil was not as bitter as expected.

So, actual IBU's can not be calculated without taking %Isomerization into account. Since learning this information from the master brewer at a local contract brewery, my beers have been much more predictable in terms of

bitterness and better overall. I believe this is because I now brew to a specific target bitterness (based on style).

Here are some formulas you can apply to calculate the IBU's for your recipes.

Hops and bitterness units in beer

1 BU = 1 mg/L of Isomerized Alpha Acid (IA)

In brewing, Isomerization is the process of altering the Alpha Acid molecule in hops through the application of heat. The altered (Isomerized) molecule imparts bitterness to the mash.

The taste threshold for bitterness is around 12 BU. Anything less can not be detected. (Swill)

Bud 11 BU
Pilsner Urquell 40 BU
Typical Ale or Lager 20 - 25 BU

Formulas for Hops and Bitterness

$$\text{Hops (g)} = \frac{S * \text{BU}}{\%I * \%A * 1000}$$

where: S = Size of batch in litres (There are 18.9 Litres in 5 gallons)
BU = Bitterness Units
%I = The percent of Isomerization reached after a specific time of boiling. (expressed as decimal) *Note 1
%A = Alpha Acid content in percent of the hops being used (expressed as decimal)

So, for a 5 gallon batch where:

- All bitterness will be from boiling hops and no finishing hops will be used
- A 45 minute boil of hops results in a 25% Isomerization (.25)
- The hops being used have a 5% Alpha rating (.05)
- The bitterness desired is 40 BU's

$$\frac{18.9 * 40}{.25 * .05 * 1000} = \frac{756}{12.5} = 60.48 \text{ grams} * .0353 = 2.1 \text{ oz. (*Note 2)}$$

If you wanted to add 5 more BU's the above for finishing where:

- A 5 minute boil of hops results in a 5% Isomerization (.05)
- The hops being used have a 2.9% Alpha rating (.029)

$$\frac{18.9 * 5}{.05 * .029 * 1000} = \frac{94.5}{1.45} = 65.2 \text{ grams} * .0353 = 2.3 \text{ oz. (*Note 2)}$$

If you know how much hops you have put into a beer that you liked in the past you can calculate the bitterness by the formula:

$$\text{BU} = \frac{\text{Hops} * \%I * \%A * 1000}{S}$$

*Note 1 - 5% of available Alpha Acid will isomerize in 5 minutes,
25% in 45 minutes.

*Note 2 - There are .0353 ounces (oz.) in a gram.

Hope someone finds this as useful as I did. Have a homebrew before
attempting any calculations at home.

Think globally, Drink locally.

Subject: Corsendonk Monks Ale ?

Anyone enjoyed Corsendonk Monks Ale and can share why it is so expensive? Can "they" make money stocking a brew this expensive? What is its shelf life? And, of course, what does it taste like? Thank you.

Around Boston, a 24 oz. bottle goes for about \$7.50, if memory serves me right. If you bought four 24 oz. bottles (96 oz. of beer), that would cost \$30 by my calculations. Is that 100 oz. bottle worth the extra money? (Is the price I remember too low?) BTW, the 24 oz. bottles have painted labels, although I can't tell whether they're hand-painted.

As I recall, the inside of the bottle contains a bottle-conditioned Belgian ale that tasted pretty good (a beer judge I am not).

Subject: hopping out/ionic concentration

Chris Campanelli (and others) have written about high IBU's wondering whether they are correct, in other words, is the Rager formula correct?

It would seem to me that for a given length of boil, say 60', there is a practical, although not absolute, limit to the bitterness one can achieve.

The bittering effect is limited by the solubility of the not-yet-isomerized hop resins, which is low. Adding more hops doesn't help much past a certain point since you can't get any more resin in solution to be isomerized. The only solution would be to boil longer.

Has anyone actually determined the IBU of one of these beers that was made with a lot of hops? If not I will add this question to my upcoming series of hop experimental beers (calling you soon Mark).

(Please excuse my inability to backspace and my poor typing. Using an antique telnet.)

- -----
A question:

When people write something like, "sulphate levels higher than 200 ppm enhance hop bitterness." (lets not argue about whether this is a sharp cutoff obviously it's not) do they mean the concentration in the finished beer or in the starting water. People often bndy about numbers like the ionic content of Burton water, but the perception of bitterness is taking place in the beer that is probably at least 150% the ion concentration of the starting water.

I do my calculations for salt additions as follows:

- 1) Make sure that the mash has sufficient CA, proper pH, and is not overly buffered by (H)CO₃.
- 2) Add NaCl and MgSO₄ as desired for the recipe to the boil, based on what the final volume will be. Am I adding less than others? Do other people concentrate their ions from the concentrations in the literature in the boil?

Subject: Yeast FAQ, other docs, and a sake note

Hi,
I am the author of the Yeast FAQ (actually chief editor is a better description). It does indeed exist. I have noticed that many people post to the digest asking for information on the retrieval of various FAQs or documents. I say to them: *READ THE HEADER OF THE DIGEST!* Every day it is the same, and every day it says:
->for archives, ftp to sierra.stanford.edu
->for archives without ftp access, email listserv@sierra.stanford.edu with the body of your message reading HELP.
I am not a major techno, nor do I wish to start a flame, but I would implore all to skim the instructions at least once.

That being said, I am going to update the yeast faq in a couple of weeks and would encourage any and all to send any new strain descriptions or techniques to me at weix@netcom.com.

Sake: Isn't that just warm Bud without the hops? Serve me up a glass now!

Subject: BBC and water chemistry

I just received in the mail an unsolicited four-color bi-fold *I'm not sure what this is* "advertisement" from The Boston Brewing Company. It begins on the cover with a history of the Koch Brewing Family.

"James Koch - Brewer By Descent"
and on the next page

"Sam Adams - Brewer of Dissent"
a history of Samuel Adams and his revolutionary exploits.
Page three goes on to explain why James named his beer after Sam and why Patriot James started the company - "I wanted Samuel Adams Boston Lager to lead another kind of revolution - independence from imported beer."
Page four continues the Koch family travails from Germany to the land of opportunity, offers "Come for a tour" AND **offers a FREE Sam Adams T-shirt and a FREE subscription to the Boston Beer Company Quarterly Newsletter** !!! The last line on the FREE offer asks me to check *one* of the following, "I am a: Beer Lover, Retailer, Distributor, Brewer."
I'm not quite sure what to make of this. Could all of Al's talk on HBD of the "B" word have had an effect?

On another subject...

My water, according to the city water report, has 300 ppm of carbonates. When I boil it to precipitate carbonates out, how many (ppm) could I expect to remain in solution? Also, why does my Ph go UP after I boil it? Shouldn't precipitating out the carbonates *reduce* hardness and consequently Ph?

 From: piatz@tamarack.cray.com (Steve Piatz)
 Subject: dilution

In HBD 1289, Cushing Hamlen asks:
 > Has anyone ever done a study of wort SG as a function of dilution?
 > Papazian gives some guidelines for dilution, but I am looking for
 > a curve, or better yet an analytical function fit to experimental data.

I posted this to the digest a long time ago (that means I don't remember when). I think the analysis behind this was fairly straightforward (and I don't remember that either). I think it is correct for dilution prior to fermentation, I don't know about after fermentation since the alcohol may throw my simplistic approach off. I originally did this when I made an imperial stout that boiled off too much water while getting the hop boil time. I wanted to get back to the planned gravity and Papazian's tables didn't cover the range I needed.

Example usage: assume 5 gallons of 1.100 wort diluted with 1 gallon of water to get 6 gallons of 1.083 wort. We added 20% of the original volume as additional water, intersection of 1.100 row and 20% column.

| O.G. | Dilution By | | | | | | | | | |
|-------|-------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|

| 1.140 | 1.133 | 1.127 | 1.122 | 1.117 | 1.112 | 1.108 | 1.104 | 1.100 | 1.097 | 1.093 |
| 1.145 | 1.138 | 1.132 | 1.126 | 1.121 | 1.116 | 1.112 | 1.107 | 1.104 | 1.100 | 1.097 |
| 1.150 | 1.143 | 1.136 | 1.130 | 1.125 | 1.120 | 1.115 | 1.111 | 1.107 | 1.103 | 1.100 |
| 1.155 | 1.148 | 1.141 | 1.135 | 1.129 | 1.124 | 1.119 | 1.115 | 1.111 | 1.107 | 1.103 |

I suppose you could take the data and pass it to GNUplot if you want curves.

The program to generate the table follows.

```
#include <stdio.h>
#define NUM_PERCENT 10/* number of columns */
#define NUM_GRAVITY 30/* number of rows */
#define PERCENT_STEP 0.05 /* percentage per column */
#define GRAVITY_STEP 0.005 /* gravity per row */
#define INITIAL_GRAVITY 1.010 /* gravity for first row */
#define INITIAL_PERCENT PERCENT_STEP /* percentage for first column */
/
main ()
[
    int i;
    int j;
    float og, fg;
    float dv;
    float dvp;
    printf (" | Dilution By/n");
    printf (" O.G. | ");
    for (j = 0; j < NUM_PERCENT; j++)
    printf (" %3.0f%% ", 100.0 * PERCENT_STEP * (1 + j));
    printf ("/n");
    printf ("-----|-");
    for (j = 0; j < NUM_PERCENT; j++) printf ("-----");
    printf ("/n");
    og = INITIAL_GRAVITY - GRAVITY_STEP;
    for (i = 0; i < NUM_GRAVITY; i++) [
    og += GRAVITY_STEP;
    printf ("%6.3f | ", og);
    dvp = INITIAL_PERCENT - PERCENT_STEP;
    for (j = 0; j < NUM_PERCENT; j++) [
```

```
    dvp += PERCENT_STEP;
    fg = (og + dvp) / (1.0 + dvp);
    printf ("%6.3f ", fg);
]
printf ("/n");

    ]
    exit ();
]
```

Subject: Dry versus Liquid Yeast

In recent HBD's there has been a number of comments concerning dry vs. liquid yeast. I thought I would share what I tasted on a recent trip to a couple of Brewpubs in Rochester, NY. I had the occasion to eat dinner at a brewpub called Rorhbachs. Their beer was verrrrrry good. They had a terrific highly hopped lager called Gregory Street Lager. The beer was one of the best I have tried to date. After discussing it with the bartender he asked me if I would like a tour. Obviously I was overjoyed at the opportunity! The brewmaster was on site and proceeded to show me the facility. I found that they used Belgium Malt (all grain process) and Wyeast to brew the beer.

The next day I had the chance to stop at the Rochester Brewpub and try a couple of their brews. I was definitely not as thrilled with their beer (however, overall it wasn't bad). As I was looking at the facility I once again had the opportunity to discuss brewing with the brewmaster. To my surprise I found the process to be Malt Extract and Whitbread dry yeast. The difference between what I had tasted the day before was remarkable, the liquid yeast was clean while the Whitbread had definitive tastes left in the beer.

Now the kicker, I had brewed the day before Thanksgiving an all grain Pale that I had planned on using a liquid lager yeast (I was attempting a steam).

However after 2 1/2 days of no activity (I had used a slant of yeast about 3 months old) I decided to attempt to rescue the beer with the only viable option, a packet of Whitbread dry which had been in the fridge since the summer. The brew took off in 3 hours and fermentation was very active. Last night I racked to the secondary and as usual tried a small glass of beer. The beer tasted exactly like the beer in the Rochester Brewpub!! Although the beer is still drinkable, I definitely have converted myself to liquid yeast from here on out.

Subject: Clarity and slow fermentation in first all-grain batch

My first batch of all grain beer was racked two days ago. The recipe followed was almost exactly Papazian's Amaizeing Pale Ale from The New Complete Joy of Homebrewing. Two things worry me about this batch. I've been brewing for nearly two years using malt extracts and have never before encountered these quirks:

1. The fermentation with Edme's dried yeast, (no starter--too busy that week) was strong for the first 48 hours and then continued at a slow rate for another six days. I've never left beer in a primary longer than one week and yet may have jumped the gun racking this after 8 days. At racking, my airlock was bubbling about once a minute and the SG was 1.012 for two consecutive days (down from 1.046), The temperature was a steady 73 degrees
F. Does all-grain brewing produce a slower but longer-fermenting wort?

2. Although I was very careful not to disturb the sediment during siphoning, this beer is very cloudy. Of course I've assumed some of this cloudiness is yeast from possibly premature racking. I suspect, though, that there's a fair amount of particle matter from the grains washed off during sparging. I sparged through a depth of about 7-8 inches of grain.
Is this cloudiness normal in all-grain brewing?

I'll sample a bottle in one week (if they haven't all exploded from premature racking). A taste at bottling was promising, featuring a wonderful hoppy nose yet encounterd brewing with extracts.

>EITHER. This baby is made just for the American market where people
>like their beers with as little taste as possible.
<snip>
>Anyone else had the chance to try any ice beer?

yea, i tried some budweiser ice draft (i was at a friends house and he
was
swilling it. i didn't buy it, HONEST!). i think this is similar to the
molson ice. i have to agree with andy. STAY AWAY FROM THE STUFF. no
tase
at all. i hear they use more corn to give it a smoother flavor.
this reminds me of something: five years ago i was involved in an
exchange
program with german students. when they were over here king cobra was
still being advertised on t.v. the adds said, "goes down smooth with no
after taste."
i remember the german students rolling on the ground with laughter after
hearing this. i asked one what was so funny (at this time i had never
really tried any beer) and he said, "beer with no aftertaste? the after
taste is the most important part of the beer!"
three months later i was in germany. i tasted real beer for the first
time
and found out that he was right.

Subject: extract pouch extract extraction

Larry Richardson <richards@priacc.com> asked about easy/efficient ways to get all the extract out of those pouches.

Just put them in the microwave. I do mine a minute, then squeeze around awhile, then another minute, &c, until they are quite warm and very soft and squishy (very fun). You could also put them in a sink of hot water or even boil them; I think they are made of the same stuff that Green Giant Niblets in Butter Sauce pouches are made of. At least the pouches I've been getting are claimed to be boil-proof. Ask your supplier.

When they are all soft cut a corner off and hold by the opposite corner. Then you can stir at the same time to avoid scorching. Some more squeezing will get most of the stuff out and a cup or so of hot water put in and then shaken around will get the rest.

Not much more irritating than cans, really

Subject: Wort boiler screen

I just had a disaster with the screen on my wort boiler plugging with hops. I just started all grain 5 gal boils and this is my third batch. The previous batches did not plug with hops. I have a Sankey keg with the top cut out for a boiler. I have welded a nipple in the side, about 2" from the bottom and right over the center is an elbow and short nipple which dip down to within 1/2" of the bottom. The end of the nipple is covered with a coarse screen. I have no idea why it did not plug up the first two times, but did this time.

Here are my questions. If you are using a Chore Girl or an EasyMasher, since both of them are just screens, why do they not plug up? If you have any other methods, please share them.

From: Mark Garetz <mgaretz@hopstech.com>
Subject: Correction of Sierra Nevada Dry Hopping

I was wrong in my post the other day when I said that Sierra Nevada was now dry-hopping their pale ale instead of using the hop back. They are no longer using the hop back, but they do not dry hop the pale ale. Martin Wilde advised me of this via email, and I double-checked with others who were on the tour. The only beers that they dry hop are the Bigfoot Barley Wine and the Celebration Ale. The pale ale is bitter-hopped with a combination of Perle and Nugget hops at the beginning of the boil, with additions of Cascade at 30 minutes to go and at the end of the boil, which they allow to steep for 20 minutes before chilling the wort.

Sorry for the misinformation.

Mark

Subject: Snakebite

Hi all,
Back in September I was in Penryhndeuadraeth, Wales in the U.K. I was staying at a B&B that had it's own small pub. At around closing time, everyone in the pub, except for my friends and I that were staying there, were told to leave. The bartender told me that the law over there states that if you are staying at a B&B that has a pub, they have to keep the pub open until you decide to call it quits for the night!! Isn't that wonderful!!! Anyhow, after hours I was chatting with the bartender and he told me about a concoction pubs used to make, but is now illegal. It was called a * Snakebite*. It was a combination of equal parts of a lager and a cider (I forget what the lager was, possibly Tetley's[??], but the cider was Strongbow). The reason it was outlawed was because of some chemical reaction that occurred that had a not so nice effect on brain cells. Anyone ever heard of this or know what it does to people's brains?? He prepared a small one for me and it tasted pretty good, but I couldn't tell if it had an effect or not, since I was trying every beer in the place ;-]

Subject: Wort Chiller Plans

Pretty good Step By Steps plans for a immersion wort chiller in HBD-1289 by Mark Stewart. I just have a couple of suggestions.

To avoid possible disaster from the failure of either a hose clamp or a hose,
I extended both the In and Out tubing on the Kettle side of the chiller up and out of the kettle and bent it 180 degrees, then attached hoses. Thus no water could get in the kettle to contaminate the wort if any failure occurred.

On the Cold immersion side, instead of the "SLINKY" spiral, I used a tubing bender (about \$1.50 in a hardware store where I bought the tubing) and I bent the tubing in concentric circles in a flatter form. This allow more coil in the ice bath with a smaller pot. You Extract brewers could do this on both coils to allow more coil contact in smaller brew kettles.

Another tool that makes this easier is a tubing cutter. This leaves no jagged edges to file and cost about \$3.50 - \$5.00 at your local hardware store.

The Monks Pale Ale is *broadly* a Tripple, and not bad. The Monks Brown Ale is *broadly* a brown abbey ale. Both are pretty good ales, brewed by a relative newcomer on the Belgian scene, new as of around '84. I actually prefer the Pale.

>
> Barleywine
> the yeast used, alcohol content, carbonation, whim of the brewer? If
it's
> alcohol content, when does doppelbock cross the line and become
barleywine?

^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^

Never! A doppel should never exhibit the esters that are prominant in an barleywine. Also, the doppels tend to be darker than Bwines, although the AHA judges seem to feel that Bwines need to be quite dark, which I believe is nonsense.

> AHA sez: 1.065-1.120 OG. 6- 12 percent alcohol by volume.
I think that should be 1.09X - 1.1XX, 8-XX % ABV.

> yeast, or champagne/wine yeasts. Aged 6 months to a year.
Well, Bigfoot is not aged like this, and I dont age mine either. It all depends on your fermentation, if you properly attenuate the beer, the aging time is greatly reduced. If you bottle at 1.030, it will need considerable time to age, but may never be as good as one bottled at 1.020.

My latest is great at brew day + 10 weeks, or keg day + 8 weeks. It was darn good at 3 weeks.

>
> * Lagers should be warmed at the end of lagering. But not that warm.
> More like 60. It helps them break down (diacetyl I think? Reference-check)

Lagers dont *need* to be treated like this. A diacetyl rest at 42F can be used quite successfully. Much of this depends on the yeast strain and overall lagering methods.

> **
> filtering and stuff...

> Chill haze, protein "colloids", some cellular material, and chunks
> of anything else still floating around can be filtered out.
> A level of 2 to 3 microns will do this. 5 microns will let almost

> all cells pass.

No! 5 microns is extremely effective in removing the yeast biomass. I assume these are the "cells" you refer to.

> clean up a beer, but will also CLEAN UP A BEER. Body, head retention
> and other qualities will be lost. The intermediate levels (2-3) will
> possibly remove some body, but not too much (I hope).
>

3-5 is a fine level for home and pub brewers. It might not be perfect for extended shelf life, but it is fine for a few months. Below 1 micron, and the foam stand will be suffer.

> falling back into body of water). It's the expense at this point.
> But it may well happen. Someday. But I have looked into it!

It can be done for under \$50. The 5 micron filter carts. are \$23, and a whole house filter can be bought at HW stores for \$22.

Good brewing,

> - A 5 minute boil of hops results in a 5% Isomerization (.05)

This is interesting, but I'd like to see your whole utilization (isomerization) table of Time vs. Isomerization. The conventional table, posted by Jackie Rager in Zymurgy, has 26.9% at 45 minutes and 5% at 5 minutes. This is the major problem with all of these IBU calculations; the utilization is debatable. Mark Garetz claims lower utilization across the board, there is lots of discussion about gravity adjustments, etc. etc. etc.

Until something big comes along to straighten out the mess, I'll use Rager's utilization numbers and formula. Why? Because it is very widely used in the homebrew community, making for a good point of reference. If someone tells me a beer has 37 IBU, and I know (maybe I have to assume) they are using Rager's numbers, I have a reference point to use in trying to duplicate it. Other adjustments/utilization tables may be more accurate, but the comparisons are what's important to me.

From: shaw@visar.wustl.edu (Andrey Shaw)
Subject: Haze or Contamination

Recently, I opened a bottle from my first batch of beer (made 3-4 months ago). It was a dark extract beer that had been made without any unusual problems and which had been sitting in my basement for several months at room temp. I have very much enjoyed this beer so almost all of the bottles were gone within the first month. Two weeks ago, I found several bottles and put them into the refrigerator and last night opened one to drink. What surprised me about this beer was the haziness, which was new; all of the previous bottles that I drank were clear. I am puzzled as to why or how this beer became hazy. It tasted pretty good so I don't think that it is bugs. Could it be protein precipitation from being in the refrigerator?

Is it common for beers to acquire a haze after several months. Should I hurry up and drink all of the rest of this batch? Any helpful comments will be appreciated.

On another note, based on comments that I acquired on the HBD, I rushed out to buy Coors Winter Lager and the Sam Adams Cranberry Lambic. Maybe its me, but you didn't tell me, I could swear that the Coor winter lager tastes just like Bud Dry and only when it is in a glass do I really notice the difference (it is darker). I guess its not bad for a commercial beer that cost me \$4.29 a six pack, but it wasn't anything to get excited about. The Cranberry Lambic (sic) was interesting and I did kind of enjoy it, but almost everyone I asked to taste it thought it was disgusting. It again wasn't anything that I would rush out and get. Interesting and novel but not great.

Subject: Commercial Beer Matrix, Part 1/2

-Part 1/2-

The following commercial beer matrix has been gleaned from various posts in HBD and rec.crafts.brewing. I find it useful, if not for cloning certain beers, for finding out what types of ingredients, OGs, etc. are pleasing to me. The best beers I have brewed were "clones" of commercial beers. They were not exact duplicates, but actually better than the originals (the advantage of homebrewing decisions vs. making money).

I find it interesting to note that some breweries use only one type of base malt and crystal for most or all of their beers, and still provide a wide variety of beers. This is probably due to the economy of mass buying, but it shows how versatile you can be using different quantities of base malts and crystal, and then changing hops and yeast. I don't know anything about the water treatments (if any) of these brews, but that could have a considerable effect as well.

The hops are, I believe, in order of boiling time, as should be evident in most of these beers by the hop variety. They are not all completely accurate, as the growing region of a particular hop can affect its flavor profile greatly (note that Redhook gives "Yakima Hallertau", which I presume is the American version of Mittelfrueh, although I'm not positive. It also lists "Tettnang", which I'm guessing is Tettnanger Tettnang, grown in Germany). You can see that some of this information needs work; also some of it may be dated.

Note that I only assembled this information into a single matrix; I did not gather it originally from the breweries. I would appreciate similar info on other breweries (large and small), other beers by these breweries, and any corrections that you note. If you tour a brewery, take notes!

Subject: XXX,yeast,ice,plugged screens

With this talk of Noche Buena, I was wondering if anyone has ever seen a dark malty beer called "XXX" out of Mexico? It was a take on "Dos Equis", but I don't know if it was made by the same company. I wasn't a brewer back then (10 years ago), but I remember it as being a good beer.

Without dredging up the dry vs. liquid yeast debate again, I'd like to point out that the switch from dry to liquid often brings your more subtle brewing mistakes to the fore. Something to watch for.

I'm surprised to hear that Ice Bud/Ice Molson have no flavor, because the Ice Labatts I tried had lots of flavor, most of it bad. Strong phenols. Enough so I actually checked the bottle for yeast sediment (of course there wasn't any). Fwiw, Labatts is suing people over using the term "ice".

And, speaking of plugged screens, I've been having a problem with stuck sparges. I use the 10 gallon cooler with straining bowl type of lauter tun. Worked great for 20 batches, but it just was not working anymore. Why, I dunno. Anyway, after having to pour the whole mash *back* into the mash-kettle to unset the sparge (HSA anyone?), I decided that I'd just put a stainless pot scrubber over the cooler outlet hole, tied on with an elastic, and leave out the strainer bowl. Well, hey, it worked like a charm! No clogs, a couple of quarts before it ran clear. YMWV, but it's likely to become SOP for me.

Subject: Hop bitterness longevity

I have a question about hop bitterness stability/longevity in my bottled beers.

The basic "problem" is that the perceived bitterness in my bottled beers seems to fade rather quickly (over a period of weeks). A beer that is extremely bitter one week, is perfect the next, and a couple of weeks later the bitterness is very subdued.

I've tried the basic 60 minute boil, 5 minute finish, as well as various attempts at dry hopping (which I really like) and hopping at various times during the boil. All share the same lack of staying power in the hops... Could it be the type of hops I use? (goldings, fuggles, willamette).

Anyone know how I can get a desired level of bitterness and have it stick around for awhile?

Thanks in advance for any advice/ideas.

Subject: Dry vs. Liquid Yeasts

Hi,

I would just like to give a small plug here for the Yeast FAQ. I talk about the magical aspects known as strain variation. Roughly this means: "Not all yeast are the same". Not all dry yeast, not all liquid, not all anything! To those who are disappointed with their variety of dry yeast but

would like to keep using dry yeast, you might try using Red Star Ale Yeast

or Llemand Nottingham or Windsor Dry Yeast.

Not to slam the Whitbread Dry (slam, slam, slam), but dissatisfaction with

it's performance in my first few batches (it gave an odd taste that I don't

know how to describe) is what drove me to compile the yeast FAQ in the first place. I wanted something that listed the available strains and their

flavor characteristics.

Beginning brewers should be especially happy with the Red Star Ale because

of it's fast starting and clean taste.

Patrick, that annoying yeast faq guy.

Subject: Re: starter gravities revisited

Cushing Hamlen asks about gravity of starters in HBD 1289.

I initially used starters with a gravity similar to what I was brewing. I was amazed at the difference in lag time between using a starter and not using a starter. Then someone on the HBD claimed that starters should be 1.020, so I switched to that gravity for my starters. It seems like I still got short lag times, but the yeast seemed to be very weak and I was getting high final gravities.

I now use starters that are between 1.030 and 1.040 and am very happy with the results.

Just my \$.02,
Darren Aaberge

From: troy@scubed.scubed.com (Troy Howard)
Subject: Wort dilution vs SG

Chushing Hamlen (cush@msc.edu) asks if there is a curve or analytic function fit to experimental data to describe wort gravity as a function of (presumably) dilution volume.

You do not really need experimental data. This is a rather simple problem.

Wort gravity is a measure of density. So, using the following notation:

D0 = initial density
V0 = initial volume
Da = density of added liquid (for water Da=1.000)
Va = added volume
Df = final density

then, adding Va of liquid of density Da to a volume V0 of liquid with density D0, will result in a liquid of density

$$Df = \frac{(D0V0 + DaVa)}{(V0 + Va)}$$

or (in case the spaces don't line up when you read the above)

$$Df = (D0*V0 + Da*Va)/(V0 + Va)$$

As an example, if you have 5 gallons of 1.060 wort, and add one gallon of water to it, you will have 6 gallons of

$$(1.060*5\text{gallons} + 1.000*1\text{gallon})/(6 \text{ gallons}) = 1.050 \text{ wort.}$$

-Troy

Date: Mon, 6 Dec 93 16:12:44 EST
From: Spencer.W.Thomas@med.umich.edu
Subject: wort dilution vs. SG

Not sure what you want. You mean "what happens if I add 1 gallon of water to 4 gallons of 1.040 wort?" Almost right formula:
1.040 wort = 40 "points/gallon" = 160 "points" in 4 gallons
160 points/5 gallons = 32 points/gallon = 1.032 wort

To do it right, you first convert from gravity to degrees Plato. Fix posted a cubic approximation to the tables recently. This gives you %sugar (by weight as sucrose) (1 deg Plato = 1% sugar w/w). Multiply by the mass of the solution (4 gallons * ???lbs/gal * 1.040) to get the mass of sugar. Add your gallon of water, and compute the mass of the new solution (original mass + mass of 1 gallon of water (don't forget to temperature compensate)). Then compute the percentage of sugar in the new solution (100 * original sugar mass / solution mass). Finally, convert back to S.G. using the Plato table (or formula).

A close approximation to deg Plato is to divide the "points" by 4. But if you use that, you might as well use the simple method in the first paragraph.

I haven't compared this to Steve Piatz's table, but his code looks like my first method.

Subject: Help!!! San Miguel Recipe Wanted.

Hello,

I'm looking for a recipe that is similar to San Miguel. As I'm pretty new at this, I'd prefer an extract-based recipe. I've checked the Cat's Meow and haven't found anything. I'd really appreciate any help offered.

Please post or respond to "evans@newton.jsc.nasa.gov" Responding directly to this post will not work.

Thanks in advance,

Chris Evans

I got one of those in the GABF edition of the local brewspaper, Rocky
Mountain Brews. I'm still waiting for the T-shirt. Guess I should have
checked "Distributor" rather than "Beer Lover"....

From: winstead%brauerei@cs.tulane.edu (Teddy Winstead)
Subject: Back To Basics Recipe

Fellow Homebrewers:

My last few batches (Double Bock, Amber Ale, and Papazian's "Holiday Cheer") have all been severely lacking. The Double Bock froze in the fridge, and had to come out (imagine the mess :-() ,resulting in estery off-flavors from the increased fermentation temps, the Amber Ale suffered from a lack of hoppiness and a little HSA, and the "Holiday Cheer" is awful (I think that I should've peeled the ginger) it has a medicinal, phenolic, rough (almost dirty, like mud) flavor to it.

So here's my query(s):

Could somebody please send me (via e-mail, so as not to clutter this list) a good, easy recipe (preferably something with some grains added to the boil for extra body)? Lots of hops, too. Also, one with a liquid yeast. Beleive it or not, I have troubles with liquid yeasts. They seem to have like a 30 hour lag time which makes me incredibly nervous.

Also, could somebody tell me whether or not it's a good idea to put soap in the dishwasher when doing your bottles in there? I'm a little worried that the dishwasher method's detracting from my beer quality.

Finally, could somebody give me a good, step by step method for cleaning and rinsing my carboy (since I don't have a hookup for my bottle-washer anymore, I think that maybe lack of rinsing has contributed to off flavors.

Thanks a million, and happy brewin'

james>- --james

Ya, it's quite funny, the Labatt Ice beer is the first beer that my wife actually likes: because of the no after-taste!!! And I have been trying for so many batches to make something that she would actually enjoy - I guess I was on the wrong path with berries!!!

I will admit that I do buy the Ice beer for guests who like "tasteless beer", that's what I call it! That makes them laugh...

Later

From: RADAMSON@delphi.com
Subject: Beer Offerings

Fellow Brewers:

I am blessed with a dilemma this season of having an opportunity to influence the tap offerings of my local pub. It has been and will continue to be a brilliant, almost quite proper, Irish Pub. It even goes by the name of Mustang Sally's. For the record, it has to be the freshest, best poured pint of Guinness on Long Island, NY - and we've hunted quite a few along our search. Anyway, his other offerings are Bass, Woodpecker Cider, Kilian's, Bud & Coors.

So, we (my brew partner & I) had an idea of providing a holiday ale (Anchor Christmas, Sierra Celebration, even SA Winter Lager, etc) to him to serve. He could charge whatever for a pint, except for us, of course. Our investment is basic: add a more beer knowledgeable crowd to his clientele; get the place known for a rotating special seasonal Micro beer, etc. I know, skip the details...

Anyway, he's going along with this so far. You're saying, "So, what's the dilemma?" - Certainly not the selection!! I love this season!

What I'd like to throw at him are some industry marketing blitz crap that will help convince him that the special beer will sell (even though he has no cost in the keg (at this point anyway)). He may have to decide which current tap to remove. Can anyone start me in the right direction for trades, articles, etc.?

Thanks in advance,

Richard Adamson, Brewer, Systems guy, Steeler Fan

From: smag@echonyc.com (Stefan Smagula)
Subject: Oven-mashing, Over active fermentation, Old Yeast

OVEN-MASHING

I have a tip for those who are thinking about trying to mash for the first time. This is how I did my first partial-grain batch. It was easy! Instead of buying or making an insulated box, I used my 8 gal. enamel brewpot, and put it into a warm oven for the steeping periods. I made sure the oven temperature was near that of the mash with the help of a thermometer. When I needed to raise the temperature of the grains (I did a "step-infusion"...I think?), I took the pot out of the oven and heated it slowly on the stove. I was happy, my mash was happy :->

--

Help! I violated the 11th Commandment:
This same 5 gal. batch (1# of cara-pils, 1# of crystal, 4# pale malt, 11# Dry Malt Ext. with about 10 oz of various hops, an OG of >1.100) had one problem: it fermented so fiercely the foam filled all the headspace in my 7 gal carboy and went all over the floor, leaving me with <3 gallons of brew. It was an expensive mess, but worse, it was a sin ;-) Is this normal for high gravity/high hop brews? (this is my first) and how do I avoid it? Note: I did not separate the hot/cold break from the wort. I used Wyeast #1214 (Belgian Ale). I don't think this problem was due to my mashing method--the wort tested OK with iodine.

-

Any advice on using old yeast?
I cleaned the yeast from the trub of this same batch using the method outlined in the Yeast FAQ--thanks Weix, the FAQ's awesome! (Roughly: boil some water, cool, mix with sediment, let settle, pour off everything but settled yeast, repeat, and then pour the cleaned yeast into a sanitized mason jar and store in your fridge). Now, can I safely use this yeast even though I cleaned it over a month ago? I have a microscope--so I could check for bacteria--but I'm not sure what levels of bacteria are "safe" (there was a good number of critters in the original Wyeast package!), and I'm not sure about the viability of yeast stored this long. Thanks.

[enter non-professional mode] I think there should be more orgasms, fake and otherwise, on the HBD! Sorry about the l o n g post.

For anyone who wants to taste a real ice beer, try EKV Kulminator
Urtyp Hell 28 from Germany (That's the entire name of the beer, honest!)

.
It is concentrated by freezing as are the North American "ice" beers.
But, the flavor (and alcohol) are so concentrated, I found this brew
to be undrinkable, unless diluted with some lighter-bodied beer. (I
never thought I'd say a beer was undrinkable, but try it yourself and
let me know how you feel about it.)
You should be able to find this Kulminator without too much trouble;
our local supermarket carries it in the imported beer section. I guess
it's actually a doppelbock in style, except for the freezing treatment.
Oh, and it is reputed to have the highest alcohol content of any
commercial
beer. (Maybe, maybe not). I know it is around 12%, and it packs a
wallop!

Subject: Snakebite

Smolinsky spoke of his little Welsh B&B giving him a taste of Snakebite and telling him of its illegal status. I have to say that this may be the case in England and Wales but us Scots are smarter than them so we have our own legal system which does not ban this tippie. Either that or my local hasn't heard anything to the contrary! In fact it is quite common around here to order a "snakebite black" which is the half lager, half cider mix but with a dash of blackcurrant. I have to admit though that neither of these concoctions really appeal to me.

On a different note I wonder if anyone could help me with the problem I have with my present batch of 'instant' homebrew. It's one of these buy your tin of wort with everything included except water and sugar. The problem is that primary fermentation went like a dream, but now that i've transfered it to my pressure barrel for secondary fermentation nothing's happening, ie no pressure build up what so ever. I've tried adding extra yeast but to no avail. Please help ASAP as this is supposed to be the main attraction of a Christmas Eve party. HELP!!!!!!!!!!

Subject: Brigand Ale/beer aging

Popped the cork on a bottle of this stuff last night. Wow! Vinous, fruity, old-ale aroma, beautiful orange-gold color, creamy head, strong!, hoppy in back. Yum!

This is a "Special," a style designation that means almost nothing, as far as I can tell. With an OG of 1080, it's more-or-less in the "strong, blond" category, I'd think.

Jackson says it's best 3-6 months from bottling. Well, the cork on this one said it was bottled 2-90. Still good. There was some crud on the bottom of the cork, which I carefully cleaned out of the neck before drinking. Also yeast "fluffies" in the bottom.

I don't know what this says about aging "on the yeast" versus filtering, but it certainly indicates that a beer can last more than a few months (which many of us already knew). Although it smelt somewhat aged, it didn't taste "old" in any negative sense. I wonder what a new bottle would taste like?

Subject: Alpha Acid extraction

I have been playing with Rager's and Garetz' tables, the equation from the hops faq and the like, and it occurs to me there is something missing. I seem to recall (from the spring issue of American Brewer, I believe) that increasing the hop rate decreases utilization. Thus, not only is the utilization rate not linear with time and boil gravity, it is also not linear with hopping rate. Does anyone out there have a polynomial for this?

You've *got* to be kidding me. This sounds like an
"Old Wives' Tale" made into law.

"Snakebites" are pretty common over here in brewpubs (at
least in the Boston area), and are made from a strong lager
and a cider, as the poster states. Usually the lager is the
lager-of-the-house, and the cider is whatever is available.
(At least one brewpub in Boston makes its own cider: Boston
Beer Works.)

If there is a chemical reaction that has a bad effect
on people's brain cells, I haven't know it, and
eye drink a lot of snakebytes....

From: pacasey@lexmark.com (Patrick Casey)
Subject: CO2 buildup during lagering phase

Hi. When I made my first and only lager this fall, I had a problem at bottling time -- the beer foamed a lot when I filled the warm bottles and later the beer had a way too high level of carbonation. Here's what I figure was going on:

At the lager fermentation temps, the CO2 produced by the yeast tended to stay in solution rather than come out of solution like it does with my ales at ale fermentation temperatures. Since I bottled the beer right out of the fridge after a 2 week primary and 2 week secondary/lager phase, a lot of CO2 was still dissolved in the beer.

This time I think I'll bring the beer out of the fridge a day or two before bottling to let most of the CO2 come out of solution. Seems like I read in Noonan's book that he says the CO2 can be brought out of solution by siphoning the cold beer straight from the fridge into a bottling bucket and then rocking the bucket to coax the CO2 out of the beer. What do you folks do?

Thanks in advance,

Patrick

From: BRUCE@ARVAX.Syntex.Com
Subject: Re: Snakebite

I believe you Welsh friend was spinning you a bit of a yarn with that brain cell story.... (I have always been fascinated by Wales, BTW...)

However, snakebites are definitely EVIL!! I have strayed to the DARK SIDE more times than I care to (or can...) remember. Many Pubs here in the bay area have Dry Blackthorn Hard Cider on tap, and are very familiar with snakebites.

I was introduced to them at Jonathan's Roadhouse Pub in Tahoe City while on a ski trip, and, ever since, I have been hooked. If a place has the cider on tap, I know automatically what I'm going to order.

They're a little sweet with some of the milder lagers, so I suggest trying it with Pilsener Urquell or one of the more robust ales. They're also pretty good with Guinness, believe it or not! I usually get them with the likes of Red Hook or Bass.

With regard to the brain cell thing, I simply cannot believe that it was outlawed for killing brain cells. We all know what does that, and it has nothing to do with a reaction between cider and beer...

These wonderful concoctions do, however have a tendency to sneak up on you and bite your behind! They are tasty, go down smooth, and have quite a kick. I don't know what the alcohol content of the cider is, but I have ended up more inebriated than I have intended on several occasions.

I suggest you search out a pub that has a dry cider on tap, and have them pull a few snakebites for you. But make sure you have a ride home if you're there past closing like you were in Wales.

Enjoy!

From: Keith MacNeal 07-Dec-1993 1147 <macneal@pate.enet.dec.com>
Subject: dopplebock vs. barleywine

Someone asked if dopplebocks are barleywines. The answer is, no there are differences between the two. The most basic difference being that a dopplebock is a lager and a barleywine is an ale. Lagers are brewed and aged at lower temperatures than ales. Dopplebocks are a high alcohol version of lager while barleywines are high alcohol versions of ale. Barleywines are generally higher in alcohol content than dopplebocks (a tripplebock might be in barleywine range).

Subject: Disappearing Bitterness

Stephen Dillinger writes:

>The basic "problem" is that the perceived bitterness in my bottled beers
seems
>to fade rather quickly (over a period of weeks). A beer that is
extremely
>bitter one week, is perfect the next, and a couple of weeks later the
>bitterness is very subdued.

I suspect what is happenning is that the iso-alpha acids (responsible for
the bitterness) are dropping out with the yeast (Yeast adsorbs iso-
alphas).

Now if you say "Well my beer is clear when I perceive it to be bitter, so
the yeast has already dropped out," I would say that reasonably clear
appearing beer can still have lots of yeast suspended in it.

Try this experiment: Shake up the beer to re-disperse the yeast and then
taste it. Yes it will be yeasty, but I'll bet the bitterness returns.

Solutions? Increase your hopping rate and let the beer settle a bit more
before bottling. And/or use a more flocculent yeast strain. I haven't
tried it yet myself, but the new Wyeast 1968 Special London Ale is
reported to be highly flocculent.

Subject: Different Beers - Same Flavor

I am having a problem that perhaps you folks out there in HBD-land could help me with. In short (hopefully), my last two brews came out with the same flavor, but I used different ingredients.

First brew -
8# US 2-row
1# US 6-row
1# rye flake
Hops: approx. 45 IBU (don't have varieties on hand)
Yeast: Wyeast - Calif. Lager Yeast

Second brew -
9# British 2-row
1# Crystal 40L
Hops: approx. 45 IBU (don't have varieties on hand)
Yeast: Wyeast - Chico Ale Yeast

In both brews, I used a 1400 mL yeast starter (very active) and fermentation started in about 5 hours. Previously, I had used only 500 mL starters, with fermentation in 24 hours.

The problem is that both beers have a pronounced flavor component to them -- sort of a pear/banana-like aroma and taste (IMO, but it is hard for me to judge). At about 40 hours of fermentation, the second brew went from having a medium-amber color with large aggregates circulating around to a light-amber color with a lot of small particles circulating. The fermentation was very active during this entire period.

Is this characteristic of these yeasts or did something happen to the yeast during fermentation? Any ideas? If I could tell the difference between phenols, esters, aldehydes, ketones, long-chain alcohols, etc. - I guess I could troubleshoot the problem better. But my beer judging needs to improved. (another story) -- BTW, the beers are very drinkable, I just wasn't looking for that flavor. Thanks.

Subject: Local Chicago Shops

Is there a list out there anywhere of Chicago areas supply houses?
I only know about my brewmaster, "Brewin' Beer" out by O'Hare. I
like his shop but am always willing to look at something new. Thanks.

Also, I am sure that I already missed this being new to this net, but
has anyone tried "Clear Beer?" My family in Minnesota sent me samples
when I told them I was making my own because they thought it was neat.
I can't even give this junk away. One would think that they would assum
e that I only liked something with flavor, body, taste, etc. but there
is no accounting for family. While I can't in good concience throw it
away (there are people in China going to bed sober after all) but i
can't stomach the junk. Anyone else tried it? Are they still making
it or did this particular brewery suffer a timely fire?

From: tpm@wdl.loral.com (Tim P McNerney)
Subject: Is Stoelting making a magic chiller?

I got this flyer from Stoelting which makes the following claims for its wort chiller:

Chills 5 gallons of wort from 210F to 56F in 15 minutes at .33 GPM.

So basically, 5 gallons of water (.33 * 15) to chill 5 gallons of wort from 210F to 56F. It seems to me that if you were able to obtain perfect heat transfer and the water you were using was 32F, the best you could hope to get is 121F.

Am I missing something here? Here is the rest of the info:

Wort chiller w/ stainless steel housing. Counterflow type. Chill rate: 5 gal. of wort from 210F to 56F in 15 minutes at .33 GPM. 3/8" ID stainless steel wort line wrapped with copper fins. Finned tube assembly centered in 3/4" cold water copper line. 8.5" high x 11.25" diameter.

Subject: Unsolicited Mail Order Catalogue

Hello HBDer's,

I have a digest (etiquette?) question. Today I received at work a mail order homebrew supply catalogue. I don't recall asking anyone to send this to me, and if I had, I'm sure I would have asked them to send it to my home address. While I appreciate getting this sort of thing, I would want to get it at home!

It would appear that they pulled my address from my sig from a couple of recent postings to HBD. While I consider this improper, I'm not sure if it is considered a breach of NET etiquette. I would have preferred e-mail asking if I wanted the catalogue. By including my snail mail address in my sig, am I asking for this sort of thing? Could some NET "Miss Manners" please clue me in to proper behavior in this regard?

Until then, just call me:

Mark "no sig" B.

From: ccamley@mmm.com (Chris Amley - 3M Telecommunications)
Subject: Noche Buena

In HBD 1289 Dr. Fix asks for a polite way to get across the fact that the "new" Noche Buena differs from the old in alcohol, color, and bitterness.

It sounds to me like it's not the same beer, and that's what SW Brewing News

should say: it's not the same beer. Any published note on this beer should

also raise the question: is it ethical to call the new beer by the old name?

Of course, the same note should point out the facts of the new beer.

NB use to be available in Southern California around the end of the year and

it seems a real shame that some people will be misled by this practice, especially given the rarity of Vienna-style brews.

Chris

>
> I haven't compared this to Steve Piatz's table, but his code looks
> like my first method.
>
```

To incorporate Spencer's concern for using the more accurate degrees Plato let's use the following:

```
phys_con = pounds/gallon of water
v = original volume of wort
og = original specific gravity
dilution = percent of original volume added as water
```

Assume that the wort and the dilution water are both at the same temperature.

```
percent_sugar = sg2plato(og)
mass_sugar = percent_sugar * v * phys_con * og
original_mass = v * phys_con * og
new_mass = original_mass + (dilution * v * phys_con)
new_percent_sugar = mass_sugar / new_mass
```

Which is:

$$\frac{(\text{percent_sugar} * v * \text{phys_con} * \text{og})}{(v * \text{phys_con} * \text{og} + \text{dilution} * v * \text{phys_con})}$$

Which simplifies to:

$$= (\text{percent_sugar} * \text{og}) / (\text{og} + \text{dilution})$$

Which gives:

$$\text{fg} = \text{plato2sg}((\text{percent_sugar} * \text{og}) / (\text{og} + \text{dilution}))$$

After doing all this the resulting table is identical to the more simplistic approach. The program follows, the #if SIMPLE determines which approach to use.

```

#include <stdio.h>
#define NUM_PERCENT 10 /* number of columns */
#define NUM_GRAVITY 30 /* number of rows */
#define PERCENT_STEP 0.05 /* percentage per column */
#define GRAVITY_STEP 0.005 /* gravity per row */
#define INITIAL_GRAVITY 1.010 /* gravity for first row */
#define INITIAL_PERCENT PERCENT_STEP /* percentage for first column */

double
sg2plato (sg)
double sg;
[
    return 259.0 - (259.0 / sg);
]

double
plato2sg(p)
double p;
[
    return -259.0 / (p - 259.0);
]

main ()
[
    int i;
    int j;
    double og, fg;
    double dilution;
    printf (" | Dilution By/n");
    printf (" O.G. | ");
    for (j = 0; j < NUM_PERCENT; j++)

Subject: hop utilization/Barleywine aging/HopGoRound/hop bags/fading
bitterness

Robert writes:

>The unpredictability of results when hopping may be due more to the
>isomerization of the hops than hop utilization.

Yes, but isomerization is one of the many factors that collectively combine to result in a number we call "hop utilization." I disagree that it is unpredictable... I feel that for a given system, one can determine the hop utilization as a function of boil time and other factors. I say "for a given system" because among other things, kettle geometry, whether or not you use a hop bag, and heat source intensity (boil vigor) affect hop utilization. I don't know how much each of these factors, or which ones of them are significant, but for a given system you can figure out a set of formulas that will give you predictable bittering.

>Isomerization is an altering
>of the molecular structure of the substance in hops that imparts
bitterness
>to beer. It is the isomerized molecules that give the bitterness. Only a
>fraction of the hops are isomerized during the boil (around 25% max) and
>the degree of isomerization is directly proportional to the length of
time the
>hops are in the boil. Maximum isomerization occurs at around 45 min. of
>exposure to the boil. After one hour isomerization actually begins to
reverse!
>Perhaps this explains why Andy's 90 min. boil was not as bitter as
expected.

Could you send me your reference for this... I'd like to read more about it.

I've read many articles that contradict this assertion. Thanks.

>So, actual IBU's can not be calculated without taking %Isomerization
into
>account. Since learning this information from the master brewer at a
local
>contract brewery, my beers have been much more predictable in terms of
>bitterness and better overall. I believe this is because I now brew to
a
>specific target bitterness (based on style).

What all the formulas (the ones Robert posted as well as Ragers, etc.) calculate are an approximation for the IBUs in the finished product, not really what gets into the wort. Here's an excerpt from a talk by Bob Foster (Coors Brewing Co) talk at the Siebel Institute of Technology:

PROCESS UTILIZATION OF ALPHA ACIDS

Formula %U = IBU(ppm)/AA added(ppm) * 100

Kettle Utilization: (EG.) %U = 45IBU(ppm)/92.4 AA added(ppm) * 100
%U = (0.4870) * 100 = 48.7%

Fermenter Drop (EG.) %U = 25IBU(ppm)/92.4 AA added(ppm) * 100

RUH Drop: %U = (0.2706) * 100 = 27.1%

Lager Drop: (EG.) %U = 23.5IBU(ppm)/92.4 AA added(ppm) * 100
%U = (0.2543) * 100 = 23.4%

Blending (30% H2O): (EG.) 23.5IBU * 0.70 = 16.5 IBU
%U = 16.5 IBU(ppm)/92.4 AA added(ppm) * 100
%U = (0.1786) * 100 = 17.9%

Overall Utilization 16.5IBU - 1.0 IBU loss = 15.5IBU
(packaged beer):%U = 15.5 IBU(ppm)/92.4 AA added(ppm) * 100
%U = (0.1678) * 100 = 16.8%

Confusing? Yes, I agree, and I'm not sure if the numbers were actuals (measured) or if they were just for example's sake, so we can only take this information with a grain of salt. However, if we assume that the numbers are in the ballpark for a real system (granted, Coors' 650bbl system), then there are a lot more significant factors than just percent isomerization.

Jim writes:

>> yeast, or champagne/wine yeasts. Aged 6 months to a year.
>Well, Bigfoot is not aged like this, and I dont age mine either. It all depends on your fermentation, if you properly attenuate the beer, the aging time is greatly reduced. If you bottle at 1.030, it will need considerable time to age, but may never be as good as one bottled at 1.020.
>My latest is great at brew day + 10 weeks, or keg day + 8 weeks. It was darn good at 3 weeks.

I have wondered about this. I bought a sixpack of Bigfoot back in '91 from a store that is notorious for poor handling. The bottle cap said 1990. I tried one immediately and it was harsh and undrinkable. Very unpleasant. It tasted like it was very highly alcoholic but not a smooth, warming ethyl alcohol. Knowing that high-alcohol beers often require aging (Samiclaus is aged 1 year before distribution), I put the beer aside in a cool crawlspace and forgot about it. Six months later, I tried another bottle -- better, but still harsh. A year after I bought it, I finally tried the third bottle: nectar! The harshness smoothed out wonderfully and it had a very interesting complexity of estery aromas and flavors over a perfectly balanced malt/bitterness/alcohol base. I have two bottles left right now, and I regret that I did not buy more.

When the 1992 Bigfoot came out, I bought a case, this time from a better store. I tried a bottle immediately, expecting the harshness, but it was not there! I know that SN has been changing their procedures (and maybe also their recipes) over the years and perhaps they have reduced the OG or the fermentation temperature or something. The beer seemed more alcoholic than the 1990 version, but it was all the smooth, warming ethanol flavor. Comments?

Norm writes:

>Until something big comes along to straighten out the mess, I'll use Rager's utilization numbers and formula. Why? Because it is very widely used in the homebrew community, making for a good point of reference. If someone tells me a beer has 37 IBU, and I know (maybe I have to assume) they are using Rager's numbers, I have a reference point to use in trying to duplicate it. Other adjustments/utilization tables may be more accurate, but the comparisons are what's important to me.

I tend to agree. I recently bought "Dr. Bob Technical's Hop-Go-Round" a hop version of the Wheel of Beer. I used it last night to compare my Rager-derived numbers with the Hop-Go-Round. For a 60 minute boil in a 1081 wort, they were almost identical, but for a 15 minute boil the H-G-R said 6 IBU where my Rager-derived numbers said 3 IBU! I think that the H-G-R is much too optimistic at the lower end of the utilization curve. I plan to tape my own scale over the existing utilization scale on the back of the H-G-R.

Further, Norm writes:

>I have had similar problems, Dion. My course of corrective action: use whole hops whenever possible and always put the hops in a hop bag. Pellets are terrible for this problem, and the hop bag will help even with pellets. I would like to hear how others deal with clogging in the kettle.

I add 10% to Rager's numbers when I use a hop bag (which is always).

Steve writes:

>The basic "problem" is that the perceived bitterness in my bottled beers seems to fade rather quickly (over a period of weeks). A beer that is extremely bitter one week, is perfect the next, and a couple of weeks later the bitterness is very subdued.

Anytime someone reports something hop-related is good for a while and then turns bad after a while in the bottle, I suspect oxygen is the culprit. I'm not sure exactly how or why, but I would recommend that you evaluate your processes and see if you may be introducing oxygen while the wort is still hot. Another thing is that perhaps it is not bitterness that you are perceiving. Perhaps it is tannin astringency which *does* go away after a while. Perhaps you are extracting a lot of tannins from your grain and you are underhopping -- while the tannin astringency is still there, the beer tastes rather balanced -- when it fades, the beer tastes too malty. Could this be the problem?

Al.

Subject: KRUSH-OFF

>From: STROUD%GAIA@leia.polaroid.com
>Subject: Wort Processor Krush-Off: Part II

>1) The Knurly GlattMill - Powered by a normal household drill, this mill crushed the malt in an impressive 26 sec., nearly as fast as the Schmidling MaltMill (21 sec) in our original Krush-Off.

Clearly, a mill that is more than twice as large should demonstrate a significantly higher throughput at a given rpm than what you have described.

This test is only valid if they are both run at exactly the same speed and no mention of the RPM was made.

It should further be noted that the MM as shipped is set up for hand cranking and the grain guides provide a restricted flow to assure ease of cranking with the very large rollers. To maximize throughput when motorized, the grain guides can be trimmed to provide a larger hole that will feed the grain as fast as the 10" rollers will take them.

I have a microbrewery customer that reports a throughput of 17 lbs per minute on his MALTMILL. That's 3.5 secs per lb, roughly 4 times the rate reported for the Glatt.

>From: hollen@megatek.com (Dion Hollenbeck)
>Subject: Wort boiler screen

> The end of the nipple is covered with a coarse screen. I have no idea why it did not plug up the first two times, but did this time.

You were lucky. If the screen is only as large as the diameter or the nipple, all it takes is one petal of a hop flower to clog it.

>Here are my questions. If you are using a Chore Girl or an EasyMasher, since both of them are just screens, why do they not plug up?

The EM screen is a 6" x 3/8" cylinder and needs far less luck to remain clear.

End of HOMEBREW Digest #1292, 12/08/93

Date: Wed, 8 Dec 1993 10:07:07 MET
From: "HANSEN M" <0031@et.aarhus.ih.dk>
Subject: A newcomers introduction. Danish brewing

I have been brewing beer for the last 6-7 years but I am new to HBD and I sure like what I see !

I am also one of the few Danish home brewers that brew the 'do it all yourself' beer. The normal procedure in this country is to buy a package that contains all the material you need. But this brew is based on dry yeast and malt-extract which both contribute to the reduction of the taste.

I have read HBD #1281 - #1284, and i have got the feeling that most of you are from America, and that you do not brew your beer the same way that we do in Denmark.

So first I am going to give you a description of the material and the procedures of the Danish way of doing these things. I apologise for my humble English.

We are two students at The Department of Electronics at The Engineering College of Aarhus, in the middle of Denmark, that have build our own brewery in his cellar. In this cellar we brew the kind of beer that is very related to the beer from Pilsen (Czechoslovakia) and Bayern (Germany). The pilsner is (as you might know) most commonly a relative light beer, but is also brewed in more dark sorts, a little like the well-known porter. I guess you all know the Danish Carlsberg Pilsner, which is a very light pilsner. (too light for me that is).

The ingredients we use is 4-5 different kinds of malt, hops, Bog myrtle (Myrica), sugar, salt and yeast.

The malt is a substance like syrup with a very fine taste. The sorts that we can obtain are :

Light Malt for the light flavoured beer.

Dark Malt for the more dark but not necessarily strong beer.

Gold Malt for the semidark and strong beer. This malt is boiled with hops in it.

Porter Malt for the very dark and porter-like beer

Barley syrup which i very similar to the light malt but with a little different flavour. Unfortunately a rare malt.

These different types of malt is of course used in all kinds of compounds. They are all bought in 15 kg cans for about \$20-\$25.

Bog myrtle gives a bitter taste a little like hops, but still different. Rarely used, or in very small amounts.

The yeast is a liquid yeast for bottom fermentation (Saccharomyces Carlsbergensis) that we simply pick up at the nearest brewery according to an ancient Danish rule which says: 'Anyone are entitled to pick up free yeast for his own personal use at any brewery'. Use of this yeast makes it necessary to have plenty of cool storage room for both the yeasting and maturing of the beer, which both must take place in 5-7 Celsiusdeg. (40-45 F.).

Our solution to this are two modified freezers (new thermostat), one 500 liters and one 300 liters. This gives us a total storing capacity of aprox. 200-260 liters in the form of 5 old fashioned 40 liters milk cans, and up to 3 20 liters beer kegs (The type that the commercial breweries uses).

This capacity gives us, if fully utilized, aprox. 40 liters every 10th day.

The procedure is this :

The first thing to do, is to make 30-35 liters of boiling water. This is done in an old milkcan, enhanced with 2 electrical heaters. Meanwhile the malt, hops, sugar and other spices are weighed out. When the water boils, the spices are added and carefully stirred. Then, depending on the malt used, 1 - 1.5 hours must pass with frequently stirring. Light malt must boil longer than darker sorts, to develop the fine taste it is known for. After the boiling, the wort must be cooled of.

For this purpose we have purchased an old milk cooler which run on cold water only. This device can cool 40 liters of boiling water to aprox.

5 - 10 Celsiusdeg. in 15 minutes. Then the yeast (which is reused several times) is added (0.5 liter) and the wort is aired up/ventilated (

I don't know the right expression) by pouring it back and forth a couple of times. Finally the milkcan's opening is covered by a sterile bathing cap (the hospital kind), and placed in the freezer (fridge) for yeasting.

Wait, wait, wait for at least 3 weeks.

Then, after the yeasting the beer is gently transported to another milkcan for maturing (to avoid the sediment), and stored at the same temperature of course. This milkcan is closed with a pressurized lid, and CO2 is added to about 1.5 atm (22 psi). This pressure is maintained throughout the next 3 weeks (at least). Mostly this is done by adding CO2 once every 2nd or 3rd day during the first 1 or 2 weeks. After this maturing the beer is drinkable, but before we drink serious quantities we remove the pressure from the can, and transport the beer gently to two beer kegs which we pressurize and store for 5 - 10 days so that the beer can absorb the right quantity of CO2. After this the beer

is finally a fine, clear and delicate tasting draught beer. The serving is done from a small refrigerator with a CO2 bottle and a suitable placed tap. We also possess a transportable box with CO2 and a tap, for feasts and its like.

This procedure is only the most commonly for unproblematic beer, and will of course be adjusted for beer with lack of behaviour.

What you have just read is only a superficial description of the methods and materials we use. I will be happy to go into details if anyone would be interested.

Second, it seems to me that most of the stuff you guys write to HBD looks a little like a closed discussion. So it is very difficult for me to gain an insight into the methods you use. Therefore I would be very interested in some basic information about the way that you guys brew your beer, thank you. (Some kind of dialogue could be very interesting)

If any of you would want to reply, it might take a couple of days before I will be able to get back to you, simply because I am looking right into to heavy examinations.

Do feel free to mail me directly.

Merry Christmas, Morten Hansen

Subject: Snakebite2

After further investigation ie I spoke to an ex-barmaid! the situation regarding the illegality of snakebite in the U.K does cover the whole of the country and not just England & Wales as I suggested.

So why can I get it in my local?

Apparently it is O.K to sell it with a dash of blackcurrant which I would refer to as "snakebite black" but was put to rights on this matter as it is more commonly known as Diesel and taken alongside a bottle of Holsten Pils!!!

Just had to clear up my previous errors.

Subject: Re: Snakebite

Well I live in England, work behind a bar & as far as the licensing law stands, Snakebite is not illegal, it may be frowned upon, and a friend of mine did say he wasn't able to get it in Merseyside due to a local byelaw..... (Truth or otherwise of this claim unverified)

And anyway if Snakebite was illegal, would it not also be illegal to sell someone a half pint of lager & a half pint of cider or any possible way for them to make a Snakebite, because by selling them I would be an accessory to the "crime"

Not that any of this bothers me at all as I don't count lager as a drink & when I drink cider I drink cider - not polluted with any of this other BS, when I drink beer, I drink gallons (hic)

 solution in the bottle)
 No food for the yeast -- You post did not mention how much
 priming suger you used about a cup is usually
 enough for a 5 gallon batch
And a Suggestion for the next batch: (assuming you did what I did
with myfirst batchs of "instant homebrew- makes 5 gallons just add
suger and water")Use the exact same kit and procedures, except
substitute amber Dry Malt Extact for the corn suger. The
resulting beer will have a less cidery taste, more body.

ALLISON.DAVID@1GW.GENE.COM writes
> In short (hopefully), my last two brews came out with the
>same flavor, but I used different ingredients.

The recipies are both for rather mild beers that would
show the effects of processing errors or contamination.
Potential effects and causes:
 Contaimination: The taste could be the hallmark of a
 wiild yeast that has taken up residence at your address.
 If this is the case, either be very carefull with stearylization
 or breew styles which can live with the taste.
 Running Hot: Even a good yeast will produce off flavors
 if picthed to hot, or fremented at to hot a temperature. The
 lager yeast esp.

Subject: HopTech Fruit Extracts

I just got the catalog today from a company called HopTech. Mostly they just sell hops, but they did have some concentrated fruit extracts. They are sold in four ounce bottles and contain enough "stuff" to make about 15 gallons of fruit beer. They don't have any sugars in them, so you add them to the beer right before bottling. Anyone ever heard of this stuff or tried it yet. It is a lot cheaper than the real fruit itself, so it would be a good cost savings, but the question is, will it be good to taste?

Subject: Pale Ale

Hi All,

I'm an all-grainer who likes a BIG tasting pale ale, not necessarily in OG or alcohol level, but very malty and very hoppy. Of course the hoppy part is easy, and some yeasts have helped with the malty part. I use M&F pale 2-row and mash at around 155degF. My idea is to add 1/4 or 1/2 lb pale at mash out, to add flavor. What would be the pros and cons of this? Or is there something else I haven't considered?

Thanks much,

John

From: npyle@n33.stortek.com
Subject: Dream Tun

I am a happy all-grain brewer, planning my 21st batch (of which about half have been all-grain) for the upcoming holidays. My grain-mill is a home-made roller mill which should suit my needs forever. My boiler is a very nice, propane fired (converted NG water heater element), 10 gallon cream can from an old dairy. I have a hop-back, and nice CF chiller to boot. I ferment happily in carboys (7g & 5g).

The component I've left out is obviously the mash/lauter tun. It is a Rubbermaid 48 quart cooler with copper pipe manifold. It does what is intended for it to do, which is to serve well as an insulated single temperature infusion mash and lautering vessel. What it does not do, of course, is step mashes, which would be nice, nor does it offer any easy way to add heat if I miss my strike temperature for any reason. Also, it will eventually warp enough from the heat that I'll need to replace it (it is showing signs of this, after many batches).

Kettle mash, you say? I don't want to lose so much heat during mashing that I have to attend the thing constantly; the best thing about mashing is that I can go do other things (such as go to work for a half day, as was mentioned here a few weeks ago). Also, I have had a lot of trouble with temperature overshoot when kettle mashing. I prefer an insulated tun for the non-attendance feature during a normal infusion mash. If I am going to do a step mash or something different, then I certainly wouldn't mind working it.

So, my question is this: if you were able to design the ideal mash/lauter tun system, for homebrewing applications, how would you do it? I'd like to do up to 10 gallon batches, but more capacity than that is not necessary. Assume that cost is a factor (always minimize it), but that I have an unlimited resource in terms of welding, pipe bending, etc. (almost true). I have propane in my brewery/garage, 110V (but no 220V), and soon will have hot and cold running water. I'm looking for something I can use for a lifetime, that is versatile, and most of all: neat!

Should I convert a SS half-barrel keg by insulating it and adding a propane burner? Steam jacket? Hot water jacket? RIMS? uP controlled (I think this

is overkill, personally)? How about an insulated vessel with a steam bubbler?

Or a removable radiator (reverse chiller)?

One more thing, how about a sparge water vessel? I currently use my boiler,
but I have to transfer the water to a bucket, so that I can free up the boiler

for the first runnings. This is one reason I batch sparge most of the time.

The idea of mixing the grain and strike water as they fall into the tun (obviating the need for "dough-in") also intrigues me.

I ask this to generate some discussion and maybe something good will come out

of it for many HBD tinkerers. I'd like to hear what works well for you, but

also what you only dream of making (maybe I'll make it!). As always, we thank

you for your support.

> For anyone who wants to taste a real ice beer, try EKU Kulminator
> Urtyp Hell 28 from Germany (That's the entire name of the beer, honest!
>).
> It is concentrated by freezing as are the North American "ice" beers.

EKU 28 is not, in fact, concentrated by freeze distillation. (See Michael Jackson's "New World Guide to Beer", p. 54.) It is brewed from a wort that does achieve at least 28 degrees Plato (about sg 1.112).

The only true eisbock I'm aware of in Germany is made by the Kulmbacher Reichelbraeu brewery, a smaller neighbor of EKU's. Their Bayrische G'frorns (frozen Bavarian) beer has a calculated OG of 24 degrees Plato, and the beer is far more drinkable (if that is the right word) than EKU 28.

The story is that a tank of beer was accidentally left out in the freezing weather and that when opened, this nectar flowed out.

The Niagara Brewery in Canada produces an eisbock with some regularity. It's an interesting beer, although it makes no attempt to scale the gravity or alcoholic heights, coming with a mere 8% alcohol by volume. It tends to have an estery background, which is probably emphasized by the concentrating process. Even so, it has a lager character to it and I don't think many judges would liken it to a barleywine.

> Oh, and it is reputed to have the highest alcohol content of any commercial
> beer. (Maybe, maybe not). I know it is around 12%, and it packs a wallop!

No; EKU 28 has the highest OG of any regularly available beer. But Hurlimann's Samichlaus, brewed from a slightly lower OG, is a bit more fermentable and so has a higher alcoholic result (and a more drinkable product, IMHO). This, in spite of the boastful claims on the EKU 28 label ("Das starkste Bier der Welt").

Subject: Pitching Rates

Hi all,
I have a question I'd like to ask concerning pitch rates for lagers. I've recently been given the opportunity to help out my local brewpub. Seems they have been using dried yeasts for quite some time now, and the new brewmaster would like to switch over to liquid yeasts. He has asked me to help him in this endeavour. I have a fair bit of experience at culturing yeast for my own 5 gallon batches, but now we're talking about pitching to 180 gallons.

Using the formula for lager pitching in the yeast faq, I have determined that

I need to pitch .72 gallons of slurry. This figure seems extremely low to me.

So I put it to you, what kind of a fermentation can I expect from such a pitching rate? I imagine it will be an extremely slow one. Any formulas for determining healthy pitching rates, or any other technical information you think might be of use would be appreciated.

I have another, unrelated, request for information, this one on brewery geometry. Basically, I am interested in any information you might have on how kettle and fermenter geometry influence hop utilization and fermentation rates.

TIA and Cheers
JE

>as fast as the 10" rollers will take them.

Jack, you have most likely already answered the question. The hopper
hole
opening into the MaltMill is only a fraction of the length of the
rollers. In
addition, there is a large mesh plastic screen that covers the opening
(for
safety reasons). I suspect that both of these factors work to limit the
speed
at which the malt kernels can reach the rollers, so I am not surprised
that the
MaltMill and GlattMill crush at about the same rate. It is interesting
to
note that the hopper holes of the two mills are about the same size.

BTW, I am sure that you are right that a larger hopper hole would
increase the
throughput on a MaltMill, but we tested it as manufactured. I can
handcrank/crush 8+ lbs of malt in ~2 min. with my unmodified MaltMill.
The
Glatt Mill is a touch slower, but similar. Does it really make any
difference
in the length of my brewday if I spend 2 vs 3 minutes crushing grain??
Not to
me; either one is a vast improvement over my old Corona!

Steve

I have been reminded by several HBD readers that ECU is not an ice beer in the same sense as the ones from Bud, Molson, etc. The ECU is frozen to precipitate out protein, but the ice is not removed. Thus, it is not a true eisbock. It still tastes pretty darn strong, though.

Sorry for the errant information!

I guess I need to do more, ahem, research into this ice beer dilemma.

I'll start with a Buffalo Blizzard Bock (Buffalo Brewing Company, Buffalo,

N.Y.) I'm gonna have one straight, then I'm gonna freeze one and filter out the ice first. It may not be a real "eisbock" either, but it'll be fun to try!

Subject: EKV 28

In HBD #1292 Ed Kopek talked about EKV Kulminator Urtyp Hell 28.

Well consulting with my family in Germany, I got the scoop on whether EKV 28 is really the strongest commercial beer around. The story in Bavaria is that the 28 in EKV 28 is the PROOF of the beer. You got it. 28 proof aka 14% alcohol. I have a bottle saved from when I last tried the stuff. If you read the label carefully, you'll notice that nowhere on the bottle is it referred to as beer. It is referred to as malt liquor.

Correct me if I'm wrong(and I know you will), but isn't there a federal law that says beer can only be a maximum of 6% alcohol? Anything stronger than that has to be called a Malt Liquor.

Oh well, that my \$0.02...

>get is 121F.

>Am I missing something here? Here is the rest of the info:

A few weeks ago someone reported that using an immersion chiller
that he was able to reduce 5 gallons of boiling wort to 90F
using only 8 gallons of Texas tap water. At first, I made an
estimate like yours (assuming Texas tap water is 60F) and
concluded that 118F was the best possible. Then I tried a
simple model of an immersion chiller.

Let T_i = the constant inlet tap water temperature
 $T_k(t)$ = the time varying temperature of the wort in the
kettle. (Here I'm assuming that the wort is being
constantly stirred so that its temperature is
uniform.
 $T_o(t)$ = the time varying temperature at the outlet of
the chiller.
 dw = a small amount of water passing through the coil.
 N = the amount of wort in the kettle
 dt = a small time increment
 $R = dw/dt$ = the rate of flow through the chiller
(coil).

Furthermore, if the coil is sufficiently long or R is
sufficiently small then we can assume that

$T_k(t) = T_o(t) = T(t),$

that is, the temperature at the outlet is the same as the
temperature in the kettle.

Then

$dw * T_i + N * T(t) = (N+dw) * T(t+dt)$ (1)

which simply expresses the fact that dw gallons at T_i added
to N gallons at $T(t)$ will equilibrate to $N+dw$ gallons at
temperature $T(t+dt)$. Dividing (1) by dt and rearranging terms
yields

$$\frac{dT}{dt} = \frac{R}{N} * (T_i - T)$$

dt N

which in the limit at $dt \rightarrow 0$ becomes a differential equation.
The solution (assuming the initial temp $T(0) = 212F$) is

$$T(t) = T_i + (212 - T_i) \cdot \exp(-R \cdot t / N) .$$

The amount of time t required to reduce the temperature from 212 to T is

$$t = \frac{N}{R} \log \left| \frac{212 - T_i}{T - T_i} \right|$$

and the amount of water required is $A = Rt$.

So if we had such an optimal immersion chiller and constantly stirred, and the tap water was $T_i = 40F$ and we wanted to chill $N = 5$ gallons to $T = 56F$ we would need

$$A = 5 \log \left(\frac{212 - 40}{56 - 40} \right) = 11.87 \text{ gallons.}$$

I have not done a similar analysis for counterflow chillers, but it seems that either Stoetling was exaggerating or counterflow chillers are more efficient (as far as water conservation is concerned) than immersion chillers. Note that if you simply mixed 11.87 gallons of 40F water with 5 gallons of 212F you would get 16.87 gallons at 90.98F, so immersion chilling is somewhat efficient.

Subject: Blow-off vrs non-blow-off

Every now and then people have been debating the use or not of using a blow-off, so I thought I would add a data point to this controversy. I brewed 6 1/2 gallons of IG 1.041 English Special Bitter style which was siphoned into a 7 gallon carboy and pitched about 3/4 quarts of yeast starter. After about 3-4 hours I reracked the wort, filling one 5 gallon carboy to about 3 inches from the brim, and the other with the remainder. Both batches began fermenting after about 10 hours and the filled carboy began blowing-off after about 12 hours. Originally, I had planned to bottle both batches after 7-10 days in primary, but after 10 days the blow-off batch was still bubbling every 13 seconds, while the non-blow-off batch seemed finished. So, after 11 days I reracked both batches and was shocked to find the gravity of the blow-off batch to be 1.020, while the non-blow-off batch was down to 1.011. The non-blow-off batch was bottled the next day, while I let the blow-off batch sit in secondary for another 10 days, at which time it was bottled with an FG=1.013. After waiting about 3 weeks I was ready to compare the batches. (I conjecture that the blow-off batch was filled too high and a lot of the healthy yeast got blown out, thereby slowing the fermentation.)

I found both batches to be similar - IMHO a good example of the English bitter style, fruity, malty, full to medium bodied with a nice Kent Golding hop aroma and flavor. However, although I am a BJCP judge, I lost my confidence in distinguishing taste subtleties after failing a self inflicted taste test during a tour of the Anheiser-Busch brewery in Williamsburg VA about a month ago. I could not distinguish between bud, bud-dry, bud-lite and Michelob. Well, maybe bud and Michelob has slightly more lingering aftertastes. (Remember the Simpson's episode where Duff, Duff-dry, and Duff-lite were being filled by the same pipe.) So, I brought samples to the BURP homebrew club meeting for a more unbiased comparison. I did tell them that one was blow-off and one was not, but I didn't identify which was which. Some of the members correctly identified the blow-off batch saying they thought it was slightly smoother, (one correctly identified the blow-off batch but said she liked the non-blow-off batch better). Some incorrectly identified the two batches and some "punted" and said no difference. All agreed that if there was a difference it was minor. Therefore, despite the wide variations in fermentation times, both batches came out nearly identical with the blow-off having little or no effect. Of course, this is just one data point and your mileage may vary.

From: tpm@wdl.loral.com (Tim P McNerney)
Subject: Is Tim McNerney an idiot?

Why yes, he is.

Thanks for everyone who pointed out the bloody obvious. The .33 GPM is for the wort (Gee, Tim, why does the amount of water exactly equal the amount of wort when you make your calculation? Must be one of those strange coincidences, Tim, and not something like an obvious flaw in your logic yelling out at you.)

A couple of people have asked about information on the Stoelting equipment, so I guess my post was not completely in vain (though it did my vanity no good).

Stoelting, Inc.
502 HWY 67
Kiel, WI 53042
(800) 336-BREW

Their line of products looks VERY nice. The stats on the wort chiller I mentioned yesterday should give some idea on some of the stuff they sell. The only problem is that their stuff is awfully pricey, but if you want to go first class, this is the way to go. The aforementioned wort chiller runs for \$314. They also have kettles from 7-20 gallons with a bottom drain valve. Their stuff really looks like the "equipment the pros use" only shrunk down to homebrew sizes (if only they left their shrinking system running for a little longer on their prices).

Sorry for wasting space with a stupid question (if you believe there are no stupid questions, go reread mine) and I hope most everyone took time to laugh at me via private email (please feel free to send me mail telling me how clueless I am, even if you didn't read the original article and don't know what I am talking about).

Thanks.

From: WESTRA_MICHAEL/HPATC2_02@i3125ent.atl.hp.com
Subject: Trouble Carbonating Lager

Hello all,

I am having trouble getting my first 'custom' lager to carbonate in the bottles. I have read a little bit about adding yeast right to the bottles and re-capping... but would like a little more help before I take a chance with 2+ cases of (so far) good beer.

RecipeYeast Labs L35 California Lager Yeast
for 5 3.5 lbs GlenBrew Hopped Pilsener Malt Extract
Gallons: 2.5 lbs light dried malt extract
1 lb American Caramel malt (10^o)
1 oz. Tettnanger (15 min.) + 1 oz. Saaz (3 min.)

Pitched at 73^o, 5 days primary (plastic) at 55^o, 23 days secondary (glass) started at 55^o and gradually moved down to 45^o. Total=4 weeks.

O.G. = 1.050 / F.G. = 1.020 (F.G. after 5 days was also 1.020)

The beer has been in bottles now for three weeks. There is very little carbonation. I have stored some bottles at 45^o, some at 55^o and even a couple at 75^o and no luck. The beer tastes good - sweeter/maltier than a pilsener (the Calif. Lager Yeast is supposed to do that), noticeable hop flavor/aroma and no off-flavors, but no carbonation.

Any suggestions would be greatly appreciated. (I apologize if this topic has been covered on the digest in the past... unfortunately I don't have the opportunity to read 'em all).

Cheers,
Mike Westra

Subject: Filtering/ BarneyWine

Hullo Brewmeisters one and all.

Just thought I'd chime in...as always...

RE: Filtering Discussion:

I had this debate last night with a couple fellow brewers. I personally think I'd have something to gain by filtering. I could probably get by with finings and do just as well. I have several times come up with a keg of beer with sediments in the bottom that would easily be filtered out. Otherwise every time the keg is moved it's stirred up again.

Advantages: remove dry hop material/ spices/ clumps in general. Leave most of the yeast behind. Clarify a beer instantly so it can be carbonated by shaking w/o needing to settle afterwards to clear. Then it can be moved w/o clouding.

Jim sez he thinks a 5 micron filter is going to remove cells. Most bacteria are on the order of 1 micron. yeast fall more in the 3 micron range. Cells can aggregate and "act" bigger. But I would contend that a 5 micron filter is definitely not going to "sterilize" a beer. And from my understanding (NOT experience) it will not REMOVE the body of a beer. It may well "thin" things a bit. At 3 microns there is more cell removal, but still not sterilization. I don't have a problem with lowering the cell count in a keg. I force pressurize, so I don't "need" them there, but I like my B-vitamins, so I don't plan to get rid of them ALL.

add: 6# Williams english dark extract
2# Brown sugar

Boil Hops: 1 oz Chinook (13a), 1.5 oz Centennial (10a)
1/2 Boil: 1 oz Cascade (7.3a), 0.5 oz N. Brewer (7.6a)='93!
Finish:1 oz Homegrown Cascade- alpha unknown! :) but stinky!

Abbey Ale yeast culture. Warm initial ferment. (65-70).
Then cooler into secondary...maybe even down to the 50 deg basement!

Bottle with 1 cup molasses. Age for a LONG time. :)

I'll draw the 2nd runnings of the sparge and make a 2-penny-ish ale.

Burton ale at that. It may end up getting spiced, or fruited.

Any input? If I get good extraction this should be OVERKILL. :)
I wonder if I'll have to pitch champ. later to deal with all the
fermentables. Hope it don't stall! Some know what a bother that
can be! (so how's it doing now norm?)

RE: The name. My girlfriend and I purchased a purple lava lamp, which
she adores. Endless hours of fascination. I figured that after drinkin
this concoction- after it's PROPERLY AGED>>>> one will probably end up
feeling like that flowing purple goo in the lamp. A kinda warm feeling
all over!

As for the name of the lava lamp itself- you can figure that out!

Just felt like sharing. I'm psyched. the yeast is poached, and dropping
into a starter today. Just got the scottish ale yeast too, can't
wait to use that! Thur night, or friday day. My house will be warm!

From: Delano Dugarm 36478 <ADUGARM@worldbank.org>
Subject: Hop Teas and Dry Hopping ~#

I am brewing a hoppy pale ale, something like Sierra Nevada's Celebration ale. I started with a 1065 O.G. wort, and hopped as follows:

1 oz Centennial (9.6%) 60 min.
1 oz Mt. Hood (?%) 60 min.
1 oz Cascades (5.4%) 10 min.

I fermented with WYeast American Ale, of course, keeping the temperature mostly below 65. The question I have is how to finish it. The last time I made this I dry hopped with an ounce of Cascades for a week before bottling, and it turned out quite well. My only complaint was that it didn't have the depth of hop taste that Celebration has. I'm leaning towards dry hopping again, but noted a suggestion that you steep hops in a hot water and add this tea at bottling time for greater flavor and aroma. Any suggestions on this issue would be greatly appreciated.

Subject: Ice Beer

Just a quick observation and trying to avoid flames, this article on "Ice Beers" was in last nights paper, it is on the Labatts -vs- any other commerical brewer who uses "Ice" method.

>"Ice Beer is brewed at temperatures low enough to allow ice crystals
> to form. It is described as rich tasting but continuing the move
away
> from the heavy beers"

So, it says right there in print that it is "Rich Tasting". if it
wasn't
in print, I for one would not believe it. I guess my fellow HBD'ers
just
don't know taste when it hits them. I also question what "they"
refer to
as heavy beer? Bud? Heavy beer is not bought, its homebrewed!

Please try this at home, remember, your not professionals, just
Homebrewers!

Subject: noche buena by any other name...

Howdy,

In HBD 1292, Chris Amley brings up the question of using the same beer name for different beers. His main concern is that since Noche Buena is brewed with a different recipe than in the past, it should have a different name.

The fact is, this is an extremely common practice. Sam Adams claims to vary their Winter Lager every year, and Anchor actually does vary it's Our Special Ale. Add on that a brewery is going to adjust it's recipes every once in awhile, especially new ones. Celis Pale Bock is definitely not the same beer that they first marketed in March of '92; in fact, it's the 4th version.

I'm not saying it's good or bad, it just is.

Happy brewin',

Alan, Austin

>A friend just brought me a couple bottles of this version of the new ice
>beers. This Maximum is 7.1% alcohol by volume!
>Still doesn't taste like much , but does have some kick.
>This was purchased in Canada.

The Canadian Beer industry has been for years protected from the influx
of
less expensive, American-made beers. With this trade arrangement coming
to
an end in 1994, the major breweries (Molson, Labatt) have been coming out
with a `new' beer almost weekly. This is a last-ditch attempt to produce
brand loyalty before the gates open wide.

The latest trend is for high-alcohol brews. The newest addition is
Labatt's
XXX with 7.4% alcohol. Strangely enough, and to quote a German
acquaintance,
`you have 50 different beers and they all taste alike! The new potent
brews
are no exception. Thank goodness for some excellent Quebec
microbreweries;
most notably St-Ambroise and Hops Brau.

Subject: Sake Connection Newsletter

Well, well!

I'm amazed by the huge response I'm getting. Seems as if a lot of people are into Sake!

I'll be passing a compiled list of all the real mail addresses I've gotten on to Fred Eckhardt on the 22nd, so you've got until then to get them in!

Many people have only sent email addresses, at this point that doesn't help much. Maybe there's a way I can digitize a copy of it, or see if Fred's wordprocessor format is compatible with anything I can get my fingers on, and I will upload a copy.

Several folks have suggested starting a sake mailing list... I do not have the ability to start one, nor do I know how to start a listserv operated mailing list. It seems most sake brewing fans are on usenet, reading rec.crafts.winemaking. Much more so that homebrew digest, altho sake is more of a beer than a wine...

Maybe J-Food-L is the place to discuss such things? It has low traffic, but I'm not sure how many people there actually care about making sake, as opposed to drinking it and using it in their cooking?

Anyway, send me your ideas and keep sending mailing addresses if you want to receive a sample of the newsletter!

Mike

>It is concentrated by freezing as are the North American "ice" beers.

According to Jackson, ECU fiercely denies that freeze distillation is used in the making of Kulminator. It indeed is a very strong doppelbock. If it was made using freeze distillation, then it would be called an Eisbock. The AHA has an Eisbock category and if memory serves, there was one in the medals this year -- you might look up the brewer's specifics there.

David writes:

>I am having a problem that perhaps you folks out there in HBD-land could

>
>The problem is that both beers have a pronounced flavor component to them
>- -- sort of a pear/banana-like aroma and taste (IMO, but it is hard for me
>to judge).

My guess would be that this is either a characteristic of the pitching yeast or you have a monstrous wild yeast infection somewhere in your system. Does your starter smell like this? If yes, then you've found your source. You may try a lower fermentation temperature as ester production (esters give the fruity aromas/flavors to beers) tends to be lower at lower temps. If you still get too much of these esters for your taste from the lower temps, then I guess you'll have to change yeasts. If it is a wild yeast infection in your system (unlikely because of your reported quick starts), you need to check your sanitation procedures and/or replace scratched plastic equipment.

From: Spencer.W.Thomas@med.umich.edu
Subject: Pale Ale

Adding malt at mash-out will not contribute to malt flavor, but will very likely give you starch haze. For a maltier flavor, try one or more of the following:

1. Switch base malts (e.g., Maris Otter, DeWolf-Cosyns Belgian Pale, Hugh Baird)
2. Mash longer (1.5 to 2 hours)
3. Add lightly-kilned malts (Munich, Vienna, toasted malt -- make it yourself at 350 for 15 minutes or so) in small amounts
4. Decoction mash.

From: "Jeff M. Michalski, MD" <michalski_jm@rophys.wustl.edu>
Subject: burnt aftertaste

Hello homebrewers,

In September I brewed my version of a Christmas ale (strong and hoppy).
The grain bill is as follows:

6 lb pale
3 lb klages
1 lb dark crystal (caramunich)
1 lb chocolate
1 lb carapils
1/4 lb black patent

Near the end of the boil I also added 1 lb of dark brown sugar.
OG 1072, FG 1021 (wyeast 1056).

It has been in a soda keg after completing primary and secondary
fermentation for at least 6 weeks.

It has an overwhelming burnt taste to it! The initial flavor is
strong malt and ETOH (and a lot of hops!) but the charcoal flavor
that follows is enough to scare away my guests. My question is
will this heavy roast flavor soften with age? I am tempted to
pull off the tap and let it sit till next year (there certainly
are enough hops and ETOH to let it withstand the wait). Certainly
next year I am changing the amount of dark grains.

Subject: Strongest Beers - the facts

In HBD #1293, darrylri@microsoft.com

D> > Oh, and it is reputed to have the highest alcohol content of any commercial
D> > beer. (Maybe, maybe not). I know it is around 12%, and it packs a wallop!
D>
D> No; EKU 28 has the highest OG of any regularly available beer. But Hurlimann's Samichlaus, brewed from a slightly lower OG, is a bit more fermentable and so has a higher alcoholic result (and a more drinkable product, IMHO). This, in spite of the boastful claims on the EKU 28 label ("Das starkste Bier der Welt").

Samichlaus used to be the strongest. It has been passed three times.

The following is posted occasionally (i.e. whenever a "Molson XXX is the strongest" claim/flame war starts) to alt.beer:

The following reflects my latest revision to the Beer Records FAQ's section on the Strongest Beer. I have revised it to reflect the authenticated current record holder, the past record holder it surpassed, and the pending record holder, subject to authentication. (Those wishing to hasten the record authentication process can do so by sending me a case ;-). I have included Samichlaus and EKU Kulminator 28 in a section called "Other Notables" as their names will often come up in arguments about the world's strongest beer.

I will not repost the entire FAQ (bandwidth considerations). Copies of the Beer Records FAQ are available from me by email (ak200032@sol.yorku.ca). Suggestions and Corrections are always accepted. Flames: Relax, just have a brew! Thanks to Conor O'Neill and Sean Lamb for their updates!

Strongest Beer:

Current:

The Guinness Book of Records has just accepted a newer contender: Uncle Igor's Famous Falling over Water, brewed by the Ross Brewery, in Bristol, UK, which is 17.3% abv. <Supplied by Conor O'Neill -- conor@inmos.co.uk>

Past:

Roger & Out, brewed at the Frog & Parrot in Sheffield, Great Britain, from a recipe devised by W. R. Nowill and G. B. Spencer, is 16.9% abv., and was the old record-holder (GBR, 1992)

Pending:

It has been recently announced that the Boston Beer Company (marketers of the Samuel Adams line of beers) will be marketing a 17.5% "Triple Bock" beer in the near future. While Sean Lamb posted that this would be 17.5% by weight, I would like to see some confirmation on this. Its abv would be in the low 20% range which would be far in excess of

anything else.

Other notables from the recent past:

Samichlaus Dark 1987 (Brauerei Huerlimann, Zurich, Switzerland) is the strongest lager at 14.93% abv. (GBR, 1992) Michael Jackson also refers to this as the "world's strongest beer"

Michael Jackson also refers to EKV Kulminator 28 as having the highest gravity (28 degrees guaranteed, but some have been as high as 30.54 degrees). The alcohol content is 13.5% abv.

From: "Robert H. Reed" <rhreed@icdc.delcoelect.com>
Subject: Maltier Pale Ale

A post was made in HBD #1293 regarding making a Pale Ale with a maltier character:

I have found that some of the Wolf-DeCosyns grains such as CaraVienne and Aromatic will enhance the malty character of beers. Without making a comment on the quality of M&F base malts, I would also suggest experimenting with the Wolf-DeCosyns Pale malt as your base malt: I believe these grains are some of finest grains you can buy.

My experience with the Caravienne malt is that it adds a very pleasing smooth caramel character to your brew and the aromatic adds a wicked, munich-like character to the aroma and flavor of your beer. I believe their Biscuit malt or home-toasted pale malt adds an interesting malty/toasty character as well.

> Subject: Pale Ale
> I'm an all-grainer who likes a BIG tasting pale ale, not necessarily
in
OG or alcohol level, but very malty and very hoppy. Of course the hoppy
part is
easy, and some yeasts have helped with the malty part. I use M&F pale
2-row
and mash at around 155degF. My idea is to add 1/4 or 1/2 lb pale at mash
out,
to add flavor. What would be the pros and cons of this? Or is there
something
else I haven't considered?

I would skip the addition at mash out in favor of using Munich (imported)
and
caramel malts in the mash. My high gravity beers (diluted into the
fermenter)
were attenuating too much, and the addition of Munich and caramel helped.

> From: npyle@n33.stortek.com
> Subject: Dream Tun

I favor using a hot water heater for sparge (hot liquor tank), and use
the
kettle to mash in. Transfer the mash to the dedicated lauter tun with
some kind of false bottom (perf sheet works great), insulate the lauter
tun. The disadvantage is you need a way to transfer the mash.

The rule of thumb is one million cells/ml/degree plato of wort. Pitch
yeast
up in a ten to one ratio to grow the slurry, let ferment each step,
decant
off the beer, and use the slurry. For a micro making lagers be sure to
use
at least 1 lb of thick slurry per BBl of wort. It is better to do cell
counts, but this requires a little lab equipment. John Mallet wrote a
good article on counting cells in the New Brewer Magazine. You dont want
to put 18 gallons of starter into 180, so decant off and use the fresh
slurry.

Bill Szymczak:

> experience)
> it will not REMOVE the body of a beer. It may well "thin" things
> a bit. At 3 microns there is more cell removal, but still not
> sterilization.

```

The discussion had nothing to do with sterilization per say, .5 micron will result in **sterile filtered beer**. I can assure you that 4/5 microns removes 90+% of the yeast biomass. I would bet the number is closer to 96+%. The local micro filters to 4 microns and there is never any residual yeast evident to the eye, nor do they throw sediment from yeast. If you want to strip your beer of proteins, go ahead and try a <1 micron filter, I have read the head retention drops by a factor of 4.

```

> count in a keg. I forcepressurize, so I don't "need" them there,
> but I like my B-vitamins, so I don't plan to get rid of them ALL.

```

It also changes the flavor of the beer, bringing out more malt/hop notes absent from the affects of yeast cells. I am still experimenting on the effects of hop aroma wrt filtering.

```

> - -----
> Barney's Blebbing BarleyWhine: (planofaction)
>
> 10# 6 Row Pale Malt

```

Why would you ever want 6 row malt in this beer??

```

> 10# 2 Row Pale malt
Why not 20 #s 2 row?

```

```

> 4# 2 row vienna

```

This will be overwhelmed by the caramel/biscuit/roast that follows.
Besides,
the beer should have immense body due to the amount of malt used.

- > 2# aromatic munich-belgian

I would add more flavor hops at 30, 20 min to end of boil, and stick with the normal dry hopping. You will increase hop flavor at 20 min additions. I prefer cask hopping/dry hopping over my hop tea attempts.

Good brewing,
Jim Busch

From: Earle M. Williams <earlew@drc.usbm.gov>
Subject: Head Retention, Beer Labels, and less...

I cracked the top on a bottle of Nut Brown Ale last night, aged two weeks, and i noticed that while the carbonation was good, there was very little head. I tried pouring the beer from about 4 inches (10 cm) and it foamed up nicely, but within about 10 seconds it had settled to a slim memory of a thick foamy head. I hadn't really tried for a thick head in this beer, but it got me to thinking about past brews that had similar characteristics. Is there something I can add or delete to my brews that would encourage more head? I would appreciate some comments, with or without puns. :>

I've put together some slick beer labels using Corel Draw (for the PC) using the clip-art that comes with the package. *Very Impressive*! I noticed the software selling for about \$US140 at a warehouse membership store. The collection of clip-art (on CDROM) that comes with this software makes the purchase more than justifiable.

I was playing with the hop utilization numbers to try and quantify the hoppiness of my last batch, and i realized that I had no clue as to the amount of hops in the canned extract. Anyone have any general or specific ideas as to how much is added to canned extracts? This was an Australian Draft from Cooper's - the first time I've used it, and I hope all works well. Is the hops in the extract altered further by my wort boil, or is it going to remain pretty constant? I'm wondering if it's possible to quantify the added BU's from canned extract. Maybe put it in terms of BUL's, or BitteringUnit-Liters. Just wondering....

Hoppy Christmas,
Earle

Mark> large SS fittings???

I would suggest a 1 1/4" to 1" bushing. If you have a SS beer keg, it is made from 304 stainless and it is imperative that you get your fitting in 304 also. You should weld it with 308 wire. One source for this is McMaster-Carr in Santa Fe Springs, CA. I do not have their current phone number since I am at work, and can only look at a catalog several years old. However the part numbers are still good:

1 1/4" x 1" Hex Bushing 304SS #4460K16 \$9.96

The price should not be too much more than the old price. One thing to keep in mind is that the heater elements have NPSM threads (National Pipe Straight Machine) while the bushings are NPT (National Pipe Taper). The 1" threads are both 11 pitch, so they will fit, but not all bushings will fit your heater. If someone while making the bushing ran the tap in too far or not far enough, then you will not get a snug fit in the threads by the time your rubber washer is snug. You may have the threads bottom out too soon and let your washer flap loose. If the first one does not work, exchange it for one which does work.

I was fortunate enough to have a SS supply store here locally when I went to buy these parts and I went through several fittings before finding one which would fit. In fact, the first one I tried did not fit, so I assumed that *none* would fit, so I bought a 1 1/4" x 3/4" and reamed out the inside to 1" and cut 11 pitch straight machine threads in it. Only then did I find out later that most fittings *do* fit NPSM to NPT.

The only drawback is that McMaster-Carr may not sell to an individual. They mostly deal with businesses. You may be able to get them to send it COD, or to give them a credit card number.

If you have any questions, I have made a heater chamber a'la Morris RIMS, have a working RIMS system and have done SS welding on my kegs for thermometer connections. I would be more than happy to help out.

Subject: Question Re: Practical Brewer

Hi folks--

Last week I stumbled across a copy of Practical Brewer, a textbook published by the Master Brewer's Association of America, at a local used book store. The price was only \$5, so I snatched it up. It seems to provide a good overview of how the "big boys" manufacture beer. However, I noticed that this edition was published in 1978. Has there been a revised and updated edition since then? It seems to me that a newer edition might have a chapter or two on microbrewery operations. Anyone have a newer edition, and if so, could we compare chapter titles?

Email welcome. Thanks!

Subject: Ngoma

Hi hombrewers,

I recently tasted some African beer called Ngoma. The beer tastes great (also has quite a kick to it), but I have a few problems with it. First, it's very expensive (\$33 a case) and second, I think it must be pasteurized because it claims to be brewed and bottled in Africa. Does anyone know what type of beer this is? Anyone tried to copy it? I would be most interested in a recipe. I'm an extract brewer now, but I'm looking forward to doing a partial mash as Norm described in the HBD, so all extract or partial extract recipes are in order.

Thanks in advance and thanks for reading such an obscure posting.

Subject: EKU KULMINATOR

Text item: Text_1

In HBD#1292, Ed kopek passed on some date regarding EKU Kulminator Urtyp Hell 28 as being the epitome of 'Ice Beer' and I just wanted to add to his comments. First, the 28 in the title refers to the percent of alcohol in the beer. That's right folks, 28% = 56 proof. The bier is billed as "Die Starkest Bier Das Welt" (sp) or "The strongest beer in the world". It is generally served right out of the freezer as an after dinner liquor in small two-ounce classes (or the equivalent metric size). It pours like, and looks like, maple syrup with absolutely no head. It puts a nice finishing touch on a heavy meal. It is not meant to quaff in bottle quantities. Ed is right, it does pack one helluva wallop

While in Berlin, we did use it to fortify other biers with the predictable results. Ruined good bier for the sake of a quick buzz. If you want to slip someone a "Mickey", EKU Kulminator Urtyp Hell 28 is one good way to do it.

At any rate, try it! It certainly is unique.

Subject: Tres Equis

Text item: Text_1

In HBD#1291, Russel Gelinas asked the question regarding "XXX" out of Mexico. Tres Equis "XXX" does indeed exist and is made by the same company as Dos Equis "XX". It is very hard to find in the good ol' U.S. but can be found in some obscure Mexican Restaurants. I ask for it every time I go into a Mexican establishment and sometimes get lucky. "XXX" is a good beer that just didn't catch on here in the states. Since I haven't had it in a while, I don't know if it is still being produced or exported. Some help here would be appreciated. I remember it being quite available in Alamogordo, NM and in El Paso, TX back in the sixties. We used to get it in Juarez, Mexico on a regular basis. Any one knowing any more about this beer might be able to help. Private post OK.

Subject: Dream tun

I tried using steam to heat my mash tun last time and liked it a lot. I used a carefully converted pressure cooker. The result was rapid, even heating with a lot of convection in the liquid. I felt better about this method than the direct flame method and consequently did little stirring. My false bottom traps a gallon or so of liquid so I normally worry about caramelization. The mash also wasn't diluted as is normally the case with hot water additions. I use a keg for the mash/lauter tun but I suspect that this method would work well with a coller setup too.

I liked the setup so well that I chopped my brew rack up to accomodate the steam heat setup. However I did away with the pressure cooker and built a steam generator instead. Its basically a large diameter copper pipe with a burner under it. I ran across a lateral burner from a hot water heater (as opposed to a circular one) so it fits nice. The water supply is from my hot liquor tank and the generator really only needs to be filled once. Fire it up and steam is quickly generated. Open the valve to the mash tun and you're heating. It is important to watch that you don't run out of water, the burner is hot enough to destroy the copper pipe if it is empty. There is also a pressure relief valve on the output of the generator however the pressure does not rise above 2 psi when heating the mash.

I have yet to insulate the mash tun, but that's next on the list.

Please be careful with pressure cookers and high pressure steam - They are dangerous! So be careful.

Subject: Old Lucifer update

John the Coyote wrote:

>I wonder if I'll have to pitch champ. later to deal with all the fermentables. Hope it don't stall! Some know what a bother that can be! (so how's it doing now norm?)

I forgot to report on Old Lucifer after things got better (isn't that just like the media? Only reporting the bad stuff). Well, after pitching wine yeast (dry, straight out of the packet) things did not progress any for several days, maybe a week. Then fermentation picked up and it went from 1.036 to 1.022 in a couple of weeks (OG was 1.085). Things settled down and I bottled at 1.022 after a total of 10 weeks fermentation. Its a fine Bwine now. I bottled it without priming sugar for several reasons. I like my barley wines low in carbonation. Most of my homebrews continue to increase carbonation over months (if they last that long). I pitched 2 different ale yeasts and a wine yeast so there are lots of different types of guys in there looking for sugar. I plan to keep some of this stuff for several years. I've read competition judge's comments that said "reduce priming sugar" on barley wines more than once. So, of course it is dead flat now, but it should be great Christmas of 94, and 95, and 96... Anyway, my lesson learned is pitch, pitch, pitch, and aerate, aerate, aerate for high gravity brews!!!

Cheers,
Norm

>containing HBD.

I must STRONGLY urge HBD readers not to waste their time with the AOL
Beer
Forum. The head of the Wine and Dine forum there, Mr. Craig Goldwyn,
is a egotistical prude who has no hesitation in using blatant censorship
to remove postings that he finds not to his own personal liking.

I was very active in the AOL Beer Forum, until a recent reorganization
caused several of my lengthy postings to be deleted with neither my
knowledge, not my consent. When I expressed by outrage at this by saying
I was "pissed off", Craig Goldwyn said he had to delete THAT posting
because it used "profanity". He also went ahead and deleted several
follow-up posts I made because they "no longer made sense" after the
original posting was gone. He also deleted several messages from other
members criticizing his censorship. I thought that this sort of blatant,
transparent censorship went out with the Berlin Wall!

He also deleted messages I left there that he claimed contained
"libellous statements" concerning Jim Koch's Boston Beer Company.
In actual fact, all statements I made concerning the BBC were backed
up by hard evidence from the Home Brew Digest, Boston Globe, and
regional Brews Papers. I think the deletions had more to do with
a direct verbal threat from Jim Koch to file a libel suit than any
lack of credibility in my sources.

I have ceased all postings to the AOL Beer Forum, and will not change
this policy until I receive a public apology from Mr. Craig Goldwyn.

Subject: fruit flavorings

Howdy,

In HBD #1293, Matthew Evans asks about the fruit flavorings offered in HopTech's catalogue.

I've tried a raspberry fruit flavoring from St. Patrick's of Texas. My brother & I used it in a wheat beer we brewed this fall. I don't know if it is the same stuff that HopTech is marketing, but I can give my opinion of it.

The flavor came out fine, & was definitely raspberry-ish, but was lacking a little. Also, I felt that the flavor softened after a few weeks in the bottle, almost disappearing. Also, even though it was obviously red in color, it added very little color to the beer itself, which disappointed me because I was hoping for a drink with color.

Overall, I'd have to say that it's an easy & cheap shortcut to producing a fruit beer, but if you are shooting for something high quality, I'd use fruit instead. It's real handy if you only want to make a few bottles of a fruit beer & the rest a regular beer (which is why we tried the flavoring). It's also suggested that you can add the flavoring to your glass instead of bottling. Even though I haven't tried this but once (when trying to determine how much in each bottle to add), I think it might be fun to get an idea how a Sierra Nevada Blueberry Pale Ale or Guinness Raspberry Stout might taste.

Hmm... now that I've piqued my own curiosity...

Subject: Filtration

There has been some limited dialogue on the digest lately about the relative advantages/disadvantages about filtering beers. I regularly filter some of my beers, depending how quickly I use them, how much time I have and for what purpose they will be used. I have also been able to compare various beers which have been filtered with unfiltered "control kegs" from the same batches. Invariably, I have found that filtered beers have a cleaner, more professional quality and are brilliantly clear, however, these beers are less stable, the latter feature I believe due to a couple of aspects of home filtration systems.

I think I remember that I read in Dave Miller's book on Pilsners, that this type of beer benefits from filtration, by removing "green beer" qualities. However, he notes that the life of the beer is reduced by stripping the beer of it's yeast. I concur with this. I find that a home-filtered pilsner that has been kept at serving temperature noticeably deteriorates after about a month to 6 weeks, depending on how much is left in the keg.

If one thinks about it, the home filtration system is affected by our abilities to first, sterilize it and then minimize oxidation. Since effective filtration depends on maximizing the surface to volume ratios of the filtration screen to beer volume, there is a potential for a "surface" with a lot of bacteria and a lot of oxygen, as well as a lot of "paper", as in my situation. I try and sanitize everything but the pads--I just don't want to risk ruining the beer with a sanitizer taste. I then "wash" the pads with lots of sterile, de-aerated water, to remove as much "paper taste" as possible.

I keep beer on the yeast for as long as possible. In the case of lagers, this is cold storage (32 F) for as many as 6-8 months. At these temps., bacterial action and yeast autolysis are minimized. I also "lager" ales which must be kept longer term. I don't bother filtering dark lagers, Wits (and other belgians) or English ales. I do filter pale and amber lagers (including pale bocks) and American pale ales, particularly if they are to be consumed at parties. These are all chilled prior to filtering to bring out the chill haze. If this is not done, chill haze is not removed. I then either drink the beer as quickly as possible or keep it very cold.

>gallons of fruit beer. They don't have any
>sugars in them, so you add them to the beer
>right before bottling. Anyone ever heard of
>this stuff or tried it yet. It is a lot
>cheaper than the real fruit itself, so it would
>be a good cost savings, but the question is,
>will it be good to taste?

In the interests of HBD protocol, I will let others comment
on how these extracts taste. I just wanted to clear
up Matthew's quantities.

Our Peach and Raspberry come in 4 oz bottles. Blueberry
Cherry and Pear come in 2 oz bottles. With the
exception of the Cherry, they are enough to make 5 gallons,
not 15 as Matthew states. This is at our recommended usage
levels, your mileage may vary, but so far no one has mentioned
that these were wrong (in fact, microbreweries have confirmed
that they are good levels). The Cherry is more concentrated
and will do about 20 gallons. All sell for the same price.

Delano DuGarm writes:

>My only complaint was that it didn't have the depth of
>hop taste that Celebration has. I'm leaning towards dry hopping
>again, but noted a suggestion that you steep hops in a hot water
>and add this tea at bottling time for greater flavor and aroma.
>Any suggestions on this issue would be greatly appreciated.

Add another addition of hops at the end of the boil and let the
wort steep with them for 20 minutes. (If you use an immersion
chiller, it'll accomplish the same thing.) Also, use more hops
when you dry hop.

From: steve_t@fleurie.inria.fr (Steven Tollefsrud)
Subject: Answer these questions, three....

Just got my order of brewing supplies shipped from England to sunny old Southern France where you can't find such things as home beer brewing is unheard of. The shipping costs were almost as much as the cost of the supplies (extracts, grains, hops and yeasts), OUCH! Still, I'm gleefully rubbing my hands together in anticipation of brewing my next batch, but wanted to bounce a few questions off the HBD before starting...

Thanks, in advance, for your response(s).

1. Re-using Lager Yeast in Fermenter: I was wondering what risks or advantages there would be if I ferment a second batch on top of the yeast left in my primary after siphoning off the previous batch. I mean to siphon the first batch off, leaving the 1/2 inch or so of sediment and then immediately pour on the cooled (80-85 F) 3 gals of wort and top off with water. How much of this 1/2 inch of trub is live yeast? Would the rest of this dead organic trub impart off flavors? Would the advantages of having a large yeast population and a quick start of fermentation outweigh the risk of off flavors from decaying trub (if there is any)? Would the temps and sudden introduction of concentrated (3 gal) wort and subsequent topping off with water shock the yeasties too much?

2. Oatmeal in Stout/Porter: I generally avoid throwing in things like the kitchen sink. Something of the German Reinheitsgeboet must have rubbed off during my three years in Munich. But I have never forgotten the taste of Sammy Smiths Oatmeal Stout and I noticed several recipes in the Cat's Meow containing different forms of oatmeal. I'm intrigued. What qualities would oatmeal add? Any suggestion on quantities? (I can only find rolled oats here) When should I add it to the boil? Or should it be steeped? Mashed?

3. When/How to Add Specialty Grains: I plan to make the following extract based stout:

- 4 lbs. Muntons Dark Malt Extract Syrup
- 4 lbs. Muntons Light Malt Extract Syrup
- 1/2 lb. Crushed Crystal Malt
- 1/2 lb. Crushed Chocolate Malt
- 1/2 lb. Black Patent Malt
- (1 lb rolled oats ???)
- 1 oz. Northern Brewer Hops (30 min.)
- 1.5 oz Hallertauer loose Hops (dry, in the primary)

None of my homebrew info sources explain when/how to properly use specialty grains for an extract based brew.

In the past I've just tossed my grains in at the beginning of the boil and boiled the hell outta them for an hour. Those batches were VERRRY bitter, though I'm not sure if it wasn't the Northern Brewer (2 oz, loose) which I was trying out at the same time. Should I not let the grains get more than 150 degrees F, as in mash conversion? Should I add them after the boil, below a certain temperature, and let them steep. What temps? What times?

Thanks again,

Steve Tollefsrud

Subject: Observations

Hi Gang,

Just thought I'd throw out a few observations:

First, on the subject of EKU28 Kulminator, I love the stuff. It is an extremely malty, slightly sweet and very strong dopplebock. I had always thought that it was an eisbock, but I am willing to believe the contrary. This stuff is definitely not meant to be quaffed in large quantities but as an occasional treat, I think its great. Personally I prefer it to Samichlaus which to my palate has less body and sweetness than is necessary to balance the high alcohol content. Another very high alcohol beer that I really like is Thomas Hardy's Ale. This is a barleywine style

English ale which is also very sweet and strong with pronounced fruity (pineapple?) flavors and aromas. A buddy of mine was runner up to best of show in a local competition with a clone of this (Toxic Thomas'). Unfortunately, Ohio has wierd laws about high alcohol beers that are still

on the books from the 3.2% ABV days so we cannot get some of the domestic barleywines like Old Foghorn and Bigfoot here but whenever I am out of state I keep my eyes peeled.

Second, I recently helped some friends of mine get started with homebrewing and since it was their first experience with the process, I decided to use dry yeast for simplicity. I have used Wyeast from the start (about 2.5 years of homebrewing) but since these friends didn't know wort from warts, I thought I'd keep it basic. Anyway, I elected for the following recipe:

4# can Telfords Premium Bitter Hopped Extract
3.3# bag of NWestern Gold Liquid Malt Xtract (unhopped)
1 oz homegrown Cascade for finishing
Red Star Dry Ale Yeast

I chose the Red Star because of good reports here on the HBD and sure enough, I tried a bottle of it last night and it was quite good. None of the estery or phenolic flavors that I have heard about with dry yeast. The beer has a nice fruityness and overall is very clean. Im sure it will encourage them to keep up with their new hobby.

Just my \$0.02.

Mark

>> Anyone know of a good way to make non-alcoholic beer. I have a friend at work who doesn't drink, and I was wondering if any of the great beer styles of the world can be brewed without alcohol.

Of the commercial non-alcoholic beers I've tried, the only one I consider even remotely a good copy of its style is the one Miller makes. American Pilsener isn't one of my favorite styles, but it is one of the important beer styles of the world.

Given how remote all the professional attempts at non-alcoholic beers are from the taste I like in beer, I haven't tried doing it myself.

>> Garetz fruit extracts:

I ordered the Raspberry and Cherry fruit extracts from Mark Garetz. I haven't yet had time to brew a fruit beer with them (I might get to a Framboise this weekend), but I have experimented with adding drops to my cyser. The raspberry worked pretty well, but the Cherry is definitely concentrated enough to be hard to control in this mode. Next time I get the urge to try this, I will dilute a dropperfull N to 1, where N is some number like 4 or 5, and add that by drops to my glass.

In any case, the flavors were certainly good, it was just hard to squeeze the cyser bottle hard enough to get the level of cherry flavor I wanted.

Subject: Sour Cherry Syrup in Stout

A question for you all. Has anyone used Sour Cherry Syrup (I found it in the Middle Eastern foods section of the local ethnic market, though it was made in Yugoslavia) in brewing?

I used it in a cherry stout that I started a couple of weeks ago, adding a 16oz bottle to a 5gal batch after the initial fermentation subsided. It foamed up again for a couple of days, due to the sugar, then calmed down; I tasted it, and there was hardly any cherry component. It was pretty seriously cherry-ish in the syrup bottle, though. Any ideas on how much it'd take to do the job? If this will work, it's a whole lot easier than fooling around with fresh fruit....

From: mlobo@sentry.foxboro.com (Michael T. Lobo)
Subject: RE: fruit flavoring (Raspberry)

Greetings:

Alan in Austin (HBD 1294) laments the lack of color in his raspberry beer. I made a raspberry stout using a soda raspberry flavoring made by Flavorchem in Il. and it is RED! Straight out of the bottle it tastes horrible (but raspberry-ish) and it will dye everything it touches red.

I used 1/2 the bottle for the stout after fermentation - at bottle time. I tasted the stuff at that time and I was afraid I had overdone it with the flavoring - really strong raspberry flavor. Well, about 1 month of aging has improved this beverage. The stout flavors balance the raspberry quite nicely, and if I hold a bottle to the light, it has a redish glow - the color is certainly there.

The flavoring comes in a small bottle (~ 2 OZ) and cost \$2.58.

Next time I use it I will use 1/3 bottle - less if I'm making a lighter beer.

regards,
Michael

Subject: New w/question

Brewers,

I am new to the list and to homebrewing. Have one batch of Continental Light, made from a kit, to my credit. My product came out fine body and colorwise w/ good carbonation. The only problem is a very (ultra - mega) yeasty aftertaste. Actually enough to make me shivver after swallowing. The guy at the store where I bought the kit said to chill the next batch before bottling and that should cure the problem. From reading the messages here, I suppose my description is a little cryptic and that without knowing other variables involved it might be difficult to suggest a solution. I just thought that maybe there is a fairly standard cause for excessive yeast flavor. The fermenting went according to directions as far as time and specific gravity readings go.

I read, in one brewing book, a note about skimming the fermenting froth from the top of the batch as it rises during the fermentation. The guy at the store said "No, don't do that." Can anyone offer advice on this yeast mystery?

Subject: perf sheet

In Friday's HBD Jim Busch writes:

"I favor using a hot water heater for sparge (hot liquor tank), and use the kettle to mash in. Transfer the mash to the dedicated lauter tun with some kind of false bottom (perf sheet works great), insulate the lauter tun. "

I have a keg that I fitted with a SS screen false bottom and have a tap coming out of the bottom of the keg as my sweet liquor outlet. The perf sheet I have is 3/32" holes on 5/32" centers. (I got this size from the Brewer's Warehouse sheets. They claim it's the standard microbrewery size. Can anyone verify?)

Tap out the bottom

Anyway, I get a lot of grain particles that bypass the screen, enough that I have to send the runnings thru a strainer to catch the big pieces. I have an adjustable MaltMill and have tried it set as wide as .055" to minimize husk shredding, but I still get granule-size particles passing the screen. Whaddaya think?

I've considered

- * Crushing twice. Once set wide to remove husks, then set close to pulverize everything.
- * Getting a smaller screen size, like 1/16" holes
- * Having the screen welded into the keg or fitting some sort of gasket around the screen. There is a slight gap around the edges, but it appears to be of less width than the holes. Also, right as the last of the liquor drains out, I get a huge amount of grain coming out the tap.
- * Putting a small extension on the keg side of the outlet to raise it about the bottom of the tun floor, letting any crud sit on the bottom.

Any help on this is greatly appreciated. My beers turn out pretty good, but my extraction is suffering (28 ppg for the bucket system, 25 ppg for this) and the frustration level is getting pretty high. Also I've had to add polyclar to the finished beer because the tannins are a bit high from all the husk material making it into the kettle and that eliminates a lot of the malty flavor that I worked so hard for.

>head. I tried pouring the beer from about 4 inches (10 cm) and it foamed
>up nicely, but within about 10 seconds it had settled to a slim memory
>of a thick foamy head.

What you need for good head retention are proteins. Proteins are what provides the surface tension which give the bubbles some strength. However, proteins can also cause haze so you have to have a ballance. Hops are a good source of proteins for head retention but you have a Brown Ale so you have to go easy on the bitterness so use more of a lower alpha acid hop. If you aren't adding hops at all then a good short-cut is to use just enough wheet (2-4 oz) to get some proteins but not so much that you get any noticable wheet flavor. Good hot and cold breaks will be necessary to clear the beer.

The above has worked for me in practice but I have a question about the theory. What is the difference between the proteins that aid head retention and those which produce chill haze? Is it molecular wieght?, length of the molecule? Why does one class coagulate and precipitate and the other doesn't or does so to a lesser degree?

Subject: BREW PROBLEM..

I RECENTLY BREWED UP A HOLIDAY BRAU AND ADDED THE USUAL ASSORTMENT OF SPICES AND THINGS.. AND I HAD SOME STRANGE RESULTS.

WHEN I MOVED EVERYTHING TO THE FERMENT TANK I DIDN'T GET A BUBBLE FOR THE 1ST DAY, HOWEVER 2 DAYS LATER IT WAS AT FULL CRANK. ON THE 6TH DAY IT BLEW BEER THROUGH THE VAPOR LOCK SOME 9 FEET INTO THE AIR(RATHER FUN TO WATCH BUT A MESS TO CLEAN..) THE HEAD PEEKED AND FELL BACK IN, I DRAINED IT TO THE SECOND FERMENT TANK AND WAITED.. IT BUBBLED SLIGHTLY ONCE AN HOUR, 2 DAYS LATER, I BOTTLED. IT HAS BEEN 2 WEEKS AND I WENT DOWN TO THE CELLAR AND I NOTICED A WHITE RING INSIDE OF ALL THE BOTTLES... WHAT IS THIS?? IT ALMOST LOOKS LIKE A MINI HEAD BECAUSE IT SEEMS TO BE THICKENED FROTH... WILL IT GO AWAY?? SHOULD I JIGGLE THE BOTTLES AND GET IT TO DROP TO THE BOTTOM? I ALSO NOTICED A THICKER SEDIMENT IN THE BOTTOM OF MY BOTTLES THAN USUAL. SHOULD I BE CONCERNED? I OPENED ONE AND GOT THIS MAJOR GUSHER (I SEEM TO BE GETTING A LOT OF THESE THESE DAYS BOTH WITH OLD AND NEW BEERS) -- SHOULD THEY BE CHILLED LONGER? IS THERE ANYWAY TO COUNTERACT THIS?

ALL INPUTS WOULD BE APPRECIATED -- PLEASE CC ME DIRECTLY IF POSSIBLE.

THANKS!!

>It has an overwhelming burnt taste to it! The initial flavor is
>strong malt and ETOH (and a lot of hops!) but the charcoal flavor
>that follows is enough to scare away my guests. My question is
>will this heavy roast flavor soften with age?

There are a couple of possible causes for a burnt taste. The first is simply the amount of dark malts (chocolate & patent). You basically have a very dark porter. In fact, a little roast barley and you'd have a stout. If it's a "roasty-burnt" character, that's probably the reason. This character will tend to smooth with time, so hang on to it and see how it progresses. Maybe you should just find some stout drinkers to share it with!

On the other hand, if it has a very unpleasant burnt taste, and aroma, it may be due to phenolics, possibly from bad yeast, an infection, or even somewhat from oxidation. It's less likely in this case that the problem will go away, though you still may want to let it sit a few months and see what happens.

Peter Brauer asked about homebrew "namebrands". I'm sure there are quite a few. The "Organization:" header in my email (which unfortunately doesn't show up in the digest) says "Fat Wanda's Brewery and Recording". This occasionally results my receiving messages that ask "Just what in the heck is Fat Wanda's?". For the record, Wanda is my partner's golden retriever, who, while not exactly fat, is a little on the chunky side. Actually, the full title of the establishment is "Fat Wanda's Brewery, Recording, Photo, Custom Fly Rods, and Garden-Fresh Produce". Dance studio and Diesel Repair to be added soon.

From: "Robert H. Reed" <rhreed@icdc.delcoelect.com>
Subject: EKU KULMINATOR

I just wanted to set the record strait on EKU Kulminator. Actually '28' refers to the number of pounds of malt that are used per 1 liter serving. This works out to be about 1.49 metric tons of malt per barrel. This explains the intense maltiness and the high alcohol level - 198 proof if memory serves me correctly. It is used as a gasoline substitute in many European communities.

It is recommended that you wear a wrist or ankle grounding strap while you are pouring or drinking this beer to minimize the chance of a spark induced fire. Just a data point...

As a former resident of Williamsburg, and a former many-time visitor of AB's plant there, I thought I'd offer some insights.

-You get two freebies, which used to be four. You needn't schlep through the tour to do it, either--just walk a couple hundred feet from the entrance and yer there.

-you can get to the brewery from the amusement park next door. There's a monorail that takes you to it, and the walk is even shorter to the freebie area (no exhibits to pass by.) Rather than enjoy the hokey atmosphere and \$2.75 AB beers at the "hofbrauhuas", take the monorail, quaff some freebies (they will politely limit you after your 2nd only if they're paying attention--never have I been bugged about getting three) and head back to the park. Return later for more freebies if you desire, as the servers change shifts regularly, and in summer when it's crowded they're way busy. OK, OK, so I was a college student back then, and free beer, even AB, was a deal.

-If you're really mad at old August and Co., you may also gain free entrance into the park, which saves you \$25 a head. This depends on them still having a way for you to just shop in their boutique area without paying the whole tariff. You pay a deposit and must return in two hours to get your money back. Once in, go directly to the monorail and ride to the brewery. As you leave the park, your hand will be stamped so you may return to the park. (people just taking the brewery tour can't get on the monorail and go to the park.) Drink a beer if you like, then return to the park. Get your money back, then drive over to the brewery (drink more beer), get back on the monorail and head for a fun filled day on rides built from money made on all those suckers who think Bud dry is a taste achievement.

Sorry if this is not germane, but, y'know.

Subject: Cranberry Lambic, Maple Syrup, Ngoma & Eku 28

In reference to Sam Adams Cranberry Lambic and the use of Maple Syrup in beer, I was at a Beer Tasting/Dinner last evening, ala Michael Jackson in Belgium on the Beer Hunter video, at a local restaurant (Allentown, Pa) where twelve Christmas beers were served throughout a six course meal. This included Anchor, Sierra Nevada, Stoudt's, Dolle Breweries (sp), Samiclaus, Schildes (Belgium Busch), Dock Street, St. Sylvester, Young's, several other Belgians, and the now infamous Cranberry Lambic. The host pointed out it wasn't a true lambic and said that it had maple syrup added to balance the tartness of the cranberries. To me it tasted like a Kriek I attempted last summer, namely not so good. But, for those looking for a use of maple syrup in homebrewing, this could be your chance.

In HBD1294 Eugene writes:

> I recently tasted some African beer called Ngoma. The beer tastes
> great (also has quite a kick to it), but I have a few problems with it.
> Does anyone have a recipe?

I have had this beer. It is obviously a lager in the Munich style, very malty and surprisingly good (well balanced). I would start by using a bock recipe. Sorry, can't get more specific than that, had just one bottle of it and that was more than year ago.

Also posted:

> First, the 28 in the title refers to the percent of
> alcohol in the beer. That's right folks, 28% = 56 proof.

My understanding is that the 28 stands for the OG in degrees Plato and, as was also posted in HBD1294, the abv is in 13% range.

And also posted:

> before my curiosity makes me waste eleven bucks, has ANYONE out there
> ENJOYED Eku-28? In HBD 580, it was referred to as "vile".

I like it, but there's no accounting for taste. My brother says he thinks it has the same aroma as the insect we call a "daddy-long-legger" after the legs have been pulled off! I guess that qualifies as vile. Please note, my brother and I haven't pulled the legs off a daddy-long-legger since the late '60's when I was about 8 years old. (25 years before Beavis and Butthead).

>that if there was a difference it was minor. Therefore,

I suggest that perhaps the 3-4 hour pause to allow for hot and cold break settling and the subsequent transfer off the trub reduced the benefits of blowoff. I've done this experiment twice and each time the difference was stunning. I used a 1 gallon jug, filled 3/4 full and a 5 gallon carboy filled to the top. The geometry was not very close. I would like to try to retry this test with closer fermenter geometries. Perhaps a 5-gallon fermenter and a 6-gallon fermenter? Perhaps a 3-gallon and a 1-gallon jug? I'll have to work on it.

>and add this tea at bottling time for greater flavor and aroma.

A member of a B.O.S.S., Terry Murphree (I hope I got the spelling right)

did an experiment recently in which he split a batch into two 3-gallon batches. He dryhopped one half and added hop tea to the other. The results were very interesting. After two or three days in the kegs, the hop tea batch aroma was noticeably stronger. After an additional month, the hop tea version had lost all of its hop aroma and the dryhopped version beat it hands down. Both the 2-3 day tasting and 1-month tasting were unanimous decisions by our club members.

I got this once from an all-extract (no specialty grains) batch.

It turns out that I scorched the malt in the kettle. It never

went away. I had it in a keg, so I just used it up to flavor some under-flavored commercial brews.

Earle writes:

>characteristics. Is there something I can add or delete to my brews that
>would encourage more head?

Head retention is a function of small proteins and dextrans in your beer. Crystal malt will add some dextrans and thus some head retention. To have control of your small proteins, you need to mash (although some extracts may give you better head retention than others -- I don't know which). I've been speculating for about a year that the blowoff method may reduce head retention by blowing off some of these small proteins. Bill -- any data here? Protein rests at the lower end (112-122F, I believe) of the proteolytic range will turn your big proteins into amino acids, whereas protein rests at the higher end (122-140F) will make less amino acids, but more small proteins (better head).

Earle also writes:

>I was playing with the hop utilization numbers to try and quantify the >hoppiness of my last batch, and i realized that I had no clue as to the >amount of hops in the canned extract. Anyone have any general or specific

The Extract Special Issue of Zymurgy has a table that lists the hop rates on many of the hopped extracts at that time (1986?).

Subject: Good to the last drop.

With all the talk about getting extract out of the bag (in a box), I am prompted to write about a procedure invented(?) by a Just Brew It club member:

The "Chopstick Method"

1. Set the plastic bag-o-extract in a sinkful of hot water to soak.
2. Locate a set of chopsticks: nice or disposable, it matters not.
3. Cut/Slice open the top of the extract bag and pour into the kettle as usual.
4. Hold the bag by the top two corners and have a helper position the two chopsticks one on each side of the bag up near where you are holding onto the bag. Make sure the opening points toward the kettle.
5. Next, your helper will press the two chopsticks together and draw the pair of them down the length of the bag towards the kettle. Stop, of course when you get down to the open end of the bag.

If done properly, you will have neatly extruded almost every drop of extract and will not have it all over you, your helper, your kitchen and the dog (or cat).

Thanks to Rob Dahlgren, inventor of the chopstick method.

Hope this is helpful.

I was able to pick up a *very* used commercial soda cooler for \$50.
The kind which has sliding doors and is in stores or taco shops. Not
anything one could normally get for \$50. A frosted mug might do the
trick, but again, I *like* my beer warm, so I have no data on that.

From: Earle M. Williams <earlew@drc.usbm.gov>
Subject: Head Retention, Beer Labels, and less...

I cracked the top on a bottle of Nut Brown Ale last night, aged two weeks, and i noticed that while the carbonation was good, there was very little head. I tried pouring the beer from about 4 inches (10 cm) and it foamed up nicely, but within about 10 seconds it had settled to a slim memory of a thick foamy head. I hadn't really tried for a thick head in this beer, but it got me to thinking about past brews that had similar characteristics. Is there something I can add or delete to my brews that would encourage more head? I would appreciate some comments, with or without puns. :>

Ahem, regarding your "lack of head" concern...
I have been adding an additional 150-200grams of wheat in the grain bag - and recent batches have produced great head.

Subject: what makes dark extract dark?

Many recipes based on extracts stipulate dark extract (or amber, if it comes to that). Full-grain recipes, on the other hand, always use basic malted barley and add extra things to get dark beers. So I have two questions:

1. What is it in a dark or amber extract that differentiates it from a light extract?
2. If I start off with light extract can I simply add more of chocolate/black patent, in addition to what might be specified in a recipe calling for dark extract, to achieve the same effect?

Peter

Subject: Kudos and carbonation

Kudos to all members of HBD. After three weeks on the net, I'm amazed by the quality of this digest. It has become my primary source of info on homebrewing.

One question. I'm having carbonation problems. The traditional 3/4 cup priming sugar per 5 gallons (for most beer styles) produces different amounts of carbonation in different batches of beer. My latest is an all-grain pale ale (a variation of Papazian's Amazeing Pale Ale) which, although delicious, is slightly overcarbonated for the style. Also, this batch reached carbonation in a mere 7 days.

Other recipes (using the same type yeast) produce beer with about the same final SG and level of alcohol and will, although primed with the same 3/4 cup per 5 gal ratio of priming sugar, take much longer to carbonate. In fact, some may never reach a high enough level of carbonation. Others have become greatly overcarbonated after 3 months in the bottle. The temperature here is a steady 73%. What's up? (I'm not interested in kegging.)

Richard Nantel
Montreal, Quebec
Canada

PS. Correction to my posting in HBD 1294. Molson produces XXX at 7.3% alcohol. Not Labatt. Also, due to public pressure, they've raised the price of this high-potency brew to discourage the cheap-fast-drunk crowd.

Subject: Re: Murphy's Irish Stout.

I, too just purchased a can of this beer. I was intrigued by the "pressure system". I saw the posting about it on the last HBD, and decided to take a closer look. Sure enough, I saw the plastic insert. I opened the can from the bottom with the tap of a pointed object (learned from my father to save cans for a beer can collection) and I can see some plastic apparatus near the bottom. That's all I know..

Might as well get insight on something I've been trying:

I got into winemaking before homebrewing, but it takes too long to make wine, so I'm into making beer now, too. Anyway, a recipe for sparkling wine says to prime it with corn sugar when it's done, and put it in 2-liter plastic bottles. When the yeast settles out, one can siphon the wine off it and into champagne bottles. But this would lose carbonation, right? Well, the recipe says to chill the wine till ice starts to form. In school I learned that cold liquids effervesce less, so this makes sense. QUESTION: has anyone tried this with beer? The first time I tried it, I didn't chill it enough, and lost quite a bit of carbonation.

Subject: Dream Tun

My dream tun is beginning to take shape, with suggestions from various HBDers.

I'm currently thinking of a SS half-barrel keg, insulated somehow (cedar boards?). I would install a pipe fitting near the bottom with a manifold in the tun. The manifold will probably be a set of pipes with holes or slots in them, facing down. It will be a dual purpose manifold: 1) steam injection, and 2) liquor draining. The holes nearest the fitting will be smaller than the ones farther away; an attempt to create an even flow of steam from all holes (this could be more work than its worth, requiring lots of trial and error). The steam injection will be the only method for heating the tun, there will be no direct fire. This should serve quite well as a mash/lauter tun for simple infusion and step-mashes. I expect to have to stir the mash during temperature increases, but not during rests as it will be insulated.

The other dual purpose vessel I would need is a hot liquor / steam generator tank. This would be direct propane fired. It could be used to heat the strike water at the start of the mash. Then the temperature would be turned up for boiling and the steam piped over to the mash tun for step mashes. It would need to be able to be closed tightly and would need an outlet at the top for steam and another at the bottom for draining the hot water. I don't expect much pressure to build up, as the only back pressure would be the weight of the mash, but I would install a pressure relief valve in case of operator error. I would need a valve between the steam outlet and the manifold because during draining, it would draw air in as the wort passed by the "T". It would be nice if this thing was insulated as well for efficiency. I think this could be a quarter barrel keg, or a soda keg with the rubber removed.

Any ideas on where to purchase these kegs? Am I loony? I could do without all the standard warnings about steam, pressure, etc. I know how dangerous it is. I wouldn't build this thing if I thought it couldn't be done safely. I would appreciate any comments on the ease / difficulty I will have in doing something like this. BTW, this will all be gravity fed: hot liquor tank, mash/lauter tun, boiler, fermenter. One big drawback is that the hot liquor

tank will be a good 7 or 8 feet high (to the top of it). The other option is a pump which will push hot water up a few feet (the steam will take care of itself). Comments?

Cheers,
Norm

Subject: Northern Lagering Methods

Hello,

I have a friend who has a cottage on the French River in Northern Ontario. He has been talking about brewing a lager for a long time now, but he does not have access to a fridge to accomodate the required lagering temperatures. Recently, he came up with a pretty unique idea for lagering, without the use of a fridge, but I'm not sure that it's going to work, so I need some advice. He is going to do a full mash and rack of the cold break into a glass carboy. The carboy is going to be sealed up in plastic and placed carefully into the river just before ice-over. The theory here is that once the river freezes, the water temperature below the ice will be at 4 deg. C. This sounds pretty good for cold fermentation. He intends to leave the carboy in the river until ice-out in the spring. He also seems pretty confident that the carboy will not break at any time during this process. There is little to no current which runs at his "brewing" location. I was skeptical to say the least, but for no good reason that I could think of. What am I missing?

From: chuck@synchro.com (Chuck Cox)
Subject: Starve a lawyer - boycott Sam Adams beer (long)

Since there is renewed interest in Jim Koch's legal shenanigans, I though some of our newer subscribers might be interested in reading about my encounter with Koch's rabid lawyers.

Last year I was subpoenaed in relation to his lawsuit against the Boston Beer Works. They claimed it was because I had offered to testify as an expert on behalf of the BBW (I wrote a letter to the BBW attorney stating my opinion but it was never used). However it became clear that they were upset about some unflattering (but factual) postings I had made about Koch to the net, most likely the HBD.

They subpoenaed me and all of my personal correspondence and written materials related to the litigants in Koch's various lawsuits. As it turns out, the subpoena was quietly dropped when I told their lawyers that while I would challenge the disclosure of personal correspondence, as a master beer judge and brewing instructor I would be glad to be deposed as to the facts of any of my public statements about any of the litigants.

Koch's habit of taking legal action against his critics is generally a successful strategy because most folks are too spineless to stand up to him. This time it backfired because not only did I fight, I exposed his tactics to thousands on the net and challenged him to let me testify.

For the record, here are some of the facts that Koch doesn't like folks to know:

Sam Adams Boston Lager was designed by brewing consultant Joseph Owades.

Joe even wrote a paper about it.

Koch is not the father of the microbrewery revolution. He is a contract brewer who got started years after the revolution had begun. Until he opened a small pilot brewery in Boston a few years ago, all of his beer was brewed under contract. Even today the vast majority of his product is contract brewed at distant regional breweries.

His antics caused the GABF to eliminate the popularity poll. Subsequent misbehaviour caused him to be kicked out of the festival. Koch only got back in by threatening to sue. In various ads he has misrepresented his GABF awards.

He is being sued by New York state for fraudulent advertising.

Here is a list of organizations that he has sued or threatened to sue (there may be more):

Boston Beer Works
Commonwealth Brewing Company
Boston Brewers Festival
Great American Beer Festival

By the way, I am told that he has lost his latest appeal in his lawsuit

against the BBW. The only remaining appeal would be to the supreme court who has never heard a trademark infringement case.

In my opinion, his lawsuits are frivolous. As numerous judges have made perfectly clear, he does not and cannot own the word "Boston". His continued litigation proves that he is abusing the legal system in order to intimidate his competition and critics.

In my opinion, Koch is behaving in an unacceptable manner. I continue to encourage beer lovers to avoid Sam Adams products because the profits are used to the detriment of the brewing renaissance. As I like to say, "Starve a lawyer - boycott Sam Adams beer".

Here is a copy of the message I posted at the time:

Brett Charbeneau wonders how to log into sierra.stanford.edu. When asked for a user name respond ftp, and when it asks you for a password as your complete email address respond r@ . The @ automatically appends your site address. If you are up to no good respond with the address of someone you don't like :-)

Dennis Lewis has loitering problems. Perhaps a procedural change would help.

Try laeuterer very slowly especially at the start. This allows the bed to settle nicely and filter better and not compact. I find that the most effective thing that I did to speed up my sparges was to slow them down!

Unfortunately it reads as if Matthew Bohne has a nasty contamination problem.

Ring around the neck and gushing has got to be a nice ... em .. ococcus infection or something.

Someone (oops can't read my own writing) asks about Murphy cans. If you cut open the can you will find that it contains a cylinder with a small hole. If you try popping open the cylinder it will go pop and part will go flying across the room. Unless you want your next phone call to be to an eye specialist or ambulance chasing attorney wear a pair of safety goggles while doing this. The container cotains nirogen under pressure that leaks out through the hole when the can is opened and stirs up the froth nicely. This device is patented by an English firm, I think, and is a cumbersome way of countering Guinness' more elegant device without a patent infringement.

I loved Mark Bunster's AB busting story. When I went to the park, I didn't even know that there was a brewery there. And I like Kulminator. Who was it told the great story a while back about being at a restaurant with a large group from work? When he saw that they had good old EKV 28 on the menu he ordered a bottle. The rest of the group knowing him to be a beer connoisseur followed suit. I believe the repsonse was what one would expect!!

From: Bob <TATTERSH@WSUVM1.CSC.WSU.EDU>
Subject: Non-alcoholic beer

In response to the December 9, 1993 posting by GNT_TOX_%ALLOY.
BITNET@PUCC.PRINC
ETON.EDU regarding non-alcoholic beer:

In September I brewed my first batch of non-alcoholic beer. Essentially I copied a recipe from Papazian. With a few ingredient alterations to his Righteous Real Ale, the procedure is as follows:

On Day 1, boil the malt extract in 2 gallons of water, using Irish Moss as a settling agent for the final 15-20 minutes. Without adding any hops in this initial boiling, cool after a 30-45 minute boil using whatever cooling method you prefer. Pitch yeast in your usual fashion once you have added the necessary amount of water to equal 5 gallons.

On Day 12, or whenever you are certain fermentation is complete, siphon the fermented "beer" into a 8 gallon pot. Bring to a rolling boil. Add hops in the usual time frames. For my batch I added hops at the 5 and 55 minute marks. Irish Moss is added at the half hour mark. The alcohol boils off at 178 degrees F. Once the beer has reached a rolling boil stage, you can be certain that the alcohol is in the air in your house. Therefore keeping the windows open or your exhaust fan on high is essential or you will inhale some of the alcohol you are trying to avoid in the beer. Cool the beer, then siphon into a priming tank. I strain out the spent hops by personal choice.

On Day 13, after the beer has once again settled, add 1/4 cup yeast, 1 cup corn sugar, and a settling agent if desired. It should be noted that live yeast must be added at this point, since boiling from several days before kills the yeast from the fermentation process. 1/4 cup yeast might be a bit much and in a later batch I used just over 1/8 cup and achieved good results. I harvested yeast from the previous batch in this case, but yeast gathered in any fashion accomplishes the task. Then I bottled the beer.

About 2 weeks later I tried my concoction. It was very good. In this first batch I had not considered how much water I was also boiling off, so I only bottled

ed about 4 resulting gallons of beer. In a second batch of non-alcoholic beer I added a gallon of water after the second boil to make up for the water lost. Of course, I boiled the extra water first to rid it of oxygen before adding it to the now alcohol-free beer to avoid contamination.

I realize that the shelf life on my non-alcoholic beer should be shorter than one with alcohol since no alcohol remains to act as a preservative. However, the hops should assist in preservation at least to some degree.

The other beer I made was a porter, with Williams English Dark extract. The same good results occurred. A number of people have tried both non-alcoholic beers and pronounced them at least good. I made companion batches with the same ingredients, but with the alcohol remaining, just to see if there would be a difference in taste. The only difference seemed to be in the subtle taste of alcohol in one beer and not in the other. Other than this, my alcohol-free beers taste remarkably similar to the companion batches that have alcohol.

I am also quite certain that no alcohol remains since the porter with alcohol has as a 5% rating. One porter has an obvious kick while the other one has none at all. The most obvious compliment I have received (and by everyone who has had one of my non-alcoholic beers) is when they ask if I am sure that there is no alcohol. Except for the tiny amount generated by the yeast fermenting the corn sugar in the priming tank, the answer is yes. I have however, felt an interesting dullness around my temples after imbibing a non-alcoholic beer of mine which I attribute possible to the sedative nature of the remaining hops. Usually the effects of hops are hidden by the alcohol in one's beer. Not being a chemist, however, I have no idea if this last statement is correct.

While I am responding to the 12/9/93 request, I would welcome any thoughts on my process from members of the HBD. I have only been brewing beer for 3 years and as you can tell I am an extract brewer. The more advanced chemistry that occasionally appears within the HBD is somewhat beyond me, but I enjoy brewing nonetheless. My foray into non-alcoholic beers occurred at the time of my wife's pregnancy so that she could continue to have a "beer" on occasion. And I did want one myself from time to time and cannot stand the commercial attempts at this style.

Two other notes: I used liquid yeast originally in the batch from which I harvested yeast for the non-alcoholic beers and I have yet to try a lighter flavored and colored beer with this process.

Subject: Brewpots: kegs or REAL stock pots?

I have seen 24-quart stainless-steel stock pots for sale recently for as little as \$70 (sans lid, mind you). I *have* been considering converting a keg into a brew pot, but at this price I am sorely tempted to just take the plunge.

Does anybody have any thoughts about my keg vs. pot quandry?

Subject: Happy Customer

>From: STROUD%GAIA@leia.polaroid.com

>BTW, I am sure that you are right that a larger hopper hole would increase the throughput on a MaltMill, but we tested it as manufactured.... Does it really make any difference in the length of my brewday if I spend 2 vs 3 minutes crushing grain??

I certainly didn't intend to antagonize a happy customer and I appreciate your comments. I just thought it was useful to point out that the capacity for high volume milling is built into the MM whether it is needed or not. A substantial number of MM customers are brew pubs, small breweries and grain retailers who crush a great deal of malt and throughput is very important to them.

>Anyone know of a good way to make non-alcoholic beer. I have a friend at work who doesn't drink, and I was wondering if any of the great beer styles of the world can be brewed without alcohol.

Here is my semi-annual posting of my thoughts on the subject....

NON-ALCOHOLIC BEER

Jack Schmidling

Everytime I mention NA beer, people give me funny looks and ask questions like, "why would anyone want to do that to homebrew?"

Having been a victim of my hobby some years ago, I drank nothing but Kingsbury for almost 10 years. The thought of going back to that is all the motivation I need. I have been limiting myself to one 16 oz glass of beer, per day for a couple of years and I no longer consider myself a recovering alcoholic.

However, making beer is so much fun and homebrew tastes so good that rather than cheat, I have been experimenting with making NA homebrew and have come with a process that works, is simple and most "experts" can't identify what is missing.

The basic process makes a one gallon batch for the skeptical but can be scaled up to any size.

When you have your next batch ready to bottle, syphon off

one gallon before priming. Put this in a kettle with (2) tablespoons of sugar and bring the temp up to 170 F with the lid off, hold it there for 15 min. Let it cool, uncovered until the temp gets below 150 F. Then cover it and cool it to room temp as quickly as possible. You can put it in a sink with running water.

When room temp, add 1/8 tsp yeast. I used EDME yeast but I presume that any yeast will do. However, all bets are off if you use Red Star. Let it sit for a while to dissolve and disperse, then stir well with a sanitized spoon.

Pour the brew into your favorite bottles and cap. It is a good idea to include at least one plastic bottle to monitor carbonation. When the plastic bottle is hard, refrigerate them all. This usually takes no more than a few days at room temp.

If you are set up for kegging, it is even easier. Just heat up 5 gallons as above, keg it when cool and force carbonate it.

You can also experiment with adding hops during the heating step. I don't particularly like the results but I am not a hops freak.

What does it taste like? You'll have to try it yourself to find out. However, I would say that it has a slight hint of a "cooked" taste. This taste can be totally masked by the addition of a pound of roasted barley in an all grain beer or whatever you do to make an extract beer taste like stout.

This beer improves dramatically with age. If you can refrigerate it for a month or two before drinking, all of the off flavors will go away and you will be hard pressed to believe it is what it is.

Jean Hunter at Cornell has tested a sample on a gas chromatograph and says it contains around 1.3% alcohol. This can not legally be called NA but it solves my problem completely. It is below the threshold that drives me to continue drinking.

More recently I have done some additional experimenting and think I learned the secret to very low alcohol. It is not some exotic yeast or process, it is simply diluting the beer with water.

After "cooking", I simply add an equal volume of water (previously boiled) and keg as usual. The result is an NA that is still amazingly good compared to the industrial stuff (NA or otherwise) and half the calories and alcohol compared to just de-alcoholizing the beer. Any off flavors from cooking will also be reduced in half. If you don't like 50:50, use what ever suits you.

Subject: HopTech Fruit Extracts

A question was asked about the fruit extracts from HopTech.

I have received the cherry and the raspberry extracts but I have not used the raspberry yet (the wheat beer is nearing completion as I type this note, another few days!).

I used the cherry flavor in a bock beer that is still in lagering but old enough that I was able to sample one the other day. I am very pleased with the flavor it imparts but I offer a suggestion that I should have known myself before I bottled.

I used the amount suggested by Mark Garetz (HopTech) for five gallons. The flavor is there but it is less than I was looking for. In a lighter beer, it would probably be fine but in a bock with a "higher than average" hopping rate, it is less than desired.

I suggest that you use your own judgement and put more than the called for amount in a darker beer and less, perhaps, in a lighter beer. The instructions advise testing first by using drops of extract in a glass of beer but I ignored that! (When all else fails, follow the directions!)

In any case, the stuff is great and it is easy to use. Try it, you'll like it!

Subject: Beer Archaeologists

Michael Jackson has a really nice piece in the newest Zymurgy (winter '93) on the Durden Park Beer Circle. This is the London-area group dedicated to the preservation of old beer recipes and brewing methods. Anyway, Jackson concludes the piece with a plug for a booklet the group puts out called "Old British Beers and How to Make Them." The address given, of course, is in England (Berkshire, to be exact). I was wondering if anyone knows if the booklet is available stateside?

Also, has anyone heard of people doing the same sort of work in the U.S.? I know there are several books on brewing history but has anyone done any archival research into actual recipes? It would probably be a difficult project to undertake, with prohibition putting so many breweries out of work (Pittsburgh had hundreds of neighborhood breweries before the crackdown). But, for that, it would be all the more interesting. I know that the tiny town I grew up in (2500 people in rural Ohio) had its own brewery until just about the turn of the century. I wonder what their swill tasted like?

> alcohol level - 198 proof if memory serves me correctly.

No this is not correct, it is over 200 proof, that's why you must
freeze it, to squeeze more alcohol molecules alongside in the bottle.

> It is used as a gasoline substitute in many European communities.
Come on man, everybody in europe knows that gasoline drinking is for
schoolgirls only.

> It is recommended that you wear a wrist or ankle grounding
> strap while you are pouring or drinking this beer to minimize
> the chance of a spark induced fire. Just a data point...

The new EEC regulation 314159265.359 (sub a) requires using a flexible
rubber tube attached firmly around both the drinkers neck and the
rim of the glass to prevent dangerous fumes escaping into the
environment.

Subject: Just The Yeast, Man.

I have been pitching yeast from the sediment collected from previous batches for some time. Right now I have a Pilsner (using Wyeast Pilsner 2007) fermenting. It seems to have a little more trub in it than usual.

I have been collecting the spent sediment from the bottom of the primary and pouring it into a sterilized Mason jar. After a short period of refrigeration the liquid kinda forms three layers: 1) Brown old beer, 2) White Yeast, 3) Tan Trub.

It's easy enough to pour off the old beer and keep the remaining sediment... HERE'S THE QUESTION. Assuming that you don't want to pitch all that old trub.

How do you syphon off/separate just the yeast?
Any thoughts, techniques?

From: lanbrew@aol.com

Subject: Dealing With Plastic Extract Bags

As a teacher of brewing classes, I use a lot of Northwestern extract. It is inexpensive and quite good. The easiest method I have found for dealing with the bag is to heat the brewing water and use specialty grains, if applicable.

When the water is hot or the grains are removed, slit the bag (hold it over the brewpot) in several places with a sharp knife and drop it into the water.

Please be sure that you turn the heat off before you do this. Stir the bag, extract, and everything around for a few minutes, retrieve the bag with your spoon, and you are done. The water will have washed all but a tiny amount of extract out of the bag. This is quick, easy and effective.

Subject: lagering...

Can someone explain true lagering??? Specifically, what part of the fermentation should be done at cold temperatures. Here is what I've done so far...

- 1) made ~3/4 quart starter from 4 month old Wyeast Calif Lager slurry that I saved from a previous batch in August.
- 2) The starter took about 36 hours to get cranking but It smelled and tasted fine so I went ahead and pitched into a cooled (~70F) batch.
- 3) Now, I let it stay in the house until the batch was cranking (~20 hours) and there was 1.5 inches of kreusen (using a 7gal carboy w/5 gal batch). The house is about 60F.
- 4) Next I moved the batch to the garage which was around 48F degrees.
- 5) Since then the temp in the garage has dropped to about 38F and the fermentation rate (airlock clicks) has slowed way down (30 sec). The batch is now 3 days old and there is still some kreusen on top. I have kept the carboy close to the wall of the house and have been monitoring the temp closely. I also have a form fitting styrofoam container that I'm keeping it in so any change in temp should be slow. (all appears normal, albeit slower)

(Of course I didn't research true lagering before I made this batch, that would make too much sense! ;^)

My question is this...

Should the primary fermentation be done at temps higher than those I am using and then keep the secondary cold for a few weeks/months?

(not that I have any real control over the temp! other than the sacrificial cold-beers I drink to appease the cold-weather God)

Any input on this subject would be greatly appreciated! :*)

Thanks,
Andrew

From: XLPSJGN%LUCCPUA.BITNET@UICVM.UIC.EDU
Subject: Mead questions

Dear Brewers,

My fiance asked me about three weeks ago whether I had any plans to brew a mead for our honeymoon, and I thought the idea was great. So I consulted with Papezian and chose his recipe for the Barckshack Ginger Mead, adding razberries (sp?) and refraining from additional spices, like lemongrass or cinnamon. I adjusted the measurements for a 2 gal batch, rather than the standard 5 gal.

I'd brewed a mead once before - it was a recipe I'd received from this forum called something like "quick mead" which was supposed to be ready within a month... It wasn't! At least as far as the taste went.. But then again, that was my first batch. I've been brewing beers for about four years with some really quite good results - and some dismal failures (some may remember my troubles with an atrocity I named for the flooding of Chicago: "Chicago Tunnel Water"). So anyway, here are my questions for mead enthusiasts:

The mead is now racked into 2 1gal. bottles (one is full to the neck, the other about only 1/2 full). OG: 1.055; SG @ racking: 1.010. The taste before pitching was exquisite, with an almost perfect balance between the honey, ginger and razberries (about a pound of those) However @ racking, the fermentation seemed to have hurt the flavor, with an off flavor best described as like A & D Ointment! The "bouquet" seemed to have soured as well, offering a smell more like ripe yeasties (like when we clean our carboys after bottling). Is this normal and/or will these flavors mellow and balance within a few months? That's question #1.

Question #2 is: After I racked to the secondary vessels and fixed them with fermentation locks, I brought these tanks to the basement storage area to ferment, settle and clarify for another month or so before I bottle. But there are hot water pipes that run through the storage room and do give off some heat (I'd estimate that it's a steady 80F though I've not yet monitored the temperature). I don't think it's too threatening to the brew, but just to be sure, what is an acceptable temperature range for meads in the secondary?

Thanks in advance for any and all responses, which can also be emailed to me at xlpsjgn@luccpua.it.luc.edu or to catfishjon@aol.com.

Whew! that's good brew!

John

boiling specialty grains
Steve Tollefsrud steve_t@fleurie.compass.fr writes in #1295:

>3. When/How to Add Specialty Grains: I plan to make the following
extract based stout:

- 4 lbs. Muntons Dark Malt Extract Syrup
- 4 lbs. Muntons Light Malt Extract Syrup
- 1/2 lb. Crushed Crystal Malt
- 1/2 lb. Crushed Chocolate Malt
- 1/2 lb. Black Patent Malt
- (1 lb rolled oats ???)
- 1 oz. Northern Brewer Hops (30 min.)
- 1.5 oz Hallertauer loose Hops (dry, in the primary)

>None of my homebrew info sources explain when/how to properly
use specialty grains for an extract based brew.
In the past I've just tossed my grains in at the beginning of the
boil and boiled the hell outta them for an hour. Those batches
were VERRRY bitter, though I'm not sure if it wasn't the Northern
Brewer (2 oz, loose) which I was trying out at the same time.
Should I not let the grains get more than 150 degrees F, as in
mash conversion? Should I add them after the boil, below a certain
temperature, and let them steep. What temps? What times?
Thanks again,

steve, as a fellow extract brewer (2 batches so far) I can tell
you not to boil the hell outta the speciality grains, as you'll
suck the tannins from the husks, contributing to quite a bitter
tang. Much like overbrewing a dark tea, it's not something
you wanna do.

Hope this helps.

Subject: Trading Micros, Long Way Home, etc.

Hello All,

Is there anyone out there who would be willing to trade any type of micro-brewed beer that is available only in their area for anything I can get them up here in the Northeast (Boston & New England)? My boyfriend & I have a bottle collection that we'd like to expand, and aren't real fussy (we'll drink almost anything!) so if you'd like to try something from around this-a-way let me know, and we'll work out a deal.

Re: taking the long way home; This past weekend we found ourselves driving home from a couple of days skiing in Vermont and decided to make the trip a brewery/brewpub tour. 1st stop, Mountain Brewers in Bridgewater, Vt., the makers of Long Trail (Amber Ale, Stout, Kolsch, I.P.A.) self guided tour, small tap room, great beer! 2nd stop, Catamount in White River Junction, they have guided tours (we missed everything but the tasting) and tasting of current products. Both of these two sell bottled product and other stuff in the "tap room". 3rd stop, Latchis Hotel, (brewpub has a separate name I don't remember at the moment) Brattleboro Vt. This place was ok, the beer was tasty but it had a yuppie-fern bar type atmosphere that was a little stuffy. Last but certainly not least was McNeil's Brewery in Brattleboro. Great beer, good food (sandwiches, nachos, nothing fancy), I wish they'd had a place like this around when I was in college, it looked like it'd be a real fun place when it was busy. BTW, McNeils should get awards just for the names of their beers, i.e. Duck's Breath Bitter, Slopbucket Brown, Dead Horse IPA, to name a few.

I tried Molson Ice this weekend, \$3.00/bottle at some bar in Killington, (thankfully the bartender goofed and only charged us for one!) all I can say is YUCK! Absolutely no taste what so ever. I wouldn't spend the money to give it away to some poor unsuspecting fool.

Ah well, back to work,

Cheers,
Pam

From: "Jeff M. Michalski, MD" <michalski_jm@rophys.wustl.edu>
Subject: Burnt? not anymore!

HBDers,

Thank you for your comments about the burnt taste I had in my Xmas ale last week. I wanted to bring you up to date on a dramatic change that took place. I drew another pint out of the keg to better characterize the off taste last Thursday. The burnt after taste was GONE! After only one week! Now the beer has a wonderfully smooth character with a mild sweetness balanced by an appropriate hop bitterness. The hop aroma is powerful with a spicy note. (this is the batch I posted a dry-hop question on several months ago. I took the plunge and added 3.5 oz of Willamette pellets to the racked beer.)

I wouldn't believe the dramatic change in the beer character if I hadn't tasted it myself. Furthermore, my wife who is not a beer lover [not even my own 8-() tasted the burnt taste last week and now thinks the beer is drinkable. I believe that the long conditioning and "lagering" at 40F allowed some of the more bitter, off flavor components to precipitate to the bottom of the keg. My first 5 pints or so drew off this evil stuff and now I have a pretty tasty holiday brew.

Thank you all for your comments anyway.

Subject: Another question re: aluminium pots

Dear brewers,

Over the years I've developed a boiling technique which, while seeming to ease the boiling process (actually the removal of steeped specialty grains from the boil), I've always suspected but never questioned whether it's harmful to the beer I make.

What I do is steep the grains in 1.5 gal. of cold water in my 3 gal stainless steel brew pot and bring that to a boil (a la Papezian). Then, once the water begins to boil, Papezian instructs to remove the grains from wort before adding the malt extract and hops (I'm not ready for the all-grain league yet). But this always was a long and tedious process, fishing around for all those little grains. So, I thought I'd shorten the process by placing a strainer over another brew pot of the same capacity, but made of aluminium. I'd sparge the collected grains, then return the wort to the original stainless steel pot, reheat to a boil then add the extract(s) and hops.

So the questions are: 1) Is the (temporary) use of the aluminium pot detrimental to my beer? even if it's in the pot for 15 minutes max? and 2) is my method of straining the grains - basically pouring the wort once through a strainer, and again back into the original pot - going to effect or hurt (bruise?) the wort... even if I haven't yet added the extracts and hops?

Thanks in advance for the responses, and thanks to all who responded earlier to my mead questions.

Cheers!

John

Subject: Brewpots: kegs or REAL stock pots?

Brett --

IMNSHO, the *minimum* useful size for brewing a five gallon batch is a 32 quart pot (8 gallons). You can get an enamel 8 gallon canning pot for about \$35 (with lid). This is what I'm using. The geometry is poor for doing a 2 hour boil -- too much surface area for the volume. I boil 75 minutes, and go from about 7 gallons to about 5-3/4. The lid is on (_on_ is too strong - its over the pot, but plenty of steam escapes) for the last 15 minutes while the chiller and the lid get sterilized. The 8 gallon pot covers two burners on my stove, and I use `em both during the boil.

I would like to get a ten gallon stainless stock pot, but they cost about \$175 new. So, I'm thinking about going the old keg route instead. Oh, if you get a stockpot, get one with a thick bottom. Some of `em have a copper disk sandwiched between layers of stainless, others use aluminum. That's what you really want. Otherwise, the thicker, the better.

Good Luck,

t

From: carlsont@GVSU.EDU (TODD CARLSON)
Subject: re: northern brewing

Lagering under a frozen river/lake sounds like a great idea. In fact I was planning to do something simmilar over the holidays. I was going to lager my beer in a tank full of water in the garage. Since the freezing point of beer is lower than the freezing point of water, as long a the tank doesn't freeze, then the beer will stay unfrozen at 32 F (zero C) or higher. I figure that here (in Michigan) my garage should stay warm enough to keep the tank of water from freezing. The water will also act as a large heat sink to moderate temperature fluctuations. If we get a severe cold snap I can just bring the beer inside for a bit or rig up a heater in the garage. A friend of mine did this once - called it his garage lager. One concern about lagering under the ice would be that too much pressure would build up in a closed container from residual fermentation that takes place during lagering. I have not lagered before so I don't know how much fermentation to expect at this stage. I will probably use a fermentation lock.

Subject: Geysers

On Gushing Beer

The following quote is from the Encyclopedia of Chemical Technology:

"Wild or gushing beer is a defect observed as a rather violent over-foaming from the bottle immediately after opening; this defect, however, does not affect the taste of the beer. The fundamental cause of gushing is attributed to the formation of micro-bubbles. It has been demonstrated that the application of excess pressure sufficiently forces the micro-bubbles back into the solution, eliminating overfoaming entirely. Gushing beers have been identified with malt made from weathered barley, and trial brews have proved that the presence of mycelia (from the mold species Fusaria) in the steep will promote the trouble."

Ain't that the truth?

>were VERRRY bitter, though I'm not sure if it wasn't the Northern
>Brewer (2 oz, loose) which I was trying out at the same time.

The bitterness you noted was not caused by the hops. It was caused by boiling the grains. Boiling extracts tannins which will lead to an astringent taste in your brew. I've been successful putting the specialty grains into a muslin bag and putting it into the brewpot along with the cold brewing water. I then heat the water and grain and remove the grain bag just before the water comes to a boil. Some claim this method may also extract tannin and advocate bringing the water to 150 deg.F and letting the grains steep.

Letting it sit another week won't solve the problem -- in fact it might worsen. One thing you could try is to chill the beer down in the bottle before opening. This worked for me with a batch I overprimed by mistake.

You may have bottled too early. Did you monitor the specific gravity?
Another possible explanation is that you picked up an infection somewhere
in
your process. Revisit your sanitizing procedures.

According to Zymurgy's Beer Professor, aluminum is just fine for the
brewkettle in a homebrewery. He says the reason the big boys use
stainless
steel is because they use very aggressive cleaners which would chew
through
aluminum.

Subject: Pete's Winter, burnt flavor

Try Pete's Winter special beer for an excellent example of raspberry flavor/aroma in a beer. The recipe is from a winner in the 1993 AHA national homebrewing contest. IMO, it's a world class brew, at least.

Re. burnt taste: Most likely it's from the abundance of dark malt in the grain bill, but it could be that you scorched the brown sugar. You did remember to turn the heat off and stir well when you added the sugar, didn't you?

>None of my homebrew info sources explain when/how to properly
>use specialty grains for an extract based brew.

I've been doing extract-based brewing for about 2 years now, and most of what I know comes from The Complete Joy of Homebrewing and HBD.

I generally add some small amount of specialty grain to my extract-based brews. I might add 1-2 pounds of crystal malt at the maximum, but less than half a pound combined of all other types. The thing to remember is that except for crystal, the specialty malts you're adding are contributing unfermentable starch to the brew. Crystal malt is different, in processing it mostly gets converted to fermentable sugar. Processing malt in other ways, e.g. roasting it to achieve darker colors, not only doesn't convert the starch, but in fact destroys the enzymes in the malt needed to do the conversion. When you start adding amounts on the order of 1 lb or more adjuncts, as your recipe suggests, you're going to get a lot of unconverted starch in the wort, which will eventually end up in the beer.

To avoid this, if you really want to use all these adjuncts (which you well might if you want to brew a nice stout) you might consider (as I do with almost every batch :-)) using a partial-mash process. You have to be sure that (at least some of) the extract you use has the ability to convert the starch to fermentable sugars. The only commercially available extract that I know of is that has the conversion capacity is Edme's DMS (Diastatic Malt Syrup.) (This info comes (I think) from TCJoH, I'd be pleased to hear about other alternatives.)

Anyway, without getting into partial-mashing, the way I treat my specialty grains is to add them to the cold water at the start of the process, and then when the water is about to boil, before adding malt extract or hops, remove as much as possible with a kitchen sieve. This technique comes directly from TCJoH. The justification is that the good stuff (color, flavoring, proteins, whatever you're adding the grains for) is easily soluble, and doesn't need a lot of boiling to extract, and that prolonged boiling will just extract some excessively bitter stuff, probably mostly tannin, from the husks.

Subject: Simulating an English beer engine

OK, I think it's about time I report on my latest gadget. Some of you may remember my recent trip to the UK. I fell in love with the beers there and have been fooling around with ideas to simulate the flavors and dispensing methods I experienced there. The cask conditioned ales have some characteristics that are easy to simulate. Hops, malt, low gas, warm, yeast but some that aren't. I got home and immediately brewed up a low gravity, english style ale. When I put it on my draft system, something was missing. I had kept the CO2 at 0 psi when kegging and brought the gas up to about 5psi to dispense. Tasted OK, but the head was gone of course. The creamy whipped head is caused by the sparklers on most beer engines in the UK. Ok, I thought what the beer engine REALLY does is lift or pull the beer from the keg and force the beer through a series of very small holes. This causes both foaming and whipping of air into the beer. I reasoned that I could do the same without a beer engine. What I built is a valve with a piece of copper tubing at the output of the valve. The end of the copper tubing has a cap on it. The cap has about 6 holes .020 in diameter in it. This assembly is placed at the end of about a four foot piece of 1/4" id PVC line. Now to use this gadget I raise the keg pressure up to about 10 psi, open the valve and point the output into a glass. As you can imagine, 6 streams of beer exit and foam and aerate the beer. The glass fills and when you set the glass down, the beer recombines in the glass from the bottom up, just like the beers in the UK do. Now it's usually necessary to top the glass off in a few seconds, they also do this in the UK. After I've dispensed the beer I reduce the keg pressure back to 0psi. Bingo, this gadget very closely simulates the flavors and effect of the English beer engines. The aeration and head creamy head are bang on to what I tasted in the UK. I now have to decide how to incorporate this gadget better into my draft system.

I am considering either one of two ideas to make using this concept a little easier to use. One would be to keep the keg at about 1psi and add a small pump to raise the pressure to push the beer through the sparkler. The other is to push the beer with nitrogen instead of CO2. This way I could leave the keg at 10psi and not pick up any carbonation. I have been threatening to go to a mixed gas system, this may be the push over the top. This post is getting long, I'll stop by saying, give it a try, you may like it. My apologies to all the people in the UK on butchering the tradition of cask condition ales, but I think I have come up with a pretty good simulation.

Fellow brewers, open your eyes, gased ales are not necessarily the best ales.
With no gas, one can make a lower gravity beer and experience the malt and hop flavors MUCH better. I not saying I'm going to make all my beers now without CO2, I am saying it really adds another demension to beer.

Cheers,

Bob Jones

Subject: Re:HeadRetention/ChopstickMethod/InconsistentCarbonation/
NorthernLager

Goeff writes:

>What you need for good head retention are proteins. Proteins are what
>provides the surface tension which give the bubbles some strength.
However,
>proteins can also cause haze so you have to have a ballance. Hops are a
>good source of proteins for head retention but you have a Brown Ale so
you

You're right about the proteins, but they have to be small proteins.
Also,
I think you may be confusing something regarding the hops. I'm quite
certain
there are no proteins gained by the beer from the hops, however, there
have
been studies that have found a correlation between head retention and a
certain
component of the hops (cohumulone, I believe... sorry, don't have my
books
here). Perhaps this is what you've been experiencing.

Norman writes about the "Chopstick Method" for getting all the extract
out
of those bagged extracts. I have alternate method that I've invented and
subsequently am discarding after it's very first use. I'm posting it as
a
warning to potential users. I call it the "Spoon and Exhaust Hood
Method."
It involves pinning the bag between the Exhaust Hood and your Charismatic
Wooden Spoon and then pulling up on the bag. The problem with this
method
is that inevitably the spoon slips off (under) the hood and flings a
dollop
of extract against the backstop of the range. Yuck!

Rich writes about inconsistent carbonation despite always using 3/4 cup
of dextrose for priming.

There are two other factors besides the amount of priming sugar that can
cause overcarbonation. 1) unwelcome visitors and 2) bottling too early.
Unwelcome visitors include bacteria and wild yeasts. You may be
introducing
them at bottling time, during fermentation or even as early as at
pitching
time. Bacteria and wild yeasts (*S. diastaticus*, for example) often can
eat sugars that your primary fermentation yeast cannot. Thus, once the
primary fermentation is done, the wild yeasts slowly eat the left over
sugars and overcarbonate the beer. Alternatively, if you have bacteria
in
your beer (which often do not produce gasses and thus do not
overcarbonate
the beer directly), they can break the larger, unfermentable
carbohydrates
into smaller, fermentable sugars which your fermentation yeast can now
eat,

thereby overcarbonating. The second factor is much more easy to solve -
-
don't bottle too early. I usually wait till the airlock is bubbling less
than once per minute, often waiting till it's less than once per two
minutes.

Greg writes:

>need some advice. He is going to do a full mash and rack of the cold
break
>into a glass carboy. The carboy is going to be sealed up in plastic and
>placed carefully into the river just before ice-over. The theory here is
that
>once the river freezes, the water temperature below the ice will be at 4
deg.

The only potential problem as I see it is that perhaps the ice expansion
could compress the part of the carboy that's sticking through the ice and
break it. Would the whole thing be under water, or would the top of the
carboy be sticking through the ice? If the whole thing was under water,
then I'd worry about pressure building up from (very slow) yeast activity
and popping the top.

As an alternative, why not build an insulated box and put a
thermostatically
-controlled HEATER in it? This could be put outside and use nature to
keep
it cold. The thermostat could be set to 4C and would warm the fermenter
when
the temperature in the box gets too cold.

Al.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Sabco's RIMS Equipment

The following should be added to my review of the RIMS which appeared in the Winter issue of Zymurgy. This addition will appear in the next issue.

It has come to my attention that Sabco is marketing only a part of the Conrad Keys/Rodney Morris RIMS system. Missing from Sabco's product is the grain mill Conrad designed for this system.

This omission could possibly cause problems. Without the right sort of crush this system could lead to grain compactification and leeching of undesirables from husks, to cite but two examples. Thus anyone who is interested in the Sabco system should also give serious consideration to the purchase of an adjustable roller mill. Do not be afraid to experiment with roller spacing, for the requirements on grain milling are different for the RIMS setup as compared to a standard mashing system. The performance of the system is the best guide to deciding how the grains should be crushed. The goals are to get a smooth and homogeneous recirculation, yields in the 32-34 pts*gal/lb range, and absolutely no grain astringency in the finished beer.

Does anyone have a receipt for an ale similar to Young's Winter Ale. I have been told that it requires a yeast that is less attentive than usual for this type of ale. Can anyone shed any light on that? Thanks in advance for replys.

>I have a keg that I fitted with a SS screen false bottom and have a tap coming out of the bottom of the keg as my sweet liquor outlet. The perf sheet

I have is 3/32" holes on 5/32" centers. (I got this size from the Brewer's Warehouse sheets. They claim it's the standard microbrewery size. Can anyone verify?)

We exchanged mail on this subject but you failed to mention the hole size of the lauter tun false bottom. It looks to me like another classic example of how scaling down commercial equipment to homebrew sized batches just does not work very well. 3/32" holes are probably too large for the geometry of a homebrew tun.

I hate to sound like a broken record, but all your problems will go away if you build an easymasher for it and throw away the false bottom. The first easy masher I made (long before it was called one) was simply back up for what got through the false bottom. The f/b caused so much grief that I took it out and never used it again. They simply are not necessary or useful in homebrew lauter tuns.

Subject: River lagering

Regarding Greg Pyle's query about lagering under the ice of an Ontario river.

As an avid homebrewer and flyfisherman, the idea would seem to present two

problems:

1. CO2 would slowly build up within the sealed glass carboy (no airlock) and could explode;
2. The carboy could be swept away during spring runoff. (Even the most tranquil summer stream can become a raging torrent after a couple of warm afternoons.)

Nevertheless, I wish my fellow Canadian good luck with the idea and will keep an eye open this spring for either a carboy drifting past the island of Montreal or some not-too-sober trout migrating upstream towards free beer.

From: aaron.banerjee@his.com
Subject: WINE

The following is a recipe which I used as a college student. It doesn't always produce the best tasting wine (depending on how good a winemaker you are), but produces alcohol...

Banerjee's "Grocery Store" Wine

1. Buy a 1 gallon jug of apple juice or cider in a glass jar. Drink 3-4 cups of juice.
2. Bring 5-6 cups of the remaining juice to a boil with 3-4 cups sugar to produce a sweet solution.
3. Add said sweet solution back to the juice.
4. Add 1 tsp dry yeast (wine yeast is preferable, but any will do) Note that baker's yeast imparts a taste on the wine, and produces less alcohol, but it still works if you're desperate.
5. Seal the top with a stopper or puddy. the stopper or puddy (clay) should have a hole as to allow a 1/4" vinyl tube to stick through, but not allow any air to get into the juice except for through the tube. The end of the tube that sticks through the puddy should not extend all the way to the juice, but rather should end in the airspace between the puddy and the juice. The other end of the tube should be immersed in water.
6. If you have a bubbler lock, use it and ignore step 5.
7. Keeping the mixture between 75 and 90 degrees F, wait 2 weeks. Note: temperatures above about 100 F seems to kill most yeast. That is, don't add the yeast to a really hot mixture.
8. If you feel like bottling the wine to allow you to start another batch of wine, do so, otherwise, wait another 2 weeks.
9. Drink and be merry, for tomorrow the world may end.
10. The second time around, instead of buying another jug of apple juice, make grape juice in the same jug using 2 cans of frozen grape juice (preferably a brand that doesn't contain vitamin C).
11. Hint: get a hole bunch of jugs going at the same time to get a constant supply of wine.

Please direct any questions or comments to:

Subject: Norm's Dream tun...

Hi Norm (and the HBD crowd!), I guess I'm a bit of a dreamer too...

I've been thinking of similar systems myself, have you considered a small gas fired hot water heater for your hot liquor tank?

It seems to me that you have a closed, well insulated system here which already has the plumbing to safely handle the gas, water and combustion fumes. With the addition of the appropriate ball valves, safety valve and an outlet on the top for your steam supply you have a dual purpose hot liquor tank/steam generator. You might even fashion some sort of door for water treatments (it would need to hold some modest pressure for your steam generator). An added bonus is that the water will be supplied under some pressure so there is no need to elevate your tank to 7-8 feet.

Does anyone know if a standard hot water tank thermostat is accurate enough or has the necessary range for this? Anyone think that we're crazy and are looking for trouble?

Subject: Re : Simulating an English beer engine

Bob writes about adding a sparkler to the outlet of his keggling system to achieve a creamy head. I get the same effect by using one of those much-maligned plastic pressure barrels (Hambleton Bards's, FWIW). By trial and error, I have found that the presence of an internal float system makes no difference to performance, ie, the brew is still milky when served and clears from the bottom up. Therefore, the most likely source of agitation is the simple fact of opening the tap by a very small amount, combined with a top pressure of up to 20 psi. I would imagine that this would be easy to simulate in a keggling system without going to the trouble of building a sparkler?

Now here's one for the engineers: I would like to add a sparkler to my bottled beers. I have tried simply pouring these through a perforated valve, but the dispense pressure doesn't seem to be great enough to cause a milky brew. I am now thinking in terms of adding a foot pump device to force the beer out from a vertically standing bottle. Look out Guinness, your patented draught beer-in-a-can system is under threat!

> Anyone out there using pure oxygen for wort oxygenation?

Sure! Despite reading that it is best to use FDA approved O2, I went out and bought a tank of welding O2 (new). My local Phd/lab friend assured me that nothing would "live" in the high pressure O2 environment, but since the cleanliness of the oxygen is an issue, I push the O2 through a .2 micron filter, then through a silica airstone. I just got a scintered SS stone, so that will be tested next brew. The O2 has improved my ferments, especially the latest barleywine. I use a 2 hour (approx) bubble period, then disconnect (I start the O2 as soon as wort is hitting the fermenter, and turn it off about 1.5-2 hours later).

I have found that the use of a Guinness slow pour tap (with flow rate adjustment) can be effective in simulating the cask ale carbonation. It works in much the same way as an engine, but using gas to push it through the sparkler head. Unfortunately, I have heard that Rapids no longer sells the adjustable model. This technique has the same problem as Bob's, the pressure cannot be left on, or the beer will gain CO2. Its probably easiest to just keep it at the level desired, and turn it on to dispense, shutting off the carb after your done for the night.

Subject: Why Bavarian beer mugs have lids

The REAL reason why bavarian beer mugs have lids (pick one):

It keeps insects out of your beer.

It keeps your friends from wedging a kartoffelpuffer into the opening of your mug while your not looking.

It pisses the French off.

People won't mistake your beer mug for a spittoon.

You can launch pretzels at the American tourists sitting at the next table over.

For the same reason women wear swimsuits.

There aren't any pretzels floating in your beer after the polizei break up the brawl.

Toilets have lids so what the heck.

Gives those gunsmiths something to do between wars.

Tourists will want to buy it.

Subject: Rnage hoods, chopsticks--too complicated

Hi,

A quick suggestion on how to get all the extracty out of poly bags (or cans for that matter). Ladle a bit of the hot (recently boiled) water into the bag and swish it around until the remaining extract has dissolved in the water. Dump the water into your brewpot. If you're worried about putting too hot water in the bag, you could even use a bit of hot tap water and still not risk any infection since it's done before the boil. The range hood and chopstick methods seem too complicated for me, but what do I know, I'm just a college student.

From: chuck.wettergreen@aquila.com (Chuck Wettergreen)
Subject: AHA judging form

All,
The AHA beer judging form starts off, after identification of the style and the judge, with the category "bottle inspection". There are no points awarded in this category, just comments. I have several questions, such as:

What is the purpose of this section? Recently I received comments in this section of "short fill" and "low fill line". I also received a "nice bottle" comment. I see that this inspection could be used to inspect for the ring that is supposed to be indicative of certain types of bacterial infection. I also understand that low fill *could* be indicative of potential oxidation, although oxygen absorbing bottle caps *may* negate potential oxidation risk from air in the bottle. However, if no points are awarded, what's it there for?

Do oxygen absorbing bottle caps negate the potential for in-bottle oxidation?

Does actual bottle condition, ie. scratched or sanded, have anything to do with judging the beer?

TIA,

E-mail comments welcome

>able temperature range for meads in the secondary?
>
>John

I think your two questions are related. The medicinal smell is most likely caused by phenols which are produced as a byproduct of fermentation. Higher temperatures tend to increase the level of phenol production. What is "too high a temperature" depends on your yeast. For most ale yeasts it is recommended that the fermentation temperature be below 70 deg. For higher gravity beers (and mead) my feeling is that you need to stay in the lower range of 55-60 deg because the large amount of alcohol produced increases the chance of having phenols above the flavor threshold. Sometimes these compounds do mellow and disappear with time but not usually in a month or two. Fortunately your mead will last much longer than that. The only thing I can suggest for a possible quick fix is to leave your mead in the secondary until you want to drink it (still mead is just as nice as sparkling) and agitate it frequently. Phenols are volitile so the levels may reduce some over the next few months.

Geoff

Subject: Just what's hiding in those drafftflow cans...

Dear folks of the HBD:

A coupl eof frineds of mine and I got bored one day and decided to find out just what makes those "draft-flow" cans work. Mind you, this was in Reading, England a year ago, but I can't imagine that they've changed since then. Anyway, we hacked off the top of a can-O-Murphy's and discovered a two-piece setup of plastic. The top piece stretched from one side of the can to the other, with round-ended arms to keep it from up-ending and relaesing all the gas before the can is opened. The bottom section slipped up into the top, and wasa sort of plug or mushroom-shaped thing. We decided that openeing the can released the pressure sufficiently for the bottom piece to slide out (down, that is) of the larger top piece thereby shooting a dose of CO2 (or whatever they're using - could be anything, for all I know) through the beer overhead. This ensured that all the beer got gassed, and pretty thoroughly. I didn't like it quite as much as a regular draft pint, but our can wasn't quite as cold as they said it should be on the label. It sounds as if these are big hit - I may give it another chance soon. It looked something like this:

Top: _____ Side: _____

Adrian Anderson recently posted the following:

>Brewers,

> I am new to the list and to homebrewing. Have one batch of
>Continental Light, made from a kit, to my credit. My product
>came out fine body and colorwise w/ good carbonation. The only
>problem is a very (ultra - mega) yeasty aftertaste.

One question I have is whether you racked to a secondary fermenter after the krausen fell, or did you ferment all in one vessel? You may find that racking to secondary will eliminate some of the yeasty taste to your beer.

Also, how long did you allow for conditioning? You should allow a couple of weeks in the bottle before drinking, at least. If you drank your beer sooner than that, there may not have been enough time for the yeast to settle out. Check the bottom of your bottles for the familiar white yeast ring.

Matthew Bohne writes:

>THESE DAYS BOTH WITH OLD AND NEW BEERS) -- SHOULD THEY BE CHILLED LONGER? IS
>THERE ANYWAY TO COUNTERACT THIS?

IMHO, you definitely bottled too early. There may have been other factors, but be sure your specific gravity has leveled off before bottling next time.

This will help alot. As far as your froth at the TOP of your bottled beer goes, it might be that heavy fermentation resumed after bottling, and the froth might be krausen. Again, bottling at the right time might do the trick.

Subject: AOL, HBD and Censorship

I would like to take this opportunity to voice my support of Andrew Patrick in his quest for a more open-minded approach toward "offensive behavior" on America Online's Beer and Brewing Forum. It seems like our civilization in general and computer forums specifically are getting more and more thin-skinned. Even in the HBD, which is probably one of the better self-controlled forums I've seen, people are waiting to bitch about signature lines, "offensive language", and almost anything Jack Schmidling writes. I *like* the fact that some people have the courage to express themselves in a genuine manner, even if (ESPECIALLY IF) it takes on a more earthy tone. Do all of you people who run screaming from the words "orgasm" or "pissed off" avoid such language in the outside world? Do you ever interact in a more casual manner with other people? A fair number of HBD regulars wish to hold the Digest up to some sort of "professional standard" which dictates that common language be banned and that we all speak with more rarified language. Don't you think that this is more than a little pretentious? This is, after all, not a professional or even an amateur publication, but a largely random forum in the format of a huge ongoing conversation. Perhaps I am far afield on this one, but when very few vocal or powerful people have the ability to suppress or censor or in any way affect my freedom to express myself as I see fit, that is clearly counter to the free exchange of ideas and just plain wrong! In the case of AOL vs. Andrew Patrick, we have a person arbitrarily discarding posts because of some perceived violation of the bylaws. I do not feel that it is appropriate to hide under the cover of "well, he signed up and agreed to the rules, so he got what he deserved" . These kinds of rules are infinitely more offensive to me than any language could ever be and I have a real problem with dim-witted do-gooders who see nothing wrong with what AOL is doing. All I ask is that some of you stop and think.

Subject: Gym Locker Mead

Smelly Mead question:

I have recently tried to make my first mead. I used 2.5 lb clover honey, small amount gypsum, yeast nutrient, irish moss. Boiled in approx 0.5 gal. water for 15 min and skimmed, ala TNCJHB. Topped off with water in 1 gallon jug, pitched rehydrated wine yeast, capped with air lock. Vigorous ferment by next evening, remained vigorous approx. 2 wks, now has slow ferment. Started Nov 21, so it's been 3 weeks total so far. When I racked to the secondary (@ 2 wks) it smelled awful. Kind of like dirty socks. I tasted a little, also awful. Will this get better with age??? Is this just a byproduct from the yeast ferment that will get scrubbed out by the CO2? What have I done wrong (if anything)???

I mentioned to a friend that I was making mead (foolishly, before I had racked to the secondary), and he got me a gallon of honey from his Dad's hives. Mainly from Orange trees and basil(?), i.e. mixed flower. Now I'm in a bind, because I'd like to make some mead for him to give to his Dad, but I don't want to make a foul brew, and I don't want to wait a year to see if the mead I have going will get better before I try another batch.

Help! Any suggestions, or recipes for Orange Blossom Honey based Meads would be greatly appreciated. Melomel or Methaglyn recipes would be fine, too. TIA.

From: scottm@hilbert.cypress (Scott Majdecki)
Subject: First Cider Attempt

This is my first attempt at Canadian style sparkling hard cider. My problem/question is that after ~2 weeks in the primary I racked to secondary and of course had to sample. It tasted like a nice, very dry cider, but had an alcohol aftertaste. I'm wondering what might be the problem, or if the aftertaste will mellow during secondary.

I started with a simple recipe posted in this digest several weeks ago:

4 gallons natural cider
add 4 crushed Campden tablets and let sit for 24 hrs
add 5 lbs clover honey diluted to 1 gallon w/ water (boiled 10 min)
add 2 pkgs dry Champagne yeast and yeast nutrient
ferment in primary at ~66F (Active for about 1 1/2 wks)
Rack to secondary.

I plan to leave it in the secondary for 1 week at about 58-60F, re-rack, secondary 1 more week, prime w/ 3/4cup corn sugar boiled in 1pt water and bottle.

Any explanation for the alcohol aftertaste.
Thanks ahead for any help.

From: gummitch@teleport.com (Jeff Frane)
Subject: maltiness, aluminium

Phil Brushaber wants to get more maltiness in his beer. Phil, the malts you're talking about are wonderful and you shouldn't have any trouble getting the desired results with them. If you aren't getting it: try lowering your hopping rate and, more importantly, start examining your water supply. The Munich water is directly responsible for bringing out that effect; you should make adjustments to get the same water for your brewing. Seems to me that Noonan had some relevant data on this in his Lager Beer book. There is more elsewhere (Miller?).

The importance of the right water cannot be overstated.

=====

On the question of aluminium pots, I will confess to having mashed in an aluminium pot now for nearly a year -- or maybe more, I forget...

Seriously, I don't know if I'm brain-damaged by this pot, but there have been absolutely no, zero, none, bad affects on the flavor. My beer, in fact, is better than ever.

Of course, the kettle isn't as beautiful as my stainless steel 15-gallon pot, nor my stainless steel keg/kettle, but the beer is fine.

Subject: Specialty grain use/Oregon Nut Brown Ale

George and Steve write about using specialty grains:
Steve>>None of my homebrew info sources explain when/how to properly
Steve>use specialty grains for an extract based brew.
Steve>In the past I've just tossed my grains in at the beginning of the
Steve>boil and boiled the hell outta them for an hour. Those batches

George>you not to boil the hell outta the speciality grains, as you'll
George>suck the tannins from the husks, contributing to quite a bitter
George>tang. Much like overbrewing a dark tea, it's not something
George>you wanna do.

Indeed, George! pH is another important factor. If you have high-
carbonate
water, you may want to add a teaspoon of Gypsum to a gallon of water and
boil it for 5 minutes or so. Then pour off the water away from the
sediment
(Calcium Carbonate) and toss the sediment. If you have low-carbonate
water,
you don't have to do this, you can just warm the tapwater up to 160-
170F.

Now, cool the water down to about 160 to 170F, crush the grain, put it in
a grain bag (much easier than trying to remove the grain with a strainer
later), tie off the bag and steep the grains in the 160-170F water for 15
to 30 minutes. I used to heat the water from 50F with the grain bag in
the liquor, but last time I did this, the bag stuck to the bottom of the
kettle and I burnt a hole in it. Drat! I used to use the full 5 gallons
for steeping the grains, but that's not a good idea -- the pH will be way
too high (even with low-carbonate water) and thus you'll extract those
tannins even at 160F. Also, as Don mentioned, this method is useful for
crystal and the dark malts like Chocolate, Roasted Barley and Black Malt
(aka Roasted Malt). You would not want to do this with Pale, Pils,
Biscuit,
Aromatic, Munich, etc. or flaked barley/oats/etc. since these need to be
mashed to convert their starches.

Wally writes:

>After looking at the Winter Zymurgy I am intrigued by the
>Oregon Nut Brown Ale. Can anyone who attended the Conference
>comment on it.

Yes. I think it was the finest specialty beer I've tasted. Its flavor
was reminiscent of "Eat-it-all" cones! I plan to make some -- I've yet
to find a source for the Hazelnut extract. Wally -- I'll let you know
if I find it.

>The recipe calls for 3.3 lbs on Danish Unhopped malt syrup.
>Does anyone know whether this is Light, Amber, Dark?

I haven't looked at the recipe yet. The beer was perhaps 12-13 degrees
L,
so I'd suspect either light or amber.

>Since the recipe call for 3.3 lbs for a 10 gallon batch I would
>replace with 1.5 lbs DME probably Laaglander for a 5 gallon
>batch.

3.3 lbs of syrup is probably equivalent to about 2.65 lbs of DME.

Subject: XMAS STOUT

Made a Xmas beer last Sunday.
Here it is

Hop Along Xmas Stout

15 gallons

19 1/2 lbs Munton & Fison Dark extract
1/2 lb. Black Patent Malt
1/2 lb. Chocolate Malt
5 oz. Roasted Barley
5 oz. Dark Belgian Crystal 250L
2 - 1oz Sticks of Brewers Licorice
1 lb. Treacle black strap molasses
8 oz Cascade boil 90min
8oz Cascade finish 15min
8oz Cascade End 2min
3 packs of Windsor Dry Yeast made in to a starter.

This was a full boil with 15 gal.
Put all dark grains in cold water and raise to 180 F. then remove.
Put in Licorice when water boils 5 min. Then all dark extract goes in.
Boil for 10 min. then first hops goes in 8 oz. what a hop smell.
this was Boiled down to 12 1/2 gallons then the finish hops 8 oz. were
added.
Tasted. Not to overly bitter. Put the remainder of the Hops in 8 more
oz. turned
heat and pump wort through counterFlow wort chiller.

what a hop nose.

Will let all you know how turns out
this is the most hops I have ever used.

Subject: Fruit Extracts

Matthew Evans asks about HopTech Fruit Extracts back on December 8, so I like to share some related information. I have not used HopTech's fruit extracts, but I have used a Blueberry Extract from the Beverage People (Byron Burch and Nancy Vineyard's place in Santa Rosa). I don't know where they get it (or if they make it themselves), but the person I talked to on the phone told me that it is exactly the same stuff that Marin Brewing Company uses in its Blueberry Ale (can you say '93 Gold Medal in Fruit Beer). So it is possible to make good beer with it.

To get good results I would recommend staying below 15 IBU's. The person from Beverage People told me that Marin Brewing Co. uses some wheat in their ale--but I ventured for the use of rice instead (to be precise I used 4 lbs Alexander's pale LME, 1.5 lbs dry rice extract and about 14 IBU's (can't remember the hops)--then add 4oz of fruit extract at bottling). I was very happy with this light, extremely drinkable, blueberry concoction. I will admit that the blueberry was not tremendously strong (i.e. could have been a little stronger). My best guess is that by adding the fruit extract directly to the hot priming liquid, I may have reduced the flavor and aroma of the blueberry extract. So I suggest adding the extract to cool beer before bottling/kegging. But in general, the beer was extremely well received--especially with my friends who like the lighter beers.

For heavier beers, I would guess that you might need substantially more than 4 oz. Good luck. tom

Subject: SS Stock pot prices

>I would like to get a ten gallon stainless stock pot, but they cost about \$175 new.

Well, that may be the retail price but you can do much better. I bought my 10 gallon stock pot mail order from Rapids Restaurant & Bar Supply for \$125, including lid and shipping.

BTW, stainless steel is a poor conductor of heat and can develop hot spots that will scorch the wort. Better quality SS stock pots (Volrath) have aluminum clad bottoms to help distribute the heat.

I can't recommend Rapids highly enough. When they they sent me a Polarware stock pot (no aluminum clad) instead of the advertised Volrath, they sent me the proper item right away AND arranged and paid for the UPS pick up to return the incorrect pot. I have no connection with Rapids other than as a satisfied customer.

Subject: re: Mead questions

John (XLPSJGN%LUCCPUA.BITNET@UICVM.UIC.EDU, whatever that might mean!) writes about mead for his honeymoon:
[startup info deleted]

> The mead is now racked into 2 lgal. bottles (one is full to the neck,
> the other about only 1/2 full). OG: 1.055; SG @ racking: 1.010.

OK, with starting gravity only 1.055, this is intended to be light.

> The taste before pitching was exquisite, with an almost perfect
> balance between the honey, ginger and razberries (about a pound of
> those) However @ racking, the fermentation seemed to have hurt the
> flavor, with an off flavor best described as like A & D Ointment!...

Would you consider trading one brand name for another and describing the taste as "Listerine"? If so, "do not panic; this is perfectly normal"! It's the taste of a young mead. I've been able to avoid it with the right yeast, but if it happens it's nothing to worry about.

>...The "bouquet" seemed to have soured as well, offering a smell more like
> ripe yeasties (like when we clean our carboys after bottling). Is
> this normal and/or will these flavors mellow and balance within a few
> months? That's question #1.

It's hard to tell from the description, but it doesn't sound out of the ordinary. Meads *do* take longer to finish, and they get some pretty weird characters at early stages along the way. The best I can advise is that if you smell/taste something that is *obviously* wrong, you've got a concern, but if you only find something strange, that you can't characterize, don't worry.

> Question #2...[fermentation temp]
> ...roomand do give off some heat (I'd estimate that it's a steady 80F
> though I've not yet monitored the temperature)...

Meads tend to do OK with higher temps. (They ferment slower anyway; higher temps seems to move them along quicker, mostly without bad effect.) 80F does seem a bit high, not unreasonable but more than you might like.

From: Cree-ee-py Boy <BIRMINGH@FNALV.FNAL.GOV>
Subject: Trappist, oatmeal stout, and red ale recipes

In HBD 1297, Aaron Birenboim asks:

> would somebody out there be kind enough to send me a nice abbey ale
>recipe. I'm leary of those in rojette's book. (all grain and
>candi-sugar preferred.)

Well, I don't have it with me, but the recipe in Dave Miller's
Complete Handbook of Homebrewing is one with which I have had good
results.

While we're on the topic of recipes, I've seen requests for
recipes for both oatmeal stout and red ale. I was brewing both at the
time, but I hadn't bottled yet so I decided to keep my mouth shut
until

I learned how they turned out. So, without further ado:

Barney's Flat Oatmeal Stout

6.0 lb DeWolf-Cosyns Pale Ale malt
1.0 lb (Briess?) roast barley
1.0 lb flaked barley (the stuff Kent sells)
1.0 lb Quaker oats (the 5-minute stuff)
2 oz Northern Brewer pellets (alpha=6.8, 60 min)
Yeast Labs American Ale yeast (3rd consecutive pitch)

Single infusion mash in 12 quarts water for 2 hours at 150 degrees

OG 1051 FG 1014

Don't be fooled by the name; this is not a Barney Flats clone. I
just thought it'd be a cool name. (Does anybody know where I can get
a

postscript file of a certain dinosaur covered with tire tracks?)

Two words for you: SET MASH. I normally do not mash out, and even
when I do I usually only do a cursory mashout. I strongly recommend
you

get the mash temperature to 170 degrees before running off, and do
not

let it cool. It was so much trouble that I swore at pitching that
unless this beer was heavenly, I'd never make another. I'm going to
try

to make one with cocoa and coffee this weekend.

This is an extremely smooth beer, with a goodly but not
overwhelming roast barley flavor. The only problem is that it is
still

flat after a couple or three weeks in the bottle because I left it in
the secondary long enough that there was very little yeast in
suspension. Pouring it from a 1-foot height doesn't generate any head
to speak of (can *your* beer do this?)

Butt Pimple Ale

9.0 lb DeWolf-Cosyns Pale Ale malt
.5 lb DeWolf-Cosyns Caravienne
.5 lb DeWolf-Cosyns Biscuit malt

.25 lb DeWolf-Cosyns Special B
.25 lb DeWolf-Cosyns caramel pils
.8 oz 50/50 mix Willamette/Cascade (alpha=6.0 avg, 60 min)
1.0 oz 50/50 mix Willamette/Cascade (alpha=6.0 avg, 30 min)
.25 tsp Irish Moss flakes (15 min)
1.0 oz 50/50 mix Willamette/Cascade (alpha=6.0 avg, 15 min steep)
Yeast Labs American Ale yeast (5th consecutive pitch!)

The respective alphas of the Cascade and Willamette are 7.4 and 4.6. The 50/50 mix is by weight, and whole hops were used for both.

Mash in 14 quarts water for 90 minutes at 153 degrees.

OG 1060 FG 1020

I call this "Butt Pimple Ale" because it's big, it's red, and it's been a pain in the ass.

This has turned out pretty well. I had some problems with it, namely that it stopped fermenting at around 1030, but I racked from the 7-gallon carboy into a 5-gallon jobber before I measured the SG. So, when I moved it closer to the water heater, I had to install a blowoff tube. When it stopped blowing off, I installed an airlock and moved it back to the normal fermentation area, at which point it began blowing off AGAIN.

This was the fifth re-pitching from this yeast purchase, and the yeast seemed to behave differently from previous pitchings. Previously a cake of yeast would form on top of the beer and remain there after fermentation was complete. Also, the yeast had not seemed to hate the lower (60 degrees or so) temperatures quite so much (although my roommate turned the heat off over Thanksgiving, so the beer may have gotten even colder than that.)

In any case, this beer has a medium-red color, pretty good body, and a slight bite in the finish which I don't think is from hops. It has some hop flavor, but I'd like more. It seems to have little hop aroma, but I don't trust my nose right now. I'll likely brew this again, but perhaps dry-hopped next time.

I only bottled this beer last night, so things could change. I'll tell more when I know it; e-mail me if you want to know more.

Subject: lagering questions

Howdy,

We (my housemate/brewpartner and I) are about to embark on our first true lagers and I would like to pick the collective HBD brain. The plan is to make

first an amber fest-style lager and then a double bock. I have a very swollen

packet of wyeast bohemian lager yeast which will be made into a 1L starter

tonight so that we will brew thursday or friday. The fermentation and lagering

will be done in our back room which is now a relatively constant 52 F and will

probably get down into the 45-47 F range in Jan. and Feb. The questions are:

1) Should I start fermentation (ie primary) directly in the cold room or should I begin in the basement (about 62F) and then move to the cold room after

things get really perking? and 2) Does someone out there have some good extract

recipes for these styles? Something approximating Wurtzburger Hoffbrau's oktoberfest would be nice for the amber and something like Paulaner Salvator

would be great for the Dopplebock. I already have a mental approximation but

some experienced advice would be appreciated.

Send your replies directly unless you have something of general interest.

Thanx,

Mark Fryling

From: Will B. Blalock <willb@hp3.imed.com>
Subject: Kegs -vs- stock pots
Full-Name: Will B. Blalock

I have a few comments concerning an item in the last digest that questioned the use of kegs -vs- real stock pots.

No doubt that if you have deep enough pockets for real SS stock pots, it is the superior choice. Actual pots have extra metal on the bottom to aid in even heating. They have lids that fit, and are easier to clean. The problem I am having with pots is that if you try to find one any bigger

than 20 quarts or so, the price seems to escalate exponentially. I have been checking restaurant supply wearhouses and pots that range from 10 to 20 gallons price from \$100 to \$200. The formula seems to approximate \$10/gallon (actually a linear progression.)

My only problem with SS kegs is ... I can't find any!!! I have called almost every keg retailer in my area and South Houston and they are telling me the same thing, "Those went out about a year ago."

I called beer breweris and their distributors only to be turned down. In short, I may have to buy stock pots since I can't find any SS kegs. There are plenty with SS casing, but they all now have aluminum casks. My next and only step is to start putting ads in the local want ads. I may get lucky, yet I too am begining to wonder if kegs are worth all this trouble, especially when you consider the job of re-conditioning I have to go through after finding them.

From: reeves@lanl.gov (Geoff Reeves)
Subject: Bottle Inspection

>The AHA beer judging form starts off, after identification of the
>style and the judge, with the category "bottle inspection". There
>are no points awarded in this category, just comments. I have
>several questions, such as:
>
>What is the purpose of this section? Recently I received comments in
>this section of "short fill" and "low fill line". e
>
>Chuck Wettergreen

This is one of my pet peeves with respect to judging. The bottle can actually tell you a lot about possible problems with the beer inside. A white ring around the neck can indicate bacterial infection. Lots of head space can sometimes cause oxidation. I've even judged bottles that are half (yes half) full of trub! Some judges feel they have to write something in the bottle inspection portion and the most common comment is something about the fill height. A few years ago as the AHA members generally became more aware of the problems of oxidation there developed an attitude that the bottle should ideally be filled exactly to the top with no air at the top. This idea is absurd! Yes, if the beer is oxidized then lots of air in the bottle neck could be the problem and it is worth noting on the judging form. If the beer is not oxidized then you can fill as short as you like and no one should comment on it. I counter-pressure bottle much of my bottled beer and the bottle can be only half full and still have no oxygen in it. I've actually commented on bottles being too full in the bottle inspection portion. When is a bottle too full? When you have to be careful opening it. My advice to other judges is that for 99% of the beers we judge should just have "OK" in the bottle inspection area. My advice to people having their beer judged is to ignore most bottle inspection comments unless they are related to the flavor of the beer. Of course no one asked my advice ;-) Chuck just hit that beer-judge-snobism nerve.

From: "Mark T. Berard" <mtberard@dow.com>
Subject: Pure Oxygen Sources

Recently (HBD #1297) Bob Jones asked about adding pure O2 to his wort:

>From: bjones@novax.llnl.gov (Bob Jones)
>Is there an inexpensive source for pure oxygen to use in wort
oxygenation?
>Anyone out there using pure oxygen for wort oxygenation?

And Jim Busch responded (HBD #1298) that he was using a NEW welding O2 supply:

>From: Jim Busch <busch@daacdev1.stx.com>
>Sure! Despite reading that it is best to use FDA approved O2, I went
>out and bought a tank of welding O2 (new). My local Phd/lab friend
(snip)

Given the "tinkering" bent of most of the people here, I just wanted to comment that old equipment shouldn't be used with pure O2, especially the regulator. O2 requires a special regulator, and it shouldn't have been used for ANYTHING else. O2 is highly oxidating, and so any oil or grease in your lines, especially the regulator, could ignite and explode. If this happens in the regulator, you have a nice schrapnel bomb, plus a ready supply of O2 now feeding the flames in your ruined garage, making it hard for the rescue team to pull your body out and rush you to the ICU.

Serious bumner. With equipment designed for the job, no problem. With the wrong equipment, this would make a steam supply pressure cooker bomb that people have worried about here look like childs play.

Also, I agree that nothing will live in the pure O2 environment. Your only worry would be contaminant gases. So I doubt Jim needs to bother with the 0.2 micron filter. Anyway, relax. Don't worry. Have a homebrew. But don't hurt yourselves! Don't let Hazard Hog get you.

Subject: Oxygen and hydrometers

In hbd 1298 Jim Busch mentions oxygen use. I would warn him that levels over 14 ppm can be harmful. I read this figure in a chemical technology encyclopedia's section on beer (Kirk-Othmer, I think). From a practical point of view, this means that care must be exercised when O2 is used to oxygenate. The limit of oxygen solubility when air is used is around 8 ppm, which is related to the partial pressure of oxygen in air, 0.21. This means that aeration with air, while safe, is less than optimum. However, wort saturated with oxygen may have over 30 ppm of oxygen (the dissolved sugars may lessen the amount of oxygen that can dissolve in wort relative to water, but probably not by too much). Breweries, naturally, will have the money to pay for dissolved oxygen probes, but these are not within homebrewers budgets.

Hydrometers - I seem to remember that Cole-Palmer sent me a supplement to their catalogue that had many hydrometers listed and the ones I considered professional were \$30-40. However, I seem to have lost that supplement. In their regular catalogue all the hydrometers seem to cover a large range. Still, they might be worth a call 1-800-323-4340.

Someone wanted Jim Koch address to send poison pen letters. The letter I received from him today mailed without a stamp from Nashua, NH listed The Boston Beer Works, The Brewery, 30 Germania St., Boston MA 02130 as an address. Incidentally I also got a letter from the AHA going on about how great they are (is this all a sign of insecurity on the part of both organisations?) and inviting me to the AHA 15th Anniversary Homebrew Rave, to be held in Denver on December 4, 1993, with a RSVP date of Nov 22. Still efficient as ever!

P.S. How come Molson Ice bottles have alcohol content printed on them? Is the bureau of anus touchers and fondlers becoming a little less, anal?

Did you take any specific gravity readings? May I suggest that you simply made very strong cider. Let's look at the recipe:

> 4 gallons natural cider
> add 5 lbs clover honey diluted to 1 gallon w/ water

I don't have any of my references here, so I may be a little off on my numbers, but assume the natural gravity of the cider is ~1.050, and that 1 lb of honey (in 1 gal water) is ~1.032. Thus your recipe has $50 \times 4 + 32 \times 5 = 360$ "gravity points", divide by the final volume of 5 gallons to get 72. So your original gravity was ~1.072, which is somewhere in the neighborhood of 7% potential alcohol. Pretty potent stuff. If you don't want as much alcohol, cut back on or eliminate the honey entirely.

I have my first batch of cider fermenting myself, and it's original gravity was 1.070. It fermented further than any beer I've ever made, going all the way down to 0.995! This gives it an alcohol content of about 8%, and you definitely can taste it. I'm looking forward to enjoying it--a little bit at a time.

Subject: New Book on Hops

The following reference has just come to my attention:

Chemistry and Analysis of Hop and Beer Bitter Acids
M. Verzele and D.DeKeukeleire, Eds.
Developments in Food Science
Vol. 27
Elisvier Sc. Publ., New York and Amsterdam
1991
418 pages

I have only had a chance to give this one a quick first reading, but from this perspective it really looks good. It is loaded with ideas relating to alpha measurement, some of whom seem elementary and potentially "homebrewable". The general discussion on hops is technical but quite good. They appear to take the cohumulone issue head on!

Dr. Verzele is at the prestigious brewing school at Univ. of Ghent in Belgium. He wrote the outstanding article (IMHO) on hops in the Brewing Science sequence edited by Pollock.

Given the publisher of this new book, it is likely to be found in many university libraries.

>batch.

I do this all the time, sorta. I brew one batch with the fresh yeast (using a yeast starter- fyi) and three days or so later, when I rack this batch to the carboy, I pitch this yeast into yet another starter. In a day this starter is real active and ready to be pitched into the second batch. I have skipped the creation of the second starter and just went ahead and pitched the sludge into the 2nd batches' wort. I've never had any problems with either method and it does allow you to get two uses out of one yeast pack. I did get an infection or wild yeast once when I tried to get a third use by using the sludge of the 2nd batch.

But, they may or may not have been the sludges fault. So to be safe, I only go for the dual use.

This is similar to my method but requires rubber gloves (dish gloves, whatever). The very first thing I do when I start to brew is to take the bag of syrup malt extract out of the frig and soak it in the sink 1/2 full of hot tap water. Begin heating the brew pot water. When it reaches about 170 (or so) degrees turn off the heat. Cut open your bag of M.E. and slowly dump it into the soon-to-be wort while mixing. When you reach the point where not much more is flowing out, open the bag and dip it into the wort and allow it to fill as much as possible. Of course, you should have your gloves on before that step! Shake the hot liquid around in the bag and dump it into the wort. It may take another scoop to get all of the malt out of the bag. With this method I can get almost every drop of malt out of the bag. And, if you're careful, and once you get used to it, it's really not messy at all. ..and it only requires one person. ..but then what do I know, I used to be a college student. ;-)

Subject: HWBTA Annual Competition

Subject: Time:9:10 AM
OFFICE MEMOHWBTA Annual CompetitionDate:12/15/93
I recently received entry materials for the annual Home Wine and Beer Trade Association's Homebrew Competition. I have entered this competition for a number of years as I had perceived it to be a well run and competitive competition on a national scale. I am feeling reluctant to enter this competition this year for several reasons. Entries are due by the end of January. The actual judging will be held at the end of March and the winners won't be announced until the Association's annual conference will be held in UK in June. Homebrew is a fragile product which when brewed to the *lighter* styles has the potential to change in character fairly rapidly. When one is not pasturizing or filtering, shelf life is short. I just have problems with any competition which incorporates exceptionally long lag periods between the entry date and the actual competition. Not announcing the competition results for another three months seems ridiculous. Competitions are for the competitors, not for organizational self aggrandizement. But perhaps I am missing a piece to this puzzle. Can anyone shed light on the rationale for this strange schedule?

>> Anyone out there using pure oxygen for wort oxygenation?

>Sure! Despite reading that it is best to use FDA approved O2,
>I went out and bought a tank of welding O2 (new)

Two possible issues come to mind. FDA O2 as used for medical applications has been rumored to contain an anti-fungal agent. I have not been able to get this firmly confirmed nor denied by my contacts in the medical world. Industrial grade O2 may not contain any bugs but may contain oil or other contaminants which do not cause problems with normal applications.

>Does actual bottle condition, ie. scratched or sanded, have
>anything to do with judging the beer?

No, not really. However, there is a school of thought which believes that presentation is a factor. If you send in a beer which is in a shoddy container it may indicate a lack of appreciation for the stuff inside and a general sloppy attitude towards brewing. Mind you, I am not advocating this point of view just relaying it. I suspect the inspection bit is a hold over from the early days when many more beers arrived at competitions containing contaminants. I don't know that it has any value now especially since the AHA does not consider it point-worthy.

Perhaps a discussion of this on JudgeNet would get other explanations and/or support or get it removed from the sheets.

>Any explanation for the alcohol aftertaste.

I think it is because you made an apple mead and not hard cider. All of
that
honey you added is going to boost the alcohol content. It should mellow
with
age. From what I've read, this could take about a year.

- -----
And now for my own question:

What are the pros and cons of lagering in secondary vs. lagering in the

bottle?

From: "Taylor Standlee" <standlee@humanitas.ucsb.edu>
Subject: Cloying Sweetness, Why?

I tested a bottle from our latest batch of Spiny Lobster Ale, a tried and true recipe, and was chagrined to find that it had no head retention, large bubbles that fizzled in the mouth and a cloying sweetness (I hesitate to say sherry like sweetness because I was very careful not to expose the hot wort or raw beer to air). The recipe I follow is:

7 # 2-Row
1 # Amber Crystal
1/2 # Wheat (for head)
1/2 # Dextine
1 oz Chocolate Malt
1/2 tbs Irish Moss
1 oz Hallertau 45 min
1 oz Hallertau 5 min
Wyeast American/Chico Yeast (made into a 1qt starter)

All grains mashed at 152 for 1.5 hours, sparged with 3 gallons of 165 H2O.
1.5 hour boil, hops added as scheduled. Wort was cooled with a copper wort chiller to 70 degrees in 35 minutes at which time the yeast was pitched. Vigorous fermentation began in 6 hours. Fermentation was conducted in the garage in at temps between 55-63 degrees. Bottled with 1 cup of DME. (Note: the bottling tank had been used to bottle a batch of root-beer, but was soaked, sterilized, and rinsed 2 times before reuse).

I was very careful in sterilizing EVERYTHING. It has been in the bottle for 2 weeks and this flatish sweet stuff is really depressing me. Any ideas as to what went wrong?

From: korz@iepubj.att.com
Subject: when to bottle/bottle inspection/Fuggles in the boil

Jim writes, quoting me:

>> From: korz@iepubj.att.com
>I usually wait till the airlock is bubbling less
>> than once per minute, often waiting till it's less than once per two
minutes.
>
>If you have good experience with this method, fine. But if you are
tweaking
>variables all of the time, like I often do, please take a hydrometer
reading
>to determine when to keg/bottle. The 'ole bubbles per unit time can be
>quite misleading.

I'd like to discuss this a bit. The cases where I could see the "bubbles
per unit time" method to be misleading are:

1. if there was a big temperature swing in the middle of the ferment
(which could cause your yeast to go dormant for a while),
2. if you are used to doing ales and then do a lager (which will have a
much
lower bubbling rate throughout the ferment -- I think I waited till 5min
between bubbles on the last Bock I did (at 45F)),
3. mixed yeasts (the Whitbread triple-strain (Wyeast #1098) has been
reported
to have a slowdown in the middle of the ferment, for example), and
4. high-alcohol (very high OG) brews (I know I should have tested the FG
on
a recent Imperial Stout -- I would have done something had I realized
that
my FG was 1050 (OG was 1120) *before* I had bottled).

Have I missed some?

I agree that hydrometer readings are a good idea, especially if a
particular
batch is extreme or did not behave normally.

Let's discuss this.

Chuck writes:

>The AHA beer judging form starts off, after identification of the
>style and the judge, with the category "bottle inspection". There
>are no points awarded in this category, just comments. I have
>several questions, such as:

>fill *could* be indicative of potential oxidation, although oxygen
>absorbing bottle caps *may* negate potential oxidation risk from air
>in the bottle. However, if no points are awarded, what's it there

>for?

Partly for historical reasons, but I think it may be just to remind judges to look at the headspace and perhaps the sediment before pouring. This information can be used later if a problem in the beer is found and suggestions for improvement are in order. I use this area also in small, regional competitions to mention the AHA National rules to the brewer if they used a raised-design, oversized or swing-top bottle.

>Do oxygen absorbing bottle caps negate the potential for in-bottle
>oxidation?

I don't think they negate it, but I feel that the effects of oxygen on beer are much more detrimental when the wort is hot than when you are bottling. I'm in the midst of an experiment on this topic. Experiments have shown that these caps *do* increase hop aroma longevity.

>Does actual bottle condition, ie. scratched or sanded, have
>anything to do with judging the beer?

It should not, but let's be realistic... a scratched, scuffed, old bar-bottle may start the judges off (subconsciously) on the wrong foot. Consider two term papers, one typeset the other printed on an 9-pin printer with an old ribbon. I'll bet the typeset one has a measureable advantage.

Chris writes:

>In his book on Pale Ale, Terry Foster includes a table of
>hops varieties and suggested uses in Pale Ale. He
>recommends Fuggles hops for aroma/finishing only, and not
>for bittering. Aside from the modest AA content of
>Fuggles, is there any other reason why I shouldn't have
>used them last week?

Cost per AA content -- consider the cost of putting 180 IBU worth of 2.3%AA Saaz in an Imperial Stout! There has been some debate, here and elsewhere, about whether the type of hops used in the boil make a difference. I, personally, feel that it does make a difference and avoid using two hops which I have found to give a "rough" bitterness even if used only for a 60-minute boil: Chinook and Clusters. Everyone has different tastes, however... try them for yourself and see if you agree.

As for Fuggles in the boil -- I use them often.

Al.

Gee, Chris, I hope you've had all the children you wanted! You haven't
actually drunk any have you!!!!???

Urf.

Terry Foster was waxing a bit snobbish. Fuggles is, in fact, a fine hop
(so is its clone: Willamette), and makes a very nice late addition. Of
course the Classic (TM) finishing hop for English ales is East Kent
Golding -- but there are a lot of really good English hops that British
brewers use, including Fuggles.

Really, they're just fine.

Subject: Head Retention

Message Creation Date was at 15-DEC-1993 12:14:00

Greetings,

I've been having erratic head retention problems of late: i.e. some batches are fine & some are lousy (even though carbonation is fine). I've tried protein rests, addition of wheat malt, as well as other malts purported to increase head retention but with no concrete results. Now I have a new theory on which I'd like some feed-back. Polyclar. I don't use this on my darker beers & they generally have the good head retention. When I do use the Polyclar (2 tsp/5 gal) I do get a clearer beer, but in general these "clearer" beers don't keep a head. Am I barking up the wrong tree, or is there a common thread here? Basically, do I have a trade-off: clarity vs. head for my light colored beers?

TIA,
Andy A

From: yeebot@aol.com

Subject: Re: First Cider Attempt

Scott,

My explanation for the alcoholic aftertaste: Alcohol! Probably lots of it.

My last batch made with 4gal cider, 2lbs honey, and Sherry Yeast produced a

batch around 10%. With all that honey in your batch, still producing a "very

dry" cider, my guess is that all that honey has been converted! I wouldn't

doubt your batch is 12%+ alcohol. Your batch will mellow with age, wait at

least a month after bottling for yummy results. I know some who wait at least

a year. A hypothesis: Cider that is made with honey (actually a "Cyser") may

take longer to mellow than ciders made with sugar adjuncts. Mead, made primarily from honey, has always seemed undrinkable under a year or so.

Anyone with comments/ideas?

Also: Good idea to rack often. Whenever 1/8" to 1/4" of sediment settles.

Question: What's the difference between Canadian, British, New England, etc.

styles of cider?

Subject: RE:RIMS & HSA

In a recent HBD, Bob Getty asks about RIMS and HSA.

I've been using a RIMS for about 2 years now. While I can't definitely attribute it to some oxidation problems I had, I did take steps to reduce HSA.

Originally, I used a setup similar to the one described, where wort is returned to a plastic tray with holes in the bottom. The amount of foaming

that occurred was quite impressive. Obviously, a lot of air was being introduced to the hot wort.

About a year ago, I decided to build a return manifold, to alleviate any HSA problems that I might have had. The manifold sits below the level of liquid in the tun, so no air can be introduced. There is now absolutely no

foaming that occurs. I have not brewed a beer with any detectable oxidation

problems since installing the manifold. I don't know if I really had a problem

to begin with, but I definitely don't now.

I brew in a 54 quart igloo cooler. The manifold is made from 1/2" id. copper.

tubes.

After mashing is complete, the wort return line is run into the kettle, and the sparge liquor line is connected to the manifold inlet.

>IMNSHO, the *minimum* useful size for brewing a five gallon batch is a
32
quart pot (8 gallons). You can get an enamel 8 gallon canning pot for
about
\$35 (with lid). This is what I'm using. The geometry is poor for doing
a 2
hour boil -- too much surface area for the volume.

The other side of the equation is that you can achieve a great deal of
evaporaton in a 2 hr boil, you just need to start with more sweet wort.
The
bottom line is you can increase the yield by extracting more sugar from
the
mash. You might also try using less heat if you have to keep the lid
on.

>I would like to get a ten gallon stainless stock pot, but they cost
about
\$175 new.....

Not sure how to kill this bit of bum information but they are available
from
several sources for around \$100. Call 800 553 7906 for a catalog from
one
such place.

Subject: update

just thought i'd let everyone know how our beer brewing is going and then ask a quick question or two.

we made a second batch on saturday and it went a thousand times better than

our first. before brewing this time i measured off the capacity of our carboy one gallon at a time and marked it with fingernail polish. (thanks to whoever suggested this idea) in doing this i found that in our last batch we had added about 3/4 of a gallon too much water. (go ahead and laugh...i did)

the boil went almost perfectly and we cooled the wort to about 90F in less

than 15 minutes in an ice water bath.

the only problem we had was that we didn't have a scale to weigh out the hops, so we had to guess on the amounts.

the o.g. was 58, but that included all the particles from the crystal malt

that immediately settled to the bottom.

the fermentation went very quickly. on sunday afternoon we were getting about 3 bubbles a second out of a 1/4" i.d. tube, but on monday the kreusen

was almost gone and we were only getting about a bubble a minute out of the tube.

so here are the questions:

1) why are wort chillers recommended? isn't an ice water bath almost as effective?

2) do ales normally have that short of an optimal fermentation time (the kreusen had settled after only about 36 hours)?

3) because of the high gravity boil the beer is not as bitter as i want it,

so i was thinking about dry hopping in a secondary. is there a recommended

time to do this or can i do it any time after the kreusen settles? also, can someone give me a range for the amount of hops to use in the secondary

(i know i didn't say how bitter our beer is right now, but i just want to know if most people use 0.5 oz. or 8 oz when they dry hop)?

sorry, my NCJoHB is at my friend's house and he is gone for a few days, so

i couldn't just look up the answers to these.

thanks y'all.

From: Timothy Sixberry <tsixber@msrapid.kla.com>
Subject: Questions

Hi fellow homebrewers/ drinkers,
This is my first publication in the digest and I wish I were answering
some
questions, but instead I must ask a few this time. I have been brewing
for
about a year and a half and have done both all grain and extract brews. I
have had good luck with both and not to many problems. It seems to me
though, that every time I think I have it down, I read about some new
method or device that is supposed to make the beer come out better. It
seems to me that the basics of making good beer are very simple, things
such
as sterility, accurate temps, good ingredients, a set of routine steps,
and
patience. So my first question is. If the beer is coming out good, why
complicate matters? An example of what I mean is the use of of oxygen
and
a bubbler system to airate the wort prior to pitching. Is this really
nessasary? I just shake the hell out of my primary a few times after
pitching the yeast, and I don't seem to have any problems. Will my beer
actually taste better if I go through this extra hassle? I can't
immagine
how a well mashed, properly fermented and lagered beer could be improved
upon even more. If my beer gets any better than it already is I don't
think
I will be able to stop drinking it. Thats a scary thought. What if I
made
my beer so good that once I took a drink of it I just could'nt stop? Man,
I
think I'd better go get me a beer to settle my nerves.

He who laughs last, drinks first.

Subject: Bottle Inspection

When I (rarely) write a comment in the "bottle inspection" part, I do it before opening the bottle. It thus serves as a reminder to me about the state of the bottle, so that IF I find flaws that might be related, I can refer back to it. (Short term memory is the first thing to go.... What was the question, again?)

I've also commented things that are obviously unrelated to the beer quality, such as a totally grungy bottle. Someone who wants me to judge their beer should at least have enough pride in their product to present me with a clean bottle. But, as you note, it doesn't affect the score.

From: cole@nevism.nevis.columbia.edu
Subject: Hydrometers / Haze problems

> Somebody asked why Jim Busch needs three hydrometers:

The reason is that the length of the tube in the hydrometer below the surface of the liquid varies > INVERSELY < proportional to the density of the liquid being measured. Since you get your reading from this length, the reading also varies inversely proportional to the density, i.e.

$$L = c * 1/\text{Rho} = L_0 + (\# \text{ of marks}) * (\text{distance between marks})$$

Writing this in terms of Specific Gravity:

$$L = c * (1/\text{rho_water}) * (1/\text{SG})$$

This is a simplified version of the full expression but it makes the point. You can think of it this way: the more dense the liquid being measured, the higher the hydrometer rises and the smaller the length of tube below the surface. This expression can be linearized for small variations around a nominal density, that of water. Expressing this variation in terms of specific gravity:

$$\text{SG} = 1 + \text{delta_SG}$$

$$L = c * (1/\text{rho_water}) * (1 - \text{delta_SG} + \text{delta_SG}^2 + \dots)$$

This means that if a hydrometer has to cover a range of specific gravities from 1.000 to 1.100 using a linear scale, there will be a 10% error in the measurement from one end of the scale to the other (due to the delta_SG^2 term). Thus, high precision (scientific quality) hydrometers use much shorter scales to improve the accuracy of the measurement. There's also the issue of measurement precision. If you want precise measurements (better than 0.001 error) the hydrometer has to have a larger change in L for the same delta_SG than those we use. Thus to cover the same range, the hydrometer becomes longer. Conversely, if you want to keep the length within some reasonable range, you have to keep the range covered by the hydrometer shorter.

If you look in a scientific equipment catalog there will be hydrometers which have smaller ranges than those used by homebrewers and they will come in a wide variety of NOMINAL specific gravities.

I have a problem that I would like to consult HBD experts on. Since I have been brewing all-grain beers, I have had lots of trouble with haze.

I have now done 8 all-grain batches. Two batches suffered from chill haze, two batches were satisfactory, and the rest suffered from haze problems that had nothing to do with chill-haze. These beers are cloudy even when warm.

* At first I used a grain-bag in a bucket style lauter tun. After the first

three batches I felt that I was not getting sufficiently clear run-off and switched to a copper manifold lauter-tun. After doing so, my run-off cleared much more quickly.

* For the last three batches I have PH treated my sparge water to reduce tannin extraction and have noticed a significant drop in astringency of the runoff at the end of the sparge.

* For the last few batches I have been careful to limit the amount of aeration of the runoff during the sparging process. I no longer try to heat the runnings while I sparge as this requires too much pouring of the hot liquor, I simply sparge directly through a hose into my boiling kettle until I have finished.

* I have had problems using both German Pilsner Malt (with protein rest) and British ale malts so I doubt that I am having protein problems (except maybe for those suffering from chill haze).

* I suspect starch haze problems. For the two worst batches, I added the crystal malts at the very end of the mash. On my last batch I was careful to do an iodine test before and after adding the crystal and found to my surprise that after adding the crystal, the test showed presence of starch where the pre-test showed none. Has anyone else observed this problem ???

* I am using a Corona mill and have been setting it to optimize (i.e. reduce husk shredding at the expense of having larger malt fragments and more uncrushed kernels. I suspect I may be extracting starch during the sparge from some unconverted chunks of malt. I certainly have to mash much longer than Miller would suggest (last batch - 3 hours for 10 # malt, 6# pale, 3# mild, 1# crystal). I would like to hear from other users of the Corona mill re: problems with starch haze / long mashes etc..

* I am aware of the potential haze problems from infection by wild yeast etc. One of my bad batches was fermented at 40 deg. and lagered at 32 for a month. I don't know if bacteria or wild yeast could survive these temperatures long enough to give me troubles. Also I have not been able to detect any significant off-flavors in the two batches which suffered the worst haze problems. That doesn't mean that they weren't contaminated - I just may not be able to tell. I would be willing to send a couple of bottles to someone who thinks he/she can detect off-flavors produced by wild yeast fermentation.

Unfortunately, I have not been able to correlate the source of the haze with any of the above changes/variables. My best two batches can be between two bad batches. I would welcome advice from experienced all-grain brewers.

Cheers,

Brian Cole

From: rcd@raven.eklektix.com (Dick Dunn)
Subject: accurate hydrometers

A while back I got a "bottling hydrometer" to use along with the regular one. It helps a lot. The full-scale range is 0.980-1.020. (This compares to about .990-1.170 for a standard brewing hydrometer.) Cost: about \$15, from William's Brewing. This is a good middle step between the old standard full-range hydrometer and expensive lab-grade equipment.

I find it useful for two reasons. First, obviously the 4+ x expansion of the scale makes it much easier to read--the 0.001 units on the bottling hydrometer are more than twice the size of the 0.002 units on the regular hydrometer.

Second, meads often finish up down around 0.990; it's nice to have some extra range on the hydrometer below that. (I suspect the bottom .010 on a regular hydrometer isn't all that accurate, since there's only a tiny section of the tube left above the liquid.)

I don't find a real need for an expanded-range hydrometer at the higher gravities. Anything that's up there is generally fermenting quickly, hence changing gravity quickly, hence a precise reading doesn't tell you a lot. I use the regular hydrometer for the early stages, then switch to the bottling hydrometer when things stop changing much.

Note that if you use an expanded-range hydrometer, you need to pay more attention to the standard cautions about not having glop on the hydrometer (especially on the part above the fluid line) and about measuring at calibration temperature or applying temperature corrections. Otherwise you're just buying precision, not accuracy.

Subject: Hops question

This is a little late, but what the hey.....

I've been reading the recent discussion about hops and utilization and also this information in the Hops FAQ and I admit to being a bit confused. I plan on brewing a beer more or less following Papazian's Righteous Real Ale.

Now, I understand the concepts of IBUs, HBUs, %utilization, etc., but I'm not sure that I'm using the formula's correctly. So I plan on boiling 6 lbs. of malt extract in 1.5 gallons water for 45 min. per the recipe. According to Papzian then, I should get ~19% utilization. On to the formulae (also from Papazian)-

$$\text{IBU} = \text{HBU} * \% \text{UTIL} / 6.7$$

I want a target HBU of 8 so:

$$\text{IBU} = 8 * 19 / 6.7 = 22.7$$

OK. Now it's this part that for some reason is bothering me (sorry, Charlie.)

$$\begin{aligned} & \text{Weight(in oz)} * \text{AA} * \% \text{Util} \\ \text{IBU} = & \text{-----} \\ & \text{Volume} * 1.34 \end{aligned}$$

Now I plan on using Cascade (AA=5.5) for bittering so...

$$\begin{aligned} & \text{Weight(in oz)} * 5.5 * 19 \\ 22.7 = & \text{-----} \\ & 5 \text{ gal} * 1.34 \end{aligned}$$

So Weight(in oz) = 1.46 oz --call it 1.5 oz

Have I got it right (assuming I've done the math correctly)? Sorry if this question has been answered in the recent discussion. I suspect that it has, but I didn't recognize the answer as such. Thanks in advance--

Rob

Subject: Bubbles/time and Threaded neck carboys

Al and Jim discuss hydrometer measurements vs bubbles per unit time.

The only time I have ever had false indications from the bubbles per unit time method is brewing ales at the low end of the temperature range. ie, fermenting in the basement during the winter.

I previoulsy used the bubbles to know when to bottle, and one hydrometer measurement at the begining of the bottling process make sure I wasn't mistaken. I didn't monitor the SG because I felt the risk of infection/aeration was too high. Since I switched over to the BrewCap (tm) system, I can monitor SG carefully, with much less chance of infection/aeration.

A while back I remember someone mention that their brew was bubbling `once per hour'. While I always waited for less activity than once per minute or two, I can't imagine being carefully transfixed on an airlock for more than an hour waiting for that second bubble (to get the time increment).

I have had difficulty siphoning out of my 6.6 gallon acid carboy because the orange cap (siphon starter) doesn't seal on the threaded neck. For those of you in a similiar situation, a solution is to use an O-ring to help seal the orange cap. A 2" OD, 3/16 thick O-ring should do the trick. It fits in the groove just below the top lip of the carboy. It doesn't work quite as well as having a standard neck carboy (the one the cap was designed for), but its inexpensive and passible. For those asking for carboys for Christmas, getting a standard neck will save a lot of grief, and they come in at least 5, 6, and 6.6 gal sizes.

For clarity, the orange carboy cap has nothing to do with the BrewCap system and should not be used upside down as it will impart bad flavors to your brew. The BrewCap doesn't fit on threaded neck carboys.

Subject: bottle inspection

The "Bottle Inspection" comments in an AHA competition can also tell you how well your bottle did in transit. I had an entry panned, big time, with comments like "phenolic, astrigent" and the ultimate insult "keep on trying" :-). At the time it was the best beer I had ever brewed, and everyone who tasted it thought so too. It had no phenols. I thought it compared very favorably with the best of brewpub ales. So what happened? Well, one strong indication was the comment "low fill line" in the bottle inspection. I *knew* I had filled the bottles correctly. So *something* happened that "hurt" my beer. Maybe the cap was loose and it picked up some "flavor" from the surrounding plastic bag. Maybe the bottle somehow got switched with another. I'll never really know. But in this case, the "Bottle Inspection" comment was a valuable diagnostic for the *brewer*.

FWIW, since I still had 2 bottles of it, I immediately tried one. It was fine. I sent the other off to a certified beer judge, who confirmed it was a good beer, without any of the phenolic/astrigent defects noted in the competition report. He did say it was "out of style" though :-)

From: Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU>
Subject: early racking question

Having read on HBD that early racking can minimize the reabsorption of diacetyl by the yeast (the point went unchallenged when it was made, I think -

is that right?) I decided to try that technique last night with a (hopefully) Scottish Ale I have fermenting. When I made the transfer, the gravity was down from a starting 1060 to about 1040, so it has plenty left to ferment out. My question is, since the beer is less than half-done, gravity wise, isn't there going to be a lot of yeast still to reabsorb that beloved diacetyl when the secondary is done?

Supplementary info about this brew for those inclined to consider my query, and some side questions. This was an extract/specialty grain recipe as follows:

1 lb. dark crystal malt
1/2 lb. chocolate malt Steep in grain bag while heating water & remove
2 tsp. gypsum
6 lb. William's English Light Syrup
2 lb. William's EL DME
4 oz. Maltodextrin pwdr.
2 oz. English Fuggles (4.7 A.A.) boil for 60 minutes
1/2 tbsp. Irish Moss last 15 minutes
Wyeast "Irish" from starter

Yes I know Wyeast has just come out with a "Scotch" Ale yeast but I haven't tried it.

A second reason I decided to rack early on was that the bottom of the primary has the most disgusting looking trub in it I have ever seen. Really, it looked like a brown version of what gets stuck like stalagmites in my kids' noses. Big CLUMPS of yuck. Why could this be? Is it something to do with maltodextrin powder (I've never used it before)? Or is it more likely that it has something to do with the fact that I didn't get a very good cold break (I attempted to "whirlpool" but I think I did it too late, after some of the cooling already had taken place, so I probably just re-suspended the break material. Duh.)?

Trying to save the yeast from the primary after racking this early was a real adventure too. I almost had to call the National Guard to keep it from taking over my house. "I'll just throw this stuff in a mason jar," I sez. Hah! After watching the foam escape the loosely-fitting (good thing!) lid

and try to crawl out of the sink, I diverted some of it to a starter
(give it
something to eat and it will go to sleep) in a 1L flask. Should have
used
the gallon jug - this morning the stopper & airlock had blown off the top
of
the flask and it was foaming away merrily. Having read all kinds of
things
about "open fermentation," though, I confidently re-plugged it and
cleaned
the outside of the flask. The rest of it, in the mason jar, I gave a
cold
shower. A brief ice-water bath and then transferred to the fridge, to
which
I returned every few minutes to "burp" the jar until the belches were no
longer quite so rowdy. This morning, thankfully, the jar was intact so
we
didn't have to have brown scum for breakfast.

How early did I rack? On the fourth day of fermentation, to be precise,
or
to be even more precise, about three and a half days after fermentation
began
(I had a 12-hour lag because I had let the starter sit around too long).
At
this time, the fermentation in the 5-gallon glass primary had subsided so
that the blowoff hose could be removed, the airlock was bubbling at about
1/
5 sec., and the krausen had subsided noticeably although it was far from
gone.

Did I rack too early? Normally, when I rack to secondary - usually for
dry
hopping or for extended settling of a light colored beer so it doesn't
sit on
the trub - I wait about a week, at which time the fermentation is mostly
over: bubbles at 2-4/min., krausen disappeared. Are there any proponents
of
"early" racking out there who would like to comment? Anybody think
"early"
racking is a waste of time? Come on now, let's take the gloves off and
have
a few rounds of good clean fun.

From: JEBURNS@ucs.indiana.edu
Subject: All-grain equipment & Kegging

I have been reading HBD for about two months now and have finally decided to post a few questions. I moved from Washington State to Indiana (my wife is going to grad school here), homebrewing is fairly popular in WA. There are also quite a few micro-breweries, my favorite is Red Hook from Seattle. I just started brewing again after the move (had to leave my carboys at home), I have found the HBD to be very helpful, its nice having a net connection. Anyway I would like to start ewing all-grain beers, up until this point I have been using extracts and specialty grains.

Question #1- It seems that there are a lot of people on the HBD who use the modified picnic cooler method. This method isn't really discussed by Miller. I would like comments on this system both positive and negative. Is it only used for single temp mashing?

#2- What are the advantages/disadvantages to using 2-row vs. 6-row malts? Is American Klages 2-row modified enough to use a single temp mash? Red Hook uses that type + you can get it pretty cheap (\$20 for #50 + shipping)

#3- I don't want to start a "my system is superior to your system" war but, I would like to hear about different methods that people use. Basically I'm looking for a method that I can use in my kitchen (no 3 billion btu cookers etc...) and is pretty simple. I understand the basic process that is involved but haven't decided on the equipment. Any suggestions or warnings about systems that I could build or buy would be appreciated. Commercial products too (Easymasher, RIMS etc..)

#4- I have two Cornelius kegs that I would like to use. I can't afford a CO2 tank and reg. So I would like to use them for parties (drink it all before any oxidation). I can order the connectors and a dispenser but I would have to rig up some sort of a pump to displace the beer. Would this work? Any suggestions for pumps? I was thinking about a foot operated bike pump. They also make a small CO2 bike pump, how many cartridges would it take for 5-gallons of brew?

Thats all. Next time I won't wait until there are so many.

> We exchanged mail on this subject but you failed to mention the hole size of
> the lauter tun false bottom. It looks to me like another classic example of
> how scaling down commercial equipment to homebrew sized batches just does not
> work very well. 3/32" holes are probably too large for the geometry of a
> homebrew tun.

<Jack, what would the scale of the brewery have to do with the sizing of the holes in the lauter bottom?? This is a function of the size of the grain itself as the purpose is to server as a seive allowing wort ot pass through but grain to remain behind?? Can you explain the basis of your comment linking the size to the scale of the brewery??

I probably couldn't before receiving another letter from the originator of the thread. My only argument was that if 3/32" holes work in large tuns but not in a small one, it must have something to do with geometry.

Turns out that grain for a 5 gallon batch "barely covers the bottom" so he is forced to make larger batches but apparently not large enough. So I was on the right track but probably for the wrong reason. The larger holes only work well with a large depth to diameter ratio but smaller holes would be more forgiving. I am not sure why one would want larger holes and thereby put such constraints on the aspect ratio but therein at least, seems to be the answer.

For the record, the screen I use on the EM has 32 mesh screen and taking the wire diameter into consideration, the hole size is roughly ten times smaller than the "professional" size.

> I hate to sound like a broken record, but all your problems will go away if

<No, really you don't :-)

Broken records tend to annoy people and my mission is to share what I
have
learned with others and learn what they have learned from them.

From: paul.beard@gatekeeper.mis.tridom.com (Paul Beard)
Subject: First batch success

Just a short note to say I tasted my first bottle from my first batch and found it drinkable (actually, pretty good).

I was attempting to emulate a Newcastle Brown style, so I used M+F Nutty Brown extract, and at the urging of the shop, added 2 Alexander's Malt Kickers. The yeast was what came with the extract.

Three weeks later, I have 50+ bottles of something that doesn't resemble Newkie so much as Theakston's OP (in color: almost black, with a gleam of ruby red when viewed against a light). It's quite malty and a lot stronger than I expected (I figured 3%, based on TNCJOHB calculations).

You guys are way over my head with a lot of your mashing and whole grain stuff; I'll likely be an extract man for a while. To get in at this level is so easy; if you can boil water and read, you're there!

If anyone else is lurking without brewing, get busy.

From: reeves@lanl.gov (Geoff Reeves)
Subject: Specific Gravity Notes

I've noticed some postings that make me believe some clarification of the measurement of specific gravity might be appreciated. One representative example is...

The SG was 1.0XX "but that included all the particles from the crystal malt that immediately settled to the bottom."

Undissolved particles (including colloids) do not affect the measurement of specific gravity. A easy to visualize example is to imagine a lake of pure water with a specific gravity of 1.000. What is the specific gravity of the water if a boat is floating on the surface? What is the specific gravity if the boat sinks? What is the specific gravity while the boat is sinking? It remains 1.000.

The caveat is that anything that sticks to the side of your hydrometer will affect the specific gravity measurement because it will change the wieght of the hydrometer. When you pull the hydrometer out if there is stuff sticking to the side you should let the junk settle and take the measurement again. The most common thing to stick to the side is bubbles which will add boyancy to the hydrometer and give you too high a specific gravity measurement. It may go against your expectations but if you have a lot of junk floating around that sticks to your hydrometer it actually gives you too low a SG reading because it will make the hydrometer sink a little further.

Of course for those that are inclined to excessive worry I should point out that I brewed for six years before even doing a temperature correction for SG!

Subject: extract editorials / good enough

In Papazian's book he says that all malt extracts are not created equal and in the recipe section he recommends certain extracts for certain recipes because of their unique characteristics. But I have never seen much in the way of specific recommendations (for or against) various malt extracts. So here is your invitation to editorialize. When I go to the beer store and see oodles of different malts, which should I try first? Which should I avoid? I just started my garage lager last night with Bierkeller amber. What can I expect? (the label says "premium german malt", but with truth in advertising being what it is ...?). As always responses should use appropriate Internetiquette.

In response to Tim sixberry's comments/question of yesterday:

"...the basics of making good beer are very simple ... why complicate matters?"

I second the motion.

Of course "advanced" beer makers are free to make things as complicated as they want. But I agree that many people get forget that others have a different agenda. We read "relax, don't worry, have a homebrew" and then get pages and pages and kilobites and kilobites of things to worry about. I suspect that there is a lot of home brew equipment around gathering dust in the basements of people who were turned off by unnecessary complications. (IMHO).

From: Jim Grady <grady@hpangrt.an.hp.com>
Subject: Re: cloying sweetness

Taylor Standee asks about a cloying sweetness and flattish beer after 2 weeks in the bottle:

It sounds to me like the beer just needs more time. I have often had batches that were too sweet & flat after only two weeks. Some of the factors seem to be:

1. Temperature where the bottles are sitting &
2. How much the beer cleared before bottling. Usually, the more it has cleared, the longer it takes (and the less sediment in the bottle which means less sediment/more beer in my glass!).

I've never used DME but I hear that DME tends to take longer than corn sugar. So, give it a couple of more weeks and it should be fine.

I don't think dry hopping will do much for you in terms of bitterness. It
will give you hop nose and flavor. I used 1 oz. of Cascade hop plugs to
dry
hop 5 gallons of an IPA recently. I liked it and so did my friends. The
flavor of the hops really came through. I've read recipes where more (as
much
as 5 oz. of a hop) or less (0.5 oz.) have been used.

THIS is one of my pet peeves too. I think the inspection is fine for rings, yeast cake/cloudiness, etc, but comments on "low fill levels" can be erroneous. The problem seems to stem from homebrewers who bottle condition being sensitive to fill levels, and thinking the "correct" fill level is within 1/2" of the crown. When I am competing, I usually fill from the keg, counterpressure, and achieve a fill level very close to what you find in a quality micro, 1.5 - 2" below the crown. This invariably begets a comment on "low fill". If the local micro fills bottles above this line, they can have legal action brought against them for selling more than 12 oz in a 12 oz bottle.

This contradicts the data I have. Experiments have shown that the maximum
(absolute saturation levels) vary between a low of 4 mg/L (SG = 1.080, T=30 C) and a high of 7.5 mg/L (SG=1.030, T=15C). I believe Rajotte has quoted much higher numbers, but these are not supported by experimentation
using a Zahm and Nagel O2 inline injector. These data are supported by another author, Dr. Ingledew, who found levels of 8-9 mg/L as the maximum.

It is certainly well known that the saturation levels of O2 are a function
of temperature and sugar density (OG) so these are important factors in the equation, but practically speaking, levels above 8 mg/L are not seen in breweries, nor are they required as typical brewers strains require O2 levels between 2-8 mg/L. It is also interesting to note that yeast

will respire the O2 in a matter of hours if not less, at these levels. I can assure you that a 2 hour bubble of O2 has lead to quite healthy and successfull ferments (quicker, and cleaner, less esters/fusels).

From: LUKASIK_D@sunybroome.edu
Subject: New Brewer...HELP cont.

Sorry, little computer glitch on my end....So to start again.... I am new to the homebrew scene (two weeks, three batches, lots of fun) and have a few questions that I hope some more experienced brewers can answer. My first batch was a basic Yorkshire Bitter Kit with a lb of dry malt replacing some of the sugar. It all went smoothly and was bottled about a week ago. The second batch is my own Olde Ale recipe using all malt (11 lbs), some grain (crystal and choc.) and a lot of hops. This batch started with an SG of 1.062, was extremely active in about 8 hours, blew CO2 like crazy for the next 20 hours and had the krause (?) settle after 2 1/2 days. I then racked it into the secondary at which point it slowly bubbled away. Well, five days later it is still bubbling at a rate of about every 3 seconds which is completely different than batch 1 and batch 3 (an Australian Lager using Ale yeast). Is this normal activity or have I done something wrong? Is it due to using so much malt ext.? Is it safe to bottle while it is still fermenting like this? Is there any good way to get a second SG reading without the risk of contaminating the brew? I would really like to get this batch into the bottle so I can expedite the drinking (hopefully be able to have a few with friends on New Years!!!)

Other questions: Are Australian Light Malts supposed to produce a golden colored beer/ale/lager (this is the color of straw)? Could someone send me a recipe for Cider as I have seen this in my first reading of the digest and think it sounds great? How close will a dopplebock be to the real thing if I use ale/beer yeast (I am not yet sett up to do real Lagers)?

The list is great. I am sure already it will answer many of my questions and give me the insights I am looking for. Thanks for the help in advance!!
!

Subject: Cheap do-it-yourself kegging system (correction)

re: CO2 "resevoir"
No, this is NOT the French spelling, it should be "reseRvoir"
normally. Maybe it was the homebrew?!
Relax...

steve tollefsrud
valbonne, france

e-mail: steve_t@fleurie.compass.fr

beer kegCO2 resevoir

2. Leave the clamp of the CO2 resevoir loosely open for about 1/2 a day to allow CO2 from the beer keg to purge the CO2 resevoir keg of air.

3. Clamp shut the CO2 resevoir and allow 1-2 weeks for "conditioning".

4. After beer is conditioned and CO2 resevoir is pressurized, switch the "polarity" of the hose connection on the CO2 resevoir, so that the hose is connected to the "INPUT" side of the CO2 resevoir. Construct a beer dispenser hose out of 3'-5' of hose, one Cornelius connector and the beer dispensing valve. Connect this to the "OUTPUT" side of the beer keg and test by dispensing some beer into a glass. If necessary, release pressure slightly from the CO2 resevoir using the pressure bleeder valve on the top of the Cornelius keg.

5. To increase the CO2 pressure at any time, construct a second length of hose with a Cornelius connector at one end and a water faucet connector at the other. Connect the water faucet end first, then connect the other end to the "OUTPUT" side of the CO2 resevoir, and force a few pints of water into the CO2 resevoir (more than the volume of the beer that was consumed).

This should definitely be done when you want to store the beer after having tapped off a few pints, in order to maintain the carbonation in the beer.

beer kegCO2 resevoir

Advantages:

1. It's cheap!
2. Closed system: beer stays preserved indefinitely
3. Naturally conditioned in the traditional English manner

Disadvantages:

1. Finding the optimum dispensing pressure is a bit trial & error at first with pressure bleeder.
2. Ties up two Cornelius kegs for one 5 gallon batch.

It isn't elegant, but hey, it's cheap and it works!

Subject: Comments on Several Items

Hey Group, Happy Holidays!

I have been trying lots of different commercial beers, lots of Winter Warmer types, to gain experience with different styles. I have discovered that I don't care for Pumpkin Ale; I can't finish a Spiced Christmas Ale (tho I did find out that the Christmas Ale I brewed turned out true to style) its just too weird; but I did like the Samuel Smiths and Young's Winter Warmers very much. So, I think this style and IPA will be my styles for the new years brewing.

Okay, More James Questions (why do I like ribbing this guy? I dunno:)
Why Wort Chillers? Because when you start doing full boils, 5->10 gallons, that is too much wort to carry to the bathtub.
Short Ale Fermentations? When you use Extract with lots of active yeast, then you can have quick fermentations because of the simple sugars present; compared to All Grain where more complex sugars are present.
How much to Dry Hop? A good rule of thumb for ANY hop addition is 1 ounce.
YMMV. Also, Cascade hops has a Vibrant nose.

Capping Champagne bottles - All of the domestic champagne bottles can be recapped with standard bottle caps. There are some French ones that have bigger openings.

I want a copy of that Shrimp Creole recipe!

A few days ago, someone mentioned that their Bottles had a Milky Layer around the top of the bottle and thought it might be more foam. From what I have been told this is Micro Derm, a bad bacterial infection. It is ground dwelling but can be stirred up into the air by kicking up dust, etc. It is dangerous but easily detected due to the milky layer at the top and horrid smell when opening.

And on Jordans Hops Addition based on Papazian's formulas:
Well I assumed you are making five gallons. Starting with 6 lbs of Pale Malt Extract (Syrup? DME? =>Syrup), yielding an approximate OG of 1.032.
Boiled in 1.5 gallons of water gives an Adjusted Gravity of 1.28. Putting this in my spreadsheet ala Rager, using 1.5 ounces for 45 minutes gives 21.95 or 22 IBU.
Which seems to be what you wanted. HBU equaling %AA x Wt. = 1.5x5.5 = 8.25

And finally, my opinion on HBD diction and grammar.
I prefer to read concise questions and answers. I can appreciate certain regular personalities on the Digest who write like they probably speak; it

does add a certain amount of color to the digest and makes it more of a gathering of friends to discuss a shared hobby. However, writing like you speak is regarded as poor practice when trying to effectively communicate. Imagine if I started writing in Surfer speak, or my semi-native West Virginian drawl, it would be very tiresome for many of you to read. The same can be said of expletives and colloquialisms. This is an open forum for the communication of ideas on homebrewing. Effective communication would seem to be in order.

Subject: Sierra Nevada Nirvana

Last weekend I got my long-awaited chance to try Sierra-Nevada Pale Ale (We took a trip into Washington). Needless to say, I was NOT disappointed. Wow! Hops with an attitude. Can a brew get any better than this? My only mistake was to promise to save a bottle for my wife :)

Does anyone have a recipe to emulate this wonderful brew? If not, what is the variety and method of hopping? I suspect it is dry-hopped, which is something I've been meaning to try.

If numerous recipes are mailed, I will summarize for the digest.

Thanks in advance,

Scott McLagan <mclagan@fraser.sfu.ca>

From: Domenick Venezia <venezia@ZGI.COM>
Subject: Rager's polynomial

The recent thread about hop utilization and Rager's utilization numbers from Zymurgy past, and Ed Hitchcock's request for a polynomial got me thinking. Although this is not what Ed was requesting, I ran a least squares fit on the center points of Rager's utilization ranges and derived the coefficients of a cubic polynomial. When plotted against Rager's ranges this polynomial is everywhere "between the lines" except for less than about 3 minutes (where it's fairly flat at about 5.5%) and at greater than 55 minutes (where it tops out at about 30.3%). So, keeping in mind the standard disclaimers and the fact that your results may vary, here it is:

$$u(t) = 5.738336 - (2.032614e-01)*t + (2.905735e-02)*t^2 - (3.140576e-04)*t^3$$

or with less than anal precision:

$$u(t) = 5.738336 - 0.203261*t + 0.029057*t^2 - 0.000314*t^3$$

Note that this yields percent values, for fractional quantities divide by 100.0.

For those for who Rager's numbers do not come trippingly off the tongue, they are:

| Minutes | % Util |
|---------|--------|
| 0-5 | 5.0 |
| 6-10 | 6.0 |
| 11-15 | 8.0 |
| 16-20 | 10.1 |
| 21-25 | 12.1 |
| 26-30 | 15.3 |
| 31-35 | 18.8 |
| 36-40 | 22.8 |
| 41-45 | 26.9 |
| 46-50 | 28.1 |
| 51-60 | 30.0 |

Note the double size bin

If one examines a plot of Rager's ranges there appears to be a discontinuity at 41-45 minutes in an otherwise smooth curve. My esthetic sense from the plot is that utilization tops out at about 33-34% at 60 minutes.

One observation is that at time=0 I would expect a 0% utilization. Plotting the center points of Rager's numbers and extrapolating gives something around 4%. By "playing" with Rager's numbers I generated a more "esthetically pleasing" curve. I threw out Rager's numbers for 0-20 minutes and substituted 0% at 0 minutes. I also tossed out his numbers above 45 minutes and added 3 of my own at 48, 53, and 58 minutes. The curve so generated agrees extremely well with Rager over the range, 23-43 minutes, but yields higher utilization values at times over 46 minutes, and lower utilization values at times under 22 minutes.

| Min
Poly | Rager
Poly | Rager's Pleasing |
|-------------|----------------------|------------------|
| 0 | NA5.7383360.000000 | |
| 5 | 5.05.4092061.206269 | |
| 10 | 6.06.2974003.290587 | |
| 15 | 8.08.1673756.102309 | |
| 20 | 10.110.783599.451752 | |
| 25 | 12.113.9104913.14923 | |
| 30 | 15.317.3125517.00507 | |
| 35 | 18.820.7542220.82957 | |
| 40 | 22.823.9999524.43305 | |
| 45 | 26.926.8142127.62584 | |
| 50 | 28.128.9614430.21824 | |
| 55 | NA30.2061132.02058 | |
| 60 | 30.030.3126732.84317 | |

The more "pleasing" poly (read fantasy) is:

$$u(t) = 3.903961e-02 + (1.290914e-01)*t + (2.213545e-02)*t^2 - (2.529119e-04)*t^3$$

After all this, a question springs to even my mind, "So what?" Are there any other hop utilization numbers besides Rager's out there? How about in Malting and Brewing Science? Help! I need a reality check.

You know, I can get carried away on the weirdest things.

Subject: hops question revisited

Thanks to Spencer Thomas for pointing out my misuse of the formulas I asked about in HBD 1300. Obviously (now, at least) by using my method it doesn't matter what the %utilization is, the formulas will always give you the same weight of hops to use. This must be why I went into Biology and not Mathematics. Anyway, my questions still remains.

Given that I know the ~%utilization, the final volume of my batch, and the approximate HBUs I want for my beer, how can I calculate the amount of hops to use?

Again, I apologize if this has been answered recently, but from what I've read the formula I'm looking for just isn't jumping out at me.

Thanks,

Rob

Subject: Tun Design

js:
> It looks to me like another classic example of
> how scaling down commercial equipment to homebrew sized batches just
does not
> work very well.

I disagree, as outlined below. A more appropriate statement would be
'inappropriately scaling down commercial equipment to homebrew sized
batches, without understanding the function of the dimensions, sometimes
does not work very well'.

js:
> 3/32" holes are probably too large for the geometry of a homebrew tun.

Hersh:
> Can you explain the basis of your comment linking the size
> to the scale of the brewery??

js:
> I probably couldn't before receiving another letter from the
originator of
> the thread.

If the example was truly 'classic', would you have difficulty
explaining why?

js:
>My only argument was that if 3/32" holes work in large tuns but
>not in a small one, it must have something to do with geometry.

The switch from the plural to the singular is at odds with the
generality you made two days ago, and therefore cannot be 'your only
argument'.

js:
>The larger holes only
>work well with a large depth to diameter ratio but smaller holes would
be
>more forgiving. I am not sure why one would want larger holes and
thereby
>put such constraints on the aspect ratio but therein at least, seems to
be
>the answer.

It seems to me that the 'answer' depends on whether the sieve or the
grain husks do the filtering. If the husks do the filtering, as you
have advocated in the past, then with an appropriate grain depth, the
size of the holes, within limits, is not too important. I would say that
in a false bottom tun, a grain bed depth which is appropriate for a given
size hole/porosity is a better geometry characteristic than aspect ratio.

js:
>For the record, the screen I use on the EM has 32 mesh screen and
taking the
>wire diameter into consideration, the hole size is roughly ten times
smaller

>than the "professional" size.

TNCJOHB advocates 1/8" holes on the ZapPap tun, which is 25% bigger than "professoinal" size. It works just fine for a large number of people.

For Dennis Lewis - the original poster:

I realize that the Brewer's Warehouse sheets are expensive! I wouldn't want to throw it out (If you do, or you have unused scraps, write me).

The

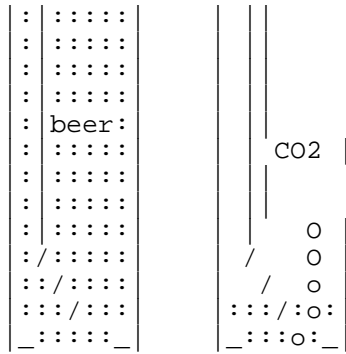

keg is probably too big to lauter in because the bed depth is small. You could cut down the screen and make a better false bottom tun, or convert to the em. There is a way to use the screen you cut in a converted keg boiler, so it won't be wasted.

>Broken records tend to annoy people and my mission is to share what I have

>learned with others and learn what they have learned from them.

I advocate neither false bottoms or ems, and have yet to design a dream tun. (hope you share the final result and thought processes, Norm). If there is anything I've learned from this digest, its that there are many equally effective ways of doing all the process in brewing. To say that "[false bottoms] are simply not ... useful in homebrew lauter tuns" is irresponsible, and simply false.

beer keg CO2 reservoir

2. Leave the clamp of the CO2 reservoir loosely open for about 1/2 a day to allow CO2 from the beer keg to purge the CO2 reservoir keg of air.
3. Clamp shut the CO2 reservoir and allow 1-2 weeks for "conditioning".
4. After beer is conditioned and CO2 reservoir is pressurized, switch the "polarity" of the hose connection on the CO2 reservoir, so that the hose is connected to the "INPUT" side of the CO2 reservoir. Construct a beer dispenser hose out of 3'-5' of hose, one Cornelius connector and the beer dispensing valve. Connect this to the "OUTPUT" side of the beer keg and test by dispensing some beer into a glass. If necessary, release pressure slightly from the CO2 reservoir using the pressure bleeder valve on the top of the Cornelius keg.
5. To increase the CO2 pressure at any time, construct a second length of hose with a Cornelius connector at one end and a water faucet connector at the other. Connect the water faucet end first, then connect the other end to the "OUTPUT" side of the CO2 reservoir, and force a few pints of water into the CO2 reservoir (more than the volume of the beer that was consumed).
This should definitely be done when you want to store the beer after having tapped off a few pints, in order to maintain the carbonation in the beer.

beer kegCO2 reservoir

Advantages:

1. It's cheap!
2. Closed system: beer stays preserved indefinitely
3. Naturally conditioned in the traditional English manner

Disadvantages:

1. Finding the optimum dispensing pressure is a bit trial & error at first with pressure bleeder.
2. Ties up two Cornelius kegs for one 5 gallon batch.

It isn't elegant, but hey, it's cheap and it works!

> present me with a clean bottle. But, as you note, it doesn't affect
> the score.

Spencer Thomas imagines that I'm presenting him my beer to judge out of "pride". Actually, I'm presenting it for feedback about the contents of the bottle. I already know if I had to scramble to scrape labels off the bottles because of the available beers the cleaner bottles happen to have already been consumed. I already know how flippin' painful it was to scrape my fingers as well as the label because I'm cleaning three bottles for each of the eight beers I'm entering. I already know, fer chrissake, that the clean bottle rules exist to prevent unfair identifying marks from biasing the judges, and not to soothe their aesthetic sensibilities. What I DON'T know is how true my beer is to style, and that's what I paid the entry fee to find out.

There's nothing that pisses me off more than getting more comments on a judging sheet about the state of the bottles than the state of the beer.

From: scott@nit.PacTel.COM (Scott Robertson)
Subject: First batch question...not much carbonation?

Yes...it's another novice first batch question...

Here's the story: Brewed, fermented, and siphoned into bottling bucket. Before siphoning I boiled a pint of water with the bottling sugar and put that in the bottom of the bucket. The instructions didn't say anything about stirring...so I didn't. After bottling all of the beer from the spigot at the bottom of the bucket.. I noticed that there appeared to be a separation in the last little beer in the bottom...beer on top, sugar mixture on the bottom.

So, it's been 5 days, and I tried a bottle that came from near the end of the bucket. There was a little pssst when I opened the bottle, but very little carbonation. I understand it is a little early to expect a lot, but is it possible that I screwed up by not mixing the sugar mix in the bottle bucket? Is there anyway to test the potential outcome without waiting? any insight would be great..

Subject: Al again?

Regarding the recent (eternal?) discussion of aluminum stock pots,
I found this while leafing through the William's Brewing Catalog:

Stainless steel is neutral to acidity, which means it
will not react with the relatively acid wort. Aluminum,
on the other hand, will react with any acid food, be it
wort or tomato sauce, possibly contributing to off-
flavor development, particularly in lighter flavored
beers. Though aluminum is economical and usable in a
pinch, it should not be purchased for use in brewing.

FWIW. No affiliation - just a satisfied customer.
Now if I only had \$160 for that 38 qt Vollrath...

Subject: Pike Place cask-conditioned ale

For those of you who get *Brewing Techniques*, there was an article in the last issue that featured cask-conditioned ales made by Pike Place Brewing in Seattle.

I just happened to be out there on business this week. I called 'em up and asked where they were served. I went down to the 74th Street Ale House and sure enough, it was there - served much like the english style: hand pump at about 50F or so. I enjoyed a few pints of this stuff - great brew, but not quite as nice as the pub cask-conditioned ales served in England. So far, it is the best I've had in the US that approximates the English style c-c ale - perhaps more pubs will ask for this stuff!

In addition to that, they had 17 others on tap - this is something us East coasters (at least me!) are not used to! Lots and lots of winter ales, some very nice wheat brews by Hale Brewing (?), etc.

Great brews in the Seattle area - local brew was served all over the place, even in the Red Lion hotel bar I stayed at.

From: Nick Cuccia <Nick_Cuccia@Talamasca.Berkeley.CA.US>
Subject: a holiday cider recipe...

No, not a recipe for cider, but a recipe that uses cider...

Nick's White Sauce

2 cups chicken stock
2 Tbsp flour
1 lb butter
1/4 cup minced mushrooms
2 cups hard cider
1/2 lb minced shallots
1.5 Tb minced tarragon
Nutmeg

In a double boiler, melt 2 Tbsp of the butter. gradually mixing in flour until well-blended. Gradually add chicken stock, stirring constantly, and place mixture directly on burner on low heat. Stirring constantly, bring to a boil, and continue stirring until sauce starts to thicken. Remove from burner, add mushrooms, and simmer for about an hour, stirring occasionally.

While the first mixture is simmering, cut the remaining butter into 1T chunks. Mix cider and shallots in a saucepan, bring to a boil, and reduce to a glaze. Remove this pan from heat, and slowly add butter, one piece at a time. The butter should not melt completely; the resulting mix should have the consistency of a Bearnease. Add tarragon and set aside.

Take the original mixture and strain through a fine sieve into a bowl. Add the shallot/butter mixture and a pinch of nutmeg, and season to taste.

This sauce is good on chicken, warm or cold veggies, or as a dipping sauce for bread.

Enjoy!

From: rcd@raven.eklektix.com (Dick Dunn)
Subject: crown-capping champagne bottles

Regarding the question (sorry, lost the actual reference) on using sparkling-wine bottles for beer: You can cap American bottles with standard beer-bottle crown caps. American bottles are one size; European bottles are a slightly larger size and won't work. If you're scrounging bottles, you don't usually run across stray Champagne (*real*, as in the particular region of France) bottles, but you're likely to find Spanish bottles from inexpensive stuff like Freixenet or Cordoniu.

Specifically, you can *sometimes* manage to cap the European bottles. It depends on the particular capper and caps you're using...you might succeed

99 times out of 100, or you might fail every other bottle. The failure modes I've seen or heard of with European bottles are:

- Cap doesn't seat properly, bottle leaks.
- Capping breaks off a piece of the crown. The probability of the broken-off piece of glass going into the bottle is equal to the probability that the bread lands on the floor jelly-side-down.
- During capping, bottle and cap jam inside capper--leading to dilemma of trying to free bottle without cracking it.

(Digression: Sparkling wine bottles are interesting to brewers because they're about twice the capacity of a regular beer bottle, and because they're designed to withstand a lot of pressure.)

Empirically, an American sparkling wine, and a beer bottle, seem to have a

27 mm crown. A European sparkling wine bottle seems to be 29 mm at the maximum diameter. This is less than 10% difference, but with some practice

you can spot the wrong bottles quickly even if the labels are missing. If the labels are still on, you should be able to get it right away...I've never seen an American bottle of the "wrong" size nor a European bottle of

the "right" size. (I'd be glad to know of any counterexamples!) It appears

to be strictly national--the American arms of French Champagne houses use American-gauge bottles. (Somebody can probably get a term paper out of that fact!)

If you're scrounging lots of bottles, you can easily cut a notch in a block

of wood, plastic, etc, to slip over the crown and check the size... getting

2 mm precision isn't hard. Or if you've got a dial caliper (even a cheap one) that will work.

From: Conn Copas <C.V.Copas@lut.ac.uk>
Subject: Re : Cheap do-it-yourself kegging system...

Steven writes about using 2 Cornelius kegs, and no CO2 bottle, as a low-tech means of kegging. My reaction? great to see such innovation. Dave Line actually proposed storing the pressure from the primary fermentation for later use, which would overcome the need to prime with triple the normal quantity. I presume that some commercial brewers must be salvaging their CO2. The idea of using 2 kegs in harness illustrates a more general point: that of the importance of having a relatively large headspace when attempting to dispense using natural conditioning alone. So, in theory, if we had a suitably large keg (say 15 galls), then we could probably dispense 5 galls of brew without ever needing to re-pressurise. Even better if the keg was collapsible, so that atmospheric pressure could maintain a near constant serving pressure.

From: John Eustace <3JCE1@QUCDN.QUEENSU.CA>
Subject: Brewery Geo/High Grav Brewing/Topping Up the 2ndary

Hi All,
Thanks to all who responded to my question about pitching to 180 gals.

However, I didn't get any response to my query about brewery geometry. Again, I'm interested in any information you might have of the effects kettle geometry and fermenter geometry have on the brewing process, from hop utilization to rate of fermentation. Even a list of sources to explore would be helpful.

I'd also be interested in more information on High Gravity Brewing. Dr. Fix's article on Diacetyl production in BREWING TECHNIQUES sparked my interest. The idea is to keep FAN levels up by brewing at optimal gravities (1.048) and then diluting the result at bottling. I believe he mentioned this practice in reference to the British Brewing industry. My questions then, have to do with when and how one does such a dilution. For instance, do I do this just before bottling, or when I rack to the secondary? Will the dilution raise the pH of the beer? And if so what effect will that rise have?

My final question has to do with topping up the secondary. I've been trying to manage my boils and fermentations such that I have enough beer to fill the secondary, leaving less than an inch between the fermentation lock and the beer. However, sometimes this doesn't quite work out, and I have to make a choice as to whether or not I should add brewing water at this stage to top up the carboy or leave the space in the carboy and hope the beer is still producing enough CO2 to protect it from oxygen. What is the consensus on this? Is topping up detrimental to the beer or is it at least less harmful than oxygen?

TIA and Cheers
JE

From: yeebot@aol.com

Subject: Recepte for Belgian White Beer (Celis White Clone)

NOTE: PLEASE IGNORE IF ALREADY RECEIVED!!!

Good to see a fellow Hoegaarden lover out there!

I have a full mash recipe I copied off of AOL that was uploaded by Dr Who2959

(We miss you on AOL; how's GENie?) who in turn captured it off of the SW Campus of the Homebrew U. BBS Network. It was a conversation between Tony Storz and Steve Daniel (who seems to know Pierre Celis!) that occurred at the end of September. I hope I didn't forget anyone/thing. Now for the recipe:

Steve writes:

I have talked to Pierre and came up with this recipe:

2.25# 2 row
2.25# 6 row
4# unmalted wheat (hard red)
4 grams orange peel
4 grams corriander
1 ounce Hallertau leaf hops

As you can see, there is a lot of unmalted wheat to convert, therefore a full mash is needed to make something similar to the real thing. If you are unable to do full mashes, try substituting 5 pounds of plain light extract, and make a mash with 2 pounds each wheat and 6-row. This will not be nearly as wheaty as the real thing, but that's life. Add the crushed spices and all of the hops only 15 minutes before the end of the boil. Stay away from honey and sugar! They are cheap, but not worth tainting the flavor of your beer to save a few pennies.

What yeasts to use?

Slants of the Celis/Hoegaarden yeast are floating around the homebrewer's community. I think there may be some in the Foam Ranger's Yeast Library. I've heard that Wyeast has a sample of that strain, but they haven't put it into production. If you can't find a white beer yeast or are not ready to make a yeast starter from a slant, you might try the Wyeast Bavarian Wheat Ale yeast. This may be one of my crazier ideas, but I think it might get you closer to Celis than using a regular ale yeast. The Wyeast Wheat Ale yeast has some Lactobacillus Delbrukii in it which would simulate the secondary lactic fermentation that Pierre and company do. What do the rest of you out there think?

P.S. I tried making a white beer yeast starter from some Steendonk dregs, once. It didn't work.

He continues:

The secret is in the yeast, though. I'm guessing they said to use amylase

enzyme in the mash as a supplement. It's not needed in the full mash recipe, but any more than 50% unmalted wheat will need it.

Now my caveats:

I haven't tried it yet, as I cannot do full mashes right now. I'm starting small/cheap and currently have Papazian's Hoegaarden "clone" (with a few minor variations) bubbling happily away in primary. I have also heard rumors that a lactobacillus bacteria is needed to actually generate something that can called a "clone". As I am VERY interested in someday brewing a true Hoegaarden clone, I would like anybody else thoughts/ideas. Good luck. Keep me informed, I'll tell you how the Pap Wit turns out!

From: philb@pro-storm.metronet.com (Phil Brushaber)
Subject: Secondary in Stainless Probs

I've had this problem before and I'm afraid like they used to say in Poldegeist.... It's baaaaack!

I know that many of your secondary in stainless steel cornelius kegs. I like to do this as it takes up less space in my lagering refrigerator. This summer I encountered this off-taste problem with a couple of American Lager's I brewed, did the primary in glass and then the secondary in stainless. The off-taste is hard to describe. At first I thought it was astringency, but it is more like a yeasty, metallic taste. The taste persists even after filtering through a .5 micron filter. It has happened when I've secondaryed in stainless (about 5 total batches) but never when I've secondaryed in glass (about 2 batches).

Has anyone else had problems developing off-tastes in secondary? Or, I suppose it might be the hops. Has anyone experienced these kind of tastes when using 100% Cascade hops? I really would appreciate your insight. I would rather not be crossing by fingers with each batch.

Finally, In case I don't get another chance... A Merry Christmas to all the brewers on HBD. Or as some homebrew wag once suggested. "A Beery Christmas to all, and a Happy New Beer!"

From: "J. Andrew Patrick" <andnator@genesis.Mcs.Com>
Subject: Free Speech Vs. "Professional Language"

Much to my surprise, since posting my 1st message about the blatant censorship that I encountered at the AOL Beer Forum, several HBD readers have expressed opinions that I "got what I deserved" for using such terrible language. Al Korzonas, Michael T. Lobo, and, GNT_TOX%ALLOY.BITNET@PUCC.PRINECTON.EDU (whoever that is!) have written (either publicly or privately) to indicate their opinions that:

- 1) AOL was justified in censoring me for using "profane" language, and/or
- 2) The HBD is "demeaned" by those who frequently use "profane" language, so we should all use "professional language" here, and/or
- 3) This is an AOL issue that has no business being discussed in the HBD.

All I did was say that I was "pissed off". That's the worst of my alleged "profanity". Allow me to quote verbatim from Webster's New Collegiate Dictionary, (c)1974 by G.&C. Merriam Webster Co:

"pissed off - adj. slang: ANGRY, DISAPPOINTED, DISGUSTED <a lot of guys are pissed off at me 'cause I came in after them and made corporal -Norman Mailer>"

Note that even as far back as 1974, Webster's did not feel that the term deserved being labelled as vulgar or profane. It would not surprise me if even the "slang" label has been dropped in more recent editions.

Those of us who live and work on the Net value our electronic freedom of speech very passionately. People who know me in the real world know that I am a very honest and opinionated person, who always says exactly what is on his mind. My close friends place high value on this trait.

I believe that I have an inalienable right to express myself in cyberspace in the same manner as I do in real space. This is just your basic First Amendment principle applied to the on-line world. If I am forced to drastically alter my on-line persona because of a few prudes who don't like seeing words like "orgasm" or "pissed off" in the HBD or AOL Beer Forums, then I am being forced to live a lie, to pretend to be somebody that I am not.

Is this REALLY what we want??

And if you still feel this discussion does not belong here, then please keep your flames PRIVATE!! I can be flamed DIRECTLY at "andnator@genesis.

mcs.com", or on either of my Home Brew U. BBS systems (listed below). Public flames only serve to waste bandwidth and make the issue you are trying to get rid off reappear that much faster.

Subject: Problems with Dark ales

Hello everyone, I am looking for some help in determining why I am having problems with Dark Ales. I have brewed about 25 all-grain ales and every attempt at a dark one (3 stouts and 1 porter) I have ended up very disappointed. I brew alot of pale ales and brown ales and these have all been very consistent.

I think my problem may have to do with water chemistry, Lately I have used pre-boiled Chicago City water. I usually do not check ph and don't really add any mineral salts.

The problem is all 4 of these beers have had a distinctly musky-like aroma and flavor. None have really tasted as roasty as I have intended. The beers seem thin tasting as well and maybe even faintly sour. My usual procedure is add add crushed grain to 3 gallons 175F water. Rest at 153-155F for 90 minutes. Sparge for about 45 minutes. Boil 90 minutes. Chill using chiller.

These are my last two that I have tried and I felt the recipes should have produced a very full-bodied creamy roasty delicious porter and stout. Instead I find them flawed but drinkable.

Porter 5.5 gallons OG: 1.052 FG: 1.012

10.00 lbs Belgian 2-row Pale Ale Malt
10.00 oz Belgian Black Patent Malt
8.00 oz Belgian Cara-Vienna Malt
8.00 oz English Dextrin
8.00 oz Belgian Cara-Munich Malt
7.00 oz Belgian Special-B Malt

1.50 oz Kent Goldings Pellets (60) 5.4%
1.00 oz Kent Goldings Pellets (30) 5.4%
0.50 oz Kent Goldings Pellets (15) 5.4%
Wyeast #1084 Irish Ale

Oatmeal Stout 5.5 gallons OG: 1.052 FG: 1.014

8.50 lb Belgian 2-row Pale Ale Malt
16.00 oz Flaked Oats
16.00 oz Belgian Roasted Barley
6.00 oz Belgian Chocolate Malt
6.00 oz Belgian Cara-Vienna Malt
4.00 oz Belgian Black Malt

1.00 oz Bullion Pellets (60) 9.2%
Wyeast #1084 Irish Ale

Any comments would be helpful, thanks!

Subject: Reusable 5l kegs ...

Hi All!

I saw a pretty nifty little gadget on the shelf of my local homebrew shop/microbrewery. (Ok, ok, so Dan shares floorspace with Lakefront. Sip and buy. Sip and browse. What a racket!) It's a reusable 5l stainless keg, similar to the "party kegs" one can purchase at the liquor store. A set of 4 comes with a reusable tapper/dispenser. (I won't mention the price, just yet) So, any thoughts? Ideas? Anyone out there *have* one of these? It sure would be nice to get away from bottling 2 cases every time. I would see putting up two of these kegs per batch and then one case of bottles for "dispersal."

Comments *always* appreciated ...

D.

From: John DeCarlo<jdecarlo@homebrew.mitre.org>
Subject: Re: AI Again?

Interestingly enough, I just saw a cooking show discussing pots and pans. The most highly recommended was copper with a stainless steel coating on the inside. But the point being emphasized is that copper conducts heat best, then aluminum, then stainless steel (of the materials on hand for cooking). Specifically mentioned was that an all-stainless-steel pot will scorch food easily as the heat will come straight through from the bottom rather than spread out evenly. So, there were lots of second-best alternatives, including stainless with aluminum or copper bottom layers to spread heat evenly and aluminum pots that were either anodized or had non-stick surfaces applied.

In conclusion, plain aluminum pots are subject to staining or pitting with acidic foods; plain stainless steel can scorch/burn easily because of poor heat conductivity; some combination is probably best but properly treated aluminum shouldn't have the same problems as cheap/plain aluminum.

From: chuck.wettergreen@aquila.com (Chuck Wettergreen)
Subject: temp step mash scorching

When doing temp step mashes with my Cajun Cooker (160,000 btu's!) I've noticed that I frequently get mash sticking to the bottom of the kettle and charring. This happens even at the lowest levels of heat and the kettle suspended above the flame on bricks. Now I've found the solution to this problem.

I purchased a "pizza stone". This is a ceramic disk about 18" in diameter and about an inch thick (they come square too) that you place in your oven to heat up and duplicate a pizza oven like found at your favorite pizza shop. I put this on top of the Cajun Cooker and turned on the heat. The stone heats up and evenly distributes the heat. No scorch, no burn, just nice even heat applied uniformly to the bottom of the pan.

I purchased a "second" in the Chicago burbs at the Piano Factory outlet mall (Housewares Outlet) in St. Charles for \$10. This store is just down the hall from the Corning Outlet that sells yards of ale and carboys inexpensively. Obviously, a first would cost more. They also have giant wooden spoons which are perfect for stirring stiff mashes...

Subject: New Brewer...Saga Continues

Thanks to all of you who responded directly to my first inquiry! Just thought I would give you an update: The third batch, an Australian Ale (which by the way has changed color and looks much better now) developed a small amount of white colored mold in the neck of the 6 1/2 gal carboy. I have no idea what caused this or if in fact it was mold (?) but since the krausen had settled I deemed it prudent to rack to a secondary as soon as possible. Since at this time I only have one 6 1/2 gal primary and one 5 gal secondary (which had the Olde Ale in it) we ended up bottling the Olde Ale on Saturday (8 day ferment). It had an ending SG of 1.022 and alcohol of 5.25% (a lot lower than I was hoping for), was still quite sweet but still drinkable. So far (48 hours) none of the bottles have blown and I am keeping my fingers crossed as I am planning on keeping it at room temp for a week before transferring to storage in the basement. I am hoping that the alcohol increases and the sweetness mellows with some ageing in the bottle. Any thoughts on this?

What could have caused the mold in the neck of the carboy? I had given it a 2 day sanitation water soak with 2 tbs. of chlorine, several good hot rinses with the bottle washer, and immediately filled it again. Is it possible that it wasn't mold in the first place? Any other possibilities? The beer by the way tastes fine (in fact it seems to have more of the bitterness that I am looking for) and doesn't appear to have any mold in it. It has dropped to 1.015 SG in 4 days and currently has about 4% alcohol. It is clearing nicely in the secondary and is obtaining a nice light amber color. I must admit that the tryp was some of the ugliest stuff I have ever seen (reminiscent of things I have seen in my 2 year olds diapers when he has been sick...UCK!!!)

I am remedying the 2 carboy problem by adding additional 5 gals. to I can also

try making some lagers.

About to try the 4th batch...an IPA.

I think I'm hooked!!!! Need to learn more patience...as my friend said "the

name of this game is waiting"...I wanted to drink the first batch.

Subject: Power Sparger

Yesterday I experienced my first-ever set mash. I was making an Oatmeal Stout, with 15% oatmeal. It was the five-minute Quaker Oats oatmeal. I lauter in a bottling bucket with a false-bottom plus a grainbag. The first couple of gallons of runnings didn't take too long, but after that, it slowed to an imperceptible trickle. Rats!! I need a

P o w e r S p a r g e r !!

Rrrright, power sparger, oh yeahhh, arrgh..... (doing best Tim Allen impression I can muster).

I remembered reading that some large breweries can apply a partial vacuum underneath their grain bed to hurry things along, and I was thinking about how I could accomplish this before the sparge completed on its own. I decided I couldn't. Then I thought maybe I could push the sparge water through from the top.

I went and got a lid for the bucket, and drilled a 3/8" hole in the top. Fetched my CO2 tank from the dispensing system (I keg), and stuffed a hose into the hole. I fastened the lid onto the bucket well-enough to hold a little pressure, and SLOWLY cracked the low-pressure side valve open. The lid bulged up some, and I waited. Sure enough, the imperceptible trickle became perceptible, respectable even, and the sparge finished in about 40 minutes.

I suspect this could be adapted for use with picnic cooler mash-tuns too. Anyway, FWIW, it worked once...

However, I didn't get any response to my query about brewery geometry.
Again,
> I'm interested in any information you might have of the effects kettle
geo-
metry and fermenter geometry have on the brewing process, from hop
utilization

Mine are of equal height to width (mash tun/kettle, lauter tun/
fermenter).
As systems are scaled up, they tend to become more shallow, 2-3 times the
width to height. I have seen many variations on geometry used in many
good breweries, so I feel there is a lot of leeway for the designer.
Pikes Place uses a fairly tall and narrow 3/4 BBl kettle. Sierra
uses a classic copper onion dome kettle, these tend to be shallow.
Fermenter geometry can have a impact on the system. The biggest issue
is where to place the chilling jackets, based on what type of fermenter
you are are using (unitanks should be jacketed differently than open
fermenters). Even the style of beer and production techniques become
important when scaling up breweries. Jacketing placement is significant
in terms of convection currents that develop inside the fermenter, and
this is also dependent on geometry.
>
>I'd also be interested in more information on High Gravity Brewing.

I have been diluting 10% in the kettle, boil the last 20 min, and
whirlpool/counter flow. I have also on occasion, added more water
into the fermenter via my counter flow chiller. I suggest adding water
to the wort, prior to fermentation. The pH can change when using much
greater amounts of water, and this might be cause to acidulate the
water.

>re:topping up secondary

I am not a fan of this, but I know many others do so with success.
Top up with boiled water, or save additional wort to add. I would
advise a CO2 balst into the secondary prior to racking if this is a
concern.

I have had some scale build up problems with my kegs, that required a

good caustic/acid wash schedule. Not sure if this is the cause of the taste, check for problem weld areas.

Good brewing,

From: chips@coleslaw.me.utexas.edu (Chris Pencis)
Subject: Thanks/Creole/Stouts

Ok Folks, here we go...

1. Happy Holidays...for those of you interested in the creole recipe, email me and I will reply with it when I get back in Jan.

2. I got my results back from my first competition (Austin Brew Ha Ha - my 6th batch, an extract/specialty grain brown ale) and I'm happy. My brew came out with a 25, and I think that I would have been scored higher if I had subclassified the brown ale category (english american etc) but it was between styles and I felt like I would have been guessing as to style anyway...(I cant try all these micros to help me define my styles in Texas - relatively few are sold here). Point being that I got nice beer reviews, no off flavors or infections. This makes me feel that I've got the essentials down - I have the HBD community to thank for this one - THANKS!

3. Semi-related literature: *A Natural History of the Senses* by Diane Ackerman. An excellent book which goes into the nuances of sensation - particularly relevant to we brewers who are dabbling with the alchemy of hops, malt etc to produce our magic are the chapters on smell and taste. Well worth an afternoon perusal in the library or bookstore - ISBN 0-679-73566-6. Standard disclaimers apply here - just a happy reader.

4. Advice on Stout recipes tried from the Cat's Meow or anywhere else would be appreciated as I am looking at trying to brew my 1st. I have a hankering to make something similar to Sam Smiths (is this dry or sweet? honest - I need to know....) extract recipes and private e-mail preferred.

Thanks all Chris

From: "Bill Kitch" <kitchwa@bongo.cc.utexas.edu>
Subject: Aluminum pots

There's some interesting information on the use of aluminum ware in Dave Miller's column in the latest _Brewing Techniques_ and in Papazian's Doctor whater-it-is column in the latest _Zymurgy_. The summary of both articles is that there is no evidence that using aluminum kettles will adversely affect beer flavor. Commercial brewery's don't use aluminum because it is attacked by the caustic cleaners that they use. Certainly stainless steel is more durable an more inert. So it sound like this may be just another myth propagated about the homebrew community. (FWIW I'm saving up for a SS pot.)

By the way: be very careful about what you read in supplier's catalogues. They often suffer from the same lack of knowledge that the rest of do.

Subject: Specific Gravity Measurement

In HBD #1301 reeves@lanl.gov (Geoff Reeves) writes

[snip]
>Undissolved particles (including colloids) do not affect the measurement
of
>specific gravity. A easy to visualize example is to imagine a lake of
pure
[snip]

This is not correct. Both suspended (undissolved) solids and dissolved
solids
will affect the specific gravity measurements. That is so long as they
remain suspended in solution. In fact this phenomenon is used to measure
the size of colloidal soil particles. If you have any doubts about this
try the following. Take a trub laden sample off of the bottom on you
boiler shake it well to suspend all the solids and quickly measure the
specific gravity (before the junk settles out). Then leave the sample
sit
until the junk has all settled to the bottom of the sample tube. Now
measure the specific gravity again. You will find that the second
reading
gives a lower Sg than the first. The difference may or may not be large
enough to be of concern but suspended solid definitely do affect the
measured Sg.

Also on the subject of temperature corrections. If one is measuring Sg
at
ale fermentation temps then the correction is small (.001 or .002) if,
however, one is measuring the the Sg of sparge runnings or boiling wort
the
corrections can be quite large (like .015 or more). So don't blow off
the
correction if you're trying to boil wort down to right OG! By the way,
sierra.stanford.edu has a file with a table of Sg corrections and a
polynomial fit. The file is /pub/homebrew/docs/sg_vs_temp.

NO TEAM. NO BUD.

FYI, a boycott of Anheuser Bush products is being organized in New England to protest New England Patriots owner James Busch Orthwein's attempts to sell the Patriots to Stan Kroenke and move the team to St Louis. As reported by Will McDonough in the Boston Globe 12/18/93 p. 67, player agent Randy Vataha asks to start the boycott Sunday @ 1 and continue until the team is sold to an ownership that will keep it here. Drop off points will be announced where fans can drop off any Anheuser-Bush products that will be trucked to a spot near the stadium and dumped to demonstrate to Orthwein our opposition. Orthwein who is the 3rd largest stockholder of AB, lost a bid for a new NFL franchise last month and seems willing to risk a number of lawsuits(TM), including breaking his lease in Foxboro, to move the team.

"Tell you friendly bartender to serve something else. Tell the guy who owns your neighborhood pub or local package store not to order Busch products..." Amen! Besides, the local breweries and brewpubs can always use the business!

From: dmorey@iastate.edu
Subject: Potential Extract of Dark Malts

Greetings fellow homebrewers and beer lovers,

This is my first posting on HBD. I have been doing all grain brewing for about a year and a half and have a question about expected extract from dark grains. I have compiled a list which was created by averaging values from multiple sources. Most sources i have found don't cover potential extract of dark malts very much. So I would like to hear the wisdom of the brewers out there. Here is the list I have compiled up to this date:

| Ingredient: | pt. gallons / lb |
|------------------|----------------------------|
| Malt extract | 35 |
| Dry spray malt | 42 |
| Corn sugar | 37 |
| Cane sugar (yuk) | 44 |
| Brown sugar | 41 |
| Rice syrup | 36 |
| Dextrin powder | 42 |
| Pale malt | 31 |
| Lager malt | 31 |
| Munich malt | 26 |
| Mild ale malt | 27 |
| Crystal malt | 22 |
| Wheat malt | 34 (this seems high) |
| Cara pils malt | 23 |
| Roast barley | 27 (isn't this high also?) |
| Chocolate malt | 27 " |
| Black patent | 27 " |
| Honey | 38 |
| Molasses | 45 |

I would like to thank all of in advance. I hope other people in our group will find this information useful.

Dan A. Morey Reminding you to drink 2 to 3 beers a day.

You can get yard, 1/2 yard, and foot glasses with the wooden stand for a pretty good price at a Corning/Revere outlet (for those of you near DC, I think one of these just opened up at Potomac Mills, but I haven't been by yet). They have good prices on glass carboys, too. I'm not sure exactly what the prices for these items are, but I do remember they are quite a bit lower than those at the local homebrew shop.

Subject: Extract experience

In HBD1301 Todd Carlson asked for comments re different commercial malt extracts. I'm interested in this topic, too, especially regarding Northwestern-brand extracts. What are they made from? Two-row or six-row barley. If two-row, what is the variety and origin? What is the yield (degrees OG/pound/gallon)? Are they consistent from batch to batch and year to year? For context, I'm brewing pale ale (using Edme DMS) and porter (using Munton & Fison Light). The owner of my homebrew store has been trying to get answers to these questions, but without luck, and has gently steered me away from Northwestern.

And, yes, I know I wouldn't be asking this question if I were brewing all-grain...

>enough to be of concern but suspended solid definitely do affect the

>measured Sg.

The "junk" in question is protein coagulate. When mixed into a solution, it does not raise the SG as would sugar. This would seem to imply that it

has a lower SG than wort. Yet it falls to the bottom. Why?

>From an observational standpoint, I have noticed that the SG measurements

increase after the trub falls out (i.e. the wort mixed with trub has a lower SG than does the clarified wort). One would think it would decrease. **

i.e. why does it sink?

** One cannot discount the possibility that this is due to temperature correction error or other measurement errors on my part. I have never, however, observed a SG decrease after clarification, and have observed increases several times.

Subject: Trying to boycott the Mega-brews

Good Luck trying to boycott A.B. (BUD) products! I think you would have a more easier time trying to boycott water! :)

Since "nearly one out of two beers is an A.B. product" (a direct quote from the St. Louis beer tour, since they sold 86 million [more or less] barrels in a year) a "strong" boycott would probably "hurt" their sales by .001%.

Just had to add my \$.02 since I feel you are wasting your time. Sorta like when teenagers were supposed to "boycott" the Beatles and destroy any kind of "things" they had relating to the Beatles. It was silly. (If you aren't in your 30's or later you probably don't remember)

From: Aaron Morris <SYSAM@ALBANY.ALBANY.EDU>
Subject: Raw honey vs processed

Bob Surratt queries about the difference between raw and processed honey. The main difference is that processed honey has been heated, and filtered. Heating makes the honey less viscous/more fluid so it will pump through hoses and pass through filters easier. The filters (usually fine cheese cloth) remove the foreign material (dust, pollen, bee's wax, spare bee parts) from the honey. Heating also drives off volatile enzymes from the honey, which may change the flavor. Commercial honey may also be a blended of different varieties of honey.

Raw honey is simply honey that has not been processed. When I extract and bottle my honey, I use cheese cloth to filter out foreign matter, but no heat is involved (preserving the volatile enzymes) and I make attempts to keep clover honey separate from aster honey, etc. For true Raw Honey, find a local beekeeper.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Re: malt extraction efficiencies

dmorey@iastate.edu gives the following list of extract efficiencies. Some of the values don't seem right, so I've appended the values I have that differ from those listed

>Ingredient: pt. gallons / lbI have:
>Malt extract 35
>Dry spray malt 42 43
>Corn sugar 37 45
>Cane sugar (yuk) 44 45
>Brown sugar 41 44
>Rice syrup 36
>Dextrin powder 42
>Pale malt 31 36
>Lager malt 31 35
>Munich malt 26 30-33
>Mild ale malt 27 29-34
>Crystal malt 22 29-31
>Wheat malt 34 (this seems high) 39
>Cara pils malt 23 29
>Roast barley 27 (isn't this high also?) 29
>Chocolate malt 27 " 29
>Black patent 27 " 29
>Honey 38
>Molasses 45 42

Note that the extraction rate for mash ingredients are a theoretical maximum, not the expected rate. Thus, a good homebrew setup typically gets 80% of theoretical maximum, or about 30 pts/lb/gal using pale ale or lager malt. The extract efficiency of 6 row is about 20% less than 2 row.

With that I bid ye all a happy Holiday season, I'm unsubscribing for the duration of 1993...

Subject: Rager's hop utilization curve

I must preface this by saying this is not a flame %)! I was quite amused by a recent post trying to fit Rager's hop utilization rates to a second or third order polynomial expression. I enjoy seeing you techies spin the numbers almost as much as reading posts from Jack Schmidling!! But be real!! The hop utilization rates are ranges over 5 min intervals. If you plot the midpoint of the ranges versus utilization and even add 0 for 0 time, you get just as good a plot with a linear fit $r^2=0.99$ for $y=0.576x$ (where y is the % util., and x is time) then you do with second a third order polynomials ($r^2=0.98$). We cannot be very accurate with hop utiliz. rates to several decimal places since the alpha acid levels are only approximate. It might be fun but it is only an exercise in curve fitting. (By the way you can't just drop data points because they don't give the correct esthetic look! So for all practical purposes $y=0.6x$ would be accurate enough. Sorry for rambling on, by I'm in the government and here to help you!

From: Mark Bunster <mbunster@hibbs.vcu.edu>
Subject: storing lagers in bottles

A rather obvious question, but one seemingly not answered by Papazian:

once you've bottled a lager (eg, a nice dark single bock), how you should store the bottles? Is it useful to keep them at temps below 60F? Is it better to keep them colder but constant (eg in a fridge), or not quite as cold but varying with the weather (eg on a porch)? And as long as I've got you all here, what is the possible off flavor damage to a lager sitting primary and secondary for about 4 1/2 weeks total? (Discounting contamination; I'm just wondering about the thick layer of trub at the bottom, which may or may not be bad, seeing as how it's naturally a bottom fermenter).

Don't try honey in an IPA. Well, you can, but the sweetness confuses a little bit with all those hops. I think it will mellow with time, but I think there are better recipes to include honey in than an IPA.

Happy beeridays,
M

Date: Tue, 21 Dec 93 11:59:39 -0500
From: edo@marcam.com (Ed Oriordan)
Subject: Questions on: Hop storage and Step Infusion

Hello,

Question 1) I store my hops (pellets) in the freezer. They are not in oxygen barrier bags, but in little heat sealed plastic bags. Would it help preserve them if I put them (still in the bags) into a glass jar and filled the jar with CO2, and then closed the jar and put it in the fridge.

Obviously it's not much work to do it, but will it be worth it? I know pellets are pretty stable already.

Question 2) In reading Miller's, Lines, and Papazians books the only one who addresses step infusion mashing by using a picnic cooler is Papazian. Does anybody out there use a step infusion in a cooler?

Papazian gives the following numbers (working from memory here)
For 1 step infusion - Add 1 qt 165 H2O per 1lb grain (Target 155F)
For step infusion - Add 1 qt 128 H2O per 1lb grain (Target 122F)
Add .5 qt 212 H2O per 1lb grain (Target 155F)

I have also found that the .5 qt he purposes does not get me to 155, but more like 145 I was afraid to add more boiling H2O(making it even thinner) so I did a partial decoction(more work than I wanted).

What are the consequences of the mash being so much thinner (than his 1 step infussion, it's 50% thinner) during the final step????
Should I use less H2O in the first step and use it in the second?
Should I just add as much boiling water as needed to get to 155?
Does anybody do a step in a cooler, if so what numbers do you do(temps and volumes per lb)?

I am to lazy to stove top mash, and I don't want to build an insulated box, so please limit answers to what I should do for cooler mashing.

The reason I am doing a protein rest is I was under the impression I needed to with 2 Row Breiss (Klages that is Harrington) to prevent chill haze and to get some needed yeast nutrients. Is that the case.

Thanks for the replies

Ed O'

Subject: raw honey

I think the diff betwene raw and processed honey is mostly filtration.
Raw
honey has lots of bee parts in it (legs, stingers, other private bee
substances we're not to mention on HBD), and filtration takes some of
that
out. I don't suppose it will make a serious diff since you should be
heating
the honey before you add it, but why have more bits of stuff in your
beer?
Papazian suggests filtered clover honey works best.

Subject: Copper bottom Stainless Steel brewpots

I was out doing some Christmas shopping yesterday, and just happen to have looked at some nice heavy Revere stainless stockpots that had copper bottoms... Too bad they didn't have any 32 quart size. The 20 quart were \$60 without lids.

In any event, has anybody tried electroplating the bottom of a stainless pot to apply a copper cladding? Are the metals compatible etc??? I do know that that a bath of copper sulphate, a copper anode and a battery charger will let you plate steel (nails etc) but when you get into stainless (chrome/nickel?) will it will it still work?

Date: Tue, 21 Dec 93 12:57:33 CST
From: philb@pro-storm.metronet.com (Phil Brushaber)
Subject: Keg Infection?

A couple of days ago I left a message about getting a medicinal/metallic off-taste in my brew after stainless steel keggung. A number of people were kind enough to reply and I now concede to a potential other problem. I'd appreciate hearing from you if you think I am on the right track, or if you have experienced/solved a similar problem.

Since I did not experience the problem with every keggung/brewed batch, I wanted to blame something in an individual batch process or ingredient. But it could also be that some of my kegs have a bacterial/contamination problem while others do not.

Let me say that I clean every keg before reuse and that I sanitize them by filling them with an Idophor solution for about 20 minutes before re-keggung. I even push in the little stopper at the top of the fill tube to release air and get solution up the tube.

But I'll admit I have never ripped these kegs appart and pulled the little liquid and gas knobs appart. I was thinking of cleaning them in either an idophor or bleach solution. I know that bleach does bad things to stainless, but I would only soak them for about 20 minutes and then rinse.

If I am on the right track, I'd appreciate hearing if someone else might have solved this problem and what kind of off-tastes they were getting. The off taste is hard to describe, but it is definately not like Coke or Sprite. I did change the large O ring, but obviously not the little ones inside the liquid/gas connectors.

Gotta get a handle on this problem. I refuse to drink/serve bad beer. I hate to go back to bottling (where I have had no problems with off tastes on any batches and essentially used similar ingredients/process).

Thanks in advance for your insight.

From: kovacml1@post01.alb.alcoa.com (Michael L. Kovacs)
Subject: yeast washing, Briess malt extract

I am a novice extract brewer (2 batches so far) and would like any input on the following items:

1. Yeast washing - I have read the yeast FAQ and the section on yeast washing seems pretty self-explanatory, but I would like some clarification from anyone out there who is using this technique. I just racked a 5 gal. batch from my primary fermenter and had a pretty good layer of yeast (I think...) on the bottom. It was the same whitish layer that settles to the bottom of my bottles. The Yeast FAQ says to add sterile water to the fermenter, and swirl it around to loosen everything. Then to dump this into the first sterile 1 qt. mason jar. After this step it says to agitate the mason jar and wait for the mixture to separate into layers. After racking, my fermenter did not seem to have much more there other than the yeast (not much hops or sediment from the malt)

I guess my exact question is... "Will it be pretty obvious which is yeast and which is sediment?" Also, assuming reasonable precautions are taken in sterilizing the mason jars and water, how high is the risk of infecting the yeast in the process.

The process of yeast washing appeals to me not just for the savings, but also for the idea of having a ready supply of yeast handy that I am happy with. I am also interested in eventually culturing yeast. Any opinions on this? Is it worth the effort? It seems like it is considerably more involved.

2. Briess malt extracts - I recently went in on a 60 lb. pail of Briess malt extract. The price was a significant savings over buying it 6 or 7 lbs. at a time. An issue of Zymurgy had an article on extract brewing and it favorably mentioned Briess. Does any one have any experience using this extract in bulk. I'm not sure exactly how I'll deal with measuring it out considering how gooey malt extract is in general. Any advice in this area will be appreciated.

(I do intend to make the leap to all-grain when I can afford the equipment

and I feel I am ready for the process. Is there anything like an all-
grain
FAQ out there on the internet?)

thanks,

Mike Kovacs

Subject: Re: Raw Honey vs Processed

> Can anyone tell me the difference in raw honey vs. the processed
> variety? Is the raw lower in sugar content since it hasn't been
> boiled, driving off some of the water?

As a beekeeper who uses his own honey in various homebrews, I can tell you that there is little difference between raw and processed honey.

Any raw honey that I bottle and sell has to be between 15-18% water (or else it could spoil and ferment). Processed honey (the kind you might buy in a large grocery store), has been pasturized, filtered, and blended to appeal to the tastes of the American consumer. For your information, most of the processed honey sold in the United States is now imported from South America.

Since raw honey has not been pasturized, it is possible that you could introduce some bacterial "nasties" to the wort, but I'm sure these would be eliminated during the boiling process. As far as sugar content, it is variable in raw honey, but I don't think it makes much difference.

When using honey in any recipe I am more concerned with the flavor of the honey (lightness vs. darkness) than with the water content. I have found that the source/flavor of the honey does sometimes affect the taste of the brew.

Subject: 5 Liter Mini Kegs

In HBD #1303 Diane Palme writes about 5 Liter Mini-kegs.

These sound like the same ones that Brew Ha Ha in PA has been selling. I got a set two weeks ago and my first beer is conditioning. Other people have told me they have had great luck with them and I hope to add further data after New Years.

BTW, has anyone had any luck taking these as carry on luggage on a plane? I am not so much worried about the trip, but rather what security would say as they went thru the X-ray machine.

doppelbock

James writes:

>1) why are wort chillers recommended? isn't an ice water bath almost as
>effective?

If it works for you, then great. I used to use an ice bath, but it did
not cool fast enough and my icemaker didn't make enough ice -- I had to
buy
some.

>2) do ales normally have that short of an optimal fermentation time (the
>kreusen had settled after only about 36 hours)?

"Optimal" is an odd word selection. The yeast will decide what's optimal
for them. This time is dependent on strain, temperature, oxygen, starter
size and original gravity. You can minimize the time by aerating well
and using a big starter. Higher temps will increase ester production
(fruity
flavors/aromas) in addition to decreasing fermentation time and
increasing
the hospitability for bacterial infections.

>3) because of the high gravity boil the beer is not as bitter as i want
it,
>so i was thinking about dry hopping in a secondary. is there a
recommended
>time to do this or can i do it any time after the kreusen settles? also,

Dryhopping will not add bitterness. Ideally you want to add dryhops when
the beer is almost done because evolving CO2 will scrub out some of the
hop aromatics. If you are sure you need more bitterness, you can make up
a hop tea by boiling just hops in water and then straining the liquid
into
your beer. If you boil 45-60 minutes, you will add only bitterness (no
flavor or aroma).

>can someone give me a range for the amount of hops to use in the
secondary
>(i know i didn't say how bitter our beer is right now, but i just want
to
>know if most people use 0.5 oz. or 8 oz when they dry hop)?

I use between 0.5 and 2 ounces.

>p.s. not that anyone cares, but i'm with lan and andrew on this AOL
thing.
>F*%@ censorship!

I'd like to point out that you "censored" yourself, which is what I
advocate. For what it's worth, Lanny and I have reached common ground
off-line on this topic and knowing Andrew, I'm certain that his IDEAS and
not his WORDS were the reason for him being censored -- for this, I too,
am
outraged.

Timothy writes:

>patience. So my first question is. If the beer is coming out good, why
>complicate matters? An example of what I mean is the use of oxygen and
>a bubbler system to aerate the wort prior to pitching. Is this really
>necessary? I just shake the hell out of my primary a few times after

It's not, but I read the HBD for new ideas for my own brewing and to help out with questions. Much of the discussion is strictly academic, but some has practical applications if you add it to other information you have read or experienced earlier. To use your example, for a 1048 ale, you don't really need anything but shaking your carboy, but for a 1120 lager, you will need to do more than that to get enough O2 in solution.

Brian writes:

> chill haze, two batches were satisfactory, and the rest suffered from
> haze problems that had nothing to do with chill-haze. These beers are
> cloudy even when warm.

Could it be too hot a sparge? Too hot a sparge water (above 170F or so) can liberate unconverted starch. Your Corona setting (*larger* malt fragments) would simply increase this effect.

Jim writes:

>This is one of my pet peeves too. I think the inspection is fine for
>rings, yeast cake/cloudiness, etc, but comments on "low fill levels"
>can be erroneous. The problem seems to stem from homebrewers who bottle

I'm with Spencer on this one. The inspection line is more of a note to myself. If I don't find a problem with the beer, I don't even mention it in the scored section of the form. By the way, I try to remember to check for sediment, so I know if this is a bottle-conditioned or CP-filled bottle.

Doug writes:

>into the secondary at which point it slowly bubbled away. Well, five days
>later it is still bubbling at a rate of about every 3 seconds which is
>completely different than batch 1 and batch 3 (an Australian Lager using
>Ale yeast). Is this normal activity or have I done something wrong? Is it

See my comments above on what affects fermentation time. Apart from sanitation there's little anyone can do to make an undrinkable batch -- I'm sure you did nothing wrong.

>Is it safe to bottle while it is still fermenting like this?

NO! Wait for the fermentation to go down to about 1 bubble every 1 to 2 minutes.

> Is there any good way to get a second SG reading
>without the risk of contaminating the brew?

Yes. Using good sanitation techniques, take a sample, measure SG and drink the sample (don't put it back into the brew).

>I would really like to get this

>batch into the bottle so I can expedite the drinking (hopefully be able to
>have a few with friends on New Years!!!)

Don't rush the brew. It's better to drink some quality microbrew for New Years than to spoil (overcarbonate) a batch by rushing it.

>Other questions: Are Australian Light Malts supposed to produce a golden
>colored beer/ale/lager (this is the color of straw)?

Being Australian has nothing to do with golden-ness. "Light" or "Gold" extracts from the US, UK, Belgium, Germany, etc. all will make a golden colored beer -- some darker than others. If you cannot get a golden beer from any extract, I suspect you are aerating your wort when it is hot, which will darken it considerably.

>How close will a dopplebock be to the real thing if I
>use ale/beer yeast (I am not yet set up to do real Lagers)?

It's not so much the yeast as the temperature. You will get a much fruitier beer than a Doppelbock -- more like a Strong Scotch Ale.

Al.

John writes:

>Short Ale Fermentations? When you use Extract with lots of active yeast,
>then you can have quick fermentations because of the simple sugars present;
>compared to All Grain where more complex sugars are present.

This is not really correct -- a quality extract wort made from all-malt extract will have a similar sugar profile to an all-grain wort. Crummy, dextrose-stretched extracts could make for a different sugar profile, but that would make for a longer, less-vigorous ferment due to the shortage of FAN (amino acids, for yeast nutrition).

>Capping Champagne bottles - All of the domestic champagne bottles can be >recapped with standard bottle caps. There are some French ones that have >bigger openings.

I believe Cook's bottles (if it's not Cook's then it's some other US sparkling wine) don't take standard US crown caps. But I agree that most US sparkling wine bottles do take the standard US crowns. Most european sparkling wines have the larger opening, but there are a few that do take the standard US crown cap (I believe Dom Perignon is one, so buy a lot when you find it on sale).

Conn writes:

>means of kegging. My reaction? great to see such innovation. Dave Line actually
>proposed storing the pressure from the primary fermentation for later use,
>which would overcome the need to prime with triple the normal

My fears would be: 1) that the pressure from the *complete* primary fermentation could get very high, even to the point of affecting the yeast and the possibility of explosion, and 2) primary fermentation often releases or produces undesirable gasses (DMS and some sulfur compounds, for example) and you would not want to use these. I believe that the commercial brewers "srub" their CO2 before reuse.

John writes:

>However, sometimes this doesn't quite work out, and I have to make a choice
>as to whether or not I should add brewing water at this stage to top up the
>carboy or leave the space in the carboy and hope the beer is still producing
>enough CO2 to protect it from oxygen. What is the consensus on this? Is
>topping up detrimental to the beer or is it at least less harmful than oxygen?

When you rack fermenting or fermented beer, you will inevitably release some dissolved CO2 (thanks to the partial pressure at the top of the siphon hose) so this will serve as a CO2 blanket as long as you use an airlock on your secondary. 1" is certainly not worth worrying about, but even if it was

more, I'd say the topping up is unnecessary. If you do top-up, use boiled water so you don't introduce dissolved O2.

Michael writes:

>they haven't put it into production. If you can't find a white beer yeast or
>are not ready to make a yeast starter from a slant, you might try the Wyeast
>Bavarian Wheat Ale yeast.

Wyeast *has* released their "Belgian White" yeast. On the other hand, a customer of mine has brewed some excellent Witbiers using Wyeast Bavarian Weizen yeast.

>This may be one of my crazier ideas, but I think it might get you closer
>to Celis than using a regular ale yeast. The Wyeast Wheat Ale yeast haso

>2 batches).

I don't think your problem is from the Stainless. Check your water chemistry (check for high Calcium or Magnesium levels) and then check your malt freshness. Stale malt has been known to give metallic flavors (see the Troubleshooting issue of Zymurgy).

>I have used pre-boiled Chicago City water. I usually do not
>check ph and don't really add any mineral salts.

I think you may have indeed diagnosed your own problem. From what I recall, most Chicago water is very soft. The dark grains that you are using will make the mash more acidic, in fact that why they were used historically. Most dark ale districts were those that had hard water and the acidity of the more highly roasted grains was used to counteract the high alkalynity of the water. What may be happening in your case is that

the acidic dark grains are dropping the mash ph below the ideal for conversion. you could try to get a ph reading from the mash, but I've never been able to read my cheap litmus papers in a dark mash. I would just add a teaspoon or so of calcium carbonate to it when you mash in and see what happens. Since the carbonate levels in my town often get as high as 300ppm, I've never needed to do this myself.

>Diane Palme, EIT

I have a set of these from Brew-Ha-Ha. I liked them a lot at first. They are a lot easier than bottling. They are also quite convenient and they fit

in the fridge in the kitchen.

Like everyone else that's used them at first I had problems with overpriming. You have to use a very light touch (<1/2 cup corn suger in 5 gallons) or they just produce foam. Too much pressure can even damage the can. Even after I mastered this I still had major foaming problems. I think that the dispenser could really use a hose type spigot so that the keg pressure could be brought down before the beer hits your glass at 90 miles an hour. Since my main experiments with the cans were with last summer's wheat beers, you can imagine the mess this made.

Now a few months later it seems that the tapper/dispenser (aka the expensive part) is damaged. I can't put in a co2 cartridge without most of the gas just blowing out the back and being wasted. Once I lose ~half the gas this way it still seems to have some sort of slow leak that means the beer will be flat by the next day. I don't recall doing anything savage enough to the tapper that should have broken it this way, but I do have 2 small children, so all bets are off...

I was dissapointed enough with them that I kept saving those nickels and dimes and got a fridge for the garage and and a real kegging setup. If I lived in a small apartment I think I would have stuck with the cans longer, just because they are so much more space efficient. As it is I think I will donate them to a freind that does live in an apt.

I'm not much in agreement with the three you mention above, but isn't AOL a commercial venture? I mean, didn't you pay for that service? I would say that, if so, you are strongly misusing the word "censoring". If they owns the turf, they get to make the rules. If they think "pissed off" is naughty, then they certainly have the right to refuse to post it.

If I publish a magazine, and chose not to publish an article of yours, either because it's badly-written or because I don't like your language, I'm entitled to leave it out. You're entitled, of course, to publish your own damn magazine.

No. What we really want is for people to be reasonably polite. If this means that people occasionally need to temper their language, I don't see this as trampling on your rights. You *do*, of course, have the right to shoot off your mouth any way you like -- you shouldn't, however, expect that other people should either like it or necessarily tolerate it. I would suggest it would be a good rule that no one say "on-line" something they wouldn't be willing to say to another person's face -- and risk getting popped one in the snoot.

From: aaron.banerjee@his.com
Subject: SPARKLING WINE

Is anyone out there making champagne for New Years?

I have been making beer in champagne bottles for a few years, and have yet to have a single explosion. Somehow, my champagne, on the other hand, seems to either be flat or explosive. The method of pressurizing I use is to bottle early, or add a small amount of sugar (as opposed to CO2 cartridges--that's cheating). My Christmas ale turned out fine, but I'll bet it doesn't compare to some of the others...

If anyone's making sparkling wine, and bottles without CO2, contact me directly at:

INTERNET: aaron.banerjee@his.com

Subject: Re: Whitbread yeast (1098)

I tried to mail this out on 12/17. Unfortunately, our mailer is down about 50% of the time, so access to the outside world is limited. If this posting appears twice (probably on different days), I apologize. You never know when a mailing actually makes it to the outside world.

Al writes (HOMEBREW Digest #1299):
> 3. mixed yeasts (the Whitbread triple-strain (Wyeast #1098) has been reported
> to have a slowdown in the middle of the ferment, for example), and ...

Russ responds (HOMEBREW Digest #1300):

> Was it ever settled if Wyeast 1098 has the 3 strains of Whitbread yeast
> or just 1 of the strains? ...

Looking at my notes from Dave Logsdon's talk, "Matching Yeasts to Beer Styles" at this summer's convention, Dave stated that 1098 was a single strain. He said that they were working on multiple strain yeasts that would be out soon. (Are any of the new varieties multiple strains?)

He also had a couple of other interesting points that I'll throw out here.

He claimed that numerous studies have shown that dry yeast does not give you a faster start than liquid. The foaming and gas production is a byproduct of the rehydration and is not actual growth. Neither form of yeast reaches exponential growth for about 12 hours.

Someone asked about repitching yeast from the secondary. Dave said that yeast should be taken from both the primary and the secondary, or you'll risk ending up with a yeast with different characteristics. His point was that a certain component of the yeast may "do its thing" early and drop out of suspension early and not make it to the secondary. Without this component, the yeast repitched from the secondary may have different characteristics.

Subject: pride & clean bottles

I was recently accused of submitting beer to contests because I'm proud of it. (I know I'm paraphrasing to make a point, so don't flame too hard, ok?) Well, certainly, there's some of that. I don't generally submit swill. (I inflict that on local brewclub members, instead. :-)

But what I was getting at was this: any beer I send to a competition is SOMETHING I MADE. It's therefore a LITTLE PART OF ME, and the presentation REFLECTS ON ME. If I send a grungy bottle, that's as good as saying I'M A GRUNGY PERSON. (Sure, sometimes, but not usually in public.) Not to mention the implicit message it sends to the judges: "I didn't have the 5 minutes it would take to clean up this bottle, but I expect you to give the beer in it a thorough evaluation anyway."

Someone else complained about how hard it is to clean bottles just to send in beer to a competition. My heart bleeds. Plan ahead. Soak the bottle for a day or two. I have yet to find a label that doesn't fall off of its own accord if you soak it long enough.

The last competition I judged, 5 judges decided for one reason or another not to show up. The rest of us spent 6 hours, judging 2 flights (typically >10 beers) each (and then the 6 of us who had any stamina left mass-judged the 8 beers in the barleywine category). And you can't spend 5 minutes cleaning your bottle. Foo.

So, if it's such a painful experience, why do I judge? Foremost, probably because it helps me improve my own brewing and my appreciation of good beer. Also, I'm giving something back to the brewing community. And, when you hit that one perfect beer of the competition, it's worth all the infected ones. And, it's fun (at least for the first 10 or so:-).

=Spencer

P.S. Does any of this relate to the discussion about "language" in the HBD?

PPS I'll be on vacation, reading HBD only sporadically, until the new year. If I don't respond to your counter-flames, that's probably why. (And cows can fly:-)

> out light and dark crystal. What is the color guideline
> for 'light' and 'dark'.

Here's a section of an article that I wrote for "The Brewprint" -
the Newsletter of the Boston Wort Processors.

Wort Processor and brewmaster at the Ould Newbury Brewing
Co., Joe Rolfe, has donated a 25 Kg sack of carastan malt from
maltsters
Hugh Baird in England to the club.

What is carastan malt ??? An essay by George Fix in the January
1993 Brewprint provides some clues. Here's a brief synopsis.

Carastan malt is produced by roasting "green malt." It is
enzymatically inactive. The roasted "green malts" produced by HB are
subdivided into four categories:

light carastan 13-17 L
carastan 30-40 L
crystal 70-80 L
dark crystal 100-160L

For this particular malt, Joe has supplied some specific information.
First, he says that it is dextrinous. The color is 32.8 L, it has a
fermentable extract of 71.1% and a moisture content of 8.8%.

Hope that helps,

Tim

> should know! The extracts taste fine, but Hoptech's ridiculous S&H
fees
> left a bitter taste in my mouth...

I agree that adding handling fees to orders is not appropriate: I think many suppliers do this so that their prices seem lower than they actually are. I believe a customer should pay for the cost of the product and actual shipping fees and any SPECIAL packing or shipping e.g., special packing for glass or overnight air shipment. IMO, filling an order, packing a box, and getting it to UPS/RPS or the Post Office is *part of the cost of doing business*.

Most suppliers list these costs in their catalog or other literature and I agree with Gary: let the buyer beware. The reality of shipping is that there is a minimum charge for a package and the shipping cost increases nonlinearly with increased weight. I think a more ethical practice is to charge only for shipping. If small orders are a hassle, then offer an incentive for larger orders i.e., free shipping rather than penalize the customer for small orders.

With regard to Phil's problem with keg infection:

> Let me say that I clean every keg before reuse and that
> I sanitize them by filling them with an Iodophor solution for about
> 20 minutes before re-kegging. I even push in the little stopper at
> the top of the fill tube to release air and get solution up the

cleaning
> them in either an iodophor or bleach solution. I know that bleach does
> bad things to stainless, but I would only soak them for about 20
minutes
> and then rinse.

I believe that Iodophor is more of a sterilant than a keg cleaning solution. I recommend using TSP to clean soda kegs or kegs that have had beer sitting in them w/o a CO2 cover. I use 1/4C per gallon in *very hot* water and let them soak for several hours, then rinse well. If your keg is visually clean and still has a soda or unpleasant odor, there is a non-vanishing probability that your beer will pick up this odor/flavor.

Without initiating a veritable plethora of net traffic regarding the socio-economic implications of o-ring/poppet valve replacement, I

suggest replacing the large o-ring, the diptube o-rings, the ball or pin valve o-rings, and the poppet valves. IMHO, rebuilding your kegs is a good investment(\$5 to \$6) and will increase your chances of making consistently great homebrew. Isn't this what it's all about?

From: gelinas@ekman.unh.edu (Russell Gelinas)
Subject: cleaning kegs

Before I keged a recent batch, I happened to take a look inside the long pick-up tube. It looked less than clean. So I took the ol' ubiquitous Q-tip and put it in the tube, and forced it through with hot water. The Q-tip came out dirty, and the tube was noticeably cleaner.

If you sanitize your kegs with boiling water, a dirty pickup tube may not be a problem; the heat should kill most anything. But if you use a sanitizing solution, it may be more important to ensure that all parts of the keg are clean before sanitizing. Either way, it's small work to clean the tube.

Re. sanitizing solutions: I've got a 5-gallon plastic bucket that I keep filled with a strong, almost saturated, solution of B-Brite. As long as I remember to tightly seal the cover, it remains active (ie. it is still very "slippery") for a long time (months). I even store things such as rubber stoppers and plastic fermentation locks right in the bucket.

Subject: Brewpubs, and other pipe dreams...

Several friends and I have been musing about what it would take to start a brewpub, now that they are legal in Texas. My main interest in this is to bring good beer to Texas, and to learn to brew on a bigger scale. I've brewed about 20, mainly partial-mash brews, and certainly dont feel like I (by myself) have the expertise to brew on a big scale.

Do you need a Masterbrewer to start, and if so where do you find one? Should you start with extract brewing, or bite the bullet and do it right the first time; what are the cost trade-offs with either method? Have any of you micro owners tried these "rent a brewmeister" folks who come out and show you the ropes for several weeks?

This is a bit tangential to most digest requests, so private E-mail is suggested and welcome. Any insights, anecdotes, or war stories would be appreciated.

Thanks, and Merry Christmas.

From: mri10@mfg.amdahl.com (Michael Inglis)
Subject: Carapils

I posted this to r.c.b with no response so I'm trying it here...

When should Carapils be added in the mashing process to obtain the residual sweetness associated with the grain? In the past I have added it at mashout along with my Crystal but I'm not sure how effective this is. I have heard two versions. The first being that there is no need to mash Carapils and the sweetness will show up if the grain is treated as a specialty grain. The second version is that the grain needs to be mashed to get anything but starch out of the grain. Does anyone have the true story?

From: Earle M. Williams <earlew@drc.usbm.gov>
Subject: Summary of responses to Insufficient head problem

I posted an accounting of a recent problem where I noticed my Nut Brown Ale (nicknamed Moonbeam after a famous California governor) would lose its head immediately after being poured into the mug (from a bottle... I haven't kegged in a while, but more on that later.) I received several responses, some in HBD and some private email. Several suggestions were given, and I'll list a few.

Cause/Solution #1 - Soap residue in mug

=====

>From: jim@n5ial.mythical.com (Jim Graham)
>Btw, just thought of something---this may be a bit on the obvious side,
>but then, I wouldn't have known it if someone here hadn't told me, so..
...
>You're not using soap to wash your beer mugs, brewing equipment, etc.,
>are you? If so, that's an instant head-killer. Apparently, there's a
>residue left by the soap that's nearly impossible to get rid of. I
rinse
>my mugs out with a mild bleach/water solution every so often (I'm
normally
>the only one using them---if anyone else is going to use them, they get
>bleached before and after no matter what).

Others had similar suggestions, and I'm sorry for not giving appropriate credit.

Cause/Solution #2 - Insufficient Carbonation

=====

>From ryptyde!mikel Mon Dec 13 14:40 MST 1993
>Head Problems:
>Two things you could try. First, add more sugar at bottling time. I've
>found 3/4 cup of corn sugar to be insufficient unless I pack down the
>sugar with my thumb and add more to make 3/4 cup. (Pretty dumb
>measurement method. I need to get some decent scales and measure by
>weight.)

This could be the culprit. Since I'm pretty sloppy at measuring to 5 gallons, I may not have enough carbonation, even though it does seem to foam up some when pouring.

Cause/Solution #3 - Not enough small proteins

=====

>From ryptyde!mikel Mon Dec 13 14:40 MST 1993
>Second, increase your head retention by adding 1 lb. of dried wheat malt
>extract. This may cause a chill haze, but will make the head last much
>longer.

Some postings in HBD also suggested I either add some wheat malt or more hops
TO get sufficient proteins in my wort. Thanks for the suggestions!

One final suggestion from someone who shall remain anonymous - try a dozen red roses! ;->

Thanks again for all the help!

Subject: Copper Electroplating

Tom Clifton wrote:

In any event, has anybody tried electroplating the bottom of a stainless pot to apply a copper cladding? Are the metals compatible etc??? I do know that that a bath of copper sulphate, a copper anode and a battery charger will let you plate steel (nails etc) but when you get into stainless (chrome/nickel?) will it still work?

What I can tell you about this is that it is best done in a lab. Electroplating is usually done in cyanide baths or in the case of sulfate baths, at high current densities 40 amps/ft-squared. Not easy to do at home in the sink. Also the stainless needs to be pickled in strong acid beforehand to remove all of the surface oxides that make stainless stain-less. Aluminum cladding is done under pressure by rolling two sheets together. It is cheaper than copper electroplating and provides nearly identical results in terms of heat transfer characteristics.

>and then rinse.

Bacterial infection is not the only possibility. This problem is
beginning
to sound a lot like a problem that I had with funny tastes in kegged
beer.
I was using the exact same procedure - sanitize with idophor, push down
the
poppets to get full coverage, force idophor through all parts with CO2. I
had no problems with my bottled beer but the kegged beer came out with
what
I suppose you could call a medicinal/metallic taste. It wasn't a
bacterial
infection taste though it was an IODINE taste. To this day I can't serve
porter to my homebrew club without at least a few snickers. My experience
with idophor is that not only does it have to be rinsed but that the
rubber
parts of kegs like O-rings and gaskets can pick up a long-term iodine
flavor.

I started tearing my kegs apart, boiling all rubber parts, sanitizing the
metal parts with chlorine or idophor, and then rinsing all metal parts.
with boiled water. The cornelius kegs aren't that hard to take apart.
Just
unscrew the intake and output valves. You can use an adjustable wrench
but
having the right extra-deep socket wrenches (~\$5.00) makes the job a lot
easier. I think 3/4" or 7/8" sockets fit most keg valves. With the valves
unscrewed the two tubes (short air tube, long liquid tube) pull right
out.

>myself. If I don't find a problem with the beer, I don't even mention
>it in the scored section of the form. By the way, I try to remember to
>check for sediment, so I know if this is a bottle-conditioned or CP-
filled
>bottle.
>

Checking for sediment is not a good test. It is easy to get lots of
sediment in a CP-filled bottle. For example the first few glasses (or
bottles) out of a keg pick up some of the yeast sediment from the bottom.
The same can happen for a whole batch if you CP-bottle before all the
yeast
has settled out or if you shake up the keg accidentally but have to ship
your
beer to the contest that day. Conversely, I know microbreweries that
filter
their beer before priming and then prime and add just enough yeast to get
carbonation. They are bottle conditioned but have virtually no visible
sediment.

My main point is that non-judges can take bottle inspection comments
seriously. They don't know that they are just notes to yourself. The
comments should be to provide constructive feedback to the brewer and I
feel that any comments that don't directly relate to the quality of the
beer are inappropriate especially when they can be perceived as negative.

Subject: Making a Belgian White Ale...

Some minor clarifications and updates to Micheal Yee's posting on the "HBU-BBS/Steve Daniel- Celis White" recipe in HBD #1302:

- The portions about the proper yeast selection were in fact written by Steve Moore, the HBU-SW Campus Sysop, and not by Steve Daniel. All other sections are properly attributed to Steve Daniel and Tony Storz.
- Pierre Celis was present at all major events at the Dixie Cup in Houston last October. He was very open and gracious with information about his brewing process, giving us added confirmation that we were on the right track with this recipe.
- Dave Noonan's brewpub in Burlington, Vermont is now making a commercial Wit based directly upon the HBU/Steve Daniel recipe. Unfortunately, I have not had a chance to try it yet, but have heard good reports.

I just brewed an all-grain batch of it with some friends, and can confirm that the yeast selection is indeed crucial. We started with some growing dregs from a Steendonk bottle. This plodded along for a few days, and then we ended up pitching some Bavarian Wheat Wyeast to get the thing going. We're still waiting on final product while we "dry-BOQ" on the Bitter Orange Quarters that Pierre recommends, but the beer was quite close to Celis in terms of color and aroma at the time of racking. If we can just get the gravity down to an acceptable range and pick up the proper flavors from the Bitter Orange Quarters, we should have a really close imitation of Celis White. We're also considering adding some lactic acid before final kegging in an attempt to simulate the results of the secondary lactic fermentation that Pierre does. I'd be interested in any HBDwisdom on how do achieve this last step.

P.S. My heartfelt thanks to ALL who replied directly to me regarding my recent posting on AOL and censorship. Even those of you who called me names that made my poor naive ears turn red!! "I may not agree with what you say, but I will gladly fight to the death for your right to say it!"

Subject: Slotted Copper/Step Mash/Miscellany

John Wheaton writes about installing a slotted copper tube to the bottom of his mash tun to make it a mash/lauter tun. This will work, John, as it is similar to my cooler setup. With only one pipe, I would probably try to put it directly on the bottom of the tun though. This will leave less liquor behind and probably prevent more of the grain from finding its way into the slots. Very little of the grain would be trapped under the pipe, I would think not enough to worry about in terms of temperature extremes. I'm sure Jack will note your reason for not using SS screen: it is less durable than the pipe. He claims that the SS screen he buys is very rugged and that durability is not an issue. I have not found SS readily available in my area.

**

Andy Kligerman raises some good points about accuracy of curves fitted to approximate data points, then says "Sorry for rambling on, by I'm in the government and here to help you!". Now I thought it was coming up to Christmas, not April Fools Day! Ha!

**

Ed Oriordan writes:

>Papazian gives the following numbers (working from memory here)
> For 1 step infusion - Add 1 qt 165 H2O per 1lb grain (Target 155F)
> For step infusion - Add 1 qt 128 H2O per 1lb grain (Target 122F)
> Add .5 qt 212 H2O per 1lb grain (Target 155F)
>
>I have also found that the .5 qt he purposes does not get me
>to 155, but more like 145 I was afraid to add more boiling H2O(making it
even
>thinner) so I did a partial decoction(more work than I wanted).

These numbers are just a guide. Every mash tun is different (absorbs different amounts of heat, etc.). You need to adjust these numbers (keep good records) to own setup. I would recommend using something like .75 quart of 145F water per 1 lb grain to hit your protein rest temp. Then use up to .5 qt 212F water per 1 lb grain to hit your saccharification temp.

>What are the consequences of the mash being so much thinner (than his >1 step infussion, it's 50% thinner) during the final step????

A thicker mash encourages one of the main saccharification enzymes and a thinner mash encourages the other (alpha amylase likes it thick??? I can't

remember). Anyway, it is in at least one of the common books. Look it up and you can then adjust your temperature to aid the enzyme that's getting the short end of the stiffness stick. Of course, this may end up making a poor environment for both enzymes! Comments?

>Should I use less H2O in the first step and use it in the second?
>Should I just add as much boiling water as needed to get to 155?

See above.

>Does anybody do a step in a cooler, if so what numbers do you do (temps and volumes per lb)?

Now you've got me. I haven't ever really tried this (sheepish grin...) Remember that this advice is worth exactly what you paid for it.

>I am too lazy to stove top mash, and I don't want to build an insulated box,
>so please limit answers to what I should do for cooler mashing.

>

>The reason I am doing a protein rest is I was under the impression I needed

>to with 2 Row Breiss (Klages that is Harrington) to prevent chill haze and

>to get some needed yeast nutrients. Is that the case.

You'll probably get lots of reponse about how you are wasting your time doing a protein rest in the first place (well-modified malts like Breiss 2-row don't need it, etc.). I am interested in the subject for future brews which may require it. Also, it would be interesting to be able to do multiple saccharification steps (say, 145F, 150F, 155F, mashout) to see the effect it has on the brew. I'm not sure this is possible though without really diluting the mash.

**

Phil Brushaber, I think you are on the right track in reworking the poppets and O-rings in your kegs. I have learned this lesson the hard way as well.

**

Jeff Frane writes:

> I would suggest it would be a good rule that no one say

Subject: Re: 5 Liter Mini Kegs

In HBD #1303 Diane Palme writes about 5 Liter Mini-kegs.

I got one of these as a gift this fall. I put up a batch this fall with quite mixed results.

- 1 - The beer was mostly foam when I first tapped it.
 - 2 - I may have over primed it - the pressure bulged out the keg quite a bit.
 - 3 - It was Ok over the next 2 days.
 - 4 - With the tap on it is taller than a standard fridge shelf
 - 5 - This beer was good, and reasonably carbonated in bottles
 - 6 - 5L is actually quite a bit of beer. This meant that I ran out of bottles all the quicker and had to wait for an occasion to open the keg.
 - 7 - I tapped one of the comercial 5L mini kegs using the same tap and it had similar problems.
 - 8 - If you add too much Co2 the kegs leak around the bottom (or top) crimp.
 - 9 - Anyone want to buy mine? :(

Subject: A-B Boycott/Budweiser

While A-B may be a multi-gillion dollar juggernaut don't suppose that they will not take notice of the Patriots call for an A-B boycott.

>From Advertising Age, Dec. 13, 1993 front page story: "California Budslide Hits Anheuser-Busch".

The article details A-B's move to cut California Budweiser prices to stop the brand's decline in market share....

"Budweiser's rate of decline has increased this year, say knowledgeable observers. Partial-year figures gathered by BEER MARKETER'S INSIGHTS show that in a flat industry, A-B sales drops are concentrated in New England and the West." Go Pats!

also....

"Normally, the beer industry points to California as a trendsetting state. In San Francisco, some observers say Budweiser taps at bars are being replaced with local or specialty brews."

Hurrah...but...

"A-B and distributors, however, argue there were some unique circumstances in California this year.

'We had horrendous weather.....economic woes....taxes....other brands selling at \$4.99 a case...."

And the plot thickens...

"A-B also announced plans to introduce another new brew next year, possibly a flavored beer." Wow, Bud with a taste!

"Some distributors last week said they had heard of negotiations with Boston Beer Co. under which A-B which(sic) would bring Samuel Adams specialty

beer to its stable. Boston Beer officials could not be reached for comment."

Busy day in court, perhaps? Old rumors that refuse to die? Nothing like some quality hearsay.

And what of the new Bud commercials...targetting twentysomethings who can do

nothing but rattle of topical lists and drink Bud? Geez. I want to drink with those guys.

Happy Holidays,

Subject: Evaluating Beer w/ Jim Koch

I recently received a new book from the AHA entitled Evaluating Beer.
What
I read so far seems pretty informative but I noticed one the final
chapters
was written by Jim Koch (the book is a collection of previously published
articles by various authors). His was a fairly short article which
basically
says that hops and malt are THE most important factors in beer taste. The
word yeast is not mentioned even once in the entire article. He does
mention
water but says that is not important because it can be treated to suit
whatever the brewers needs are. As an example he points out the Bud
tastes
the same whether iuts made in Tampa, Newark or St.Louis. I suppose this
means AB could produce Pilsner Urquell or Bass Ale if they had the right
hops and Malt. Other than this chapter the book appears to be worth the
price.

From: David P. Atkins <ATKINS@macc.wisc.edu>
Subject: Heileman Brew. Co Beerwatch

Hello again,

Just as I posted the Ad. Age piece on Budweiser, I found the following information concerning Heileman; brewers of Colt 45, Mickey's bigmouths, Special Export Light (GABF medal winner, I think) Old Style, Rainier & Lonestar.

Advertising Age, Dec. 13, 1993, "Heileman Buyer Eyes New Markets"

"The new owners of G. Heileman Brewing Co. plan to aggressively expand into new markets, including buying competitors, while maintaining a regional approach to selling beer.

Richard F. Gaccione said he and his new bosses are of one mind on the company's strategic plan: aim for growth by tapping new markets or buying smaller competitors, and by focusing market resources on new brands."

Being a resident of Wisconsin and also being surrounded by some fine microbreweries and regional operations, I express some concern of a hungry fish entering the pond. Berghoff of Monroe Wisconsin and of Berghoff Hotel, Chicago fame is the property of Strohs. Leinenkugel's (sp?) is the property of Miller.

What of Sprecher, Capital, Point, Schell? Have any list members heard any business rumblings concerning regional breweries?

Will the quality and character of regional brewing be adversely effected by takeovers or will just the name on the letterhead be changed? For instance, Berghoff no longer brews beer for the Berghoff Hotel and anecdotal accounts tell of the brand's loss of appeal in light of an expanding local beer market. All points of view and information are encouraged.

Thanks and more Happy Holidays
David Atkins

From: Alec Saunders <alecs@microsoft.com>
Subject: High malt glucose syrup, etc.

Hi all --

I have three questions for you:

(1) I recently started brewing again, after a prolonged hiatus (7 years!). When I went to the local home brew store I asked for some dried malt extract instead of corn sugar to go with an english bitter kit I had. The proprietor of the store sold me stuff called "high malt glucose syrup" instead. I made up the kit with this syrup, and then put it downstairs to ferment about a week ago. I just tested the gravity yesterday to see if it was ready for bottling, and had a sip of the beer that was in the graduate cylinder. It was FABULOUS --> no cidery overtones, lots of body, and an incredible malt flavour. What **is** this stuff? I assumed, from the name, that it was just glucose syrup. It sure doesn't leave a taste like glucose, though!

(2) The proprietor of same store tells me to bottle as soon as the gravity falls below 1.010. Says that if I let the beer ferment further I'm "losing alcohol". This doesn't make sense to me. Can anyone explain?

(3) There seems to have been a lot of discussion about starter gravities in HBD. I've just gone and made up a pile of starters (boiled up 2 gallons of wort, then canned it in mason jars). The starters turned out to have a higher SG than I was expecting -- about 1.050 vs. the 1.040 that I was trying for. I suspect that the 1 Kg bag of dried malt extract I purchased was a little overfull. In any case, my question is simply this -- does anyone have a good feel for what the optimal SG for a starter is? Is my 1.050 going to cause a problem?

Thanks for all of your help.

Alec.

I took second place in the national Weiss is Nice competition
with a totally simple recipe.

For 5 gal:

6 lbs Yellow Dog Extract
1/2 lb. cracked crystal malt
1/2 oz. Hallertau hops

YeastLabs Weizen yeast in 1 qt. starter

Steep crystal in water as water is brought to boil.
Add hops and extract.
Boil for 90 min. (longer boil is better for wheat beers)
No finising hops.
Force chill and pitch yeast at 68 deg. F.
Ferment till done.
Rack to secondary and lager at 40 deg. for one month.

The YeastLabs Weizen strain deserves all the credit. The true
Weizen cloviness really comes through.

Subject: Fixed Kettle Thermometers
Full-Name: Will B. Blalock

I have seen pictures of SS kettles and hot liquid tanks that have thermometers attached on the sides midway between bottom and top. Is this easily done? Does it take a special thermometer which has to be welded to the side or can it be attached in an easier way? Where do you find these flat thermometers (or do you cut the stem off a typical style thermometer? Is it worth it?

From: WESTEMEIER@delphi.com
Subject: Bulk hop purchasing

I hope this doesn't get interpreted as a commercial, but I would really like to share a good experience and recommend it to everyone:

Our homebrew club (the Bloatarian Brewing League) has always bought grain in bulk quantities (like a ton or two at a time). This method has been so efficient and economical that we decided it would be worthwhile to try buying hops the same way.

We gathered everyone's list of what hops they expected to be using between now and next harvest, and consolidated them into one big list.

Then we checked some suppliers and settled on The Hop Source in Oregon (Glenn Tinseth, 503-873-2879). Since it was a bulk order (over 25 pounds), Glenn gave us 50% off his normal prices for the 92 crop, and 25% off his 93 crop prices. We wound up buying 72 pounds of hops, and Glenn's only restriction was that we order in units of pounds.

When the hops arrived, they were packed in one-pound, oxygen-barrier vacuum-sealed bags, and the 92 crop looked as good as the 93 crop. Bright green and beautiful.

I'm sure that other hop merchants will offer similar deals, so this isn't really a "plug" for The Hop Source, and I certainly don't have any connection of any kind other than as very satisfied customer.

If anyone is looking for hops to carry them through the winter brewing season, I strongly encourage you to get your club together and put a bulk order in now.

One final note: I have found that once the oxygen-barrier bag is opened, an excellent way of keeping the hops pretty fresh is to wrap them in aluminum foil and crimp the edges tightly. Zip-lock plastic bags are useful, but they don't keep the oxygen out, while aluminum foil gives you as close to an airtight container as you're likely to find. Obviously, you want to keep them in the freezer or at least the refrigerator (or even outside if you're in a cold climate), since the vapor pressure will be reduced by the lower temperature, also contributing to freshness.

Subject: Hops Storage Question

Ed Oriordan writes:

>Question 1) I store my hops (pellets) in the freezer. They are not in oxygen barrier bags, but in little heat sealed plastic bags. Would it help preserve them if I put them (still in the bags) into a glass jar and filled the jar with CO2, and then closed the jar and put it in the fridge.

Yes. This will approximately double the storage life, or another way of looking at it is this will cut the rate of deterioration in half. Whether this makes any practical difference or not depends on how cold the hops are,

(you've got them in the freezer, so that's good) and how fast you use them.

If you use the hops within a month, it isn't going to matter much (assuming you keep them in the freezer). But if you store them longer, then it's worth the effort to CO2 flush them. I would suggest you fill the jar first, then put the hops in, then top up the jar.

A more important question, though, is how have the hops been stored before you bought them? If they were stored in "little heat-sealed plastic bags" then they may have gone through a significant amount of deterioration already, again highly dependent on the temperature of the storage. I *am* assuming

that these bags are polyethelene and not a barrier bag. Polyetheylene bags

are the same as zip-lock or sandwich bags, and aren't an O2 barrier. * BUT*

the homebrew industry is waking up and some of the major wholesalers are distributing their hops in O2 barrier material in small bags. So if these

are the bags you have, then further putting them in the glass with CO2 is unnecessary. How can you tell the difference? Get a sandwich bag and compare the look and feel of the material. If it looks and feels substantially the same, then these bags provide virtually no protection. OTOH, barrier material is "shiny and polished" looking and is usually considerably stiffer than polyethelene. The ones I have seen from a major

distributor also have little bumps molded into them (helps the vacuum sealer

out). Your homebrew store may also have done their own packaging in barrier

material (I don't mean to imply that only distributors provide hops in barrier packaging, some of the better homebrew stores and hop suppliers also

take great care in their packaging and storage.) Probably the best test is

leave the hops at room temp for a few hours and then smell the bag. If you

can smell hops, then the bag is not barrier material.

Subject: capping/hoptea/etcetera

A couple things:

(These may already have been dealt with & I missed them--work has been interfering with my life...)

On capping champagne bottles--normal caps will work on american bottles BUT the capper I have (it's the jerk-and-squeeze-em type, not a bench top) will not work because the champagne bottles below the bulge are bigger in diameter than beer bottles below the bulge. You need to have a bench-type capper (with the bottle free-standing) in order to cap em.

Someone talked about making a hop tea (instead of turning the hops loose in your wort). Could someone with experience describe the process of making hop tea--how to do, when to add, etc. Or does someone have a good method of dealing with loose hops, so they don't muck up the straining? TIA

A big thanks to the wylie one for talking me into fresh hops. Just did my first batch, and MAN the difference! No more pellets, hopped extract, etc for this brewminor!

Time to celebrate the ancient tradition of Beermas! Cheers to all!

Subject: 5 Liter Kegs

There has been a recent chorus in the HBD about 5 Liter Mini-Kegs so I'll take this opportunity to chime in ...

I've been using the 5 Liter keg and Beer King CO2 tap for about 6 months now, or about 4 batches. Four of my kegs were purchased from a local Homebrewing Supply Store the other is a salvaged keg that had a commercial brew in it. So far I'm satisfied with their performance. They fit, snugly, on the top shelf of my refrigerator and I can enjoy a cool glass of Homebrew each night with my dinner. I don't use the CO2 until the natural pressure is too weak to dispense beer and then I only use enough to keep the brew flowing. Still, I usually go through 2 or 3 cartridges using them this way. The first half glass is all foam and yeast but after that all seems well.

The kegs seem to transport well. During the summer months I started taking one to the lake for the sailing club to consume after the races.

The kegs are just the right size to sit in a bucket of ice and provide brew for everyone. When used like this one CO2 cartridge is all that's needed.

Longevity is my remaining concern. Some of my quart bottles are 25 years old, I don't think these kegs will make it that long. I haven't had leaking seams or bulging kegs (I always leave at least 1 to 1.5 inches of space at the top) but, they are showing signs of use. The kegs are plastic coated steel and mine are beginning to show some signs of rust on the outside where they have been bumped or scraped.

Subject: RE:MASH/LAUTER TUN

Mashing in a SS keg with a screen false bottom. If your doing this in a RIMS setup, it will work fairly well. However, if your applying direct heat to the bottom of the keg, as you mention, yes, you will scorch/burn your mash. The next logical step is to remove the false bottom and add the slotted tube. If you plan to use just a short piece of slotted tube, rest assured that it will promptly clog. Consider enclosing the tube with a simple lint filter (used on washing machine drains), EasyMasher, Chore boy, or even the screen removed from a kithchen pasta strainer. All will work well if clamped over the slotted tube with a small hose clamp.

From: John Mare <cjohnm@ccit.arizona.edu>

Subject: RE: Cider flavour; priming

Mark asks about the use of sugar for priming and the cidery flavour he is experiencing. In my opinion, the cidery edge to your beer is not the result

of the priming sugar, but if you want to test this use light dry malt extract as I always do. For me, bottling 5 gallon batches, the following gives very consistent results: For ales, 1.25 cups DME in 2 pints of water,

boil for 15 minutes, cool in closed kettle, pour into sanitized bottling bucket (a 5 gal plastic bucket with spigot), siphon beer from carboy without

aerating, stand for 15 mins while preparing bottles, bottle! For lager I use

1.33 cups DME to give a little more prime. For ales I find I have adequate

prime in 7 days at 68!F, full prime by 14 days. For lagers at 50!F or lower,

the prime takes much longer (2-3 weeks).

I have been told by people who work for A-B that, in fact, their brewers
can tell the difference between Budweisers from different sites, and
can even tell *which* site the beer originated from. This is obviously
a highly-specialized skill, which personally I can do without. But...
Make no mistake, though, A-B is technically capable of producing
extraordinary beer if they chose to. They may even have some brewers
who would *love* to do so. But if you'll talk to any of these people
they'll tell you who controls the beer: the marketing guys (gee! Jim
Koch!).

What's Koch doing telling anyone how to actually brew beer, anyway? And
please, Jim, no more crap about your granddaddy's recipe. Unless, of
course, Owades was grandma's milk man?

Subject: Water Hard/Soft Info.

Hello readers,

Whilst browsing a book in my library's reference collection, I found an item that may be of interest to homebrewers and beer hunters alike.

To determine a city or town's water hardness, you can use the EDITOR & PUBLISHER MARKET GUIDE: An annual publication providing data on daily newspaper markets in the US and Canada. If you know of a town or city with a daily newspaper, this publication will provide the data.

Why does a Market Guide care about water hardness? Lots of reasons.... but I won't blather here.

Instead, to the chase. Each market is highlighted with various types of data, including "Tap Water". This directory does not provide Ph readings but it does inform the reader if a town's water is hard, soft, medium, neutral, alkaline, acid, city, county, or fluoridated.

For example:

Madison, Wisconsin
Tap Water: Alkaline, hard; fluoridated

or Chico, California
Tap Water: Alkaline, soft; not fluoridated

While not the most informative source, it could be handy to curious brewers prospective movers, beer hunters, triv buffs, etc. The directory does not provide any explanation to the above descriptions, so it ain't science.

Feel free to email with any reference request AFTER JAN. 4TH 1994. I will not be in my little library till then. Most academic and urban public libraries carry the title.

Subject: (simple)beer/wine suggestions

Season's Greetings! I have been homebrewing for ca. 3 months. I would appreciate any (reasonably) simple suggestions for jazzing up brew kits. Also, I have very much enjoyed some fruit wines I have made, even though they should be aged more. Cranberry was exceptionally strong and sweet, with a slightly bitter but enjoyable aftertaste. Apple has been a tad weak, but the apple flavor is noticeable and pleasant. It's way too early to tell on the banana, parsley, or rhubarb. I'll be starting five gallons of mead in two weeks or so. Any other suggestions for fruit wines, or comments about these, would be greatly appreciated. (I'm trying to do these without a press, by the way.)

Many Thanks!!! --- K. P.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
Subject: copper manifold/cleaning brass/mashing corn meal/grain source

copper manifolds:

John wrote (in HBD #1304):

>The reason for not using a rolled up screen is the durability of it when
I am
>mixing the grain during mashing.

I can't imagine how you could dislodge the rolled up SS screen, provided
it
is attached with a SS hose clamp. I have not had a problem in my
admittedly
very limited experience (6 mashes).

The only reason I can imagine using slotted Cu pipe instead of SS screen
is
the limited availability of the latter. I bought my 1st easymasher from
Jack,
and then made two more myself. I was lucky enough to find a large piece
of
SS screen in a dumpster behind a machine shop. (I am not too proud to
look
into dumpsters.)

Just for the record, I would like to say that I am really happy with my
easymashers. I seriously doubt if I would have gone to all-grain if I
had
had to use a picnic cooler/Cu manifold or a Zapap approach. To me, the
easymash approach is much simpler and cheaper. I have never had a slow
sparge, and extractions are generally 30 pts/(lb/gal) or better.

This is not intended to be a plug for Jack's business. I think you
should
make your own easymasher. Just stay away from my dumpster ;)

cleaning brass:

On a related note, I have come across a large number of brass fittings
that
may be useful in brewing, but I don't know what they were used in before.
I was wondering how I could clean them up so that I could be sure no
toxins were left adsorbed on them. I have thought about boiling them in
some kind of acidic solution, perhaps vinegar. Does anyone have any
ideas
about this?

mashing corn meal:

I have seen flaked corn used as an adjunct. I would like to know if I
could
substitute corn meal. For that matter, could regular wheat flour be used
as an adjunct?

grain source:

Does anyone know where I can get big sacks of quality 2-row malted
barley mail order?

Thanks,

Joel Birkeland

Subject: Where did it go?

Greetings from Zion (where homebrew is not only delicious but a misdemeanor too)

I have one question for other brewers using Cornelius kegs.

How do you refrain from draining your keg everytime you tap it? Last weekend I popped for a keg system and force carbonated 5 gal. of oatmeal stout. I decided to share it with some friends and we emptied it in what seemed like mere minutes. It was fantastic. WAS fantastic. It's gone.

Homebrew seems to last much longer when you share it in 16 oz portions, rather than 5 gal. at a time! Oh well. Following this experience I feel obligated to caution prospective keggers.

Beware! Kegging requires super-human restraint. I guess I'll bottle every other batch just to keep beer on hand for guests.

Enjoy yourselves.

From: yeebot@aol.com

Subject: Hoegaardse Wit vs. Celis White, a survey.

I had the most incredible (mis)fortune of drinking Hoegaarden on tap in Amsterdam last summer. I was transformed! Upon returning to the US, I learned from the barkeep that Hoegaarden was no longer available here and was turned on to Celis White, which I'm sure you all know, is brewed by Pierre Celis who revived Hoegaarden in the 60's. Well, I'm not quite sure what it is: maybe it's the Tap vs. the Bottle (Celis), the water (Hoegaarden vs. Austin) or maybe even the "double" Westmalle trippel I had before I tried the Hoegaardse. But even the fine new brew of Celis, IMHO is no substitute for the Hoegaardse Wit.

Michael Jackson writes that Celis White is fruitier and more full-bodied than Hoegaardse Wit. My memory tends to disagree. But always reserving the Final judgement until I have both in front of me, I ask for help: Can I get Hoegaardse Wit and/or Celis White on tap anywhere in the NYC area? Anywhere in the US? (I hope to do some trekking this summer)

Also, What's your opinion?

Just rambling, (happy holidays!)

From: ivan@mutt.cs.jmu.edu (Ivan Shantz)
Subject: stainless/copperbottom brewpots

I have been listening in with great fascination for the last little while and have enjoyed it a lot. As a consumer of homebrew rather than a producer, I have had nothing to contribute. However the discussion of stainless brew pots has me intrigued. I think it began with a question as to the feasibility of installing a petcock or some such device in a copper bottomed one and proceeded to the question as to copper plating. As to copper plating I know nothing but am a bit curious as to why one would attempt such a thing. As I understand, the goal of the clad bottom is to add mass to the bottom of the pot and thereby reduce the probability of scalding. Copper and aluminum are used because they transfer heat so well and therefore the entire bottom of the pot is of a temperature rather than having hot spots again reducing the danger of scalding/scorching. It would seem to me that a lot of copper would have to be electroplated to achieve this effect and while it appears that homebrewers are exceptionally patient folks and figure things on a bit different equation than the general populace (praise be to the deity of the hops) I question the practicality of such a venture.

As to installing spouts etc. The fellow who said that it makes no difference so long as you are not trying to go through the bimetal section could be right. However as a machinist and sometime welder I would proceed with caution. I suspect that it varies from pot to pot how the bimetal portion is adhered together. If it is electroplated then he is indeed correct. However there are a number of other ways to stick two metals together and it may have been done on the assumption that the temperature of the pot will not exceed 100c/212F (boiling point H2O). Having gotten into some dicey spots with various projects at the machine shop and also having separated the aluminum portion from the bottom of one of my wife's cooking pots by boiling dry I would be inclined to immerse as much of the pot, particularly the bimetal portion, in water as possible while I was welding it. The same holds for silver soldering. If you don't know how to do this without electrocuting yourself please find someone who does. (These folks are professionals, please do not attempt this on your own, if you're a little kid and can't read your folks can't sue us because we wrote this in little letters on your screen and they were negligent to let you up this late).

Happy Brewing

Subject: HB shop loons/Spray Malt/Extract Tang/Keg Prices

Alec Saunders writes:

>(2) The proprietor of same store tells me to bottle as soon as the
>gravity falls below 1.010. Says that if I let the beer ferment further
>I'm "losing alcohol". This doesn't make sense to me. Can anyone
explain?

This is one in a long line of ridiculous drivel coming out of homebrew
shops
these days. Are the people opening these stores a bunch of marketing
majors
who heard that homebrewing was the latest rage or are they old-timers
with the
experience of brewing bathtub brew for 20 years? I've heard all kinds of
silly advice in the past couple of years, reported to be coming from
homebrew
supply stores. This really gets my goat, as you can probably tell. They
should at least bother reading some of the books and magazines they sell.
The
funny part about it is that they spout this dogma as if they really know
what
they're talking about (they should but they don't!). Well, I feel better
now.

BTW, all three of the people who run my local HB shop seem to quite
knowledgable, which means they usually agree with me ;-).

**

I was wondering the other day about this term "spray malt", which I
believe
refers to dry malt extract. I making some assumptions here, but bear
with me.
If it is made by spraying wort for the drying process, it seems that HSA
would
be a very big problem. Actually, any drying method used would have to
take
special precautions to avoid HSA. Has this been discussed here before?

**

Virtually every extract brew I've made, including some partial mash
brews, have
a flavor that I would term "extract tang". It is a difficult taste to
describe,
but my friend used to call it "green tasting". He brews extract brews
and
claims it mellows with age, but I haven't noticed this (maybe my beer
doesn't
last long enough!). I've noticed this flavor from the very first brew I
made
(partial volume boil, no specialty grains, lots of HSA) to a very recent
partial mash brew (full volume boil, mashed 2-row, specialty grains at
mash-out, standard HSA precautions). Anyway, this is not a swipe against
extract brewers because I've tasted extract brews which were
undistinguishable

from all-grain brews; its just that my extract brews are quite different from my all-grain brews. I typically use Munton & Fison canned malt syrup when I use it (rare these days) if that matters. Have others noticed this occurrence, especially over a long period of time? Just curious.

**

Recent HBD reports indicate that the used 1/2 barrel straight-sided sankey kegs from BCI cost \$43.50. This is in error (I just received a price sheet). The actual cost is \$61.50. The barrel shaped sankey's in that size are indeed \$43.50. Is it worth it to pay more for the straight sides if you are going to use these things as tuns and tanks? Is it that much more trouble to install fitting on the barrel shaped kegs? FYI, sankey is the style of tap on the keg. BTW, I thought I might buy the sankey valve removal tool and possibly avoid having to cut a keg. They want \$225 for it! Yikes! I'll find another way...

**

Remember: Deck the Halls with Hops and Barley! Fa la la la la, la la la la...

Subject: Yeasty/Sulphury

I've got a new angle on these off-tastes I have been getting when kegging in stainless steel. I got another opinion. My wife is the head of new products/recipes at Tony Roma's restaurants. She has been the head of R&D of a number of national chains. I mention this not because I like to brag on my wife (although I do) but because she has a much more "educated pallet" than I do. (Advertising guys have no "taste" as we all know).

Alison suggests that the taste I have been trying to get rid of is not metallic or iodine-like, but yeasty/sulphury.

You know she may be right. I stuck my head in the fermenting refrigerator where I currently have a couple of batches perking away... Discounting the CO2 smell (I know CO2 has no smell), the smell generated in the fridge overnight is VERY much like the taste I have been getting.

Because of space needs I have been secondarying in cornelius kegs which I keep in the lagering refrigerator. Is it possible that doing secondary in closed kegs is not allowing the yeasty/sulphur compounds to escape, but in fact is dissolving the taste in the beer? Does this sound possible or am I heading down another blind alley on my Beer Detective investigation?

```

I have two of these. I used Sankey kegs. It is *very* easily done if you can weld stainless steel. The thermometers come with 1/2" Male NPT fittings. Just weld a 3/4" x 1/2" SS bushing into the keg, put lots of teflon pipe tape on the thermo threads and screw it in.

****Do Not Forget The Teflon Tape****

You can obtain these thermos from most any good industrial hardware supply. One is McMaster-Carr. (310)695-2449. They will ship to anybody COD, but a catalog is nearly impossible for an individual to obtain since they are HUGE and costly to produce. Here is the thermo I bought, there are several other styles available:

Part # 3946K176 3" Back Connection Dry BiMetal Thermometer
6" stem, 20 to 240F in 2F increments. \$31.02 plus
shipping.

Subject: Hops Storage and rate of deterioration

In Homebrew Digest #1306 (December 24, 1993), Mark Garetz writes:

"Yes. This will approximately double the storage life, or another way of looking at it is this will cut the rate of deterioration in half."

Thanks for information Mark. I am interested in the 'rate of deterioration' versus bittering/aroma ability. The statement 'this will cut the rate of deterioration in half' makes me wonder if I should scrutinize how my local vendor (and their suppliers) handle their hops . As I venture into the more exotic varieties of hops, (which are less commonly used), should I assume that I will need more quantity to achieve the same quality because of aging?

Has anyone developed a scale to indicate rate of deterioration of aroma/alpha over time?

Thanks,

Scott McLagan <mclagan@fraser.sfu.ca>

"Whenever I can find cherries again, I plan to try adding them to my standard
bock. It seems reasonable (to me) to wash the whole fruit in a mild
bleach solution, rinse, dry, smash (how?), force into a carboy (how?), then
siphon from the primary onto them. I'm thinking about 10 pounds of cherries to
a 5 gallon batch. Maybe freezing/thawing before smashing? Do the pits
matter?
Any comments appreciated, I'm flying blind."

I was brewing a cherry-lemon-orange mead recently, and, lacking the
cherries,
I wandered down to the local corner store and browsed through their
freezer.

I found a wide variety of reasonably-priced two-pound packages of frozen
and
pitted fruit. I read the label carefully, and could find no preservatives
on
the package mentioned anywhere. I bought a couple of pounds of black
bing
cherries, took them home, and pulped them with a metal meat tenderizer
that
I had at hand (like a hammer, but square, its working surface(s) covered
by
variously sized small pyramid-shaped teeth, so that one may tenderize to
the
degree of pulpiness desired :-), then added them to the hot protomead I
had
near a boil, in the pot at hand.

So, cherries do not seem to be hard to find, if one looks creatively. I
don't see much difference between picking them myself, pitting them
myself,
freezing them myself ... and buying them in that last state ... except
for
a few hundred thousand calories of energy and a lot of time.

The idea of rinsing fruit in a bleach solution, no matter how weak,
sounds
unwise. I've heard other solutions suggested, um, copper permanganate,
maybe ?
(Don't take this, alone, as sufficient authority for using it.)
Hydrogen
peroxide, I understand, is used by food processors (according to this
list,
at least), for sanitation.

Generally, freezing and thawing is regarded as effective at killing a lot of infective organisms, or at least putting them into a quiet state. Freezing and thawing also breaks cell walls and allows flavoring elements to flow out more easily. And, of course, dropping tenderized fruit into a boiling liquid solution is regarded as suitable for any serious sanitation, or at least, a solution over 170 Fahrenheit.

From: "Timothy R. Peters" <76307.3666@CompuServe.COM>
Subject: Addition of water at time of bottling

I recently brewed a partial mash porter. For various undetermined reasons I ended up with a volume that appeared to be under 4 gallons.

I waited until fermentation was complete, primed with 3/4 cup corn sugar in 1/2 gallon of water, added it to the beer and bottled. I now have a feeling I should have done something earlier to correct the low volume, or done nothing at all.

Was this OK? Since I brewed with enough grain (9 lbs of grain and 3.3 lbs of extract) to make 5 gallons and ended up with what was essentially a concentrated wort, did the the addition of extra water this late do anything to affect the beer aside from lowering the terminal gravity?

Thanks for your help and
Season's Greetings,

Timothy Peters

Subject: Kirschenbier results

Since it's been so quiet, it seems time to share the fate of my first kirschenbier (cherry beer). Good news: it's pretty tasty (I'm enjoying one now).

Ingredients:

2 "small ziplocks" German crystal malt
2 "big ziplocks" Briess dark malt powder
3 Oz Hallertau hops, loose
2 1lb cans Oregon brand sour cherries in water (Tip-thanks to John Wyllie!)
1 envelope "Munich dark strong" dry yeast

I simmered the crystal malt and 1/2 handful of hops in 1 gallon for about 1 hour, sparged, and added the wort to 2 1/2 more gallons of water I had heating. Mixed in the dry extract (Gawd, I hate that part) and brought it to a low boil, then added the rest of the hops - boiled for about 1 1/2 hours. Chilled, brought it up to 5 gallons and pitched.

I did the primary fermentation in my refrigerator. After about 6 weeks (when I got the unholy urge to add cherries) I bottled half of it to prevent ruining an entire batch. I pulverized the cherries (and water they were in) in a blender and added the resulting goo to a clean carboy, then racked the remaining 2 1/2 gallons onto them.

It really looked disgusting for a long time. Eventually most of the cherry pulp settled to the bottom and I racked again (now it was slightly less pulpy than OJ). Another 2 weeks and I racked yet again, finally getting rid of most all of the cherry pulp.

I bottled it 3 days before Xmas, that I might inflict it on my relatives. Surprisingly, it had a pretty good cherry flavor, although it was, um, less than well carbonated. I plan to do it again next year, but rather than run the cherries through the blender, I'll just freeze/thaw them first and use more. I'm sure I lost nearly 1/2 gallon trying to get rid of the pulp.

"Some day" I plan to buy a scale, record accurate dates, etc. and I may be able to share more accurate recipes.

My sister showed up with a few bottles of spruce beer that someone in her office had made. IMHO, 1/2 bottle was a good sized serving. Now I've tried it - it was "good", but I won't ever make 5 gallons of it... It was quite the ego-boosting experience; since my beer tasted like cherries instead of pine trees, it was the clear favorite ;-)

I wish you all a happy new year!

As a matter of "fact", he could! I would even venture that the malt can
be
substituted, with modest success. The points Jim make are quite valid
wrt
his lagers. He uses (I assume) Weihenstephan 34/70, a very clean
reliable
performer. Not sure if AB yeast would be as good, but Jim's decoction
sytem
from Pub Brewing is certainly capable of making a killer Pils. As Jeff
Frane
pointed out, many AB brewers are quite good, and would like to make more
flavorful beers. Where do you think all those Weihenstephan Diplom
Braumeisters work?? AB also employs a tasting panel that continually
evaluates each of the AB breweries products, and reports the perceived
differences between them, what a skill! If the big boys ever wake up, it
could be tough for some of the Koch's out there.

RE: hop storage

I was reading the comments on oxygen barrier packaging for hops. I
realize that there is some loss when using non barrier bags, but if
they are frozen, how much does it matter over a year, and dont some
quality noble hops *improve* with a degree of oxidation? I completley
agree that it is better to buy in barrier bags, but it certainly ups
the cost considerably, and if you buy direct at harvest time, and
repackage them/freeze them, how bad are the losses? I think the
biggest problem is with retailers who dont repack, dont chill, and
dont store in a dark place.

Best,
Jim Busch

From: perkins@zippy.ho.att.com
Subject: Question about bottles

My question is about what bottles to use. The only definitive statement I've seen is to use "returnable" bottles. Since virtually all bottles in New York State (where I live) are returnable by law, I need a little help making the distinction. I gather that

- * Grolsch swing-tops are good
- * refillable bar/restaurant bottles are good
- * champagne bottles are good

What about lighter (weight) bottles? I've been saving Brooklyn Lager bottles (similar to Sam Adams bottles) for a while. Will they be OK or should I hit the local establishments for something else? How many times can I expect to reuse these bottles (or any of those noted above)?

Thanks for the help.
Mark

I think I'd use some Campden tablets, one or two per gallon of water
that the fruit is washed in. Soak one or two hours then rinse. The H2S
produced by the tablets should take care of anything lurking on the
fruit.

RC> more easily. And, of course, dropping tenderized fruit into a

> sanitation, or at least, a solution over 170 Fahrenheit.

I don't think I'd do that. I have done in the past, and most of the
cherry aroma and taste seemed to disappear into that hot wort, never to
be seen again.

If you have a food processor, the steel blade, lightly pulsed, will
macerate the fruit better than you could do with a meat tenderizing
hammer (without the splash too).

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)
Subject: Counterflow chiller model

A few weeks ago, Tim McNerney asked if Stoelting was making a magic chiller which claimed it could chill 5 gallons of wort from 210F to 56F using only 5 gallons of tap water. At that time I'm sure I bored most of you with my model of an immersion chiller which predicted a minimum of 11.87 gallons of 40F tap water was required to chill 5 gallons of boiling wort to 56F (while 48.75 gallons would be required if the wort was mixed with the water). Therefore, the conclusion was that either Stoelting was exaggerating or counterflow chillers are much more efficient than immersion chillers. Based on my following model of counterflow chillers, I think the latter is true (for a properly designed counterflow chiller).

This model assumes only one spatial dimension x , $0 \leq x \leq L$, measuring distance along the length of the tubing. In other words the cross-sectional temperature is assumed to be constant (no thermal boundary layers). The copper fins covering the wort line of the Stoelting should help in making this assumption reasonable. It also is probably reasonable if the flows are turbulent. Diffusion in the direction of the tubing is ignored.

Let $T(x,t)$ = the water temperature at point x and time t .
 $T_w(x,t)$ = the wort temperature at point x and time t .
 T_i = $T(0,t)$ the inlet water temperature (tap).
 T_b = $T_w(L,t)$ the temperature of the hot wort in the kettle.
 k = heat conduction coefficient (radial)
 A = average cross-sectional area of water.
 A_w = average cross-sectional area of wort.
 V = velocity of water.
 V_w = speed of wort (V_w and V are both taken to be positive although the flow is in opposite directions).
 $R = A \cdot V$ = flow rate of water
 $R_w = A_w \cdot V_w$ = flow rate of wort.
 $a = R_w / R$ = flow rate ratio.

The equations for the temperatures are:

$$(1) \quad A \frac{dT}{dt} = k (T_w - T) - R \frac{dT}{dx}$$

$$(2) \quad A_w \frac{dT_w}{dt} = k (T - T_w) + R_w \frac{dT_w}{dx}$$

With boundary conditions

$$\begin{aligned} T_w(L,t) &= T_b \\ T(0,t) &= T_i, \end{aligned}$$

where d/dx and d/dt are partial derivatives. We are interested in the steady-state solution (d/dt terms=0), in particular we need $T_w(0)$, the temperature of the wort as it exits the chiller. If $R=R_w$ the solution is

$$(3) \quad Tw(0) = Tb * \frac{R}{R+kL} + Ti * \frac{k}{R+kL}$$

and if $R \neq R_w$, $R_w = aR$, $a > 0$, $a \neq 1$, then

$$(4) \quad Tw(0) = \frac{Tb*(1-a)*\exp((a-1)kL/aR) + Ti*(1-\exp((a-1)kL/aR))}{1 - a * \exp((a-1)kL/aR)}$$

It is easiest to consider the case when $R=R_w$, equation (3). This equation says that the wort temperature can be cooled to nearly that of the inlet temp T_i , if either the rate is sufficiently low (R is small), or, for a fixed value of k , the length L is large. Equation (4) also reflects the obvious fact that if the water flow is large with respect to the wort flow (a is small but positive) then $T_w(0)$ will also be close to the inlet temp for fixed values of k , and L .

It is also interesting to note that if the boundary conditions are changed so that the flow of the wort and water are in the same direction ($T_w(0,t)=T_b$, $T(0,t)=T_i$ and now $a < 0$) then the solution is

$$Tw(L) = \frac{Ti - a*Tb}{1 - a} + \frac{Ti + Tb}{1 - a} \exp((k*(1-a)/a)*L) .$$

If for example, $a = -1$ (same flow rate of wort and water in the same direction) then $T_w(L) \rightarrow 0.5*(T_i + T_b)$ as L gets large. For this "un-counterflow" chiller the same amount of water would be required as if you mixed the water and wort. This is what you would expect and serves as a "sanity" check for the model.

It may be better to send any technical comments on the model or errors anyone finds to me directly and I'll repost a summary.

Subject: Water question

Since the tap water here in the Phoenix area is so "interesting" - PH about 8.0, very hard, Ca, Fe, Mg, Benzene, TCE (thanks, guys) I've traditionally brewed using Crystal bottled water. I'm planning to get off my butt soon and contact them for an exact analysis, since they take great pride in their water's consistant flavor. They supposedly use reverse osmosis, then introduce flavoring minerals. Anyone recommend a good practical reference for the water chemistry desirable for different beers - for a non-chemist, that is. The only books I've got are Papazian's 2 releases (little and big). I also wonder if digital PH meters are out there somewhere?

The black beers I brewed suffered from the recently discussed sourness (due to low PH?). The dark ambers I've been brewing seem to do very well with stock Crystal water, but I'd like to try brewing a black lager before summer hits again. TIA

From: dmorey@iastate.edu
Subject: Potential Extract <> Fermentable Products

Hello once again,

Thank you for the responses to my questions about the extract potential of dark grains. Since my posting there are been a few questions about my sources, so here they are:

BREWING QUALITY BEERS, Byron burch, Joby Books, 1991

THE NEW COMPLETE JOY OF HOME BREWING, Charlie Papazian, Avon Books, 1991

BETTER BEER & HOW TO BREW IT, M. R. Reese, Garden Way Publishing, 1978

THE COMPLETE HANDBOOK OF HOME BREWING, David Miller, Garden Way Publishing book, 1988 (I have heard this is now out of print, is this true)?

THE BIG BOOK OF BREWING, David Line, Amateur Winemaker Publications, 1985

* I also did repeated SG measurements for the various sugars.

For my final point, I want to clear up what I ment about potential extract. Yes, it is true that the black malts produce no fermentable products during the mash, but, they DO contain soluable matter. This soluable matter does change the specific gravity. Just as adding large amounts of salt to water (and salt being non fermentable) the specific gravity of the solution will rise. As homebrewers, we are interested in SG readings because they are an indication of our sugar content, but not an absolute measurement. Also it provides feedback on how efficient our process is and how close we have come to duplicating a recipe. Well, that is enough of my spouting off.

Thank you for your time and happy fermentations,

Dan A. Morey

P.S. Tis the season to have a homebrew, but then again when isn't?

Subject: hop storage

Ed's note about keeping hops reminds me of a trick I recently figured out for easily "vacuum sealing" stuff in ziplocs (at least). I take a straw and stick it into the bag, then zip the bag as far shut as I can, and hold it tightly around the straw. Then I suck on the straw until no more air comes and quickly draw out the straw, sealing the bag behind it. Not as good as a commercial vacuum pack, but better than doing nothing. And easy & cheap.

I have been using our dishwasher at home now for several batches.
I usually set it for PotScrubber setting (double duty), and
heated drying, with NO rinse agent.

Rinse agents do leave stuff on the glass that will kill the head
of your beer. Also, make sure the labels are off before loading
into the dishwasher because they may clog the screen at the
bottom. We had a label sneak past us and, although it came off
the bottle just fine (no residue), it wrapped itself over the
heating element in the dishwasher and started to smoulder.

hope this helps

george

Subject: SS Screen

>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)

>The only reason I can imagine using slotted Cu pipe instead of SS
screen is
the limited availability of the latter. I bought my 1st easymasher from
Jack, and then made two more myself. I was lucky enough to find a large
piece of SS screen in a dumpster behind a machine shop. (I am not too
proud
to look zinto dumpsters.)

I wish I could credit the source of this idea but a universally
available
source of ss screen is almost as handy as a dumpster.

Most kitchen strainers are made of stainless and contain more than
enough
mesh for several easymashers.

Subject: sparge and extraction rate

I have some questions about sparging and extraction rates on which I appreciate your wisdom.

First, I mash in a picnic cooler with a manifold pipe arrangement on the bottom. I single or double step mash. I achieve a step mash by adding boiling water to increase temperature. I finally add all of the sparge water to the cooler (I guess that this is called batch sparging), stir and let everything settle. Finally, I open the drain plug and start filling the boiler (I usually recirc the first bit for clarity). This takes 15 - 20 mins.

Now, - I usually get 20 - 25 pts/lb/gal.

- Is there a relationship between sparge rate and extraction?
- Is my process all screwed up?
- Does any one else use a similar setup and get similar or better extraction?
- Does any one get 30 - 35 pts/lb/gal?

Thanks in advance.

Yes, bleach is a bad idea; a solution weak enough not to cause problems later (either killing the good yeast or creating an off-character) isn't going to be strong enough to do much good. The problem is that it's going to be hard to get rid of the bleach once you get it in with the fruit.

Campden tablets will work, but one per gallon is plenty.

> RC> ...And, of course, dropping tenderized fruit into a
> > boiling liquid solution is regarded as suitable for any serious

Yes, this is enough to kill wild yeast, and the acid in the fruit will keep the other critters that annoy us (the common bacteria) at bay.

> I don't think I'd do that. I have done in the past, and most of the
> cherry aroma and taste seemed to disappear into that hot wort, never to
> be seen again.

Hmmm...I've done it and I haven't had problems with losing the cherry character. It's hard to argue with experience on either side, I guess. I've just poured the hot wort over the cherries and immediately cooled the whole mess.

I do chop the cherries a bit; I don't just use whole pitted cherries. Could that be why my heat treatment works and yours doesn't? I dunno...

A good test of how well you're extracting fruit flavor into the beer seems to be that you see the fruit floating in the fermenter getting very pale.

> If you have a food processor, the steel blade, lightly pulsed, will
> macerate the fruit better than you could do with a meat tenderizing
> hammer (without the splash too).

"macerate" surely isn't what you mean...perhaps "chop"? ;-)

My experience says you want it chopped fairly coarse--as you say, lightly pulsed, and only a few pulses per load through the food processor.

Chopping too finely doesn't improve the extraction of fruit character, but it definitely exacerbates problems at racking...the more pulp you create, the more it clogs everything.

I was thinking about this late last night as I was wondering the aisles of the supermarket (love those 24-hour stores!) I stopped in front of the beer display -- the standard imports, Frankenmuth (local, more or less), mostly BudMillCoors. Hmm... Michael O'Shea's Amber... Not bad, certainly more flavor than the standard American swill, produced by Genesee, one of the few surviving regional breweries. Also, the Miller's "reserve" line. Hmm... thinks I, if the big guys decide to go into the "micro" market, they've already got the distribution channels, and the capacity... Could do it pretty quickly... The bean-counters have to be convinced there's a market, that's all.

Look at Coors. Winterfest is a reasonable Continental Dark (we scored it high 30s in a blind tasting, as I recall). They're supposedly coming out with a Stout real soon, now, too. Miller's got their Reserve line (not to mention "Leinies"). It's happening, and it's happening because of us (homebrewers)!

Subject: Specialty Malts at Mashout / Smooth Operator

Andy Kligerman writes:

>While reading the moast recent HBD, I raree thought came to me! When I do an all grain breew, I add the crystal malts and carapils in with the rest of the grain at the start of the mash. Since the other grains are enzyme rich, am I defeating the purpose of these malts when trying to achieve I high malt, full bodied beer? Should I add these at the mash out?

You've hit one of the highly debatable areas of homebrewing. I put crystal malt in at mashout (I don't know about carapils, haven't used it). I do this because I figure I don't want the enzymes to do any work on the sugars in it, and because it has already undergone a mash within the husk. I also save off dark grains (choco and black) for mashout because I feel I get smoother flavors from them this way. Of course, as I said in an earlier post, my dark beers need some help, so I'm no authority on this one. I posted a few weeks ago on an article in Zymurgy (by Micah Millspaw and Bob Jones) I read on this subject. Well, the article was on beer stability, but it had some references to this. It was in the same issue as Dr. Fix's HSA article. Check it out.

**

I've just now finished making a batch of brown ale based on my best pale ale recipe. I substituted 1 lb. of Belgian Special B 200L Crystal malt for the light crystal I usually use in the recipe. That Special B is special stuff, wonderful taste and aroma. I'll never use American chocolate malt again as long as I can buy the SB. It adds sweetness and maltiness that plain old choco malt can't touch. This beer really worked out well for hitting temperatures without adjusting anything, and I had no problems at all with my newly-built hop back. Whirlpooling helped keep the hops (pellets in the boil) from getting sucked out the drain. This was the smoothest (in terms of the procedure) all-grain beer I've made. I'll report later on how the beer comes out.

From: Stephen P Klump <sklump@magnus.acs.ohio-state.edu>
Subject: "Returnable" Bottles

Hello Fellow Homebrewers!

Mark Perkins asked about bottles to be used with homebrewing:

This subject causes undue stress and controversy with many homebrewers....with good reason. No one, I repeat, NO ONE wants to fill a bottle of their finest, only to have it crack or chip on capping, or explode due to thin walls of glass.

Let me tell you of my experiences:

Bar bottles are excellent for homebrewing. They have thicker glass than the "no refill" types of bottles (Sam Adams etc). One drawback, is that the labels are tough to remove compared to the "no refill" variety.

Grolsch bottles are easier to use (and bigger) with the rubber gasket for "capping"

I have used "no refill" bottles with smooth lipped top with no problems. (knock on an oak keg for luck) They do have thinner walls of glass, but so far, no cracks, explosions, chips etc.... (there was one batch which exploded a returnable and a "no refill" due to overcarbonation- but since it was very overcarbonated, and a returnable blew as well, I am not going to give up on them...)

No refill bottles used: Anchor, Sam Adams, FX Matt, Heinekin, Grolsch (12oz), etc.

There are several types of "screw cap" bottles which I have recapped and have had no cracks, chips, leakage, etc.. Sierra Nevada bottles have a very thick rim..for your own refernce, compare one to a Pete's Wicked Ale bottle top. Pete's is noticeably thinner... Types of "screw cap" used: Sierra Nevada, Rolling Rock, Molson.

I did not come across the use of screw cap bottles by accident, I used to go to Canada to buy a case or two of Molson Golden. These bottles were returnable, and screw-cap as well. After some tests with diet-Choke left over from a party, it was determined that recapped bottles would hold carbonation, and the use of these in homebrewing began....

I hate to sound like JS or JdeC when I say that I have had no problems with recapping returnable, no refill, or some screw-cap...maybe it is the spirit or St Gambrinus smiling on my efforts.. :) But with the exception of the two bottles from a very overcarbonated batch, I have had great luck.

I hope my 2 cents helps.
Cheers!
Stephen

Subject: full volume boils?

full volume boils?

I have been making extract/grain batches, including one with a rather rough mini-mash, and am looking into moving to a full volume boil in preparation for all grain recipes.

My question is this: how does one get all that water boiling in a single lifetime? I haven't had much trouble getting 2 or 2.5 gals boiling on my stove (it's electric...old house w/no gas), and can keep a nice steady temperature too.

I understand that one shouldn't use the cajun cooker things indoors for lack of oxygen, but I'd like to hear from the 'net experiences.

thanks in advance

Subject: SS Keg to boiling pot QUESTION

Salutations!

I had to unsubscribe to the HBD for the last semester as I took 18 credits and had to work 30 hrs a week. I also only managed one brew in the last few months. Well that's all done with and now I'm back (this has digest has gotten so large no missed me I'm sure). Anyway, I'm tring to catch up on back issues and am looking specifically for some help.

I was lucky enough to come across an 8 gal. SS keg! I got the thing and

now need some expert advice on how to convert it to a brew pot. I'm going to cut the top off and then put a valve twards the bottom on the side.

This thing has a 3 inch bung hole in the side and I obviously want it plugged. I remember people talking about being careful not to use the wrong kind of welding what ever so as not to poison one's self with heavy metals. Where are the specifics on this? I can't seem to find anything now...

Thanks for any advice or pointers anyone might give me!

From: John Edens <johne@sa-htn.valmet.com>
Subject: chiller efficiencies ad nauseum

Perhaps because I live in wet, humid, Houston, I am missing the significance of the immersion chiller. counterflow chiller debate.

I see a lot of equations and design theory being tossed around and my gut reaction is: So what? I probably use more water taking a shower than I do chilling my beer. And I only use water out of the cold water tap for the beer, which means there is no heating costs involved. If the purpose is to get a quicker chill, then I can understand that, but one should be able to acheive that by pushing water as quickly as possible through a coil that as much surface area as possible in contact with the hot wort.

Or is this a case of overdesign for the sake of overdesign?

From: Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU>
Subject: terminal gravity

I seem to have chronically high terminal gravities, usually around the low-to-mid teens. I am pondering in which order to address possible deficiencies in my process. Currently, I am an extract & specialty grain brewer (1 partial-mash to date) using Wyeast liquid cultures via starter solutions.

1) Yeast population/health. Possible courses of action include increasing the amount of pitchable yeast by either feeding them MORE malt, or using a two-step starter; being very careful about brewing when the yeast is really ready (RIGHT after the starter has fermented out?); trying "yeast nutrient" in the starter.

2) Aeration. Probably the easiest thing for me to try would be to make one of those "carburetors" that has been mentioned here by drilling little teeny holes in a piece of rigid plastic tubing to squirt into the carboy.

3) Water chemistry. I have no idea what is or is not in my water; can water chemistry affect the "endurance" of the yeast?

A related issue might be raised wrt specialty grains. I'm used to getting starting gravities around 1040-1042 from six pounds of extract syrup. If I steep .75-1 lb. of crystal, patent, or whatever, and end up with an O.G. of 1048 (yes, this happened recently), then can I safely assume that the extra gravity points are "unfermentables" and will also show up in the final gravity (1016 or so instead of 1010)? The recent thread on extract potentials of grains got me wondering about this.

The collective wisdom of the digest is eagerly anticipated.

From: Timothy Sixberry <tsixber@msrapid.kla.com>
Subject: RE:Dishwasher Bottles

Hi Bruce,

The use of a dishwasher to sterilize bottles probably depends on a few things.

- How hot is your hot water heater set for?
- Does your dishwasher have a heat dry system?(most do)
- How dirty are the bottles?
- How clean is it?

I have used my dishwasher to sterilize bottles many times with no problems,

and I'm pretty sure yours will work to. What I do with my bottles is to make sure they are rinsed well right after use, then let them drain and dry

out completely. I prepare the dishwasher by running it through one rinse cycle with a little bleach or idopher to stearlize and get rid of any food

particles. Also check the drain screen for food too. Then just put as many

bottles in as you can. Mouth down of coarse. Put a little idopher (not bleach) in and let er go. Make sure the heater is on, I havn't tried it with just hot water.

ps- I have kegs now, and let me just say.

Its the only way to fly! Good luck man!

From: ari.jarmala@mpoli.fi (Ari Jarmala)
Subject: Diluting beer

Subject: Addition of water at time of bottling

Timothy R. Peters wrote about adding water to already fermented beer to dilute it and to increase the volume at the time of bottling.

I have done this frequently with my all-grain batches. It's usual that I brew a 40 l batch of say 4,5 % alcohol by weight beer and bottle 72 bottles of it (=24 l). The remaining 16 l I dilute with 8 l of cold tap water (the water is excellent here) to make 24 l (=72 bottles) of 3,0 % abw beer. Of course, this diluted beer has less body, alcohol, maltiness, bitterness and hop aroma than the original brew. But it's supposed to be so, I want it that way.

I haven't encountered any problems with this procedure so far and I've been doing it for more than 10 years now. However there are a couple of crucial topics:

a) Be sure that the water you dilute the beer with is suitable. It must not be contaminated with nasty microbes and it's chemical composition should be good enough. It may be wise to boil the water for 30 minutes and cool it down before you add it to your beer.

b) Carefully calculate the amount of priming sugar.

Subject: Water question [HBD #1309]
Message-Id: 92931229014129/0002419419NA4EM

Since the tap water here in the Phoenix area is so "interesting" - PH about

8.0, very hard, Ca, Fe, Mg, Benzene, TCE

^^^^^^^ ^^^

ACK! Phoe!

You can get rid of the PH problem by boiling your water with gypsum. I think this may also reduce the magnesium (Mg) some which can help with the bitterness in your Black beers. If you are doing all grain, the high PH is definantly a problem as it causes excessive extraction of tannins from the grain husks.

Digital PH meters are reasonably inexpensive. Brewers Resource in Woodland Hills, CA (1-800-827-3983 for orders, 1-818-887-3282 for info) has one for \$35 that isn't temperature compensated. My local supply shop (St. Louis Wine & Beermaking) has that one and also has one that is temp compensated for \$80. You can reach Roy or Koelle Parris at 1-314-230-8277 next week as they are closed between Christmas and New Years day to be with family.

Subject: Celis White Clone Recipe
Subj: Celis White Clone Recipe
Read: (N/A)Status: RECEIVER ONLY (Echo)
Conf: InterNet_Mail (1)Read Type: GENERAL (+)

Recently there was a request for a Celis White Clone recipe. Here is a recipe that I came up with and uploaded to Compuserve in early November. Thanks to Steve Daniel and Steve Moore from the Home Brew University BBS (713-923-6418) and my electronic friends on Compuserve who helped steer me in the right direction by giving me a starting point.

Pugsley's Pseudo Celis White #5

malt: 4.5 lbs. 6 row (or 2 row)
specialty: 4.0 lbs. Unmalted Wheat (Bulgar from Health Food Store)
4 grams dried orange peel
4 grams crushed corriander seeds
1 tsp. Alpha-Amalase enzyme
lactic acid
hops: 1 oz. Hallertauer
yeast: 1 pack Wyeast #3056 Bavarian Wheat
optional: 1 tsp. gypsum

OG 1.041 FG 1.011

Bring 2 gallons water to boil. Add unmalted wheat and hold at 185-195 degrees for 20 minutes. Add cold water and 6 row malt to bring down to 130 degrees. Add 1 tsp. amalase and gypsum (pH 5.3). Allow protein rest for 25 minutes. Raise temperature to 150 degrees and hold 20 minutes. Complete conversion by raising temperature to 158 degrees and holding for 20 minutes. Mashout at 168 degrees for 5 minutes. Acidify sparge water to pH 5.7 with lactic acid. Sparge with 4-5 gallons of 170-180 degree water. Boil wort for 90 minutes. Add hops and crushed spices 15 minutes before end of boil. Cool wort and pitch yeast.

While this will not fool everyone into thinking that this is the real Celis White, I was very happy with the outcome. The spices are "up front" without being overpowering. However, some people like a wallop from the spices and you will need to experiment with the spice amounts.

After a couple months the spices have faded a bit, so next time I will double the spices and probably try Wyeast White beer yeast.

This recipe should give you a good starting point with which to experiment. If anyone else has a recipe for a Celis White clone, or have any comments or questions on my recipe, please feel free to E-mail me or post.

Tony Storz (Houston)

From: Darin Bennett <dbennett@mailstorm.dot.gov>
Subject: A dream of 'cream'

Greetings fellow homebrewers,
I am an almost virgin (1 batch) homebrewer on a very tight budget (and in a small apartment no less) which has for now constrained me to extract brewing. My first batch, a 'Dutch Light Lager', was racked about 2 weeks ago and my sample at that time showed a good bit of potential. My true love (besides beer in general) is heavy stout beers and in particular, Watneys' Cream Stout. I was told that the 'creaminess' can be created by using particularly large amounts of malt. My question is, is this really true, if so, can I add malt (powder, other?) to an extract kit or is there another simple and inexpensive way to pull this off?

If you are willing, reply to HBD or mail me at dbennett@mailstorm.dot.gov either is fine.

TIA,
darin

Subject: full volume boils?

> how does one get all that water boiling in a single
lifetime?

That's an easy one. Buy that cajun cooker (note how
application of money solves yet another homebrew problem :-))
They go under various names like Cajun Cooker, King Cooker,
Fish Cooker. Home depot sometimes has 'em. Any self
respecting homebrew store has 'em. Cost <\$50. They put out
over 100,000 BTU and sound like a jet engine at "Military
thrust." Outdoor use preferred. They don't throw off carbon
monoxide but they do suck up lots of oxygen and throw off mondo
water vapor. I use it. I like it.

Frugal gadget heads will scavenge water heater burners and hook
'em to their natural gas line. Usual liability disclaimers
apply. You're SOL on that one anyway.

Last resort. Split your full boil into multiple pots on your
electric stove.

Subject: Beer Sphere and chillers

Ok, first I have a question, then a helping hint from Zymurgy.

First off anyone have any experience with the "Beer Sphere" CO2 dispensing system. It lets you store 5 gallons of homebrew with a tapping system using CO2 cartridges, and I saw for sale for \$49.95.

Now the hint. Chilling wort. Someone in the newest Zymurgy had the best method of cheap chilling I've ever read:

Take three 2-liter soda bottles. Sterilize them with bleach and rinse. Fill 3/4 with boiled water and freeze. When it comes time to cool the wort, remove the bottles from the freezer and sanitize with your choice of sanitizing agents. Immerse bottles in the hot wort. Author claims the wort is colled in 20 minutes, and bottles can be placed in the freezer for reuse.

Subject: Beer King mini-kegsystem

OK, it just goes to figure. After glancing by recent postings on the Beer King dispensing system, Santa dropped off one of these German-made contraptions under the XMAS tree. With nothing more than instructions and simple figures printed on the box, I can't help but ask for some Beer King experiences - be it good, bad, or indifferent. Is this thing the next best thing since sliced white or is it worthy of exchange for some good old-fashioned homebrew equipment?

If you are lucky, you might get 165F water out of your water heater, but this is barely enough for *santization* much less *sterilazation*. Of course, who needs sterilazation for bottles? I find it simpler to use a sanitizing agent and a quick rinse. Finished beer is not too likely to get infected, unless it already harbours the beasts in the still beer.

Yes, but more important is the conversion during mashing. First, the sugars need to be created in the mash, then adequate sparging is required. Batch sparging is fine, but you need to add more water as the first run through, otherwise you are leaving lots of sugars stuck to the grain. After the bed is set, sparging of around one hour is quite normal.
>
> - Does any one get 30 -35 pts/lb/gal?

Sure, but I use a perf sheet bottom. I'm sure you can up the efficiency from 25 pts.

Just want to point out that while SB is a great malt, it is not
chocolate.

I have a brown ale that used too much SB and it very different from the
chocolate character. I'm not convinced that porters are as good using
SB as when using chocolate. Now, a blend of both.....

Watch for chlorine, too. This is one of the main advantages to bringing
the water to a boil. Or, carbon filter it, but I would still get the
water up to 160-170F at least.

Good brewing,

From: steve@Pentagon-EMH6.army.mil (Steve Lichtenberg x79300)
Subject: high gravity ferments

Hi all--

I have a couple of comments and a question or two.

For each of my last two brews, I have been experimenting with getting two different beers out of each batch. I recently made an upgrade to my set up that allows me to brew 10-15 gallon batches. This has proven to be fantastic as the difference in the amount of work required to brew a 5 gallon batch and a 10 gallon batch is practically nil.

I have been brewing fairly high gravity batches (1.080++) and either diluting part of it to 1040 -1050 before or after fermentation. I am beginning to believe that doing high gravity boils and high gravity ferments causes some nice things to happen to my beer. There are some down sides as well (hop utilization is poorer so you have to use a lot ; -))

but the positives make it worth the effort. I can ferment in one vessel instead of having many carboys bubbling away all over the house. (very important with a wife that is scared of big glass carboys, two kids running

around and assorted pets). IMHO this makes for a smoother beer and I can

play around with different tastes. I split the strong beer into two kegs

one full strength and the other diluted with one or two gallons of boiled

and cooled water. Since the flavor of the diluted beer is spread out further, I can experiment with adding spices or dry hops to gain additional

flavor. This has worked out well for me and I am probably going to make it SOP.

Now, on to my questions.

While mashing last night, I had a small problem with grains sticking and scorching to the bottom of my pot. What does anyone do to help prevent this. Of course, the obvious turning down the heat and stirring more frequently will help but if I turn down the heat too far I will be heating water till next week (kitchen stoves are not very good heat sources

Oh for a commercial stove :<(and more frequent stirring is difficult due to other demands on my time ;newborns do that) . Also what is the best method for removing that burnt material from the bottom of the pot TSP and a Scotch BRITE pad worked but with a lot of scrubbing.

Second, I recently purchased a 50 pound bag of diatomaceous earth (supposed

to be good for keeping ants and slugs out of the garden) I doubt I will be using all of this for pest control and would like to explore using it as a base for a filter. Is Plain Jane DE of sufficient consistency to be used in this fashion? If so does anyone have any plans for building/maintaining a DE filter?

TIA for any help in this matter.

Believe it or not, there are parts of this country and in the world that
are in
an almost perpetual state of drought(sp?, as in really dry, not as in
kegged
beer). Even if water is abundant, clean drinkable water has probably
gone
through a lot of processing to make it that way. It seems a shame to put
clean
drinkable water down the drain, to mix with all the other sewage, just
because
we have added heat to it. If we could capture it and re-use it for some
other
purpose, or waste less of it, we have achieved something, if not just a
little
self-ritious smugness that we are doing a small part in conserving
resources.

Remember, Detroit had the same attitude toward designing cars, now look
at the
mess we/they are in.

Subject: Bottles

Many of the local homebrew shops here in Vancouver, BC sell plastic beer bottles in 1 and 1/2litre sizes. Some are a green (Mountain Dew-type bottle), and others are a brown long neck stlye. Both use a plastic screw top.

After emptying a bottle, I rinse & air dry, but before bottling, I rinse again with a weak iodine & water solution. Although I have used lables which I've produced via PC & laser printer, I prefer the wine-tag (the type

that fits over the bottleneck) labels.

I highly recommend this type of bottle! I've never had an infected bottle,

they hold carbon & flavor and travelled well when I sent them as XMas presents.

I wonder though ? I've never kept a bottle around for more than 5 months,

these may not store beer as well as glass bottles.

The plastic bottles are affected by altitude - evidenced by my foamy lunchtime treat when skiing.

The pH of the water may or may not be a problem. The hardness has no relation to this, but rather, the alkalinity is what's important. You cannot tell if the pH of the water will affect the pH of the mash without having a handle on the alkalinity.

For black beers, you DO want a high alkalinity water because these grains are very acidic and can counter the buffering power in a high alkalinity water. If you check water profiles, you will find that the world's dark beers all originate in locales with highly carbonate (high alkalinity) water.

One comment about using high alkalinity waters: they drastically increase hop utilization, and not in a pleasant way. They will produce a very harsh bitterness when the hopping rate goes above an estimated 30 IBUs.

To tell if your mash is reacting well to your water, CHECK THE PH OF THE *MASH*. If it's within 5.0-5.5, RDWHAHB. If it's not, consider adjusting it into this range: use CaCO3 if it's too low, use CaCl2 or CaSO4 if it's too high. (This is a bit simpleminded, but this issue is brought up so often that it needs a simple solution that is 95% right.)

Subject: Re: Extraction/Returnables/etc.

Chuck Mryglot (cmryglot@disney.CV.COM) asks:

> Does any one get 30 - 35 pts/lb/gal?

Yes. I use a stove-top masher, a 10-gal stainless stock pot with a copper manifold, and do a 3-stage temperature step mash (122F, 150-156F, and 170F). My yields are consistently 30 pts/lb/gal or slightly higher. Sparge rate and recirculation are always a hot topic on HBD, so I can only speak from personal experience, but I do very little recirculating and my sparge only last 20 minutes, so obviously one can get good extraction with short sparge times. BTW, I sparge with "standard" 170F water.

You may want to try "continuous" sparging rather than "batch" sparging. Someone posted a good explanation for this a while back. I can't seem to find the original reference, so I'll quote JS who paraphrased the argument pretty well (no wise cracks, please :-):

It has to do with the gradual dilution effect and that the grain is always meeting up with a differential between it's remaining sugar and the dissolved sugar in the sparge water. The greater this differential is, the more sugar will be removed.

It is also easy to see that in the last batch, after stirring the water and mash, the whole liquid will arrive at some gravity. When the liquid is drained, the liquid held by the grain will be that gravity and that sugar is Lost.

Other variables are your sparge water temp, sparge water acidity, grain bed configuration, etc. I've never messed with these so I'll let others comment on that.

On the subject of reusable bottles, Stephen P Klump <sklump@magnus.acs.ohio-state.edu> writes:

> Bar bottles are excellent for homebrewing
> One drawback, is that the labels are tough to remove compared
> to the "no refill" variety.

I have to disagree with this statement. Not all refillables have hard-to-remove labels. In fact, you would think that the brewer would want easy-to-remove labels themselves.

If you get Huber in you neck of the woods, get a couple of empty cases. The labels soak off after 5 min in hot water. No ammonia, no scrubbing. They just float off of their own accord. I'm sure there are other brands of beer that have labels that behave similarly.

Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU> asks about high terminal gravities:

> I seem to have chronically high terminal gravities, usually around the
> low-to-mid teens.

May I suggest that "low-to-mid teens" isn't really all that high for a terminal gravity. I will admit that I probably under aerate, pitch too

little yeast, etc., but I find my beers often finish at 1.012 - 1.015 or so with no ill affects; they don't seem particularly sweet or have any tendencies to overcarbonate. I don't have any data to back me up, but I think that a beer that finished much below 1.010 might have sweet/bitter balance problems just like a beer that finished too high. Does anyone out there have a list of *finishing* gravities for commercial brews?

From: gummitch@teleport.com (Jeff Frane)
Subject: Re: dishwashers, etc

Hey! How come Norm Pyle can submit an article with lines greater than 80 chars in length, and when I respond to it, my article gets bounced! NO FAIR!

So here we go again:

I missed the originally posted query about using a dishwasher for sterilization of bottles, but caught two responses. I have to weigh in in opposition to this concept, for several reasons.

When I first started brewing, I used the dishwasher and discovered several problems:

1. No way of knowing how hot the dishwasher actually got -- so no way of knowing whether heat alone would sanitize my bottles.
2. I added sterilant to the water (poured bleach into the dishwasher before turning it on) -- but there's no way to determine whether it really gets sprayed up into the bottles. Probably not.
3. The damn dishwasher wouldn't hold enough bottles for a complete five-gallon batch.
4. The dishwasher needed to be run first, because it always had dirty dishes in it.
5. The bottles needed to be run through the dishwasher and kept in the dishwasher until it was time to bottle. Not very convenient.

Believe me, I **hated** bottling in those days.

But -- absolutely free!!! the miracle solution!!! (theory courtesy of WYeast's Dave Logsdon, practice courtesy of 7-8 years of bottling): USE THE OVEN!!!!!!

I've found the best way to preserve sanity in bottling is to isolate the phases.

Phase 1: Clean bottles. This may require de-labeling, although after a few years you'll build up quite a supply (especially if you run a competition --additional FREE TIP!). Soak the bottles in TSP and water; a rubber trashcan works great. (ANOTHER FREE TIP: change the water periodically and do not leave the nasty bottles soaking for weeks on end. You will get some truly disgusting things growing in the water, especially if you followed the previous FREE TIP and added bottles from a competition. Some of those people grow some really weird stuff in their bottles.)

Rinse well inside and out (Jet bottle washer a handy gadget!). Put 'em away.

Phase 2: Sanitize bottles. Take each clean bottle and wrap a little piece of aluminum foil over the mouth. Put the bottles in a cold oven, turn to 350F and bake for 90 minutes. Let the bottles cool, remove and put 'em away in cases.

Phase 3: Bottle.

See? This way you're never doing all three phases at once, each one takes a very short time, and you never burn out. I bottle five gallons in something under an hour these days and never stress out. Although I keg a lot of my beers, being able to bottle this easily means the basement stays well stocked, and I have portable beer for visits, competitions, or to send to friends.

And to answer to question that always comes up: NO! The oven doesn't break the bottles. I've bottled literally hundreds of gallons of beer with this method, and I have *never* lost a bottle to heat exhaustion.

Norm Pyle writes: (but I had to chop it out because his lines were TOO DAMN LONG!!!!)

>

While I agree with Norm wholeheartedly that Special B is fantastic malt (but a whole pound, Norm!? whew!) I don't think it's a substitute for chocolate malt. It doesn't have the nuttiness of chocolate malt, and it does have that sweetness -- which isn't always the idea. Additionally, a number of people have discovered that using a big chunk of Special B adds a peculiar flavor to their beer, something that might be described as "raisin-y". I've discovered that 1/4 pound or so adds a nice round note and good color without that funny taste.

I notice that Norm says "American" chocolate malt. I didn't even know there *was* an American version, but I wouldn't touch the stuff either. The American black malt is useless, and I can't believe the chocolate malt is any better. British chocolate malt, however, is every bit as wonderful as Special B -- just different.

I inadvertently chopped out a query about bringing five gallon batches to a boil, so can't properly credit it. But, I will say from many years of experience that a big gas cooker is no different than a big gas stove. True, it produces more heat (which does help!), but I've never found myself gasping for air when I use mine. Of course, the houses may not be airtight... but I believe the problem is using charcoal briquets -- that's what kills people. On the other hand, I've never heard of anyone brewing on a barbeque, either.

*** Resending note of 12/29/93 14:57
To: HOMNEBRE--PB1

SUBJECT: belgian double
I've decided to brew a double, which I've never attempted, and I've seen very few recipes for all-grain. With the recent introduction of belgian malts in the bay-area I've decided to go for it... But first I got questions:

1. I'm planning a 5-gal batch with a total grain bill of 14 lbs, hoping for an SG of 1075. Is this appropriate for a double.
2. Can I substitute 9-10 lbs two-row for belgian pale malt. Is there a unique character to belgian pale malt that makes it inherently better.
3. planning on 1 lb each of 'aromatic' and special-B too much/too little ?
4. Is candi sugar, or some other sugar, really needed for this style ?
5. should I assume extended aging time similar to that required for barleywine

I'm using the Wyeast abbey ale strain and hallertauer hop pellets, mostly at the start of the boil.

Advice & suggestions greatly appreciated. Prost

Subject: Boilovers

Just subscribed to the digest and have already gotten many great ideas/hints to refine my (admittedly) rough brewing process. I thought I'd pass a tip along, directed especially to those who are somewhat new in this art (as I am).

The best way I've found to prevent your wort from boiling over is to keep an eye on it until it just starts to rise. As it is rising, take the pot off the heat until it returns to its original level. You can then put it back on without fear of another boilover. Really does work.

Disclaimer: the author assumes no liability nor makes any warranties, express or implied, as to the information in this article. ;)

From: fingerle@NADC.NADC.NAVY.MIL (J. Fingerle)
Subject: Cleaning bottles

I just saw Jeff Frane's comments on bottle washing and I just want to say RIGHT ON. Sanitizing in the oven is simple, quick, and for me after 24 batches, trouble free (knock on wood.) However, I'd like to add a couple of points.

1. Bottling will be very much more enjoyable if, every time you finish a brew you RINSE out the bottle in preparation for the next use. Don't let the beasties grow, and don't let the yeast sediment solidify.

2. When I need to bottle, I use a jet washer (my apologies if that's a TM) to thoroughly rinse a bottle with hot tap water. I let it drain, in the strainer, then put the bottle in the oven.

At this point, Jeff put aluminum foil over the mouth of each bottle. I don't know why. Jeff...?

The purpose of the jet washer is really to remove dust and whatnot. The purpose of the heat in the oven is to kill off the beasties.

3. I then fill the oven with about 50 bottles, start the temp at the minimum, and slowly raise it to 300F over the course of an hour.

4. If I want to bottle immediately, I crack the oven door for ~15 mins. Normally, I bottle the next morning, so I just let the oven cool down naturally.

On the subject of bottles-I have Miller, Lite, Bud, and Bud Lite returnable bottles, and a host of disposable ones, from Sam Adams, Dock Street, New Amsterdam, Watney's, Bass, etc. The ONLY bottles I've ever had problems with are Guinness'. Those suckers cracked during bottling.

I recommend, however, that you pick up several cases of EMPTY Miller Lite returnable bottles from your beer distributor. Why? Well they are brown, sturdy, and the wax box they come in has a two piece lid that hangs outside the perimeter of the top of the box which gives extra support. For me, each case cost \$1.50 for a deposit.

Hope this helps someone out there.

Subject: Freezing PET bottles for chilling

Someone wrote about a nifty tip from Zymurgy about freezing PET bottles of water to dump in your wort to chill. I thought this was a good idea too when I first read about it. My only concern is that when you take the bottles from the freezer and put them in your sterilant to sanitize, won't they freeze a thin layer of around the outside of the plastic which will then be transferred to your wort? Has anybody ever tried this?

From: Mark A. Stevens <stevens@stsci.edu>
Subject: Re: dishwashers, etc

In Homebrew Digest #1311, Jeff Frane (gummitch@teleport.com) pointed out several problems that he sees with using a dishwasher to sanitize bottles,
and suggested using an oven set at 350.

I've been using the dishwasher technique for the last couple years, and haven't really had a problem, but Jeff's post has me thinking that maybe this is more luck than anything else because, as he pointed out, there is no way to know if any sterilizer got sprayed up inside the bottles and there's no way of knowing how hot the dishwasher gets.

The oven idea is certainly an interesting alternative, but I'm worried about the ability of glass bottles to withstand the heat of an oven. Shouldn't glass be tempered in some way if you're going to put it in an oven? Can beer bottles really withstand the heat of an oven? I suppose this is worth trying, I just don't want to have to pick shards of glass out of my oven later ;-)

Prosit!
Mark

Subject: San Diego Micros?

Happy Holidays to y'all!

Forgive the quick request, but are there any recommendable micro
breweries in
San Diego worth mentioning?

I am going out there 2-9Jan, and would love to visit as many as I can.
Thanks for the info in advance.

Happy New Year!

Subject: Kegging Questions?

Greetings!

My Christmas wish was granted and I received a keggling system. CO2 tank, regulator, pressure gauge, 5 gal "soka" keg etc etc.

Now I have a batch in primary fermentation and I was wondering:

1. Should I carbonate with corn sugar/DME or with the CO2?

Papazian's book mentions using DME/corn sugar and the literature i got with the keggling system says to use the CO2?

What have people found to be the best/easiest?

2. Are there gizmos available to allow me to hook up two kegs at once for conditioning/serving?

Subject: RE: oven bottle cleaning / pumps

Hello,

A couple of questions and responses:

Jeff Frane writes:

Rinse well inside and out (Jet bottle washer a handy gadget!). Put 'em away.

Phase 2: Sanitize bottles. Take each clean bottle and wrap a little piece of aluminum foil over the mouth. Put the bottles in a cold oven, turn to 350F and bake for 90 minutes. Let the bottles cool, remove and put 'em away in cases.

I've seen this mentioned before and I think I'll probably try it next time.

Seeing as that I don't necessarily want to sterilize the bottles, what is the minimum temperature and time requirements be? 200F for 30 minutes? 350F for 90 minutes seems to be a little bit of overkill :-)

Second,

Anton Verhulst writes:

Lifting 10 gallon batches has gotten to be a bit of a pain :-) for me and I'm not quite ready to set up a gravity system and drill holes for spigots in my SS pots just yet. I'd like to get an electric pump in the 5 to 10 gallon per minute range to move hot wort and sparge water around. Does any one have recommendations and/or sources? Several months ago some one mentioned WW Grainger as a possible source but provided no address or phone number. Thanx.

You're welcome.

I looked through my McMaster-Carr catalog (#99) and on page 1358, they list a drill-powered liquid pump for \$26.58. It claims to deliver 6 gpm at 2400 rpm off a 1/4" or larger drill. It has a neoprene impeller housed inside a nylon housing with a stainless steel shaft. It looks like it would do the trick nicely. It's small and looks like it's capable of doing what you want. Since McMaster Carr catalogs are not easy to get, here's the info:

McMaster Carr

From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)
Subject: Medicinal tastes and chlorine

I recently brewed an all-grain oatmeal stout that turned out so medicinal tasting and smelling (phenolic?) as to be completely undrinkable. The recipe was:

8 lbs Klages
1 lb oatmeal
1/4 lb roasted barley
1/2 lb chocolate malt
1 lb crystal malt
1.5 oz Willamette
Wyeast 1084 from 1 quart starter

OG=1.056 FG=1.013

The intensity of the flavor leads me to the conclusion that it is due to either chlorophenols or an infection. I surmise two possible sources of chlorine: (1) inadequate rinsing of bottles and/or fermentor after sanitizing with bleach or (2) a high concentration of chlorine in my tap water. Our town just opening a new water softening plant a couple of weeks

before I started this batch, and the water has a slight chlorine odor. I spoke with the water dept people and they said the water has a chlorine residual of 1.5 mg/L, which they have increased from the normal 0.5 mg/L in order to "clean out" the new plant. Could this level of residual chlorine account for my strong medicinal taste? For my current batch I used an activated charcoal filter AND preboiled to remove the chlorine.

Can an infection result in a such a very strong medicinal taste and odor? The bottles do have a small ring at the liquid level which I haven't seen in my other beers, but the beer does not taste sour.

Thanks for any comments.

Subject: sanitizers and septic tanks

A friend who now lives in the semi-wilds of Maine (40 miles from Portland is hardly wild) is worried-about/running-into septic tank problems from bleach used to sanitize his brewing equipment. Is this a plausible worry at canonical levels (which define: 1 tbp, 1 oz, 1/4 cup, ... per 5 gallons?)
)
(There were comments on this some time ago but I don't have access to them.)
Are B-Brite and/or iodophor (a) as effective, (b) friendlier to septic-tank bacteria at canonical levels (again which define---and does iodophor degrade on its own or should it be rinsed out?). Please reply to cjh@ileaf.com; I'll summarize and post if I get anything.

Subject: "Beer Sphere" plastic keg review

In today's HBD there was a question about this product, and I recall there was another question about it a week or two ago. I own one.

Plastic kegs, from Edme or Hamilton Bard, are for making cask conditioned ales. They have valves that keep the pressure at approximately 11 PSI or lower. This is so you don't have to have a series of soft and hard pegs to manage the conditioning. It will either be at 11 PSI or softer.

The HB Beer Sphere differs from the Edme products, because it has a floating pickup. This prevents picking up any sediment until you reach the bottom. The Edme kegs work well for parties, where the first few pints are cloudy, after that they run clear. If you want a pint or two every day, the Sphere is the better choice.

The CO2 does not carbonate the beer, it merely provides enough positive pressure to allow beer to flow. I recommend that you use one cartridge at kegging time to flush air from the keg. (Cap, fire a cartridge, loosen cap to force the air out, tighten.) Cartridges won't be necessary if you're taking a pint or two a day, only when you're serving a lot of beer.

Due to sediment, these kegs do NOT travel well. If you transport the keg, your beer will not be drinkable for several days. It doesn't make a good "take to a party" keg.

Subject: Water Composition

Out of curiosity, I called my local City Water Department and inquired about the composition of the water here in Kirkwood, MO. The water here comes from deep wells in the Meramec River Valley, unlike the rest of St. Louis County which uses water from the Missouri River. The numbers were given to me as Milligrams per Liter which is the same as PPM (?).

[question about heating fermenter]

The direct answer is that yes, there are heaters for fermenters--they
strap
around the center of the fermenter like a belt. (Painful reminder to
some
of us, of our own carboy-like physiques:)]

But more to the point: You don't need to be fermenting mead at anything
like 80-85 degrees! It would probably give you fast fermentation, and
yes,
mead fermentation is sometimes very slow...but yeast at that temperature
will produce off-tastes in mead just as they would in beer. Don't try to
compensate for a naturally bucolic pace of fermentation by forcing it
with
higher temperature.

Personally, I'd aim for perhaps 75 F to get the fermentation started
quickly, then try to keep it around 70 F. Treat the yeast right; give
them something to eat; don't make them work in a sweatshop...and they'll
do a good job for you.

Mead can be an exercise in patience.

When looking at these large scale flamethrowers, look for the ones with about 16 individual flames, not a single jet engine. They produce a little less heat (150,000 vs 185,000Btu) but I doubt you could tell the difference. Where the difference really comes in is when it's already boiling, and you want to attempt a simmer. The single flame types have a really hard time with adjustability, and are very gas inefficient at lower settings.

Subject: Wort pumps

Tony Verhulst asked about pumps from WW Grainger.

WW Grainger is indeed a good source. They probably have a location near you, wherever that is. Call them at 800-323-0620.

The pumps you should consider are hot water circulator pumps.

Stock no. 1P760, 1/100 HP, 115V, 1700 RPM motor is the one I use on my Pico Brewing Systems 1/2 bbl setup. It is the one they sell with it. I find it quite adequate for the job. List \$105.61, wholesale \$68.48.

Stock no. 1P956, 1/25 HP, 115V, 3400 RPM motor is one you might want to consider. List \$117.80, wholesale \$76.42.

Both of the above pumps are manufactured by Teel and feature bronze pump body, ryton impeller, stainless steel impeller housing and shaft. They have 1/2" NPT threads on both inlet and outlet. I have added hose fittings to mine so that they can be easily installed and removed.

I recommend that you use two pumps--one for hot liquor and one for wort. This way you can pump sparge water in at the same time that you are pumping sweet wort out. An added benefit is that you have a backup in case one fails. I have had zero problems with these pumps through seven batches. Be sure to run hot water through the wort pump to flush it out when you are finished.

When using pumps to move hot wort around, aeration is always a concern. As long as I am careful and fill all hoses with liquid before I start pumping, I see no evidence that these pumps cause significant aeration.

Hope this helps.

I got a few replies suggesting I use a little of something I have in short supply, patience :-). As I now work for a startup with a number of employees less than the number of bottles produced by a 5 gallon batch, I actually got to drink some of my own Christmas brew on Christmas! I can now confirm that wise recommendation. This is absolutely the best Christmas Ale I've ever made. It also helped that I made it early enough that it had matured by Christmas. I expect the last couple of six packs to dissapear on New Years :-). Bottom Line: I will not reduce the amount of ginger next year, and will brew early for Christmas again!

Happy New Year!

Yes. This is from the Miller Reserve brand manager on
Compuserve:

#: 283576 S9/Beers & Breweries
29-Dec-93 17:44:59
Sb: #MR Velvet Stout
Fm: Jeffrey A. Kellar 73112,2062

Roger,

The stout is no hoax and a nice beer I believe (but then I
would). I will
take full responsibility for all aspects of the beer. But I
figured the best
way to create fast brewing credibility was to bring out a
stout. It will be
in market Feb. 1 just in time to pour a few half and halves with
MRAA. Besides
I have been wanting to brew a stout that is clearly a stout but
has
drinkability so we can bring more drinkers into the specialty
category.
I think our (my) Velvet Stout will do it.

Its an all barley recipe, and we are using the same ale yeast
as with MRAA.
Its hopped pretty heavy with cluster and cascade and has a
higher than
average carbonation level for a stout. But I am assessing
several levels and
may change before February. It is as with all the Reserve
brands a
nonpasteurized beer.

I am to say the least excited about it and the response it will
get. People
may find it to be a bit thin but analytically it stacks up quit
well against
Guinness. Drop me a note with other questions.

From: Lee=A.=Menegoni@nectech.com
Subject: adding "creaminess" to beer / cleaning burnt stuff

RE: Creaminess like Watneys Cream Stout

I suspect the creaminess experienced in Watney's Cream Stout is the product of unfermentable complex dextrins in the beer which add to the body. One way of increasing the unfermentables/complex dextrins, particularly for extract brewers with no control over the dextrin content in the malt extract, is to add Malto-Dextrin powder. My understanding of this product is that it is an unfermentable complex dextrin which adds body but no taste to a beer.

RE: Removing Burnt stuff from bottom of mash kettle

I use a stainless steel version of the Chore Boy to scrub burnt stuff off the bottom of my brewing equipment, I call it a Kindda'EasyScrubber. I find that the stainless does a better job for scrubbing than a copper Chore Boy. I also find it is easier to clean the burnt stuff off after mashing, while sparging, than to let the stuff cool, dry and harden. I actually use them new as a filter ala Chore Boy when racking chilled wort, EasyFilter. I find that the stainless scrubby has more material in it and does a better job of filtering than the copper Chore Boy. When I replace the filter scrubber it becomes a clean up scrubber.

I don't have experience with Papazian's recipe you mentioned. However,
ginger, like most spices, mellows with time. I brew a Honey-ginger beer
that in its infancy (2-3 weeks after bottling) has a very strong ginger
taste. After 2-3 months, the strength of the ginger is very nice. Allow
your beer to age a few months.

You mentioned a soapy aftertaste from the ginger. I have not experienced
that with my ginger beers. Please enlighten me.

Subject: beer hunter psa / mega micro / mead

For those of you in New England who get WENH (New Hampshire PBS), they are running the Beer Hunter series on Wednesdays at 7:30 and Sundays at 3:30. One exception is next week since the Guv is preempting it. Sunday will be (mostly) about Anchor, or how a washing machine heir really cleaned up in the beer business. Seriously though, it's a good segment.

Now if you're still with me, Allan Janus (in #1311) asks if a Bud Kriek can be far off. I answer very far, since I heard a radio ad which represented A-Bs flagship product as flavorful! So while Miller seems to be making an effort to market beers with flavor, A-B is proclaiming the emperors new clothes with a bit of micro bashing thrown in. Heineken took the same approach in a recent radio campaign in the Boston area. Methinks the big players are getting nervous.

A question about mead. I racked my first mead to secondaries last night and, on drinking the hydrometer sample, found a nasty biting plastic flavor. I recall a comment made recently that off flavors are not unusual in young mead, but this off?

Happy Brew Year!

Carl

Subject: Holiday Cheer Results

I too brewed Holiday Cheer this fall, unfortunately I followed Papazian's recipe directly. This results in way too much ginger taste in the beer. However, I'm finding that the taste is starting to mellow after about a month in the bottle. I bottled this brew in both 12 oz bottles and in Grolsch 16 oz bottles. The Grolsch bottles are noticeably more drinkable while I find that the smaller bottles have a sort of rubbery taste (reminds me of those pink pearl erasers we used in grade school).

I'm hoping to get rid of the rest of this batch tomorrow night by forcing it on my neighbors.

Subject: Re: Dishwasher Bottles

y2046@hrpi16.DNET.hcc.com (Bruce) asks:
> I have been wondering if it would be acceptable to use my dishwasher
> to sterilize my bottles.

I've been using my dishwasher to clean bottles for over a year and it works great. The secret is to rinse the bottles just after they are emptied. Once I have decanted a homebrew, I immediately rinse the bottle and then ignore it until I'm ready to bottle the next batch.

When I'm ready to bottle a batch, I fill the dishwasher with bottles---I can get 52-54 bottles in it, so that's almost enough to bottle my six gallon batches. Before I load each bottle, I rinse the inside using a bottle washer with hot water. I then put my dishwasher on the longest setting with heated drying and put in about 1 tbl bleach. NOTE: There is no soap. I run the bottles, let them dry via the heat cycle, then run them again on a short cycle with no bleach or soap. I let the bottles dry again via the heat cycle, then let them cool. I don't open the door of the dishwasher until the moment I'm ready to begin filling the bottles.

I fill the bottles over the dishwasher door as I pull each bottle out. This keeps the spilled beer on the door of the dishwasher. When I'm done bottling, I put in the gear I want washed and run the dishwasher with soap on a short cycle. This cleans the beer off the door and the equipment inside.

This keeps the mess to a minimum and seems to clean the bottles well enough. I've never had an infected bottle using this method.

Credit for the method goes to someone else; I read about it here in HBD. Works great.
