Practical experience has also shown that it is best to pitch yeast freshly harvested from slants at the maximum acceptable rate. Anticipating the results in the next section, this for lager yeast amounts to pitching 1 volume of yeast *SOLIDS* for each 250 volumes of wort. Thus, we need $5\text{gal}/250 = 0.02\text{gal} \cdot 128\text{oz}/\text{gal} = 2.5\text{oz}$ of yeast solids for a 5 gallon batch. Using the estimation that yeast solids are 1/10 the total volume of a yeast culture, that means that one needs about 25oz or a little more than 3 cups culture. For ale yeast all of these numbers are reduced by a factor of two, so (3/2) to 2 cups of an ale yeast culture would be sufficient.

In the procedure described below new wort is added just after the end of the period of high krauesen, and in particular after the foam starts to recede. The reason for this is to keep the yeast in the aerobic exponential growth mode. This will insure a steady buildup of yeast cells, and thereby minimize the number of wort charges that are required. The importance of taking great care when adding fresh wort can not be overemphasized. To avoid infections not only is it necessary to properly sanitize equipment, but it also important to sterilize necks of vessels and jars by flame or 200 proof alcohol solutions. The easiest way to flame a jar at home is with a lighter (esp. the ones for pipe-smokers!). Be extremely careful, and don't use both alcohol and a lighter.

The first four steps described below are done under the cleanest conditions possible using 1000 ml. starter jars. At the end of step (iv) there will invariably be more than enough yeast in each starter jar to pitch a 25 liter brew (about 6gal); i.e., there will be at least 1/10 liter of yeast solids as can be checked by visual inspection. These numbers are based on the requirements of lager yeast. As will be seen below there will be no harm in producing too much yeast in this procedure since at the end only the correct amount will be added to the fermenter.

From: WEIX@swmed.edu

Subject: yeast faq 6b of 8

(i) Preparations:

- a. Carefully inspect all the slants that are to be propagated. Those which have unusual growth patterns and/or discoloration should be discarded. The ideal is thin white yeast layer on top of the solid media.
- b. Autoclave the starter jars and the rubber stoppers for the airlocks for 5 mins. at 15 psi. Alternatively, use your favorite chemical sanitizing agent.
- c. Add 250 ml. (about 8 oz) of wort to each starter jar. Wipe their necks with a 200 proof alcohol solution. After this add the airlocks.
- d. Pasteurize the wort by adding the starter jars to a water bath at 60 C (140 F), and hold this temperature for 20 mins. Cool to 18 C (75 F).
- e. In a clean room with no air movement (turn off fans and air conditioning for at least 15 min to give the dust a chance to settle) and then place starter jars, yeast slants, inoculation loops, and a 200 proof alcohol solution in a clean, quiet spot (i.e. lock the door after first insuring that Fido, Fluffy, and Junior are on the other side of it :-)!).

(ii) Inoculation:

For each jar, start by sterilizing its neck. Then sterilize ("flame") the inoculation loop. Open a slant, quench the loop in clean agar ("sizzle") and use the loop to remove some yeast. Remove the airlock and then add the yeast to the starter jar. Replace the airlock, and then start work on the next jar.

(iii) Initial Buildup:

- a. Place the starter jars in a location where 68F (18C can be held). Aerate twice daily by vigorously shaking jars. 1L Erlenmeyer flasks are excellent for this purpose because they permit vigorous swirling without getting the wort up by the neck and opening. Also good are 1.5L ex-wine bottles.
- b. A widely used practice is to discard any starter that is not active within 48 hours. Certainly if some of the starters are active within this period, then the inactive ones should be discarded. In any case, any starter not active within 72

hours should definitely be discarded even if this means they are all discarded.

(iv) Second Wort Charge

a. When the foam has receded prepare 250ml. of fresh sterile and aerated wort for each starter.

b. The new wort is to be added to each starter, and this should be done as cleanly as possible.

c. Before pouring the wort into the starters, it is very important to swab the necks of the starter jar and the wort jar with a 200 proof alcohol solution to prevent contamination or flame them with a lighter.

d. It is also desirable to reduce the temperature to a point closer to the temperature that will be used in production if that is lower than 18 C. The temperature should be reduced *slowly*, e.g. few degrees a day. Large shifts in temperature (>10 deg F or >5 deg C) can cause marked slowing of yeast growth.

e. The starters should be aerated at the start and then again after 12 hours. New activity should be seen before 24 hrs. Those which are not active within 36-48 hours should be discarded.

f. Increase the volume of wort until you have sufficient volume to pitch.

(v) Pitching the Yeast

a. At this time you should have a jar with about 500ml (a little more than 2 cups) of yeast for a 5gal ale batch. I would suggest pitching *just after* the krausen (foam) dies down, the logic being that the yeast have amassed glycogen reserves and are at their healthiest. Some other sources recommend pitching at high krausen, reasoning that the yeast are in the exponential growth phase. Whatever you do, avoid overdilution (greater than 10 fold increase in wort volume) and keep accurate notes. The total volume will vary with batch size, yeast type, and your personal experience/whim. Remember to keep yeast notes along with your beer notes so that you can learn from experience!

b. Clean the outside of the jar with 200 proof alcohol or weak bleach and allow to dry.

c. Pour the yeast slurry carefully into the primary.

From: WEIX@swmed.edu
Subject: yeast faq 2 of 8

SECTION I: YEAST CHARACTERISTICS

ACTIVITY

Some yeast strains are more active and vigorous than others. Lager strains in particular do not show as much activity on the surface as many of the ale strains. Most packages provide an adequate quantity of yeast to complete fermentation with varying amounts of lag time depending on strain, freshness, handling, and temperature. If you find it too slow, make a starter as recommended on the package or as listed in Section III.

TEMPERATURE

The slow onset of visible signs of fermentation can be improved by starting fermentation at 75 deg. F (24 deg. C) until activity is evident, then moving to your desired fermentation temperature. A few degrees does make a significant difference without adversely affecting flavor.

The normal temperatures for ale yeast range from 60-75 deg. F (16-24 deg. C). A few strains ferment well down to 55 deg. F (13 deg. C). 68 deg. F (20 deg. C) is a good average. Lager strains normally ferment from 32-75 deg. F (0-24 deg. C). 50-55 deg. F (10-12 deg. C) is customary for primary fermentation. A slow steady reduction to the desired temperature for secondary fermentation typically works well.

The fermentation rate is closely related to temperature. The lower the temperature, the slower fermentation commences. Fluctuations in temperature such as cooling and warming from night to day can adversely affect yeast performance.

ATTENUATION

Attenuation refers to the percentage of sugar converted to alcohol. Apparent attenuation of yeast normally ranges from 67-77%. The attenuation is determined by the composition of the wort or juice and the yeast strain used. Each yeast strain ferments different sugars to varying degrees, resulting in higher or lower final gravities. That will affect the residual sweetness and body.

Really, it's slightly more complex than that (isn't everything ?-). There's "apparent attenuation" and "real attenuation". The difference comes about because alcohol has a specific gravity less than 1 (about 0.8). Real attenuation is the percent of sugars converted to alcohol. So, if you had a 10% (by weight) sugar solution (about 1.040), and got 100% real attenuation, the resulting

specific gravity would be about 0.991 (corresponding to about 5% alcohol by weight). The apparent attenuation of this brew would be 122%! George Fix published a set of equations relating apparent and real attenuation and alcohol

content last year. For example, let

A = alcohol content of finished beer in % by wt and

RE = real extract of finished beer in deg. Plato.

Since A and RE are generally not known to us, additional approximations are

needed. The following are due to Balling, and have proven to be reasonable. Let

OE and be defined as follows:

OE = original extract (measured deg. Plato of wort)

AE = apparent extract (measured deg. Plato of finished beer).

Then,

$RE = 0.1808*OE + 0.8192*AE,$

and

$A = (OE-RE)/(2.0665-0.010665*OE).$

The "tricky part" here is the expression of the sugar content in degrees Plato. This is a fancy term for % sugar by weight, and corresponds *

roughly* to "degrees gravity" divided by 4. That is, a 1.040 wort has an extract of

10 degrees Plato. He goes on to calculate an example: To take a specific case,

first note that from Plato tables an OG of 1.045 is equivalent to OE =

11.25 deg. Plato, while a FG of 1.010 is equivalent to AE = 2.5 deg. Plato.

Therefore,

$RE = 0.1808*11.25 + 0.8192*2.5 = 4.08$ deg. Plato,

and

$A = (11.25 - 4.08)/(2.0665 - .010665*11.25) = 3.68$ % wt.

The apparent attenuation is 75% (from 1.040 to 1.010), the real attenuation is

$(11.25 - 4.08)/11.25 = 64\%$. N.B. Most attenuation figures are given in terms of

apparent attenuation. (Thanks to Chris Pencis quoting Stuart Thomas quoting

George Fix).

FLOCCULATION

Flocculation refers to the tendency of yeast to clump together and settle out

of suspension. The degree and type of flocculation varies for different yeast.

Some strains clump into very large flocculate. Some flocculate very little

giving a more granular consistency. Most yeast strains clump and flocculate to a

moderate degree. Flocculation simply refers to how well the yeast stick to one

another. A yeast that is more flocculant will fall out of suspension better, but

since it will be in the bottle at least a week before you drink it, it really

doesn't matter so much for clarity. How it does matter is that if the yeast

settle out too quickly, they may leave some chemical reactions unfinished.

Mostly these strains: 1) May not be as attenuative because of shorter contact

time with the sugars, 2) May not finish reducing all the diacetyls, leaving a butterscotch flavor.

pH RANGES

Typical pH range for yeast fermentations begins at about 5.1 and optimally 4.8. The pH of wort is usually about 5, depending on the starting pH of the water and the grains or extracts used. During the course of fermentation the pH reduces to typically 3.9- 4.1 and as low as 3.1 in some wines. pH may be checked using pH paper test strips, which are available at many homebrew shops. Typically there is little need to adjust the pH.

ALCOHOL TOLERANCES

The alcohol tolerance for most brewing yeast is as least to 8%. Barley wines to 12% can be produced by most ale strains. Pitching rates need to be increased proportionally to higher gravities. Alternately, Champagne and Wine yeast can be used for high gravities sometimes reaching alcohols to 18%. To get the characteristics of particular beer yeast strains in Barley Wines or Imperial Stouts, some brewers start with the desired beer strain, brew to 5-8%, and finish with a champagne or wine yeast.

SMELLS AND TASTES

Although the principle tastes present in a beer are the result of the malts and hops used, the strain of yeast used can also add important flavors, good and/or bad. Yeast that add little in the way of extra flavors are usually described as having a "clean" taste. These yeast are especially useful for beginners because they permit experimentation with different ingredients without worrying about yeast influence. Yeast produce three main classes of metabolic by-products that affect beer taste: phenols, esters, and diacetyl. Phenols can give a "spicy" or "clove-like" taste, but can also result in medicinal tastes, especially if they react with chlorine in the water to make chlorophenols. Esters can lend a "fruity" taste to beer. Diacetyls can give beer a "butterscotch" or sometimes a "woody" taste. The desirability of any one of these components depends largely on the style of beer being brewed. In addition, there are certain by-products in these families that are more noxious than the others. A lot depends on the individual palette and the effect you're aiming for.

A final note: some yeast, especially lager yeast during lagering, can produce a "rotten egg" smell. This is the result of hydrogen sulfite production. Although the scent of this bubbling out of the air-lock is enough to make the

strongest homebrewmeister blanch, fear not! The good news is that this will usually pass, leaving the beer unaffected. Relax, etc.

OBTAINING CULTURES AND MISCELLANY

Most of the dry strains are available by mail-order or at your local homebrew store. Wyeast are also widely available (by which I mean, of course, that *my* local store carries a wide selection). The BrewTek strains and the Yeast Culture Kit strains are significantly less available, so the company contact numbers are included as a public service.
BrewTek: (800) 8BRE-WTE
Yeast Culture Kit Company: (800) 742-2110.

Subject: Whats Weihenstephan??!

IN the last digest, Jack asks, Whats Weihenstephan??

Heres German brewing lesson #101:

Weihenstephan is the oldest continuously operating brewing center in the world. It is located north of Munich, in the fabulous town of Friesing. Weihenstephan has two breweries, a state run "industrial" brewery that makes some so so beers, and the small school brewery that is affiliated with the extremely anal and respected Weihenstephan brewing school/institute. They operate a yeast bank which is the source for many of the most popular strains of lager and weizen yeasts (Weih 66, and 34/70 for ex). A single strain of yeast on a cotton ball (dry!) costs about \$200! Think about that next time you buy the same yeast for \$2-3 from a yeast culture supplier. Weihenstephan is an extremely respected and difficult school to be accepted into. You must speak fluent German to enter, and a difficult test (oral & written) is given. As if this isnt enough, you must be an experienced brewer to attend. Often this means you do duty as a grunt worker in a brewry cleaning tanks to get the "experience" required. I believe you also need to do this apprenticeship under a Diplom Braumeister (a graduate of Weihenstephan). Usually , Diplom Braumeister's never actually brew after graduation, they often are employed as heads of the QC division of Bud or Miller. In germany, they are also fond of opening hausBraueries (brew pubs). A very anal & difficult school. Dr. Narziss has been the professor/god for quite some time and authored excellent papers on things such as rapid high temperature fermentation and aging of lager beers, "the Narziss" method of quick lagering as mentioned by Dr. Fix in BT issue #2.

BTW, Jack, nice Maltmill! It did get a bit pricy since I needed the upgraded gear and spacing option, but I now have it motorized with a 10" pulley on the mill and a 3" pulley on the motor. After mounting the mill on an extension of my workbench, I just pop the trash can under the mill, and start pouring 65 pounds of grain through the thing. Now if I can just engineer a ceiling mounted grain hopper, I'll be all set (with auger feed of course :-))!!

Good brewing,

Jim Busch

From: tima@wv.MENTORG.COM (Tim Anderson)
Subject: Labels and whining (mine)

The only labelling I have ever done is to write the batch number on the cap with a felt pen. I use a rather complex numbering algorithm:

Batch # = Previous Batch # plus 1

After much research I settled on "1" for my original batch number, Arabic numerals and base 10. For example, my latest has "24" written on each cap, whereas the previous batch had "23". It is important to use the same number on each bottle in the same batch. For easy reference, I keep a chart on the wall near where I keep my brewing supplies, with a list of all the numbers from "1" to "100". At bottling time, I just have to look at the number on the cap of a bottle from the previous batch, find a number on the chart that looks the same, and use the next number in the list. By the time I go to write the number on that first cap, my adrenaline is really pumping.

I'd be happy to provide more details via email.

tim

ps I think the Oregon Brewers Festival has gotten WAY too big. The best thing about it was that Samuel (tm) Adams (tm) wasn't invited.

From: jdecarlo@homebrew.mitre.org
Subject: Wort Aeration

While I think it is a good idea to do experiments, one of the hardest parts is interpreting them. I have personally come across situations where people were using Wyeast cultures without making starters and observing 48 hour lag times.

While I normally advise making starters, I have twice helped people just really aerate the wort and see lag times reduce to half a day or so. So clearly the amount of aeration of the wort can have an incredibly dramatic effect on the time required for the onset of fermentation.

For the more gadget-oriented among our community, something like an airstone can make the process much easier (I know people who have gravity-fed metal pipes going from a stainless brewpot from a keg to a stainless fermenter, with no exposure to air along the way--something like this works well for them). For those of us with minimal equipment, it is obvious that there are easier ways to aerate the wort, at least to a sufficient level.

But there are so many variables involved. For instance, if you are making a barley wine using an ale yeast and want to ensure sufficient oxygen available to the yeast you might just shake up the fermenter every day for a week or so. Or you might find it easier to have some sort of pump do the work for you.

Unfortunately, some people tend to either overenthusiastically adopt or reject new approaches, which can make it more difficult for others to determine the usefulness for themselves.

IMHO, the bottom line is that most everyone I have brewed with, including myself, often underpitches the yeast and underoxygenates the wort. But whether you sit down and shake up the fermenter or use a small metal tube with holes drilled in it or a faucet aerator or an airstone with pump probably depends on your environment more than anything else.

Subject: doppelbock and fruit beers

Fermentating way in the "lagering chamber" is an OG 1085 doppelbock (baumerator?) Yeastlab Bavarian Lager is being used at 50 degrees F. I am assuming this yeast is going to poop out with a reasonable amount of sugars remaining due to the alcohol level. If this is correct, then how does one get carbonation when bottling a beer of this style? Will adding the typical priming sugar (1 cup dme) rejuvenate the yeast enough to get some carbonation or are the yeast going to be killed off by the alcohol level? I won't be bottling this batch until October and don't want to wait that long to find out if this will work or not. Any advice would be appreciated.

Fruit beers: I've always ignored posts relating to fruit beers with the attitude of why wreck perfectly good beer by adding fruit. Well, my wife and brother have convinced me to attempt a raspberry beer. What I would like to do is brew a large batch of wheat beer, then split off a few gallons to experiment with fruit. That way if I hate the fruit beer, at least I'll have a batch of decent wheat beer for my efforts. So now I'm looking for advice on adding raspberries to a wheat beer. From what little I've read, it appears that adding raspberries to the secondary is one method. If so, how much and how do I prepare them? Also, do I need to adjust the hopping of the beer when adding fruit? If so, less boiling, less finishing, or what? Thanks in advance.

BTW: I am experimenting with raspberries due to a ready supply in the backyard, fighting the hops for space. Anyone in the south bay area want to swap for some homegrown Cascades. I've got about half a pound more than I figure to use in the next year. email me if interested.

From: Mark S. Hart <hart@hvhp1.mdc.com>
Subject: Canadian U-brewns
Full-Name: Mark S. Hart

Salutations,

About 1 1/2 weeks ago I read this article in The Wall Street Journal by Larry M. Greenberg. The following is a condensation of that article. I left out a lot of the quotes from patrons, the explanation of the brewing process, etc. for brevity.

"It's another night at the U-brew. What laundromats are to clothes, Canada's U-brewns are to the thirsty and heavily taxed. Here, for about 90 Canadian dollars, would-be brewmasters legally can whip up a 13 gallon batch of potent suds.

In place of commercial breweries' big buildings, elaborate plumbing and computerized chillers, U-brewns offer storefront or warehouse space, huge metal pots, plastic tubs, lots of well used bottles, recipes and some know how.

Low tech perhaps, but low cost, too. U-brewns sidestep federal beer taxes and most provincial taxes. In a land where levies are huge (a six-pack of domestic brew goes for the equivalent of US \$5.35) dodging the taxman is a heady incentive for beer quaffers.

The first U-brew, started six years ago, in London, Ontario, with the idea that beer lovers would be happy to rent equipment, make a mess away from home and save money.

A culture has grown at the U-brewns, where friends gather, usually on week-nights. Most budding brewers say they start because of the savings - then enjoy the camaraderie.

There's something of a party atmosphere at the U-brewns as friends get together to batch up some brew. However, It's illegal to drink beer at a U-brew, a law perhaps honored as much in the breach as in the observance.

Employees at the U-brew will filter and carbonate the beer for customers before patrons return to cap it on the shop's bottling machine. Some U-brewns even have a microscope to analyze yeast. Some places are gussied up. Many are air-conditioned. Polished wooden floors, copper cooking pots instead of stainless steel, and even hanging plants are found in upscale establishments. Others are more rudimentary, with cracked concrete floors.

The phenomenon hasn't caught on in the U.S., where beer prices are far lower although Canadian investors recently opened one in Los Angeles, hoping that

aficionados may want to make exotic ales."

Has anyone out there in HBD land ever visited one of these places. It seems like a good idea, kind of like HBD put in person. It could really help the people who don't have the space or want to purchase equipment. I would be interested to hear the reviews of anyone who has visited/tried a U-brew.

Thanks,

Mark.

>and Willamette (5.3%) hops respectively.

Pale malt is fine. In a recent conversation I had with Mary Ann Grueber from Breiss Malting, she said that Klages is virtually non-existent these days and has been largely replaced with Harrington, but there is not any discernable difference in brewing qualities. Klages and Harrington are both pale malts, BTW, so you most likely got Harrington.

Liberty, OTOH, is nothing at all like Willamette. Liberty was bred as a domestic replacement for Hallertau Mittelfruh (virtual umlaut over the u), the classic "noble" aroma hop from Germany. If you can't find Liberty (or real German Hallertau Mittelfruh or Hersbrucker), then good substitutes are either Mt. Hood or a new hop just released called "Crystal" Crystal used to be known in the trade as CFJ-Hallertau and like Liberty and Mt. Hood were bred as Hallertauer replacements. Also note the domestic "Hallertau" is not very close to the real thing: The three that I have mentioned are much, much better. And of course the real thing (Hallertau) is still the best, but more costly.

FYI, Willamette is very similar to Fuggles (from which it was bred) but has a slightly more spicy note than Fuggles. In general you can interchange the two.

From: ron_hall%80@hp6400.desk.hp.com
Subject: Cheap Corny Kegs

I recently posted a request for info about a source of cheap kegs, and I was swamped with mail asking me to share what I found out. Well, here it is.

I got several responses suggesting DeFalco's of Houston, Texas. They sell used pin-lock kegs for \$15 ea, or 3 for \$35, plus shipping. I also got several responses saying that The Beverage Co. of Anderson, California has used ball-lock kegs for \$22 each or pin-lock kegs for \$17 each, and that several people had gotten these with no problems. In both cases, the kegs come "as-is" from the soda distributor, still have pressure in them and therefore are assumed air-tight, and also have residual soda syrup in them.

Well, I ordered 3 from DeFalco's, which cost me \$35, + \$15 shipping, + \$6 for three new lid o-rings. They arrived in about a week via UPS, all shrink-wrapped together. They were in good shape, no dents or dings, but with some label scum and REEKING of Coke syrup. They all say

"PROPERTY OF THE COCA_COLA COMPANY", but I assume they were procured legally :). I have rinsed them several times and replaced the o-rings, and the smell is almost gone. Hopefully it will not show up in my first kegged brew.

I bought a regulator at Steinbart's in Portland for \$39, and all the connecting hardware for another \$30. I got a 5 lb. CO2 bottle at a local

welding supply shop for \$65 (permanent lease) and \$7.70 for the CO2. The interesting part came when I took it home and hooked it up. The gas bottle sputtered and coughed, lost pressure quickly, and smelled like putrid, skunky beer. I took it back to the welding shop, and they emptied

it and found a cup or two of skunky beer in it, and naturally said, "Gee, I've never seen that happen before". Apparently the the previous user had

run it dry, and beer had backstreamed into the gas bottle. Lesson of the day

is: (1) don't run your bottle dry and leave it connected, and (2) have check

valves in your gas lines. Got a new bottle and I'm ready to go.

The number for DeFalco's is (713) 523-8154. I don't have the number for the Beverage Co. handy, but it's in the Celebrator Beer News classifieds. Standard disclaimers apply.

From: korz@iepubj.att.com
Subject: Re: Tun size/Klages/Liberty/Fridge Conversion

There have been a few questions regarding tun size and also a mention or two about grain depth. I've read (forget which book) that the ideal grain depth is 12 to 18 inches. Now, before everyone starts redesigning their laeuter tuns, I'm willing to bet that the ideal grain bed depth is highly dependent on the type of false bottom or slotted-pipe or easymasher pipe that you have in the bottom. In professional systems, there are debates raging about whether round holes or slots are better and the cross-sectional shape of the holes is debated also. So, I'm just relaying what I've read but if you record the depth of the grain bed on several batches of various size (which is what I'll be doing from now on) perhaps we can get enough data to make some general rules about grain depth versus efficiency, no?

>What are the special characteristics of Klages malt?
>Ditto for Liberty hops.

Klages is a 2-row barley strain that *used* to be grown in the U.S. It's replacement is called Harrington. Basically, what you wanted was a good 2-row Pale malt. Liberty is a U.S.-grown variety that was selected because it had qualities similar to Hallertauer Mittelfruh. If you can't get Liberty, Mt. Hood is a close cousin or you could use any number of German-, U.S.- or British Columbian-grown Hallertauer hops.

From: WEIX@swmed.edu
Subject: resend of yeast faq 1 of 8 (keeping my fingers crossed)

Sorry about the first post of this section: sometimes our mailer acts up!

Hi to all fellow homebrewers. This is the updated, revised and expanded version of my recent Yeast FAQ. Almost all of this data was plagiarized from somewhere by me or others; however, I have not knowingly used any copyrighted stuff. (I was very careful *not* to check anything for a copyright ;-).) I have altered the focus of some documents to more accurately reflect what I feel to be the interests of the *home*brewer. Some of the information is very basic; some, more technical. I have tried to give a basic introduction to what yeast are, how they affect beer taste, and the proper handling of yeast. Some portions of the following were taken from the Wyeast information circular e-mailed to me by David Adams; the sections pertaining to yeast culturing are adapted from an upcoming book by Dr. Fix. Dr. Fix also provided the section on the proper method of yeast rehydration. Most of the information on the "reputations" of the many yeast strains was collected from the HBD over the years by Doug O'Brien. Many thanks to David Adams, Dr. George Fix, and Doug O'Brien. I would also like to thank Al Korzonas for his helpful suggestions on the characteristics of some yeast strains and for his comments and help in clarifying the sections on propagation and culturing. Thanks also to the many people who made small suggestions or requests for clarification. My name is Patrick Weix, and I am a graduate student in the Genetics and Development program at UT Southwestern at Dallas <weix@swmed.edu>. I hope you find this document useful.

N.B. This document is composed of rampant hearsay and rumor. Any attempts to pin anything on me or my co-conspirators will be resisted. If all else fails I will call your boss and ask him why you are reading the HBD at work instead of grinding out the Fitzsimmons contract. What do they pay you for anyway? Don't you have anything better to do?...

=====
=====

INTRODUCTION

Yeast are unicellular fungi. Most brewing yeast belong to the genus *Saccharomyces*. Ale yeast are *S. cerevisiae*, and lager yeast are *S. uvarum*

(formerly carlsbergerensis). Another type of yeast you may hear mentioned, usually in conjunction with weizens, is *S. delbrueckii*. You may ask, "If all ale or lager yeast are the same species, why all the fuss?" The fuss is over strain variation. All dogs are the same species, yet no one will ever mistake a Basset Hound for a Doberman (at least not twice :-). Using different strains can add fun and spice to brewing, especially if you have some idea of the differences. I originally put together this guide to catalogue the different affects of different strains. This information is in Section II. Section I outlines the general characteristics of brewing yeast and tries to answer some of the more frequently asked questions about yeast that seem to cycle onto the HBD. Section III explains how the homebrewer can culture and maintain yeast strains in the safety and comfort of his/her own home.

From: Montgomery_John@lanmail.ncsc.navy.mil
Subject: degree of extract

Hi all,

This is my second post to this digest and I meant to include in my first posting a "Thank you all" for all the great information I've absorbed while watching from the sidelines...."Thank you all". :)
That said, on to the matter at hand.

In the May/June issue of Brewing Techniques, "Spreadsheet for Recipe Design" article, Mr. King shows a column in the spreadsheet labeled Deg of Extract. Below this are numbers corresponding to various grains and their respective extraction (rates?).

Eg:

DEG OF
EXTRACT

PALE MALT 27
WHEAT 25
etc... .
.
.

I checked my only two references (TCJoH,TCHoH) and didn't see anything that indicated where these numbers came from. Is this something I need to generate myself, ie. make 1 gallon batches with 1 pound of grain and check the gravity? Or are the numbers listed fairly standard and for use in calculations?

I always thought the degree of extraction was dependent on the quality of grain, quality of crush, mashing efficiency, etc. and would vary.

Can someone please clarify this? Thanks.

>it off. When it gets to the other side, they drop the paper on a rich
>media plate, incubate for a day or so, and the yeast grow up.

Dave Rose
Dept. of Cellular and Developmental Biology
Harvard U.

I guess this is a viable alternative commonly employed by researchers. It
is mentioned in a section on *S.cervesiae* research techniques, co-
authored
by Richard Wobbe of Harvard Medical School, in Current Protocols in
Molecular Biology. It looks like a pretty easy and inexpensive way to
mail
strains, though as Dave points out, it has some drawbacks for the home
culturer. As long as the recipient has the means to revive the strain,
it
may be worth a try. My only concern is that this procedure may select
against certain strains present in a multistrain culture. This is a good
piece of information, though, and some people may be interested in trying
it out.

>From: arf@genesis.mcs.com (Jack Schmidling)

>I though fission was another name for budding which makes it equally
> incorrect as an explanation for flocculation. The other reproductive
process
> encountered in yeast (but not beer yeast) involves sporulation and
sexual
> reproduction.

We're talking two forms of reproduction here: asexual, achieved by means
of
either fission or budding and sexual, involving a mating, of sorts,
resulting in an exchange of genetic material and the subsequent
reassortment of this genetic material to produce spores (more or less).
Fission and budding are two different means of achieving the same end:
production of two genetically identical cells, where previously there was
only one. I can't give you the mechanics of this at the moment, but both
processes are distinct from one another. Forgive the use of taxonomy,
but
Sacchomyces bud, whereas, for example, *Schizosacchomyces* undergo
fission.

Neither is an explanation of flocculation. To my understanding, the
ability to flocculate is incumbent upon the ability to reassociate (or

aggregate) once growth begins to slow. Perhaps Dave Rose can explain this more thoroughly. Whether beer yeasts can sporulate...well your guess is as good as mine: some lab strains of *S. cerevisiae* can.

ANNOUNCING ... MASHOUT '93

The Mid-Atlantic States Homebrewers
* * * * *
6th Annual Campout - To Be Held

September 10-12, 1993

in Rocky Gap (near Cumberland), MD

Fun for the Whole Family! - Including:

- Saturday dinner & Sunday breakfast,
courtesy of the BURP Homebrew Club
- Vienna/Oktoberfest Beer Competition
- Water sports at Rocky Gap Lake
- Hiking, biking, carousing, game playing,
finger pointing, eating, drinking, etc
- Lots of FREE BEER! (Donations of homebrew are
most welcome)

Directions: From Washington, DC, head west on I-270/I-70.
Just past Hancock, MD, bear left onto I-68 toward Cumberland.
Go past the town of Flintstone, up & over Martin Mountain.
Watch for signs for Rocky Gap Park and the Pleasant Valley/
Rocky Gap interchange. Rocky Gap Lake will be on the right.
At the interchange, go left over the bridge all the way to the
end (not far) and turn left - this should be the 2nd road. Head
back up the mountain and turn right at the 1st road, Breakneck
Road. Follow Breakneck until you're just past the mountaintop.
Turn right at the 2nd driveway past the mountaintop. A sign will
be posted to help you identify it. The camping area is right on
top of the mountain at the end of the driveway.

What to Bring: Food (for meals not provided by BURP), water
(there is none on the mountain top), homebrew, camping gear, musical
instruments, swimwear, bicycles, flying toys, all the other usual
stuff you'll need for a weekend of camping.

For further info, please e-mail to the address below. BURP would
appreciate a response from those interested so we can determine how
much food to buy (We promise a Special Treat for Saturday dinner).

See y'all there! Bill

Subject: pronunciation of trub

In hbd 1210 Al Korz etc. lists the pronunciation of many brewing terms. I for one have never liked the pronunciation troob for trub. It is such a fruity word. Thankfully, it is also incorrect. While Websters unabridged dictionary lists the pronunciation as troob or the rugged trub, both are incorrect if one uses the German pronunciation. There is still doubt as Websters gave two spellings, trub and trueb as the German spelling for the word meaning dirt or haze or whatever. These would be pronounced approximately troop and trip.

Subject: Nigerian Guinness

FYI, from the August 21, 1993 issue of The Economist (in a survey of Nigeria):

"Guinness, for example, has developed a stout brewed from malt extracted from millet and sorghum, because of the [Nigerian] government's import ban on barley malt. It looks the same, tastes different, and has been a smash, helping make Nigeria Guinness's third-biggest market, after Ireland and Britain."

I guess necessity is the mother of invention. Anybody ever tasted Nigerian Guinness or brewed with millet malt? Inquiring minds want to know!

From: rcd@raven.eklektix.com (Dick Dunn)
Subject: green chile beer again (notes on Coopersmith's "Sigda's")

A late addition to the chile-in-beer discussion, but I got some recipe-like info. A couple of folks had already mentioned Coopersmith's in Ft Collins, CO, which makes "Sigda's Green Chili [sic] Beer".

I think Sigda's is an excellent beer. The chile and beer flavors blend nicely. It's got just the right amount of bite--not enough to hurt, nor to make it the sole province of chile aficionados, but definitely enough to leave no doubt that it's a chile beer. More importantly, it's got a real character of the chiles. Compared to Cave Creek, I'd take this any day.

The basic recipe is a pale ale, only light malt (no crystal, etc.), and lightly hopped. Ummm, lessee...they're using English malts. Mash is a single infusion; don't remember temperatures.

During fermentation, they add chopped green chiles of the sort folks commonly call "Anaheim". (They get them frozen in bulk.) They use 20 lb "mild" and 30 lb "hot" in an 8 bbl batch. Keep in mind that the "mild" and "hot" here are relative to Anaheims, which are all down toward the mild end of the scale. The chiles are in hop bags in the fermenter. Anyway, that's just for the fermentation...when they transfer to the aging/serving tank, they remove the Anaheims and add 2 lb of chopped serranos for the aging period. This beer is served in-house only, directly from the aging tanks. That is, none of it is bottled, although you can buy it by the jug to take home. It's rather cloudy; they don't make much of an attempt to clarify it. (They fine, but don't filter, their beers.)

Just for perspective--since the 8 bbl batch size is a bit awkward for home brewing:-): It's about equivalent to a pound of Anaheims and somewhat over half an ounce of serranos for a five-gallon batch. (Remember, the weights refer to prepared [peeled/seeded] chiles.)

It would be interesting to see whether a beer like Sigda's could be bottled and kept for a while. I have my doubts; I suspect that the chile taste would fade or mutate somehow. I'd also guess that if it could be success-fully fined or filtered, you'd lose a lot of the character.

[and while I'm at it, a plug: If you have occasion to pass through Ft Collins, Coopersmith's is well worth a visit. In addition to the chile beer (which seems to be regularly available) they'll have half a dozen others on tap, including some unusual ones: I caught the tail end of their raspberry ale today. There was a blueberry wheat beer in a fermenter so I suspect that will be available in another two or three weeks. They'll also give you a tour of the brewery by someone knowledgeable if you're there

on a Saturday afternoon.

I hate to admit it...Ft Collins and Boulder are similar-size towns with
four

breweries each, but Ft Collins brews easily win on variety and interest.

Subject: molds on yeast plates: a solution

A while back, when I was away on vacation, there was a discussion of mold contamination of yeast plate cultures. Since there hasn't been a definitive solution yet (I'm not quite caught up though), let me suggest what we resort to for the protection of plates that must be kept open for long period in our lab:

>From 0.5 to 1% sodium propionate in the medium will suppress practically all molds, without affecting the growth or viability of yeasts. The propionate can be either added before autoclaving, in which case the medium will turn cloudy, or as a sterile solution just before pouring the plates, in which case the medium will stay clear. There is no growth difference in either case.

While not reinheitgebotmaessig, propionate is FDA-(or USDA-?)approved to prevent molds on foodstuffs.

Subject: R. Morris rims artical.

Hello again brewers,
Without even waiting for an answer to my previous question about
brewcaps, I going to ask a second:
Does anyone out there have a copy of Rodney Morris' RIMS article
from the Maltose Falcon news letter? And if so, would they also
happen to have an "electronic" version they could send me?
I've read the rims summary from sierra.stanford.edu, but
unfortunately all the brewers who submitted their designs,
described the differences between their setups and Morris'.
Hence, I'm still in the dark as to the exact setup.

ALTERNATIVELY, is there a more internationally available source
of such a full description?

Happy brewing, Rob. Thomas.

Regarding the "Brew Cap"

>From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>
>Subject: BrewCaps (tm?): how and why?

>Hello all,
>Could someone enlighten me on the purpose and use of the brew cap?
>All I know (well, suspect) is that it is used on a carboy, which is
>then turned upside down.
>If this is a really obvious question please email me privately.
>By the way, I've never seen one either, so a description might be
>useful.

>Isn't the quest for knowledge a terrible thing!

>Rob Thomas.

The 2-3 advantages (perhaps there are more) of this system are:

1. Since the carboy is placed upside down, you can drain off the trub as it settles in the neck of the carboy.
2. You can collect the spent yeast in the same manner. Thus, you can proceed with secondary fermentation in the same carboy & avoid having to rack to another (avoiding possible contamination & oxidation).
3. The collected yeast can be captured in a reasonably sanitary manner & repitched if you keep it clean & healthy.

The disadvantages that I'm aware of are:

1. Forget lagers unless you have a walk-in refer - since the carboy must be upside down, it must be mounted on a stand of some sort therefore the whole mess will be too tall to fit in a refer.
2. Since the cap is on the bottom, it seems difficult to dry hop or add finings (although I think the manufacturer gives some info on how to do this).
3. Although small (probably) there is a risk that if the blow-off tubes get clogged, since the cap can't pop off, the carboy may burst.

From: "Nadi Findikli, Ericsson/GE RTP 919-990-7213"
Subject: the beauty of labels

visual presentation is a part of beer as it is of any other food. that is why we all get so excited when we hit the right shade of amber or just a tint of red, or whatever turns you on. labels are part of the presentation of beer. so what if it takes a bit longer to prepare bottles, it is part of the process. you'll feel better when you present a bottle that looks as nice as the beer in it tastes.

on a technical note, if you have registration problems with labels prepared on a word processor, use a drawing or publishing program. these pay much more attention to dimensions than word processors, which tend to stretch things to fit the text. publishers also make graphics, border text etc easier to manage.

i say don't be content with writing the name of your beer on the bottle. make something worth the pain of cleaning labels off bottles.

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Lagering Room

Although I like my new "lagering room" (chest freezer/Airstat) a lot and I probably will never make ale again, there was one problem that was bugging me.

The 40F low end temp should be adequate for fermenting and serving beer but it just never seemed quite cold enough without using pre-chilled glasses.

After doing a little judicious temp measuring, I learned that the air temperature varies from 5 to 10 degrees above the actual beer temp. To determine your own delta, put a thermometer in a glass containing a pint or more of water and watch it for a few days.

I dug up the article by Mike Kenny on modifying the Hunter for lower temps and decided to give it a try. Upon opening the unit, I "discovered" a cal pot but found this had only about a two degree range and it was already in the middle of that.

Mike explains how to calculate (Ohms Law) the exact resistance for any temp, along with adding a switch to disable the mod. I took the Schmidling way and simply soldered a 150K resistor across the sensor lead terminals and got lucky. When programmed for 40F, the temp in the pint of water is exactly 40F now. The air temp is about 35F but I just ignore that and the beer temp is just the way I like it.

It is a very simple mod and requires nothing more than removing two screws and soldering the resistor to very accessible terminals. Getting it back together takes a little "feel" because the battery terminals have to be fitted back into their connector but anyone with a little more finesse than a gorilla should be able to do it.

Thanks Mike. (mkenny@bcmlg01.attmail.com for details)

From: Kevin Schutz <kschutz@atmel.com>
Subject: Form of Spices for Holiday Brews?

Hello All!

With Fall just around the corner, thoughts have been turning toward brewing up some holiday brews. I wanted to check with all my fellow brewers to see if anyone has had any experiences with choosing the appropriate forms of spices to include in batches. For example, is it better to use whole cloves or ground cloves, anise seed or anise extract? I'm interested in using most of the easily available spices (Anise, Cardimon, Cinnamon, Clove, Ginger, & Nutmeg come immediately to mind).

I'd also be interested in suggested amounts of various spices to start with. I'll probably turn a quick 2.5 gal trial batch within the next week and then move up to 5 gals.

Thanks in advance for your help! If I get alot of responses, I'll catalog the responses and post them.

From: RBSWEENEY@memstvx1.memst.edu
Subject: Brown Ale Bananas Foster recipe

Here's an interesting little recipe I tried recently with pretty good results:

Brown Ale Bananas Foster

3/4 lb British crystal malt - 20 Lovibond
6 lbs Pale 6-row
3 oz Southern Country New Orleans Bananas Foster mix*
1/4 lb Chocolate malt
1/2 cup Grandma's mild molasses

*- includes brown sugar, sugar, spice, natural and artificial flavoring:
(orange, lemon, banana, rum flavor, food starch modified and malto
dextrin)
caramel color, silicon dioxide

1 oz Kent Goldings plugs (4.7% alpha) - 60 min in boil
1 oz Kent Goldings plugs (4.7% alpha) - 5 min in boil

2 tablespoons Irish Moss - 15 min in boil

Wyeast #1007 (German Ale) - repitched 11 teaspoons slurry

Mashed all grains in 2.5 gal of 156 water for 90 min (w/ 1/2 tsp gypsum)

sparged with 4.5 gal of 170 water (w/ 1/2 tsp gypsum), added molasses and
Bananas Foster mix and boiled 75 min. (the brewpot smelled like rum and
fruit

while it was boiling, something like a fruitcake). Chilled wort with
immersion

chiller for 10-15 min., racked to carboy and pitched yeast. Left beer in
primary four days at around 70 degrees, then racked to secondary and
added 1/2

oz of gelatin finings and kegged three days later using forced
carbonation.

Original gravity - 1.042 (78.4% extraction efficiency; if yours is
generally

different adjust the recipe accordingly)

Final gravity - 1.009

Alcohol: 3.4% by weight, 4.2% by volume

Color Units/Gal - 25.6 (using calculation described by Dave Miller in
Brewing

the World's Great Beers)

I have made a few previous brown ales but this was absolutely the best.

My

experience with commercial brown ales is limited to Newcastle and I'm not
one

of its biggest fans--no flavor to speak of, IMO. This concoction on the
other

hand has flavor to spare plus a unique and to my mind wonderful aroma,
kind of

a caramel/toffee/rum combination. Its great even at room temp.

As always, brewer beware, your taste may vary.

From: "Bret D. Wortman" <wortman@centurylub.com>
Subject: FZ on beer -- just for fun.

The following taken from "The Real Frank Zappa Book", by Frank Zappa with Peter Occhiogrosso, Poseidon Press, 1989. Emphasis removed in
may places due to the inability to reproduce italics, boldface, and all caps all at once. :-)

The remainder is quoted from the book:

I have a theory about beer: Consumption of it leads to pseudo-
military behavior. Think about it -- winos don't march. Whiskey guys don't march either (sometimes they write poetry, which is often more horrible, though).

Beer drinkers are into things that are sort of like marching -- like football.

Maybe there's a chemical in beer that stimulates the [male] brain to
do violence while moving in the same direction as other guys who smell like them [marching]--"We, as a group of MEN, will drink this
refreshing liquid, after which we will get together and beat the snot out of
that guy over there."

Beer seems to produce behavioral results which are psycho-chemically different from those produced by other alcoholic beverages.

Alcohol (the part that 'gets you drunk') is only one ingredient.
There are other things in beer, and those [herbal and/or biological] components could affect the [male] brain, creating this violent tendency.

Go ahead and laugh. One day you're going to read about some
scientist discovering that hops, in conjunction with certain strains of 'yeast creatures,' has a mysterious effect on some newly discovered region
of the brain, making people want to kill--but only in groups. (With whiskey, you might want to murder your girlfriend--but beer makes you want to do it with your buddies watching. It's a buddy beverage--
for buddy activities.)

Think about it: "Who IS this 'Mr. Coors'? What does HE do for a
'good time'--and why does a man who owns a beer company need a 'top-secret security clearance'?" Did you see him during the Iran-contra
hearings?
He has a top-secret security clearance. Do they guys at Anheuser-
Busch have the same clearance? And when you see a beer commercial, besides 'the buddy pitch,' don't they also throw in a little jingoistic, bunting-encrusted, flag-waving hoopla,--the all-American beer
syndrome?

Every major industrialized nation has A BEER (you can't be a Real Country unless you have A BEER and an airline--it helps if you have some kind of a football team, or some nuclear weapons, but at the very least you need A BEER).

I think the mutant behaviors exhibited by people 'under the influence' should be studied more closely. Gin drinkers, for example, are a breed apart.

People choose an allegiance to a certain beverage. Like bourbon guys--they're bourbon guys and that's it. And scotch drinkers? Forget it. They don't want to know from 'pink gin.'

In contrast to Mr. Beer Guy, picture a guy who is religiously devoted to Chateau Latour. Is he marching? He ain't marching.

Subject: mailing strains/flocculation/sporulation

Hello:

In response to a post regarding a simple method of preparing yeast strains for mailing, Todd Gierman noted that it might not be a good way of mailing multi-strain cultures, since one might be selecting against one of the strains. This is a good point, and I certainly wouldn't recommend shipping mixed cultures on paper. Using this method, the strain should be struck for singles on the receiving end, and this would reduce a multi-strain culture to only one of its components, unless the colony morphology of the various strains is very distinct, in which case each could be picked for re-combination later. I would think that the best way of maintaining multi-strain cultures would be to isolate the individual component strains and store those, where this is possible. Any mixed culture is going to change in terms of the relative prevalence of individual strains during propagation, and if you don't have the individuals stored you run the risk of losing one or another component. By maintaining separate cultures and then mixing them before each use, one should get more reproducible results.

Todd also asked whether I knew anything about flocculation. Not much. Basically, though, the flocculation characteristics of a strain are a function of the composition of the cell wall; some strains are "sticky", some aren't. "Stickiness" of a given strain can increase under certain circumstances, most notably when cells mate, since the ability of cells to stick to one another increases the probability that they will mate successfully. However, mating is just not something that happens with brewing strains under normal circumstances. Flocculence may also increase as cells run out of nutrients, but I don't have any information to support this idea. I always figured that cells were kept in suspension by CO₂ evolution, and that they settle out when CO₂ production ceased; in other words, the "stickiness" of the cells hasn't changed, but they settle because they aren't getting kicked around any more. But, again, I don't have any data to support this view.

Todd also mentions sporulation. Yes, at least some brewing strains are capable of sporulating. However, sporulation requires nutritional conditions (starvation for nitrogen and the presence of acetate as a carbon source) that don't occur in wort. So, the frequency of sporulation in beer is around zero.

Subject: Currency, Aeration

As no one else seems to want to, I will take it upon myself to speak out on net protocol.

The yeast FAQ is a noble effort but I think some self-restraint is in order regarding eating up big chunks of the Digest.

I am not about to criticize anyone for what they post or how often but one must keep in mind the fact that what makes the Digest most useful is its near real-time currency. Getting an answer to a question the very next day is a powerful reason for participating. When the Digest is flooded with very long articles that could be just as easily serialized, the currency is lost.

Breaking long articles up into small pieces but sending them all out the same day only guarantees a bottleneck and deprives readers of the answers they are looking for.

I would like to suggest that users voluntarily limit articles to 200 lines in any given day. That is after all about 20% of a typical Digest and would still allow significant participation by others. That thousand liner the other day was just a bit much and I suspect more are on the way.

It is also obvious that much of the cleaning up of the FAQ could be done by email now that the experts have been identified.

>From: jdecarlo@homebrew.mitre.org
>Subject: Wort Aeration

I hate to nit pick over your otherwise rational look at the discussion but I think your advice on shaking a fermenting carboy of barleywine every few days to aerate it is wishful thinking. As there would be nothing but CO2 in the head space, no oxygenation could take place.

>From: korz@iepubj.att.com
>Subject: Re: Tun size/Klages/Liberty/Fridge Conversion

>There have been a few questions regarding tun size and also a mention or two about grain depth. I've read (forget which book) that the ideal grain depth is 12 to 18 inches. Now, before everyone starts redesigning their

laeuter tuns, I'm willing to bet that the ideal grain bed depth is highly dependent on the type of false bottom or slotted-pipe or easymasher pipe that you have in the bottom....

Just to open the discussion, I get the same yields in my half liter pilot system as I do in my 10 gallon easymasher. I recently made a 1 gallon version of the easymasher for slightly larger pilot batches and still get the same yield. Grain depth varies from 1 inch to about 10 inches in the three systems and I can achieve yields in the 30's with all three.

My guess is that there is an optimum grain depth for a given geometry of mash tuns of commercial sizes but in the small homebrew size, other factors become far more important.

Subject: re: carbonating doppelbock

> Question about carbonating a doppelbock with 1.085 OG.

Your yeast may or may not poop out. However, the best thing to do is to krauesen by making up a half-gallon of new starter (1.040), getting a vigorous fermentation going in it, and then pitching the whole thing. Of course, since this is a significant fraction of your total wort volume, you want it to be a high quality wort, similar to your original wort.

Subject: Pico-Brewery

Ok, ok. My mailbox is overflowing! Before you flame, keep one thing in mind: this is NOT an advertisement. I'm just responding to your requests.

For more info on the Pico-brewing setup(s), call 1-313-482-8565, and they will happily send you a brochure.

The most common question was "what is the price?" The answer is "it depends". If you buy a fully loaded 3-kettle system WITH a pump, it will set you back a cool \$900. There are less expensive options.

Another common question: what's it made of? The kettles are constructed from legally obtained 15.5 gallon stainless steel kegs that are no longer suitable as pressure vessels. A fair amount of machining, welding, etc. goes into making them suitable as a brewery.

How big is it? Imagine three 15-gal kegs sitting side-by-side, about a foot apart. That's how much space you need. It needs to be in a place where you can run the 200KBTU propane burners, too (or 100KBTU with natural gas).

Subject: Maintenance of Re: Cheap Corny Kegs

I recently started keggng my beer in pin lock kegs. I learned a couple of useful things.

- 1) Dissassemble the keg
 - a) remove the pin connectors (a 13/16" socket with notches filed in the appropriate places makes a nifty pin lock maintenance tool)
 - b) Press out the poppets with a nail punch or philips screwdriver.
 - c) lift out the long and short downtubes (The short one may be stuck in the pin lock fitting)
- 2) Inspect all parts for cracks, scum, etc.
- 3) SCRUB out the kegs with TSP solution. I use about a cup in 5 gallons of warm water.
- 4) Rinse everything with clear water
- 5) Replace the large o-ring, and the two small o-rings.
- 6) Reassemble the keg
- 7) Sanitize with iodophor solution
- 8) Fill with beer :-)
- 9) Empty :-)))

IN the last digest:

From: jdecarlo@homebrew.mitre.org
Subject: Wort Aeration wrote:

<But there are so many variables involved. For instance, if you are making a barley wine using an ale yeast and want to ensure sufficient oxygen available to the yeast you might just shake up the fermenter every day for a week or so. Or you might find it easier to have some sort of pump do the work for you.

If you do this, you will *rouse* the yeast which can help to keep the fermentation going, but will in no way *add* oxygen to the fermentation. It is a CO2 environment anyway. Pumps will add oxygen but this inevitably force the yeast to throw Diacetyl which I do not care for. BTW, this is how the Peter Austin Breweries (Wild Goose, Red Feather, Ringwood) actually *promote* Diacetyl production in thier beers.

From: hbaum@uts.amdahl.com (Michael Hohnbaum)
Subject: doppelbock writes:

<Fermentating way in the "lagering chamber" is an OG 1085 doppelbock (baumerator?) Yeastlab Bavarian Lager is being used at 50 degrees F. I am assuming this yeast is going to poop out with a reasonable amount of sugars remaining due to the alcohol level.

Healthy lager yeasts *should* be able to ferment to at least 8% ABV. If you dont have luck, add krausen yeast (1 litre wort, plus yeast plus 12 hours or so). Even if you get adequate attenuation, krausen yeast will aid in bottle conditioning since the primary yeast may well be dead by then.

From: korz@iepubj.att.com
Subject: Re: Tun size/Klages/Liberty/Fridge Conversion

<There have been a few questions regarding tun size and also a mention or two about grain depth. I've read (forget which book) that the ideal grain depth is 12 to 18 inches.

I have had great success with this design , a shallow lauter tun. It is 2 feet wide by two feet high, and is never more than half full even with 65 lbs of malt. I have mashed/lauterred 90 lbs in it.

<In professional systems, there are debates raging about whether round holes or slots are better and the cross-sectional shape of the holes is debated also.

Not really debates, more a cost benefit issue. V wire slotted bottom is undoubtely the *best*, and most expensive. It is an inverted V, big end down. I have found perforated sheet to be more than adequate, even with

weizens of 70% wheat malt (and decoction mashing).

Good brewing,
Jim Busch

From: "david p. atkins" <atkins@vms2.macc.wisc.edu>
Subject: Salvaging Flat Beer/Brown Ale Recipes

Hello all,

I have two cases of tasty yet discouragingly flat pale ale. My second batch--extract with 1/2 lb. specialty grains, WYeast English Ale Yeast, OG 1.046, FG 1.006 and primed with 1 1/4 c. dried malt extract.

I fear that the yeast was pooped out when bottled--had to keep the batch in the secondary carboy for several days longer than anticipated (the joys of breaking "inexpensive" cappers). After 3 weeks, I have a touch of fiz but nothing to get excited about.

Any tips on resurrecting this batch? Also if anyone would proffer some extract brewing recipes/experiences concerning brewing brown ales in general, with molasses for an Old Peculiar-esque ale in particular

Thanks,
David Atkins

From: Nate Clark <NC6967@conrad.appstate.edu>
Subject: Re: BrewCaps and the questions about...

Attn: John Mare and John Janowiak

I am currently making my second batch of ale using a Brewcap, and I find it makes priming and bottling a whole lot easier. To answer John Mare's questions:

As John Janowiak wrote, the trub can be drained off the bottom, after allowing it to settle in a collection tube. If you wait about 12-24 hours between drainings, the collection tube is packed with yeast and no beer escapes. I have

noticed an increased yeild of about 2-4 bottles per batch. Not much?

Read

on...

The cap is held on by a re-closable plastic tie. I have had no trouble with it

popping off. The cap fits snugly around my carboy without the tie.

As for making things easier, the Brewcap eliminated my least favorite part of

brewing- the racking and siphoning. To prime, you place the boiled sugar (or

whatever you use to prime) on top of the inverted carboy and open the valve.

The priming sugar is sucked into the carboy. My bottle filler fits nicely onto

the end of the collection tube and I don't (generally) spill any brew.

Cleaning

is fairly simple. I recommend the brewcap, even to new brewers. It is an

inexpensive way to do, shall we call it "two-stage brewing?" (1 glass carboy and

one Brewcap.) The stand I made from two old pool chlorine buckets.

But do take into consideration John Janowiak's comments on lagers and hop cones

in the brewcap. I use hop pellets and have had no trouble.

(There is undoubtedly a little bias in my answer, as BrewCo is located only a few miles from my window.)

End of HOMEBREW Digest #1216, 09/01/93

Date: Wed, 1 Sep 93 08:56:22 EDT
From: "Michael K. Lebar" <lebar@ctron.ctron.com>
Subject: Lager Fermentation Questions

I'm currently brewing a lager that has an OG of 1.055. I pitched Wyeast #2112 Calofornia liquid lager yeast without making a starter so fermentation took about 3 days to get going. The carboy is in a temperature controlled frig at 51 degress F. The brew has been fermenting at a moderate rate for 11 days. This is my first experience with a lager and I was hoping that the members of the HBD could answer a couple of questions. Is 11 days too long (I'm used to ales finishing in 5 to 7 days), if not, what is normal? When should I rack to the secondary and begin lagering?

Thanks in Advance,
kl

Date: Wed, 01 Sep 93 09:40:28 EST
From: "Patrick Paul" <paulp@cc.ims.disa.mil>
Subject: Peach Beer

Over the upcoming weekend I am planing to try and make a peach beer.

My current design is to make a wheat ale using premier wheat extract
(I have not make the leap to all grain yet, but soon). After the
initial ferment dies down (two to three days in this weather), I will pit,
skin and dice or puree about twelve pounds of peaches, freeze the
resultant pulp overnight, defrost it the next day and then pitch it into the
carboy with some pectinase. then bottle with about a cup of malt
extract when it calms down again.

My questions are:

- 1) Any advice on hopping rates and types?
- 2) Should I rack it before I add the pulp?
- 3) Should I add the pectinase with the pulp or wait a day or two?
- 4) Is twelve pounds too much for a five gallon batch?
(all the fruit beers that I have seen call for a lot of fruit)
- 5) Any thought on a good yeast for this?
- 6) Lambic brewers bake the hops first, would this help here?
- 7) I have seen no reference to a peach beer before, does everyone
else know something that I don't?

Thanks in advance for your help.

Patrick S. Paul

From: tony@spss.com (Tony Babinec 312 329-3570)
Subject: vienna/fest beer recipe suggestions

In a recent HBD, someone raised a question on the use of Belgian malts in the making of an Ocktoberfest beer. Here are some alternate grain bills.

The aim is to produce a beer of starting gravity around 1055, and as your mileage may vary, you should adjust accordingly. The color should be around 10 - 12 Lovibond. For whatever reason, many homebrewers and brewpubs make a fairly dark amber Oktoberfest. Keep in mind that Bass Ale at 10L is a good color reference.

The following grain bill features Cara-Vienne:

9 pounds pilsner malt
1 pound cara-vienne (20L)
2 ounces Special B

Cara-vienne is a superb crystal malt, so the above grain bill tries to feature it. The Special B is in there for some added coloring, and if you don't have any, then substitute a dark crystal malt (120L).

George and Laurie Fix present a grain bill along the following lines:

9 pounds pilsner malt
6 ounces german light crystal malt (10L)
6 ounces german dark crystal malt (60L)
6 ounces (German or British) crystal malt (120L)

At the time they wrote their book, they felt that good quality pilsner and crystal malt were more readily available than was good quality Munich malt. Their recipes were tested in competition.

Dewolf-Cosyns has a good Munich malt, so why not feature it in a grain bill:

5 pounds pilsner malt
4 pounds munich malt
1 pound U.S. cara-pils
1/4 pound crystal malt 40L

I haven't tried an all-Munich recipe, but if I did, I'd use a good quality Munich. Also, 10 pounds of Munich would produce a too-dark beer by the above guidelines, so if you're concerned about the style parameters, consider a blend of Munich and pale malt.

For hops, use Hallertauer, Tettnang, Saaz, and Styrian Goldings separately or together. Aim for bitterness of 22 - 25 IBUs, or roughly 5 - 6 HBUs.

For yeast, use a good liquid lager yeast, and ferment at lager fermentation temperatures, say 48 - 50 degrees. If you don't have a lager fermentation setup, consider using Wyeast "European" ale yeast as it will produce a malt-accented clean-

tasting ale if used at conventional ale fermentation temperatures.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: peracetic acid/venturi suction

I know the peracetic acid thing was flogged to death (or at least ill health) a few months back. At the time I paid little attention, due to the price of H2O2. However, I can now get my grubby paws on the stuff cheap. The Lablaws/Superstore/President's Choice line now sells the stuff as a more environmental bleach alternative. It comes in 1 gallon jugs and sells for about the same price as bleach. I can get white vinegar cheap in large volumes at Price Club. So, my question is, can one make an effective sterilizing agent by simply mixing the two? And how does this stuff react with kegs? I am concerned about using iodophores since my wife is allergic to iodine, and I would like something a little less cumbersome than boiling water to sanitize my kegs.

On a completely separate note, I finally found a venturi suction doo-hicky (well, I mean I bought one and didn't have to glom one from the lab). I've got it on a quick connect along with my chiller and bottle washer. The thing is great! I run the hose from it to a two-hole bung, the other hole holds a racking cane. By creating a partial vacuum in the carboy I can siphon into it without pre-filling the siphon hose, or without sucking on it. I can even transfer beer up hill! No more lifting heavy carboys up and down off the counter! And the best part, the gadget cost me all of a whopping \$4.50 Canadian! I picked it up at Gordon's Cave a Vin in Montreal, for those remotely interested.

Subject: Kegs becoming overcarbonated with time

I have posted a few articles on calculating dispensing pressure with different diameter/length tubing. If you drink 5 gallons of homebrew within 2 weeks everything works fine. However, if you only drink a pint of beer a day, like I do, your beer will eventually become overcarbonated because the nice cold temperature at which you dispense the beer also allows the beer to absorb more CO2 over time. My kegs, I have two on tap all the time, sit for 4 to 6 weeks and could absorb quite a bit of CO2. No amount of adjusting CO2 pressure will correct this to pour properly. You could disconnect the CO2 and bleed off some of it from the kegs and dispense but it's a real pain bleeding off dissolved CO2 - it takes time and patience.

The solution to this problem is to get your CO2 cylinder filled with Nitrogen/CO2 (30% / 70%) mixture. This is available at any fire equipment store that fills tanks. By running this mixture your beer will absorb CO2 alot slower. The only drawback is that Nitrogen is a very light gas and if you have any possible leaks it will escape, so check all your fittings with some soapy water when they're under pressure. This gas mixture is used alot for dispensing beer by most bars that have many different types of beers on tap.

Hope this is helpfull!!
May your beer give you great head!!
John

From: Jeffrey Muday <mudayja@ac.wfunet.wfu.edu>
Subject: Rootbeer question--how can I sweeten it up?

I brewed my grandfather's rootbeer recipe, which uses a small amount of yeast to impart bottle conditioning. I added too much yeast and needless to say started working and continued to ferment going on 3 weeks.

Originally, the recipe called for immediate bottling, but I was afraid that I would be making beer grenades. So, now I'm stuck with a 4-5% alcohol dry rootbeer.

This rootbeer doesn't have too bad a flavor, but I would like to impart the expected sweetness of traditional root beer. Is there any way I can add more sugar without creating beer grenades? Are there any un-fermentable sugars that I can safely add?

thanks for your help,
jeff (mudayja@ac.wfunet.wfu.edu)

Subject: Canadian U-Brew's

In HBD1215, Mark Hart asks about anyone's experience with the Canadian U-brew's. While I have never brewed beer for myself at one of these places, I have tried the beer and would rate it as "American Ale". That is, low hop and malt flavor and aroma and well carbonated. Typical commercial brew, but then again that's what 90% of the population drink anyway.

I've brewed for almost 6 years now, all grain, I culture yeast and grow hops, brew once a week, so I considered myself "experienced". What a cool idea it would be to get a job at one of these U-brew places and spread the word about "quality" beer, I thought. One day at lunch I ventured over to the U-brew, 2 minutes from my office, started talking to the proprietor and he hired me on the spot. I am now the evening and weekend brewmaster. They pay me to help people make beer. Can it get any better? (I feel like Tom Hanks in the movie "Big" where he gets the job at the toy store evaluating products)

The shop has 8 70 Liter gas fired copper kettles, glycol plate chillers, 6 counterpressure bottlers, warm and cool fermenting rooms, filtering rooms, etc, state of the art stuff. All brews are extract based, with some recipies calling for grain steeps. We do wine too, and I'm hoping to introduce Mead.

These U-brew places are popular, as the article Mark quoted states, it's a good "guys night out", no one gets sloshed and drives and everyone takes beer home. Every night is a brew-party and we quite often make 300-400 liters of beer.

The U-brew setup is an entire system, start to end, sold by a Canadian company (no advertising here), if anyone would like more information, please email the address below and I would be glad to supply it to you.

From: Domenick Venezia <venezia@zgi.com>

Subject: Secondary Fermentation

I've had 4.5 gallons of beer in the secondary (glass) for 7 days with 2 oz of hop pellets and 2 tbsp Polyclar in hot water.

Although fermentation had ceased (no bubbles in ≥ 5 min) in the primary, the secondary began producing bubbles almost immediately at the rate of 4/min (after 7 days 2/min). I've heard Polyclar liberates dissolved CO₂ (is this true?), so is what I am seeing just that?

Some of the hops are floating, some laying on the bottom, but there is a recycling going on, where hops are sinking from the top and rising from the bottom continuously. We're not talking churning here, but an obvious low level of activity.

Also the beer does not seem to be clearing appreciably. Usually by this time there has been a clarity gradient in the carboy, clearest at top fading to cloudier at the bottom. Has something gone horribly wrong? Or I am just "worriedly pacing the waiting room"?

I had planned on a 7 day dry hop, but I expected clear beer too. How long should I wait for clarity, and how long can I dry hop?

From: scojam@scojam.Auto-trol.COM (Scott James.)
Subject: Briess Malt & Sparging Q's

Howdy brewers,

I have some questions about Briess malts:

- 1) Does the 2-row or 6-row need a protein rest? I'm told the 6-row doesn't.
when I bought the 6-row the guy told me it's highly modified.
- 2) Is the 6-row also known as Klages? is the 2-row?
I've had different homebrew shop owners tell me "it's pale malt" or "it's klages"...I'm confused.
- 3) Is one of these considered lager malt?
- 4) Does "pale malt" imply malt to be used in pale ales or the Lovibond of the malt in question?

About Sparging:

- 1) My last beer used 2-row pale malt (above) and had a chill haze when I never had it with the 6-row malt beers. Things I'm considering changing:

- * When heating and recirculating first runnings, don't heat first runnings.
the first runnings have starch and husk particles (doesn't run clear).
Currently, I've been heating all runnings. I typically heat 3 batches of 2 gallon runnings. I've been getting 1.031/lb/gal from the 6-row.

- * acidify sparge water (1/2 tsp. acid blend to get pH=5.2) sometimes I acidify the water, but many times forget. (like in the cloudy beer)

- * sparge water should be 165F, and not 170F or 180F like in the past. (but I usually never got the tannins, just very present malt character.)

- * maybe I should use finings (bentonite/polyclar)... I never had to in the past and hate to make things more complicated now.

Thanks for any ideas/opinions,

=====

Subject: Brewcaps

I'd like to thank John Janowiak and Nate Clark for their response to brewcap questions. I had a miserable bottling experience last Friday evening and was looking to change my process. After reading both postings (I've been behind reading the HBD), and pondering all through lunch,

I think this is for me.

>From what I now gather, the brewcap is a 'system' and is different from a carboy cap. I have an orange carboy cap which has 2 'stems', one for 3/8" and the other for 1/4" (?), and fits snugly over the carboy head. I currently use it for starting siphons by inserting my racking tube in the 3/8" stem and pressurizing the other. It would appear easy to engineer the rest of the system from what I have read here. I did notice the use of inverted brewcaps in the Tumbleweed report but was too busy at work to think or ask intelligent questions.

Now for a few questions:

I like the idea of primary, secondary, and bottling all in one container. It really cuts down on the possibility of oxygen contact in the various steps. (the fact that it appears to be less work doesn't hurt either) How well does it really work? I have noticed that trub and spent yeast pile up on the sides of the carboy (electrostatic attraction?) Can you actually drain off (almost) all the trub and spent yeast and get really clean bottling?

How, exactly, do you dry hop without un-inverting it?

Sucking the priming sugar water in is a neat trick. (I thought of using a 1/16" tubing run up through the blowoff tube to do this. of course you'd have to plug the main blowoff tube to get it to work) How well does the priming sugar mix into the beer? Any special techniques for mixing them together? Do you suck the unprimed beer (that you drain to suck up the primer) back into the carboy?

Do you use an airlock with this technique? Would someone describe the setup. I suppose you could just put the blowoff cane in a bucket of water.

The stuck blowoff issue bothers me because I really don't want a glass bomb going off in my basement. Maybe Kinney Baughman at Tumbleweed could pass on his experience? I have never had a plugged blowoff tube because I use a 1 1/4" vinyl tube press fit into the mouth of the carboy ala Papazian. The only thing I can think of is to use 3/8" SS tubing instead of a 3/8" OD, 1/4" ID racking cane to give the blowoff tube more internal area.

One additional advantage: Easy, no oxidation risk monitoring of final gravity.

Thanks

Subject: Air versus beer temperatures

Jack writes:

> After doing a little judicious temp measuring, I learned that the air
> temperature varies from 5 to 10 degrees above the actual beer temp. To
> determine your own delta, put a thermometer in a glass containing a
pint or
> more of water and watch it for a few days.

There's another factor in the temperature of fermenting beer versus the ambient (air) temperature around the fermenter and that is that fermentation is exothermic, meaning that it generates heat. I think that this may have been something I did not take into consideration when I brewed a very high gravity Chimay-clone -- I think the ferment just got too hot. Anyway, the point that I wanted to make with this post is that if you have information about microbrewery X fermenting beer Y at temperature Z, it's probably the actual beer temperature they are quoting. On the other hand, if it's a homebrewer's recipe that says fermented 10 days at T degrees, then it's probably the ambient temperature and NOT the actual temperature of the fermenting beer.

So where does this lead us? Well, perhaps we should make it a point to specify what temperature we are measuring when we post a recipe, no?

i.e.:

OG 1078
FG 1013
Glass primary, 10 days @ 50F ambient
Glass 2ndary, 30 days @ 50F ambient
Glass 2ndary, 30 days @ 34F ambient

Another factor is wooden kitchen closet floor or cement basement floor!

Then again, having written this, I assume that perhaps the temperatures listed in some batch lagering operations may actually be the ambient temperatures, but jacketed fermenters are most certainly reporting the fermenting beer temperature.

I seem to have posted more issues than answers, no?

Comments?

Al.

Someone asked a week or two ago whether or not they needed to use a blowoff tube on the primary. Mr. Papazian on TNCJOHB p. 136 says using a blowoff tube will result in beer with less "bite". On p. 69 says that if you use pelletized hops and a blowoff tube, you must filter out the hops with a stainless weave strainer. And, I remember reading that a blowout tube was suggested with pelletized hops, but can't find it in the book now.

Subject: Trub, trueb

Ulick Stafford <ulick@beethoven.helios.nd.edu> comments on the pronunciation of trub:

HO>is still doubt as Websters gave two spellings, trub and trueb as
HO>the German speelling for the word meaning dirt or haze or whatever.
HO>These would be pronounced approximately troop and trip.

Here, as usually, we see (hear?) the anglosaxons ignoring the German umlauts. The word should actually read trub _with umlauted u_ (u with two dots above it). It can be translitterated with English alphabet as trueb. The vowel ue in this case is also long.

The correct pronunciation is impossible for an english speaking person, because in English there is no such vowel as ue. Ue is a front vowel and it resembles e, but e is a back vowel. Start the training...

Al K. brings up a good point about keeping an eye on the temperature of your beer as it ferments. It's easy to brew someone's recipe, use the same grains, and then come up with something totally different from what they did, just because your fermentation temperature was different.

What I did is bought some temperature-sensitive LCD type thingies ('thingies' is a technical term) that I stick to the side of my carboys, and this tells me what the temp of the glass, and therefore the beer, is. It is more accurate than air temp for all the reasons stated (concrete or wood floor, air circulation, etc. etc. etc.). There are so many variables involved, it just makes sense to monitor the actual product, rather than trying to predict the temp from other factors.

I think Sheaf & Vine brewing supplies (They're on the net, great service & prices, I don't work there, etc. etc. etc.) have these, they're a couple of bucks a piece.

- - - - -

I'm in the process of building "the cave", an insulated room in the bottom of my barn. Last winter, as an experiment, I put a bucket of water in that corner, and it only froze during the coldest week of last winter (below zero for a week).

I haven't quite figured out how to regulate the temp, but it'll probably be a temp probe stuck into a carboy full of water or something - that way I get the most accurate reading, and can run either the A/C or heater from there. Hopefully, it won't need much of either.

- - - - -

About the bandwidth thing & the yeast FAQ. Yes, the FAQ is fantastic. I do agree with the point, however, that it would have been easier on the bandwidth to have posted one part per day.

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>
Subject: trub, acid 'washing' etc

Hello all,

I'd just like to add my two cents worth here:

Firstly, the pronunciation of trueb for us anglosaxons. The nearest sound to the ue in trueb is trying to say treeb while keeping your lips in an o shape. At least if you speak nearly Queens English: I have no idea what happens if you start with a Bronx accent!

If anyone has comments or flames about the above, could they be constructive about them, AND email me privately. I'll summarise if it's worth it.

On another matter, although it's a bit late for the yeast FAQ, (which I also found excellent IMHO) I read in the handbook of microbiology we have in our library that the predominant method of "acid washing" yeast is not washing as such. What they do is suspend the yeast in aqueous acid (sulphuric, phosphoric or tartaric) at pH 2-2.6, 5-10 degC for 2-4 hours and then add the WHOLE LOT to the wort. They say that the limits of temperature and time must be strictly adhered to, since some yeast deactivation occurs under these conditions. As a reference point, the Aldrich chemicals catalogue says that a 1 mol/dm³ aqueous solution of tartaric acid has a pH of 1-2 at 20degC. (for Aldrich above read Fluka). This acid is usually available as a powder in wine making shops. A 1 molar solution is 150 g/l.

Finally, could everyone who wishes to flame people do so directly to the person in question. If bandwidth is being abused by posting informative but huge articles, then it is certainly being abused by people publicly flaming the poster, and also people publicly flaming the public flamer: especially if they have nothing else to say. (OK, so my glass house is falling around my ears!)

That'll do.
Happy brewing,
Rob. T.

Subject: Re: Rootbeer question--how can I sweeten it up?

Lactose is not fermentable but does not add as much sweetness/lb as sucrose which can make it a fairly expensive alternative. The last time I made root beer, I bottled it in old plastic soda bottles (2 l. PET). I bottled immediately after pitching the yeast and put the bottles in the fridge after a week or so. Anyhow, we don't drink root beer that quickly and it did get to be pretty dry, opening a bottle would send a geyser of foam all over the sink but no bottles burst! I have had problems with glass bottles bursting when making root beer.

In response to Domenick's question regarding the use of Polyclar in a
dry-hopped beer:

Adding Polyclar will liberate fairly large quantities of CO₂. If the
beer
was fermented at cooler temperatures, there will be more CO₂ in solution
and
you will experience more foaming. Keep in mind that Polyclar is an
adsorbant
that primarily attacks tannins. The clarity problem you mentioned may
due to
proteins or yeast in suspension. Bentonite or silica gel work well for
precipitating proteins. Isinglass finings should be used to precipitate
yeast, although time and patience will also work.

My experience with using pellets to dry hop beer is that some clarity
will
be sacrificed and invariably, some of the fine hop powder is carried to
the
bottle or keg unless filtration is employed.
This does not occur when dry hopping with flower hops; however, some hop
lupulin glands may survive the journey to your bottle or keg.

Subject: GABF DD, etc.

I wanted to clear up some misinformation that is floating around netland about the Great American Beer Festival. I've just talked to Marsha Shermer of The Shermer Group (don't know if the spelling is correct) who is involved in marketing the GABF. She can be reached at (303) 499-9646, which was listed as Lori Tullberg's number on rec.crafts.brewing. Lori markets for the Association of Brewer's and that is not her number (it's Marsha's). Anyway, the AAB contracts out a lot of the work to independent companies such as Marsha's. Now, what I originally was looking for: Designated Driver information. Marsha told me that there is a DD option, sold only at the door. The cost is \$8 for a DD (pretty steep IMHO for someone to walk around a bunch of drunks and then drive some of them home!). I believe the cost for Designated Drinkers is \$18.50 or so. Oh, one more piece of misinformation to correct: The GABF is at Currigan Hall, 14th and Champa in Denver. r.c.b had it in the Colorado Convention Center. Parking downtown is free after 6 pm. See you at the Fest!

"While it would have been nicer to post the FAQ on yeast over 2 or 3 days and maybe during mid week when the HBD has been running light lets not lose sight of the fact that this yeast information has been some of the best data posted to the digest."

Nobody is disparaging the quality of the FAQ. Jack said as much.

But the sucker's huge - eight parts !! - and has been posted and reposted.

Perhaps instead of accruing every single posting on the topic of yeasts and calling it a FAQ, one might attempt first to identify what, exactly, are the Frequently Asked Questions with respect to yeast ... and then address, exclusively, that smaller set of concerns.

As it stands now, the Yeast FAQ came across as a book, not a FAQ.

"It was a lot of work to compile this information and it is very useful to many of us. This data on yeast, IMHO, made better use of this forum than your misinformation on wort aeration. You don't own this forum, none of us do, and it is hopefully for the reasonable use of and by all of us. Brew more Blast less."

Ahh, ahh ... no personal attacks, please. Jack's intelligent and reasonably well-informed (from a layperson's point of view) speculations hardly qualify as "misinformation".

>
> The solution to this problem is to get your CO2 cylinder filled with
> Nitrogen/CO2 (30% / 70%) mixture.

An alternative solution, which is a teeny bit easier: TURN OFF THE GAS!
Over the last few months I've followed all this concern about tubing
lengths and dispensing pressures et al with an increasing amount of
amusement. According to all this data, my system doesn't work - but
then it's easy to prove a bumblebee can't fly either.

So when the CO2 level is correct, turn off the gas. When it begins to
fall off, give it a nudge with a little more gas and turn it off again.
The beer will not overcarbonate and your gas cylinder will probably last
longer. And you can go back to worrying over whether your beer is any
good, or whether you should have left out the cherry bark in your last
pseudo-lambic.

Sorry, I'm with Jack, although I seem to recall being blasted by him a
year or so ago when I suggested something he'd done (an offer for a free
MaltMill) had ruined the day-to-day utility of the HBD. Or maybe that
was a different Jack Schmidling?

I think that great big files -- even really interesting and useful ones,
are better off being summarized and then made available through FTP and
some other source, then posted directly to the Digest.

<<Omgod, is Frane agreeing with Schmidling? Head for the shelters!!>>

Subject: FAQs

Jack Schmidling writes (in HBD #1216):

| As no one else seems to want to, I will take it upon myself to speak
out on
| net protocol.

| The yeast FAQ is a noble effort but I think some self-restraint is in
order
| regarding eating up big chunks of the Digest.

Are you an expert on net protocol? How many newsgroups/digests have you read where FAQ's (Frequently Asked Questions) are discouraged? In all the ones I've read, they are encouraged--and for the very reason you give to the contrary: space. In the long run, it saves space if there's a definitive place to look for info a given subject. It saves repeated questions; and it saves repeated answers, especially if the FAQ ends up in an archive somewhere. Then, if someone has a question about yeast, someone else would just send him email saying "Here's how to download the yeast FAQ".

If it takes a couple of passes to get the information corrected, then so be it--it is only a one-time deal. Once the FAQ is complete, it needn't be posted again; or it could be reposted at long intervals.

| I am not about to criticize anyone for what they post or how often
I am. What do you think you just did?

I think FAQs are a MUCH better use of space than, say, someone defending EVERY SINGLE position he's ever taken (right or wrong) with long, drawn out, and often-repeated arguments.

| but one must keep in mind the fact that what makes the Digest most
useful is its near real-time currency. Getting an answer to a question
the very next day is a powerful reason for participating. When the
Digest is flooded with very long articles that could be just as easily
serialized, the currency is lost.

I, for one, can handle a delay in even a whole day's digest, if it means I get a very good source of information such as the yeast FAQ. Take it easy--it's only a one-time deal (OK two, if you want to be picky and count the corrected version).

If you look at the dates (and I did), the yeast FAQ only delayed response by ONE day. There were articles that were sent on Friday 8-13 that would've been published in the following Monday's digest (the one with the FAQ in it), but were delayed until Tuesday. Big deal.

| I would like to suggest that users voluntarily limit articles to 200
lines in any given day. That is after all about 20% of a typical
Digest
| and would still allow significant participation by others. That
thousand
| liner the other day was just a bit much and I suspect more are on the
| way.

What if your article needs more than 200 lines to be complete? I don't

know about you, but I hate to see "(to be continued)" when something interesting is happening. The continuity is lost; the interest is lost; the argument is less effective.

I agree that fast turnaround IS an issue, but the problem is not caused by one guy posting a large FAQ; and it didn't just start recently. The problem is the limit on the digest. How many of us have experienced long delays between the time you post and the time you see your article published? And then you have to wait for the replies to make it to the digest. Last time I posted, a couple of months ago, the publishing delay was at about two days. When the delay is just two days, the time until you see a reply is probably six days, because the odds are that there will be a weekend in there somewhere. It looks like the queue must be small lately; but it does happen sometimes.

Instead of limiting articles even further, I would suggest allowing each digest to be larger, or not limiting traffic at all. That way, you WOULD see your article in the next digest--regardless. After all, everything we submit eventually gets posted when the queue catches up; so the total traffic would be the same, but not delayed. We may have large digests one day and small ones the next--that's fine with me. If there were a large article posted that you'd rather ignore, just skip it and go on to the next one.

If the current limitation is in place because some mailers may choke on large files (I suspect it is), and if this is a REAL problem and not just a superstitious holdover from earlier computing days, then I suggest that the digest be published TWICE a day, for an even faster turnaround.

Actually, I have suggested it to the moderator, but he has a lot of other things to do (I fully understand). But maybe if several of us make the suggestion, he would deem it more important.

| It is also obvious that much of the cleaning up of the FAQ could be done by
| email now that the experts have been identified.

I would suggest that only changes be published until it is finished. Then post the whole, corrected FAQ.

FAQs are the ULTIMATE in signal to noise ratio.

MORE FAQS, WE NEED MORE FAQS! Post away!

-Alan

Subject: Overcarbonation

>From: Cisco <FRANCISCO@osmo.ccit.arizona.edu>
>Subject: Kegs becoming overcarbonated with time

>if you only drink a pint of beer a day, like I do, your beer will eventually become overcarbonated because the nice cold temperature at which you dispense the beer also allows the beer to absorb more CO2 over time. My kegs, I have two on tap all the time, sit for 4 to 6 weeks and could absorb quite a bit of CO2. No amount of adjusting CO2 pressure will correct this to pour properly.

AMEN!

I just posted my frustration on r.c.b. about the problems I am having with my 10 gallon keg which lasts (surprise-surprise) twice as long as the 5 gallon kegs. I even went down to a 1/8" i.d. tubing which barely trickled at 12 psi and only three feet long. I concluded that the beer is overcarbonated and nothing aside from adding a couple gallons of new, unconditioned beer would allow it to dispense properly.

I have run two 10 gallons batches through this keg and both of them became impossible to dispense after they got down to the last 3 or 4 gallons.

After reading your article, I replaced the hoses with the original 1/4" i.d. stuff and reduced the pressure. However, this has problems also because the seals on Cornelius kegs become unreliable below 10 psi.

I abandoned the nitrogen/CO2 mix because it didn't seem to contribute anything to the beer and it's real value seemed only useful in high volume commercial operations but my experience with 10 gallon kegs is forcing me to rethink it.

The problem with the mix is that you can not force carbonate with it so one needs to maintain two tanks, one for carbonating and one for dispensing. This is not the end of the world but is an additional expense and hassle.

Just for the record, I actually ran three batches through the ten gallon keg and had no problem with the first one but it was an ale and kept at basement temp. The problem started with the advent of my "lagering room".

I should also point out that I had the problem with a five gallon keg but thought that I might have overcarbonated it initially. Furthermore, I have had a keg of sweet stout for months in the "lagering room" and it still serves properly.

>#2112 Calofornia liquid lager yeast without making a starter so
fermentation
<snip>
>the members of the HBD could answer a couple of questions. Is 11 days
too
>long (I'm used to ales finishing in 5 to 7 days), if not, what is
normal?
>When should I rack to the secondary and begin lagering?

No, 11 days is not too long. I fermented my last lager two weeks in the
primary at 50F and then racked to a secondary. Two weeks after that, the
temp was then dropped to 45F and the beer was bottled 4 or 5 weeks later
(don't have my notes here). It did take 4 months after bottling for an
off aroma to disappear, but after it did, the beer won a couple of awards.

Patrick writes:

6) Lambic brewers bake the hops first, would this help here?

Lambiek-style homebrewers bake their hops to artificially age the
bitterness
out of them. Real Lambiek brewers use aged hops (2-3 years old).

7) I have seen no reference to a peach beer before, does everyone
else
know something that I don't?

Brian and Linda North brewed a spectacular wheat beer with peaches. Alas,
I don't have any details on it.

I would just like to suggest that in general, if you sanitize fruit
before
you cut it up, you save yourself a lot of trouble. I theorize that any
wild yeast or bacteria will only be on the OUTSIDE of unblemished fruit.
That's why I choose unblemished fruit (as best I can) and sanitize by
freezing and then blanching (quick dip in near-boiling water).

Cisco writes:

>this to pour properly. You could disconnect the CO2 and bleed off
>some of it from the kegs and dispense but it's a real pain bleeding
>off dissolved CO2 - it takes time and patience.

I'm sorry, but I must disagree. If you do the math first and then

choose your hose lengths/widths accordingly, you will not have overcarbonation. You just must first choose the temperature and the number of volumes you want in the beer and then choose the pressure, hose lengths, hose diameters based on the formulas give in HBD back issues and in Dave Millers' very good article in the 1992 AHA National Conference Proceedings. If your beer is overcarbonating, the pressure is too high or (as Jack pointed out) the temperature may be higher than you think.

Jeff asks how to safely sweeten dry rootbeer.

Well, an obvious answer is Lactose, but there are two things you must be careful of:

1. Lactose may not be fermentable by yeast, but I'm quite sure it's fermentable by lactobacillus/pediococcus. So, if you have any bacteria in your batch (which you may have considering how dry the rootbeer turned out) you will get glass grenades by adding lactose.

2. Lactose is not very sweet. To get the sweetness of a store-bought rootbeer, you will probably have to add at least a pound, maybe two, of lactose to 5 gallons of rootbeer.

Domenick writes:

>I've had 4.5 gallons of beer in the secondary (glass) for 7 days

<snip>

>Some of the hops are floating, some laying on the bottom, but there
>is a recycling going on, where hops are sinking from the top and rising
>from the bottom continuously. We're not talking churning here, but an
>obvious low level of activity.

This is why I use whole hops for dryhopping.

>Also the beer does not seem to be clearing appreciably. Usually by this
>time there has been a clarity gradient in the carboy, clearest at top
>fading to cloudier at the bottom. Has something gone horribly wrong? Or
>I am just "worriedly pacing the waiting room"?

Possible reasons for cloudiness:

1. bacterial infection
2. wild yeast that won't flocculate
3. starch haze
4. could be that the backpressure in the airlock was too high and too much CO2 was dissolved in the beer -- when you added the hops and Polyclar(tm), you gave the CO2 nucleation sites and it began to come out of solution (this is probably the least likely, since I couldn't imagine this happening for 7 days, or could it?)

Scott writes (asking about Briess malt):

>1) Does the 2-row or 6-row need a protein rest? I'm told the 6-row doesn't.
> when I bought the 6-row the guy told me it's highly modified.

Briess is quite a bit higher than most malts in Protein level, I, personally, would give it a protein rest.

>2) Is the 6-row also known as Klages? is the 2-row?

> I've had different homebrew shop owners tell me "it's pale malt" or
> "it's klages"...I'm confused.

Klages is no longer grown in the US. It's replacement is Harrington.

Briess

2-row is Harrington. I don't know what the current strain of 6-row is being

grown in the US. I would stick to 2-row if you can. Most have a high-enough

diastatic power for the amount of adjuncts we homebrewers use (almost none)

and the 2-row has a much lower percent weight of husk and higher percent weight of starch. (I think it may even generally have a lower protein percentage, but from what I recall of the Briess literature, it was the same for both their 2-row and 6-row.

>3) Is one of these considered lager malt?

Most US base malts are kilned so lightly that I would consider then a lager malt.

>4) Does "pale malt" imply malt to be used in pale ales or the Lovibond of

> the malt in question?

It implies slightly warmer kilning temps and thus more color and more caramelly flavors.

>About Sparging:

>

>1) My last beer used 2-row pale malt (above) and had a chill haze when I
> never had it with the 6-row malt beers. Things I'm considering changing:

>

> * When heating and recirculating first runnings, don't heat first runnings.

>the first runnings have starch and husk particles (doesn't run clear).

>Currently, I've been heating all runnings. I typically heat 3 batches
>of 2 gallon runnings. I've been getting 1.031/lb/gal from the 6-row.

Your extract efficiency is commendable, but I agree that maybe recirculating

the first runnings would decrease the husk material in the boil which would

reduce tannin extraction.

> * acidify sparge water (1/2 tsp. acid blend to get pH=5.2) sometimes
>I acidify the water, but many times forget. (like in the cloudy beer)

YES. Most definately do adjust your sparge water down to the 5.2-5.4 pH range in the RUNNINGS -- you want the runnings to be around 5.2, not necessarily the sparge water. High pH sparge water will, indeed, extract more tannins from your husks.

> * sparge water should be 165F, and not 170F or 180F like in the past.
>(but I usually never got the tannins, just very present malt character.
)

Agreed, but a minor point -- 170 is in the ballpark.

> * maybe I should use finings (bentonite/polyclar)... I never had to
>in the past and hate to make things more complicated now.

If you do the rest well, you probably won't have to resort to finings.

Al.

From: Nate Clark <NC6967@conrad.appstate.edu>
Subject: Peach beer, Brew-Caps, and trub

In the last installment of HBD, Partick S. Paul asked about peach wheat beer:

- > 2.) Should I rack it before I add the pulp?

I have only recently tried a mead, using peaches for flavoring. I added diced peaches at the end of the boil right after I removed the "wort?" from the heat. I was trying to sterilize them without releasing the pectin into the mead. I let the peaches stay in the primary, but when I racked to the secondary (wasn't using a Brewcap) I removed all of the peaches. This seems to have worked fine. The mead is still in the secondary but it is crystal clear. The samples I've managed to steal have been excellent :)

- > 5.) Any thought on a good yeast for this?

Champagne? :)

On to Brewcaps and clean bottling (questions submitted by Scott Wisler):

Yeah, yeast does tend to cling to the sides of the carboy, but for the most part it drains off, leaving a translucent film around the neck. I haven't noticed too much getting into the bottle (after all, you do need some yeast in the bottle). Brew Co. recommends 'twisting' the carboy every so often to loosen the yeast. The yeast that insists on clinging to the neck usually stays there through the bottling process, requiring a carboy brush to remove.

Dry hopping is not recommended.

With a Brewcap and the carboy inverted, I empty the blowoff tube of sanitizer. It acts as an airlock, and I don't want it spilling everywhere. I take the other tube (the yeast collection tube) and hold the end of it above the level in the carboy and submerge it in the pot of boiled priming sugar. I open the valve and the sugar is sucked down into the primary. To mix, I right the carboy and use the blowoff tube to mix, then invert and bottle. It seems to mix evenly. I apologize for my sloppy use of blowoff tube and hose. The blowoff tube is a sturdy pipe that runs from the neck of the carboy, through the fermenting beer

to the air space between the beer and bottom of the carboy. The blowoff
hose
attaches to the blowoff tube. I don't know how often Kinney reads HBD,
but I'll
pass on your comments to him.

"troop?"

Around here, we say trub, it rhymes with tub. But you are correct, in
true
German, it closely resembles troop. Actually, I was taught to say it
like
trip, but while making the i sound, I round my lips and don't move them.
Also,
around here (that is, the South) we (me too) have a tendency to hold our
vowels
long, which is a no-no (nein-nein?) in German. Anyone could sound
halfway
official saying tryoop, like some people make the y sound in music or
coupon
(after all, english is a germanic language.)
I look like I'm kissing when I try to say it!
Also, this is from high school german experience, so I will except
criticism.

From: Dave Smucker <TWF99@ISUVAX.IASTATE.EDU>
Subject: Wyeat 2112 California

In HBD # 1217 Michael K. Lebar asks about Wyeast 2112 California yeast.

This is a yeast I use a lot for my standard "steam" beer. One major difference is that I ferment at ale temperatures i. e. the mid 60ies. I also ferment in 15 gallons batches in a stainless steel keg and this is not the most ideal fermenter geometry. Taking in to account these items I still consider Wyeast 2112 to be a slow fermenter compared to ale yeast. My typical time is 3 weeks and I pitch a large starter. (I start the Wyeast in 1/2 pint which I then pitch in a 5 pint large starter.) I normally don't go to a secondary because I'm a "Miller" fan and rack off the trub 12 to 24 hours after pitching.

When to begin lagering? When you get your final SP or at least very close.

From: Paul dArmond <paulf@henson.cc.wvu.edu>
Subject: A miscellany of things...

In response to recent questions about blowoff. (oh god! here's something that EVERYBODY will have an opinion on...)

I have consistantly used bowoff for several years. I find that it gives a slightly smoother taste. I'm also very sensitive to higher alcohols and it's my impression that blowoff removes these. My mad friend, the Revernd Perry 10X Mills uses an open fermenter. We frequently share each other's beers and I can get a headache from his, but not from mine. Who knows, it may not have anything at all to do with blowoff, but I think it does...

As regards to exploding carboys, I do think that using the 1" id tube is a good idea. I had one batch that I added a couple of ounces of pellet hops to at the end of boil. I filled the carboy too full and the hops floated up into the neck and plugged it up. I was using a cork with a small blow-off tube and was concerned that there was no blowoff even though there was a lot of visible fermentation. So (you guessed it), I pulled the cork and poked a bamboo skewer into the compacted hops.

KA-blooley! Instant beer geyser! Beer all over the place and hops stuck to the ceiling. If I had the sense that Grid gave a goose, I would have taken it outside.... It was really spectacular. Surprised is hardly the word for my reaction.

If I had been using a large blow-off tube, I could have run a coat-hanger through the tube and kept it pointed into a bucket. I don't know how much pressure a carboy can stand, but there was a lot built up. A slight scratch or imperfection in the surface of glass can weaken it tremendously, as anybody who has cut glass will know. So my firm opinion is that the advice in TCJOHB to use a cork and small diameter blow-off tube should not be followed. It sure as heck got me into trouble. There is no drawback to using a larger tube and many advantages.

Charlie P. may sit at the right hand of Grid and be met by adulatory and worshipping masses everywhere he goes, but he is wrong on this one.

On a less controversial note, the last time I was in the farmer's Co-op I looked around for iodine for sanitizing. I found this stuff called "Povidone-Iodine Surgical Scrub 7.5% (titratable iodine 0.75%)." It looks just like BTF, but it doesn't foam as much when you shake the bottle. The iodine concentration seems about right for an idophor, but I don't know what this stuff is. The only active ingredient is the Povidone. The application seems to be a skin disinfectant for vets. Like when you have to reach into a cow with both arms up to the shoulder to correct a calf's presentation during birth. (Don't laugh, it's only funny from a distance...)

I couldn't find it listed in my ancient Merck Index, but I suspect

"Povidone" is a commercial name. Does anybody have a reference on this stuff? It's \$7/qt., so there is some incentive to find out if it's usable. Most of the dairy idophor has weird stuff in it like lanolin (it's used for a teat dip to prevent mastitis), so it probably shouldn't be used for brewing. Unless, of course, you suffer from chapped lips. :-)

Paul.

From: GANDE@slims.attmail.com
Subject: Beer Mix...

John Francisco mentions "beer mix" - CO2 and nitrogen in HBD1217.
Alot of brew pubs use this stuff for a number of reasons (which are
not relevant to this post).

Homebrewers desiring the use of this gas should be aware that they
must use different regulators as the nitrogen is packed in under
higher pressure than CO2. CO2 is normally under 800LBS pressure and
CO2 gages normally top out somewhere around this. Nitrogen on the
other hand is usually under around 2100LBS and require the
appropriate regulator/gages.

To keep you from hooking up the low pressure CO2 regulator to the
beer mix and blowing your head off, the bottles come with a different
valve. It's female, part number is CGA580.

Subject: keg overcarbonation

Jack, perhaps your problem with kegs getting overcarbonated is because the beer hasn't actually finished fermenting. The fact that it is happening with (mostly) lagers, which can take much longer than ales to ferment out, might be an indication.

WRT the yeast FAQ (and any other very large posts): I hate it when someone injects common sense into an argument, but as my great-grandmother used to say, "A post a day keeps the flames away". Post just one section per day. It allows for timely responses/corrections and it doesn't overload mailers.

Fwiw, I'd also like to see twice-a-day digests. (I suppose then you could post twice a day.....)

Yes, Povidone is an iodiphor, and would work fine as a sterilant.
However, I believe most of these hand-scrub formulations contain a
great deal of detergent along with the Povidone, and thus would
probably not be good for your beer if you were using a "no-rinse"
method. I believe the sterilants used in brewing contain Povidone,
but an acid or some other non-detergent base.

Subject: Kegging FAQ - Part 1

Thank you, Dion, for getting me off my butt...

I've had this file for a while, but never got around to putting it out in the real world. Finally, i thought I'd save Dion the typing...

Al Richer

Kegging Basics; or how to eliminate bottle-washing from your life.

- - -

I have seen the light, and it is made of stainless steel....

Greetings. After having asked several dozen stupid questions about kegging, I have decided that I should pull all of this information together into one article for the amusement and edification of the Digest.

I. Items needed for a kegging setup

Kegging is the process of packaging beer so it may be dispensed. To this end, you need a package. The normal container for the homebrewer is the Cornelius or Firestone stainless-steel premix soft-drink container. It is available from many sources, including restaurant auctions, scrapyards, cooperative soft-drink retailers, and other sources. Use your ingenuity, and you will seldom go wrong.

The other items to go with your keg are used for the dispensing process. They allow you to dispense the beer under gas pressure, and to connect and disconnect the equipment from your keg.

These items are:

A CO2 cylinder. Most hobbyists purchase a 5 Lb. one. If you have the space, though, a 20Lb. cylinder is a good bet. It only costs a few more dollars to fill and lasts much longer. I have both, the 20Lb. for the keg refrigerator, and the 5Lb. bottle for portable use.

a pressure regulator. This reduces the 800 PSI of gas pressure in the CO2 tank to a manageable dispensing pressure (usually 12 to 15 pounds).

Regulator check valve. This device attaches to the outlet of your regulator and prevents reverse pressure flow from your keg back into the regulator. This can prevent a considerable mess, and helps prevent contamination of your CO2 lines and fittings.

Hose with gas-in fitting. These items conduct the gas to the keg from the regulator, and allow you to connect the

gas line to the keg. The gas-in fittings come in either ball or pin lock. Buy whichever fits the keg you obtain, as one is as good as the other for the homebrewer.

Liquid-out fitting and beer faucet. This is the part that the beer actually comes out of. It has a fitting like the gas-in one, but keyed differently to prevent interchange. On the end of the hose from this fitting is a spigot to control the flow.

The liquid-out fitting requires a length of hose attached to provide restriction to the pressure in the keg, allowing the beer to be dispensed without excessive foaming. What I use (with information gleaned from the HBD) is a length of 3/16" PVC tubing between the liquid-out fitting and the beer faucet. One foot of 3/16" tubing will allow for a 3 PSI drop in the keg pressure.

For a standard keging rig at about 14-16 PSI (chilled keg with a light ale), you'd need about 6 feet of 3/16" tubing. Vary this as your equipment requires.

This can be calculated by use of a chart, which shows the pressure needed for different carbonation styles at any given temperature. These charts are available from the HBD or rec.crafts.brewing on the net, or in the homebrew archives.

When it comes to the pressure-regulating items and the gas bottle, don't scrimp, as cheap or defective fittings can be very dangerous. Gas at 800 PSI is not trivial to handle, and an accident could be fatal.

Subject: Siphon pump

Hello readers,

Has anyone ever used or heard of using a manual siphon pump like that which is part of a gasoline siphoning system--several feet of hose which culminates in a cylindrical bulb pump. While the hose may be of a dubious quality, what of the pump?

Could be that special piece of hardware for Unleaded Lager or a nice Ethyl Lambic.

Happy pumping,

David Atkins

From: rxh6@po.CWRU.Edu (Randall Holt)
Subject: Povodone-Iodine (i.e. Betadine (tm) as a disinfectant)

According to the PDR, povidone-iodine is a broad spectrum antibiotic capable of killing gram- and gram+ bacteria, mycobacteria, fungi/yeasts, viruses and protozoa, all in the space of 15-30 seconds of contact. But, it's recommended for external use only (even if it's the active ingredient in Massengill douches). Supposedly, it washes off skin and natural fabrics easily.

SO, based on recommendations by the manufacturers, I wouldn't want this stuff in my gastric system. On the other hand, and at your own risk, if you think you can wash it off of your brewing equipment, it will very effectively wipe out all bacteria/yeast/fungi present. From personal experience in the lab, it cleans off glassware very easily, and provided the contact time is relatively short (<30') will clean off of plastic tubs as well. If you do try this out on brewing equipment, I would hazard a guess that residual antiseptic will interfere with normal yeast activity - so rinse exhaustively.

Subject: Kegging FAQ - Part 2

[Continued from PArt 1] - ajr

II. Preparing to keg - How to get ready.

If you buy all of your equipment new, than you can skip this part. What I am going to go into here is the cleaning and overhaul of a standard pin-lock Firestone keg. Cornelius kegs are similar, but I have not worked with them and would not speak of them without personal experience.

With a keg that has been used for soft drinks, the rubber parts that are in contact with the drink become impregnated with the sugar syrups. These will then flavor any beer you might bring in contact with them, so they need to be replaced as part of the cleaning and preparation process. These are located in the bases of the gas-in and liquid-out fittings, and around the lid of the keg.

Remove the gas-in and liquid-out fittings, using a 13/16" open-end wrench inserted through the gaps in the handle surround. Once loosened, these should remove easily. Once unscrewed, set these aside, and remove the dip tubes from the fittings welded to the tank. The gas dip tube is rather short, and the liquid dip tube is the long one that extends to the bottom of the tank. Remove the o-rings from both of these and replace them with new ones from the hardware store. O-rings of the proper size are easily available in the plumbing area of most good hardware stores. Reinsert the dip tubes and reinstall the fittings, tightening them with the wrench. Do not overtighten, as it is unnecessary and will make it more difficult the next time.
NOTE: The gas-in fitting is the one with two lugs. The liquid-out fitting is the one with three lugs. I got them mixed up too...8*)

Replacement of the top gasket is easy. Just open the head by lifting the bail, then drop the head down into the keg and rotate it to remove the lid from the keg. The O-ring should come out with the lid. Simply remove it from the lid and replace it. New ones of these should be available at your homebrew supplier, or try a pool supplier for a pump O-ring of the proper size. Bring

the old one as a comparison sample.

Cleaning the keg is rather simple. I usually prepare a solution of washing soda and soak a new keg full of it for 24 hours, followed by purging the solution with CO2 through the fittings on the tank. This is followed by 2 gallons of boiling water, well-agitated in the tank to clear the residue, and purged thru the fittings with CO2. The boiling water rinse is also a good way to clean out a tank before use, along with a weak chlorine rinse for sanitizing.

III. Kegging - The process

Kegging is considerably simpler than bottling, but has a set of gotchas all its own.

The first step is sanitizing the keg. I personally do this with a rinse of hot water and B-Brite of a gallon or so, shaken in a sealed keg, then expelled through the keg plumbing with CO2. After this, I do the same thing with boiling water, again expelling through the plumbing, to clear the B-Brite residue. One pass is usually sufficient, though if I'm being paranoid, I'll do it twice. After this step, you must handle the keg in a manner to retain the sanitation. This means not taking out the lid and laying it down on the work-bench in the basement. Treat the keg as you would a sanitized bottle ready to fill.

Next, add the priming syrup to the keg. I usually use 1/2 cup of sugar to 1 qt. water, boiled for 10 minutes for sanitation. I cool this to blood temp, then add it to the keg. Next, with a sanitized siphon hose, siphon your finished beer into the keg, being careful not to splash, but swirling enough to get a good mix on the priming sugar. Once filled (keep the beer level below the CO2 inlet, otherwise don't worry), reinsert the lid and cinch it closed. Before doing this, I usually turn on the CO2 to the keg and purge the airspace above the beer to clear the residual air in the tank.

With the keg sealed, pressurize it to 15-16 PSI to seat the head. If it begins to leak, open and reseal it, which usually cures the problem. Make sure that the lid isn't angled, which is easy to do and can cause leaking.

Allow the beer to carbonate for 1-2 weeks before drinking. I usually discard the first 1/2 mug out of the keg, as it brings the yeast out with it. After that, it's home free.

I need a beer after all this typing...

Subject: Test Strip, Povidone

I'm wondering if anyone out there on the Digest knows what the methodology used to make "test strips" is: Specifically, how can I embed chemical A in a material that will stick to the strip (made of plastic), allow a color reaction when dipped in chemical B and retain the color on the strip? Replies by email to conserve bandwidth, please.

Paul dArmond writes:

>On a less controversial note, the last time I was in the farmer's Co-op
I
>looked around for idodine for sanitizing. I found this stuff called
>"Povidone-Iodine Surgical Scrub 7.5%

He also says that it is not in his ancient Merck Index. I believe it is in my new Merck Index, and if memory serves I just read about it the other day (of course the book is not where I am at the moment). But again, from memory I believe that Povidone is essentially the same stuff as Betadine, also a topical sterilant, used mainly by hospitals. I'm not sure if it's useful in brewing. This weekend I'll look it up and post anything interesting.

Subject: Keg FAQ / Haze = Tannins???

I'm all for a keg FAQ as I would like to undertake this venture in the future.
In the meantime, I have to fly by all the kegging discussions (and believe me, the same questions come up again and again) as they don't apply now. The FAQ would give us a good reference point and probably cut down on some of the traffic.

Well, they say that it is better to keep your mouth shut and have everyone assume you're a fool, than to open it and remove all doubt. (mouth opening wide):

This conversation between Al and Scott has me confused. They talk about chill haze and tannins as being related. I thought tannins were to be avoided because of an astringent flavor component, rather than anything to do with haze. Are tannins protein based? I too have had a chill haze problem with a recent batch and was surprised to hear talk about acidifying sparge water as a cure. Well, have I removed all doubt???

Cheers,

Subject: Breckenridge Brewery Tour

I recently visited the Breckenridge Brewery in (where else?) Denver! The business started in Breckenridge as a brewpub, and then added the brewery uptown in a location just across the street from the under-construction Coors Field (this is a MLB baseball park, not a barley field!). Its not exactly the best part of town right now (lots of empty warehouses and run down buildings) but I'll guarantee in the spring of '94 (Coors Field opens for the Colorado Rockies) it'll be all glitz and glamour.

They claim that they are a brewery that serves food, not a restaurant that makes beer. This is indeed the case, from my observations. There is at least as much floor space devoted to the brewery as there is to the restaurant. The layout is a bit strange to me, though, as the brewery is spread out over 3 different areas in the building. The brewery was not in operation when I was there but most things are right out in the open so I did my own tour and showed off my experience to my father-in-law.

They have a monstrous, auger-fed grain mill (I couldn't see where the grain is kept). The grist is then augered over to the mash tun, which looks like it has no heater (i.e. they do a single-step infusion). The mash-tun apparently has a water inlet (from a gas fired hot liquor tank) which comes in from the bottom, so as grain falls from the top, it mixes with water from the bottom. The output of this is pumped over to the gas fired boiler. The output of the boiler goes through a small chiller (I'm guessing it is cooled with a refrigerant rather than just with water) before being pumped to the fermenters. I looked but couldn't spot a DE filter, I'm sure they use one. There are also large insulated cooling tanks all around. From these, the beer is pumped all the way across the restaurant to the bottling line (and presumably over to the bar!). The bottling line is an interesting setup, behind glass so I couldn't get too close. One interesting note about the bottling: the bottles are sanitized either with steam or a solution, they are turned upside down, and then pass across 6 or 8 feet of open air before being filled and capped. I don't suppose there is much risk of contamination but the bottling room didn't look particularly clean (at least the floors were quite grubby). They then go through the label machine and into cases. Interesting looking stuff (for this engineer) to say the least. I don't have any guesses as the size of the vessels in this place but they were at least 4 times larger than any I've seen in the typical brewpub. I don't know what kind of annual output they boast. All in all, a fun time: good beer, good

food, fun things to look at and dream about.

Oh, the beers: Avalanche- Nice malty smooth amber.

IPA - Good IPA, hoppy sharp, alcoholic

Mountain Wheat- More of a pale ale than a wheat, although they use something like 40% wheat malt. Not a lot of wheat characteristics but a very tasty brew.

Oatmeal Stout - A wonderful full bodied stout, good stuff.

They also had a guest beer from HC Berger Brewing in Fort Collins, which I appreciate. If you're in Denver, check out the BB!

Subject: Talkin' German

Howdy,

I didn't want to do this (it's a bandwidth thing), but having a background in Sociolinguistics, I can't help myself any longer.

Ari Jarmala (HBD #1217) says English speakers can't pronounce the German umlaut "ue". Untrue. Ask the American I know who passes himself off as German all the time in Berlin. Also, his phonetic description of the vowels is a little off. "u" is a back vowel & "e" is a front vowel, but where he really trips is assuming that the representation "ue" in "trueb" has anything to do with that. It doesn't. This particular umlaut is referred to as a high front rounded vowel. Rob Thomas does a good job of describing it (HBD #1218).

But most important, I agree with Nate (HBD #1218). We are mostly Americans speaking English, so let's talk like Americans speaking English. If you really want to say "trueb" in an entirely authentic German manner, your average Joe Bob on the street is gonna look at you funny & say "Bless you". Also, we'd have to learn the phonology of about a dozen languages whose beer styles, as homebrewers, we emulate. That could get confusing. American English is a language that loves to borrow & adapt words from other languages (yak, skunk, tortilla, kangaroo, Mississippi, etc), & if we spent all of our time trying to say a word in the original language, we wouldn't understand each other half of the time. Also, by saying a word in the original phonology, we're ostracizing those who we should be convincing that there is more than one kind of beer. Make it friendly, not foreign. Use words that sound comfortable to their ears, not like some hacking sound. Be proud, say "troob", and brew more Oktoberfest!

Sorry for the use of the bandwidth for the linguistic lesson, but I just couldn't take it any longer.

Happy brewin',

Alan, Austin

I used to do this with all of my beers, but now when I brew regular
American
or British ale, I do an infusion of 160F water, rest at 153 for an hour
and
mash off at 170. Works fine, and saves a chunk of time since it takes me
a
few minutes to raise 65Lbs of mash from 120 to 152.

I have never ever done this. I agree with the theory, but like you
suggest,
the sweet wort pH is the part we care about, not the sparge per say (the
mash
will buffer the pH, depending on the mineral content of your mash/water)
.

Good brewing,

Subject: First Impressions/Povidone/Peracetic Acid

I've only been on the HBD list for a week, just in time to catch the yeast FAQ & all the ensuing flack & counter flack. I have to say my initial impression is not very good. I joined this list because I thought it's purpose was to discuss homebrewing (which, in my opinion as a new reader the yeast FAQ was related to), not go into lengthy diatribes of net protocol. Maybe I was mistaken?

Paul dArmond asked about povidone. This is a topical disinfectant of Iodine absorbed into polyvinylprolidinone (I assume the surgical scrub is an aqueous emulsion of this). Thus the active bactericide is the iodine.

As regards to Ed Hitchcock's question of making peracetic acid: You can indeed make peracetic acid by simply mixing H2O2 & acetic acid (I'd be a little careful though & keep it cold while mixing with efficient stirring). However in my humble opinion why bother? The small amount of bleach that you use to sterilize your equipment is hardly environmentally significant. If you're really worried about it why not just use the peroxide solution? H2O2 itself is a pretty good disinfectant, although I don't know if it efficiently kills the organisms that your worried about in brewing.

Excuse me while I slip into my asbestos suit.

Subject: Diacetyl \n Oxygen/v-wire bottoms

Jim writes:

>If you do this [shake the fermenters periodically], you will *rouse*
>the yeast which can help to keep the
>fermentation going, but will in no way *add* oxygen to the fermentation.
>It is a CO2 environment anyway. Pumps will add oxygen but this
inevitably
>force the yeast to throw Diacetyl which I do not care for. BTW, this is
>how the Peter Austin Breweries (Wild Goose, Red Feather, Ringwood)
actually
>*promote* Diacetyl production in thier beers.

I can offer another datapoint. At the Tadcaster Brewery (Samuel Smiths)
,
they use a very flocculent yeast which they force back into suspension
using some kind of sprayers (I've never seen them in person, I've just
read about them) which inevitably aerate the fermenting beer. I had
always thought that it was just their yeast's tendency to flocculate out
of suspension that caused so much diacetyl to remain in their beers, but
this additional datapoint ties in with Jim's comments.

Also Jim writes (quoting me):

><In professional systems, there are debates
>raging about whether round holes or slots are better and the cross-
sectional
>shape of the holes is debated also.
>
>Not really debates, more a cost benefit issue. V wire slotted bottom is
>undoubtely the *best*, and most expensive. It is an inverted V, big end
>down. I have found perforated sheet to be more than adequate, even with
>weizens of 70% wheat malt (and decoction mashing).

Not really raging either, but it looked good in print. Actually, one
specific
case I know of is the system at the Weinkeller Brewery in Westmont, IL.
Udo,
the owner told me that he had the standard screen (just round holes)
replaced
with "a custom-made screen of my own design." This screen had a cross-
sectional shape like this:

```
-----  
/ / / / / / / / / /side view  
//////////
```

where the wide part of the Vs was on top.

Another system I saw advertized (I was part of a group that was looking
into
building a brewpub and my portion was the equipment, so I got a lot of
sales
literature) had a cross-sectional shape like this:

```
-----  
| | | | | side view  
| | | | |  
-----
```

in other words, from the top, they looked like small holes, but from the bottom they looked like counter-sunk holes and these were round holes in an offset pattern:

```
  0  0  0  0  0
0  0  0  0  0  0  top view
  0  0  0  0  0
0  0  0  0  0
```

Every manufacturer said they had proof that their design was better than their competitors. So, what else is new.

Al.

From: barbm@aol.com

Subject: Brewing w/ fruit/juices

I'm looking for some help from some of you barleywine brewers out there. I'm a bit late in putting up this year's Christmas holiday brew and was thinking about a barleywine using fruit juice instead of whole fruit. I've got some basic questions that I hope you folks can help answer.

1 - Using fruit juice and adding it to the secondary, will all the fruit flavor/aroma ferment out? Would it be best to add at bottling time? If I add at bottling, how do I take into consideration the amount of added sugars?

2 - I've been told (by a local brew shop) that one will usually end up with off flavors if you add the fruit at the end of the boil, or in the primary. Yet, almost all the recipes I've found call for these methods. Any comments from those experienced with fruit brewing?

3 - Finally, would I be better off to just forget the fruit/juice and use extracts for the flavorings? If so, does anyone have any sources for quality extracts? I'm looking for cranberry and apple, currently.

Subject: Carboy Brush

The last few batches I've done were in 6-1/2 gallon carboys. These are real nice, until time comes to clean `em. I bought a carboy brush from my friendly homebrew shop, shaped like so:

0
|
+====

I really don't like it very much. It just can't clean the sides very effectively, although it is a little better in the neck area. Its really bad trying to clean the yeast-ring left at the surface of the fermenting wort. When I think I'm through, very often I'll see little brush-marks form in the "steam" that condenses inside the carboy. This tells me that its not *really* clean, so I go back at it. I figure it should be so clean, the water just sheets right off, the way you clean your burette in the analytical chem. lab. A round brush, like a chimney-sweep uses seems like it would be much better. Does such a thing exist for cleaning carboys?? Or does someone have another idea?

And what's in Bottle Brite?

Thanks,
t

Subject: re: Sour bier

Some time ago, I posted a question about my first batch of bier being sour, or tart. I said it tasted like apple cider. Well, that batch is long gone. It seems that age did a lot for it. Of all the people who tried my bier, not one complained about it, eventhough it was "potent." ;^) Perhaps I added too much sugar and that's what made it both strong and tart? Comments?

Anyway, this weekend I bottle my second batch. I split the wort into approx. 3 gal dark bier, and 2 gal dark CHILLI bier. Seems to have gone well. There was some discussion about chilli bier. If there is any interest, I coult ellaborate on how I made mine, as if I'm an expert. Well, gotta go.

Lagers, Mike.

Subject: Various Topics

Here is my two cents worth on the discussion of the long FAQ posting.

I found the information to be VERY informative. I do not find this objectionable in the least. More on various subjects would be very gladly accepted. I do not believe that I have access to the sierra system for downloading as I am on GENie and do not fully understand the internet link as of this time. I have only been on the inet for a short time and can not respond about the delay but if someone needs information on a subject they should not be posting a question and hoping for an answer for something being done within the next day or two.

RE: fruit beers

I recently made a Belgian Abbey style beer. In a fit of madness, I decided to make it raspberry. I purchased a bottle of Raspberry Natural Extract from The Beverage People (normal disclaimers) and added the 4 oz at bottling time. Let me just say that it was definitely RASBERRY. There are various flavors and if the peach is not available, it probably will be soon. I currently have the raspberry and a sour cherry. At the AHA conference I got a small sampler of blueberry. These can also be added to beer before it is dispensed. I like to add the flavors to the weizen that I brew. I like the weizen by itself but occasionally will add about 5-6 drops for flavoring.

Nice labeling system Tim. Sure ya couldn't make it any easier. I mean come on now, I have to add with your system (1+1=?)

From: boomer@sylsoft.com (Richard Akerboom)
Subject: Re: trueb and the Pink Panther

As a german speaker, I know how to pronounce "ue" or the u-umlaut in trueb, but there is no equivalent sound in English, so how to describe it to others? I suppose knowing the french equivalent would help some, but I don't speak French.

Today the answer came to me. Recall the Pink Panther movie with Peter Sellers where he is asking the clerk at a guesthouse for a room, but pronounces "room" sort of like "rheum"? That is the closest to the "ue" that I can come up with in most English speaking people's experience.

Hope this helps.

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>
Subject: Hydrostatics/liqueur recipe/fruit beers

2 points about the recent BrewCap thread:

(1) Since I'm philosophically opposed to discussing one of my products in the open forum, I'd be happy to send info on the BrewCap to anyone who sends me private email. If anyone wants to summarize and post on the digest, that's up to them.

(2) But I must comment on John Mare's question below since it involves an interesting lesson in hydrostatics, something I've learned a lot about after playing with upside-down fermenters.

>What prevents the weight of beer from
>popping the cap off when the carboy is inverted? Any advice on use of
this
>item will be appreciated.

It was as surprising to me as it is to most people to discover that 5 gallons of beer which weighs close to 50 pounds does not generate 50 pounds of water pressure. Water pressure is a function of the height of the vertical column of water. In general, 3 feet of water generates 1 psi. Therefore 5 gallons of beer in an inverted carboy puts a little less than 1 pound of pressure on the cap at the bottom. That is, to say the least, a negligible amount of pressure.

That there is so little pressure on the cap also explains why one can siphon priming sugar into the bottom of the carboy with no problems. I didn't discover this trick until I had been brewing with the BrewCap for about a year.

Here's my procedure for making liqueurs from fruit:

My liqueur experiments are still experiments. My suggestions are to be taken as rough outlines of the procedure. The sugar content of various fruits varies considerably so there's no way to give precise measurements for sugar/sweetness levels. I'd appreciate email on any improvements to the process that anyone discovers.

For the blueberry liqueur I have going now, I buzzed the berries in a blender first and added an equal amount of vodka to the puree. So, for ex., if I've buzzed up 1 gallon of blueberry puree, I'd pour 1/2 gallon of the puree into two 1 gallon apple cider jugs and fill each one with vodka. After a couple of weeks, the puree will sink to the bottom of the jug. At this point, I presume it's extracted about as much of the blueberry flavor as it's going to extract.

Now you need to strain the puree from the vodka. You must do this in stages. First pour it through something relatively coarse like several layers of cheesecloth. The penultimate filter for me is a layer of ladies nylon hose. The final filter is a coffee filter. This yields a very clear liquid.

Whip up some simple sugar solution. 1 part water to 1 part cane sugar. Add to the vodka/blueberry extract until you like the level of sweetness. Sip and enjoy.

Someone asked recently about the best way to make a raspberry flavored beer. I know you have plenty of raspberries in your backyard but a small plug for the raspberry essence that Mark Garetz of Hoptech sells: We used it in a raspberry wheat we had on tap at Tumbleweed this summer and it sold like hotcakes! Mind you, this is a fruit beer in a town that had never heard of fruit beers! We added the essence at kegging and it imparted a wonderful raspberry fruit flavor to the beer that was true to the flavor of raspberries. No artificial flavors here. The best thing about it was that it was simple, simple, simple.

Cheers ya'll,

From: Domenick Venezia <venezia@zgi.com>
Subject: Secondary, dry hopping

In the continuing saga of the novice brewer, I have some observations and questions about secondary fermentation and dry hopping.

I bottled the "churning" batch of beer that I spoke of in a recent HBD. It did not appear infected, and the SG sample had no off-flavors. It appears that the continuous activity was CO2 liberation by Polyclar, and simply secondary fermentation.

What is a typical reduction of specific gravity in a secondary? I had not expected as much as I got:

OSG to primary : 1.054
SG to secondary: 1.020
Final Gravity : 1.012

I used hop pellets for the dry hop. They were easy to add to the carboy, they washed out easily, and they were a pain in the butt to bottle with. Some of these tiny bits were floating on top, some were seemingly suspended, some had sunk, none ever compacted on the bottom but would kick up at the slightest provocation. They tended to clog the spring loaded bottling tube, but enough got through so there are little bits of hops in the bottles.

I dread the thought of trying to add 2 oz of whole hops to a carboy. I think they would wash out easily enough, but stuffing them through a 1" hole does not sound like fun. I could bag them, but stuffing a bag of hops and marbles through a 1" hole doesn't seem like fun either. Has anyone seen 1" tube bags? How about plugs? What do you veterans do?

The SG sample was good enough that I think I will try this batch again quite soon, but change the process to avoid standing barefoot in hot wort, avoid melting the kitchen floor, and avoid hop pellets somehow.

Thanks to all for your comments to my last posts about blow-off and the endless churning secondary ferment.

I love this stuff.

From: Don Put <dput@csulb.edu>

Subject: Secondary, dry hopping

Subject: Lager Sludge

I've got a problem with a lager that I brewed about three months ago. After bottling--BTW, this is an extract brew, my last one before going all-grain--the yeast, Wyeast Bohemian, settled out nicely. I then lowered the temp to about 35-38F for continued aging. Within a day or two a haze developed in the beer that really is distinctly different from the normal chill haze. It further developed until it looked like the flakes in one of those "Christmas balls" that you shake up and watch the "snow" settle. It has been about 5 weeks since I bottled and most of this stuff has settled out, forming a 1/4 inch layer that stirs up easy on top of the yeast. The beer has also developed a harsh back of the mouth bitterness and finish. The recipe was very close to Papazian's "Propensity Pilsner," with the addition of dry-hopping using Saaz plugs for about seven days.

So, a few questions:

- 1) Is this a characteristic of wild yeast contamination? There has been no gushers or over-carbonation.
- 2) Is it an undesirable side effect of dry-hopping with plugs? Maybe I should have dropped the entire batch to 35F while still in the secondary to allow this "stuff" to settle out.
- 3) The beer tasted very fine at bottling and at about 2 weeks after, then this strange taste developed. Will this go away with more aging or should I chalk this one up to experience and dump it? (It is fairly undrinkable at this point).

This is the first lager that I attempted having recently acquired a dedicated lager refrigerator. I followed Miller's guidelines for fermentation times and temps. Any thoughts or ideas from those of you more experienced in the brewing of lagers will be greatly appreciated. BTW, a friend in the local brew club, and a brewer for 8 years, tasted it and was stumped. However, he drank the whole bottle I poured him. He says it starts nicely, then deteriorates into a "lingering back of the mouth bitterness." He'd never seen this type of sediment before.

TIA,

don

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>
Subject: Tadcaster brewery/spraying

hello all,

Al Korz brought up the Tadcaster brewery, their highly flocculant yeast and spraying in HBD1219. Well, working on the assumption that since Tadcaster is in Yorkshire (UK), and the system sounds like the "Stone Square" system (aka Yorkshire Stone Square System) that I just read about in Hough, Briggs, Stevens and Young Malting and Brewing Science, I thought I'd comment:

the Yorkshire Stone Squares were originally vessels made of stone and later slate (now often steel). They have a lower compartment separated from an upper one by a deck. In this deck is a manhole with a raised flange

and tubes leading to the bottom of the lower compartment.

During fermentation, the yeast/beer is forced up to the upper compartment through the manhole. From here the beer returns to the bottom via

the pipes and the yeast remains on top. Because of the high flocculence of the yeast used, the beer is also pumped up from the bottom to the top and literally sprayed through a fish tail head (like on a watering can)

The only comment made in the book about flavours associated with this system is "it is claimed to give a characteristic type of beer". Under the heading Diacetyl and 2,3-pentane dione however, they say that oxidizing agents (not necessarily O₂, could be Cu, Al or Fe ions)

are necessary. Increasing temperature, or exposing beer containing yeast to air increases diacetyl formation. It is also increased by conditions leading to rapid yeast growth (eg aeration!). The diacetyl flavour can also be caused by lactic acid bacteria, when the problem is called Sarcina Sickness.

Well, that's about all I can remember for the minute,
Happy brewing,
Rob T.

Subject: chill haze/peracetic acid/anchor steam

Norm Pyle writes:

>This conversation between Al and Scott has me confused. They talk about chill haze and tannins as being related. I thought tannins were to be avoided because of an astringent flavor component, rather than anything to do with haze. Are tannins protein based? I too have had a chill haze problem with a recent batch and was surprised to hear talk about acidifying sparge water as a cure. Well, have I removed all doubt???

Tannins are phenols. Chill haze can be caused by starch, but usually is due to phenol-protein compounds. According to George Fix, the best way to reduce chill haze is to get the wort of the break material, which removes half of the haze forming material.

Duane Romer writes:

>You can indeed make peracetic acid by simply mixing H2O2 & acetic acid (I'd be a little careful though & keep it cold while mixing with efficient stirring). However in my humble opinion why bother? The small amount of bleach that you use to sterilize your equipment is hardly environmentally significant. If you're really worried about it why not just use the peroxide solution? H2O2 itself is a pretty good disinfectant, although I don't know if it efficiently kills the organisms that your worried about in brewing.

Excuse me while I slip into my asbestos suit.

Leave the suit behind. My concern was partly due to the current Net wisdom that bleach is bad for stainless kegs. However, I just looked up the reaction index at the back of the Cole Parmer catalogue, and both Acetic acid and peroxide are bad, while bleach is listed as "No effect". Can anyone elaborate?

Jay Vanni writes:

> Now, I feel ready to try something more advanced. I wonder if anyone has a recipe that will yield something resembling Anchor Steam beer (If mentioning this brand name is against the rules, please forgive me, I'm new). Equipment, techniques, and ingredients are no boundary for me - I just want to try imitating this beer. Any help?

2 row pale malt, a hefty dose of crstal, bitter with Perle, finish with Cascade. Use Wyeast California Lager yeast, fermented at 62 F. Lots of hop is the key. There are a few Anchor Steam recipes in Cat's Meow you can look up. Last time I tried Anchor, I noticed a distinct similarity to

Young's Special London Ale, with a rich maltiness, though I didn't do a side-by-side.

Subject: Pressure Regulators

I'll soon try my hand at brewing some draft beer. Here's a question re: the use of a pressure regulator. (Thanks for the posting Al)

I have what I think is a pressure regulator. I obtained it from my last job a couple of years ago from a pile of stuff to be thrown out, thinking I may need it someday (deja brew?). Physically it is a 2 1/2" dia brass body with 5 evenly spaced pipe threads tapped around the perimeter. Into each are screwed the following: a 0-4000 psi gauge, a 0-30 psi gauge, a relief valve (stamped as such), a large fitting, and a small fitting. A "T" handle sticks out the front. A label on it says, "NITROGEN AND INERT GASSES." It's made by the Victor Equipment Company, and looks to be part no. SR 250 A. Is this what I want? If so, should I have it tested for reliability or accuracy? Should it be cleaned? Anything else?

From: philb@pro-storm.metronet.com (Phil Brushaber)
Subject: Lagering Time In Secondary Fermenter

It used to be when I would brew Lagers I would primary in glass for a couple of weeks at 50 degrees, then transfer to a Cornelius Keg for secondary at 40 degrees.

With summer's heat my brewing slowed down. As a result my "primary" refrigerator became a secondary refrigerator. This time I did my secondary in glass where I could monitor the progress. After a two week primary, then a four week secondary I could still see a few bubbles rising in the glass.

I thought my secondary was finished, but when I boosted the temperature from 50 to 60 degrees (to execute a diacytal rest) the fermenting took off again. So much so that the bubbles proceeded to fill up my airlock!

Two questions fellow "Lagermeisters"...

1. All the sources I read said that secondary should take place at 50 degrees. My experience would lead me to believe this is too low.

2. How long should one typically expect a secondary to take? When is it safe to bottle or keg?

>Subject: Trub: you say potatoe...

>Now, I'm all for understanding the origins of things, but just because a word is pronounced one way in Germany does not mean that it needs to be mimicked here.

Thought I would add a little confusion here. On saturday I attended a lawn party at which my wife and I were the only ones who could not speak German and many attendees could speak no English. I figured this was a good place to settle the issue and as I needed a conversations starter, I surveyed them on the word "trub", spelling it every way I have seen it.

The concensus was..... true-bay, just like it looks but with the 'r' rolled accent on the first syllable..

The root or the word was agreed to have something to do with clouds.

>From: R_GELINAS@UNHH.UNH.EDU (Russ Gelinias)
>Subject: keg overcarbonation

>Jack, perhaps your problem with kegs getting overcarbonated is because the beer hasn't actually finished fermenting. The fact that it is happening with (mostly) lagers, which can take much longer than ales to ferment out, might be an indication.

This is possible but I would think by the time I keg them, there aint much left. Furthermore, if I just left it sit, unattended for weeks, I could agree but as I monitor the pressure regularly on all kegs and adjust as needed, I wouldn't think it would make any difference whether the CO2 came from fermentation or the tank. But I will keep it in mind. For the time being, I am reducing my dispensing pressure to around five lbs and using 1/4" tubing till I see which way the wind blows.

Subject: PIZZA AND BEER FAQ PART 1

BEER AND PIZZA FAQ (Part 1 of 29)

Q0001: Which pizza goes best with an Imperial Stout?

A0001: Don't be a twit. Anybody who knows anything about beer will tell you that drinking an Imperial Stout leaves you little room for anything else.

=====

Q0002: My wife says that all this pizza and beer is making me fat. Is this a bad thing?

A0001: All homebrewers reach this "crossroad" at some point in their lives. The real question you have to ask yourself is: do I want to stay slim and get laid or do I want to enjoy life?

=====

Q0003: Does Sierra Nevada Pale Ale compliment a pineapple and Canadian bacon pizza?

A0003: Of course.

=====

Q0004: I find that a Pils Urquel is too delicate for a pizza with the works (including anchovies). Is there a beer that can stand up to such a gastronomic deluge?

A0004: Yes. Weizens are a good choice as are smoked beers. The added benefit is that those late-night belches are exquisite.

=====

Q0005: I saw Kathy Ireland on the cover of an old issue of Zymurgy. Do you think she and Chuck, you know, did it?

A0005: Many have speculated that since Charlie Papazian has remained slim then he must have made the wrong choice at the Homebrewer's Crossroad of Life.

=====

Q0006: I recently relocated to the Pacific Northwest. Having been born and raised in Chicago I find these new beers way too bitter. What's the deal?

A0006: Indigenous populants of the Pacific Northwest (IPPN) have a misplaced sense of hopping rates. Get used to it. Furthermore, never confront them about it as they tend to be overly sensitive.

Subject: trub,trueb,treber and all that.

Hello all,
now that we can all approximate the u umlaut (ue) sound, and incorporate it in the word trub, I ought to point out something that I discovered last night while reading a german book on brewing (by Narziss, aka Gott). The german word that means the same as the English word trub is TRUB. There is NO umlaut!
There is a word Trueb or Trueber which means cloudy, but that isn't the word used by brewers. There is also Treber, which translates as draff (ie the grains after sparging).
Hence, the pronunciation is trub, with a germanic t and u, if anyone really wants to speak English with a German accent (after all, we call Muenchen Munich, so why should we call trub trub?).
I hope this clarifies things for you all, I've certainly given up.

Actually, the beer one (I haven't checked who makes it) that I picked
up to replace the one that was unsuccessfully peeled from the aquarium
doesn't have much more of a range than the fishtank ones. I can't
remember if the low end goes down to the 50's but the high end is
not above 85 I'm sure.

Subject: H(ot) S(ide) A(eration)?

As I mentioned in an earlier note, I've been reading Brewing, published in 1912. The author is President of the Institute of Brewing, etc., etc., so I presume he's good for the current (1912) understanding of brewing processes.

In the discussion of cooling (p. 66) he talks about "coolers", or long shallow pans in which the wort cools by exposure to ambient air, and (the relatively new-fangled) "refrigerators", which actively chill the wort by running it over or around tubes filled with a cold liquid. He then says (emphasis mine) "Certain of the constituents of the wort have the property of absorbing oxygen from the air at tolerably high temperatures, and this `hot aeration' as it is called, to distinguish it from the cold aeration or absorption of oxygen by the cold wort while passing over the refrigerator, is *very generally regarded as beneficial*. It is true that some authorities have questioned its importance, but I think there is a general consensus of opinion that these more or less obscure oxidation changes are *desirable* and that they do exert an appreciable effect on the brightening capacity of the finished beer."

Now, clearly brewing science has advanced since 1912, and it seems to be now generally accepted that HSA is bad for the flavor. But it's interesting to see how accepted practice changes...

Am considering a Thanksgiving-type ale that would involve the addition of
some pumpkin pie spice (allspice, cinnamon, nutmeg, etc.). My question
(s)
is, has anyone tried this before, (i.e., dryhopping with this stuff)?
Should I do this after initial fermentation has terminated? Should I do
this in conjunction with some aromatic hops? If so, what kind and how
much? About how much of this pumpkin pie spice should be added for 5
gals? I'm really just after the aroma of pumpkin pie and am not
interested in altering the flavor toooo much. Hope there's someone out
there that's played with this kind of thing before. I would appreciate
any and all feedback on this and can be e-mailed directly at
mstewart@unssun.unr.edu. Thanks much,

Mark
(p.s., am considering using a brown ale recipe that I've made in the past
and the pumpkin pie spice I saw was Schilling brand).

Subject: Kegging FAQ is a go!!!

>From all the responses I have gotten, a kegging FAQ is an overwhelming YES. I now officially volunteer to be the keeper of the FAQ. Please send me every bit of information about kegging you know not only including techniques, but also suppliers of kegs and parts. I have gathered much of this already, but I will need your help to make it complete.

I expect that the next 3+ weeks will be for collection. Then I go on vacation for 2 weeks and will work on the compilation of results when I return. Expect to see it uploaded to sierra.stanford.edu and announced the middle of October.

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>
Subject: Stainless Steel and Chlorine

In the recent post by Ed Hitchcock, he mentioned the current HBD wisdom of not using Bleach (chlorine) in Stainless Steel kegs and the current interest in iodine. While I would like to know exactly what the Cole Parmer catalog was referring to with NO EFFECT, it may not pertain to what I am relating here.

Being a metallurgist, (i have a feeling that most of us are college grads of one form or another, using the convenient computer systems at work,[:o) I checked out the Metals Handbook Vol. 13- Corrosion, on Chlorine and Stainless and here is what I found.

Chlorine (aqueous) is highly corrosive to austenitic stainless steels, which includes the 304 alloy most commonly used for Food Grade containers. The mechanism of corrosion homebrewers mostly have to be concerned with is Pitting Corrosion. This is caused by localized concentration of chlorine ions. Those ions become concentrated by evaporation of water containing chlorine. The corrosion is manifested as tiny pits which, due to increased relative concentration of the chlorine in the pit to the surrounding environment, quickly put pinholes in your tanks.

To prevent this type of corrosion, the key is good rinsing of the bleach water from the steel. First off, let me say that the 1+ tablespoon bleach per gallon (4ml/liter) is not much in the context of the industrial corrosion that the Metals Handbook is written to. Most of what I read dealt with continuous flow through pipes, etc. Anyway, If you rinse with warm boiled water until you don't really smell it, and then prevent water droplets on the sides by either filling the keg with beer or drying them out with a towel, you will not have the localized concentration necessary to induce pitting.

One other thing that can be done with Stainless Steel is passivation. A 20% by volume solution of (HNO3) Nitric Acid will ensure a uniform oxide film which will prevent the localized concentration/activity difference which initiates this form of galvanic corrosion. But I don't think this should be necessary.

While I am discussing stainless steel, I have a word of caution for those of you get stainless steel tanks welded with fittings. There is a

time@temperature range (800-1600F) for austenitic stainless that results in Sensitization. This term is used to describe a precipitation of chromium carbides away from the grain boundaries which results in intergranular corrosion and brittleness. You can practically snap it with your hands. This is a common problem in welding of 304 stainless where the weld zone should be cooled below 1100F within five minutes or the precipitation will start to occur. This also means that heat between 1100-1600F for more than five minutes should be avoided ie weld time. If any of you are noticing leaking or cracking around your fittings, this is what has happened. The only way to fix it is to anneal the whole thing at roughly 1950F for 5min/.1inch section size followed by fairly rapid cooling to avoid Sensitizing it all over again. By the way, 304L (L for less carbon) does not usually have this problem, nor does 316L or 321.

Hope this wasn't too longwinded.

Subject: My first all grain batch - a screw up.

Message:

Well, I attempted my first all grain batch this past weekend. Using a rectangular picnic cooler with a copper t'd manifold for mashing and sparging. Picnic cooler is a 10 gallon. Mashed 6lbs highly modified pale malt and 8 oz crystal with 6 quarts of 168F water for 1 hour. Did the iodine test. The color was blackish but it turned to clear when I stirred it up a bit. Here's the part I think I screw'd up. When sparging with 3 gallons of 170F water, I had a very difficult time of not disturbing the grain bed. Most of the time it was very turbulent. Anyways, the OG ended up being 1.024!!!! I quickly went to the fridge and pounded a couple of homebrews, yeast and all! Here's my question... how important is it that the grain bed is kept relatively undisturbed while sparging? Also, will the liquid turn colorless near the end of the sparge. Mine didn't. How do you add 3 gallons of 170F sparge water without disturbing the grain bed? Could it be that my cooler is too large, ie the grain bed is not deep enough? I decided to ferment it anyways. I'd love to give this another shot this weekend. Greg.

Subject: (SNPA) Clone. Was re:SN Stout Request

I'm having trouble posting to rec.crafts.brewing so hopefully this will satisfy most of the recent email requests for this recipe.

- -- Included File --

OK - I know, I know... the response I posted was for Sierra Nevada Pale Ale NOT the Stout!!! But someone used SNPA - that means PALE ALE... well anyway... I got lots of request for the recipe so here it is:

6.6# light malt extract
.5# Laaglander DME
12oz Belgian Cara-Vienna 22L
8oz Belgian Cara-Pils 7L
1oz Perle pellet 7.1AA 60min
.5oz Cascade pellet 5.5AA 30min
.5oz Cascade pellet 5.5AA 15min
1oz Cascade whole 5.7AA dry hop
1tsp Irish Moss 15min
Wyeast 1056 American Ale

OG = 1050
FG = 1013

Brewing Notes:

Do a full boil (60 min).

Hop rates are based on a 5 gallon boil so if you boil less then increase the hop rate to compensate.

Crush then steep the grains until ~170 deg, then remove.

Wort was chilled to 68deg before pitching.

Once the grains are removed, shut off the heat and add all of the extracts. This will avoid scorching the extracts and darkening the wort. Stir well then add heat and bring to a boil.

Add the dry hops in the secondary for around 5 days. When you rack the beer to the bottling bucket, tie a sanitized hop bag to the end of the hose or racking cane that goes into the bucket. This will catch any stray hop bits that might get sucked into the racking cane. In practice you won't get much if you use whole hops so you can omit the bag if you'd like. If you haven't tried dry hopping I encourage you to do so. The hop nose is fantastic and adds so much to the character to the brew. I don't feel you will be able to match it with normal finishing hops.

I have not had the chance to compare this to a real SNPA but people tell me it's very close. The OG is a bit shy of the true mark which is 1057 so I would increase the DME by maybe 1/2# to compensate. The mouth feel is a bit heavy from what I remember so you may wish to reduce the specialty grains somewhat. If you're not sure then just go with it the way it is. You won't be disappointed.

enjoy!!

Would you believe, someone flamed me for not paying closer attention to the title of the post I responded to then - asked me for my SNPA recipe???? Sheesh... some people :-)

Subject: Re: Yeast FAQ Ruckus

Hi All,

Well, I feel that since my post was the cause of all the wasted bandwidth (either for the FAQ itself if you agree with JS or for the flame-fanning in response if you don't), that I should speak my piece. To JS's credit, he originally sent me the piece he went on to post about netiquette by e-mail a few days before it appeared in the HBD. At the time, I thought it was just a personal response, so I wrote him back explaining my reasons. I did not save my exact message, because I did not expect it to make its way into the public forum, but I will repeat the main points here. The main reason that I feel compelled to "answer the charges" as it were is that I dislike the implication that I did not know what I was doing and furthermore didn't care. I reposted the whole mess because:

1. It had undergone extensive revision. I change the intro, reformatted some of the general info sections and expanded others, updated the dry ale yeast data, expanded and changed the liquid ale yeast, expanded and changed the liquid lager yeast, updated some of the weizens, clarified some points in the rehydration section, cleaned up the section on culturing, and added two whole new sections. Just posting the changes would have meant a lot of work for me in separating them out, and tons of work for anyone who would try to make sense of the new info ((cut and paste)^3).
2. I did not serialize it over several days because:
 - a) the variable length of the queue makes it difficult to predict when something will come out, and
 - b) the sections did not fit easily into 8k chunks, making it difficult to find good stopping points.
3. As to fine-tuning it by e-mail, I had already been through many rounds of revisions and updates with every yeast expert who reacted/responded to the first message as well as many yeast novices who requested clarifications, simplifications, or expansions of key points.
4. Given that I had changed it so much and desiring to avoid the infamous group think phenomenon, I decided RELUCTANTLY to submit the mess to the collective wisdom of the HBD for another rehashing/trashing.

The deciding point for me was the realization that at the end of one week, the digest would be at the same place whether I serialized or not. Even with all the debacle, I am glad that I reposted because I have had several good responses to info in the updated version. Those hardy souls and I have communicated by e-mail, and I hope to have the mess ready for sierra by this weekend. Fear not, I shall not repost the beast again!

Finally, as for the results of his 10 to 1 poll, I would suggest that irritated people are 10 times more likely to respond than those who are satisfied, and that his was the only negative comment that I have received

from anyone regarding either the value of the FAQ or the size. (That is not an invitation!!) I hope that no one else is discouraged from doing FAQs or information resources or whatever. It is a great way to learn about a subject and contribute to the art of homebrewing by computer all at once. I do apologize for any inconvenience. If anyone needs to reach me, I am

Subject: All-grain questions

I went all grain several months ago and will never turn back. However, I've got some new problems. I'm sure you experienced all-grainers can help me solve them.

1) I've had haze problems since I started mashing my own grains. Not chill haze, rather the beer never clarifies properly. I know the most likely source is unconverted starches. However, my mashes all passed the iodine test (sample taken from top of mash tun). Is there a better conversion test? Is there another possible source for this haze?

2) Sparging questions:

a) How much recirculation. "Recirculate until runoff is clear". Sounds great in print. However, for amber or darker beers this is not as obvious as it sounds. In last batch I recirculated the first 5 qts. Is this excessive?

b) When to stop sparging. "Don't over sparge". I like this about as much as "cook until done". The three techniques I know of are 1) sparge until running reach certain gravity (1.010?), 2) Sparge until pH is too high (> 5.5?), 3) Sparge until boiler is full. Both Miller and Papazian give mash & sparge water quantities, but the last time I used these my final runnings were 1.020, seemed wasteful.

3) Separating break material & spent hops from wort. When I syphon my cooled wort from the boiler into the fermenter, my syphon tube clogs leaving 1/2 to 1 gallon of wort/trub in the boiler. I usually pour the last of this glog into mason jars, allow the trub to settle and decant the wort for use as starters. One quart of glog doesn't bother me but for my last triple I was left with nearly a gallon. Again seems wasteful. Techniques? Equipment? (I know, Jack, I should drill a hole in the bottom of my boiler and install a SS screen w/tubing etc. I'm seriously considering this but would like to hear other alternatives.)

TIA, WAK

Subject: Light struck beer

Cheers to Chris Campanelli and his Pizza and Beer FAQ. I for one am looking forward to parts 2 through 29! Nothing like poking some fun at various flames that have been going on lately. On to business. I have been relegated to brewing outdoors since several years back I had a glass carboy explode in my bedroom closet (The saddest day of my life - superbowl stout exploded, taking out the carpet and most of the clothes in the closet). Now I have recently gone back to glass fermenters, 6.5 gallon vice 5 gallon. I was wondering when light struck beer begins to be a problem. My recollection is that hop acid, when exposed to light, will impart a "Skunky" smell. If so then even while fermenting you are capable of light damaging your beer. Could anyone expound on this for me. Do I need to keep my primary fermenter in a box (remember the closet is out!)

.
TIA.

Subject: Lager Brewing

In response to questions from Phil Brushaber regarding lager fermentation: I have been brewing lager beers for many years and my experience has been better lagers are brewed at cooler temperatures: I conduct primary fermentation at 48F and secondary fermentation at 42F. There is no question that fermentation at these temperatures takes several months. Once secondary fermentation is completed, I typically lager my beers at 32F-35F for three to four weeks. An important point to be made is that during cold fermentation, a substantial amount of CO2 dissolves into your beer. An excellent reference on this topic is "Brewing Lager Beers" by Greg Noonan

Subject: Re: True-bay

Although I thought the issue of trub pronunciation had died down, Jack stirred up an overwhelming sense of curiosity inside me. So much, in fact, I just have to ask one more question... Where were these german speakers from? It's possible that they said 'True-bay,' as german has different dialects just as english does. However, the word they are saying is clearly spelled 'truebe.' It is an adjective form of our brewing word, trub, a noun (trueb in german), meaning dreary. It is quite possible that if these germans were unfamiliar with brewing, they could have related 'dreary' with the weather, thus the German phrase 'das truebe Wetter,' the dreary weather. Hence the clouds. My arguement is simple. In english it's trub (noun). We have been trying to discover the pronunciation of the german word Trueb (noun). Your german friends appearantly were saying truebe (an adjective). Under nearly every case using the noun, it would be spelled Trueb in German. Therefore, I submit to you that the correct pronunciation of trueb as we use it in brewing would be closely approximated in english as "troop," if one remembers to keep the "oo" short. Of course if you say trube (rhyming with tube), most american brewers will understand you.

Subject: RE: Old freezer chest

Wally,

I have been using a 18 cubic foot chest freezer which was old when I bought it for \$40 23 years ago. I used it as a freezer until I purchased a "William's" temperature controller 3 years ago. Now it is my brewchest. In contrast to when it was a freezer, the motor is now off much of the time since it only has to maintain 40 - 65!F instead of freezer temperature. I monitor temperature with a dairy thermometer in a bottle of dilute chlorine, and find my temperature fluctuations to be minimal. The chest probably varies by 3 - 4 !F, but the mass of the beer fluctuates hardly at all. There is no brand name on the chest, but I know it precedes the "frost-free" era of freezers and refrigerators, and therefore does not possess the more complicated temperature controls needed for the defrosting process. I think you're probably right in assuming that and old (preferably \$40) freezer is the best bet.

Subj: Older Chest freezers
From: BrewerBob@aol.com

Wally, I have a chest freezer with a Honeywell temperature controller that works just great. It turns the power to the freezer on or off. I set the freezer control to coldest setting. I have used the freezer as high as 63 deg for fermentation and as low as 40 deg for lagering. Much of the time it is set at about 50 deg for serving, I have two taps on the lid!

As far as the electric bill is concerned, I really don't know what it costs me but I would think it would have to be less than it would be if I used the freezer as a freezer since it is not keeping it as cold and I don't open it often. My controller keeps the temperature within plus or minus 1.5 degrees of where it is set for unless I leave the lid open for a long period of time.

Press Release:

The Northeast Florida Society of Brewers, co-sponsored by The Hogtown Brewer of Gainesville, FL and The Home Brewery of Brooksville, FL, announce the 1st annual First Coast Brewer's Challenge, an AHA sanctioned homebrew competition to be held the first week in November, 1993. Competition is open to all home brewers. Entry deadline is October 29, 1993 with the final judging taking place on November 7, 1993. Beer styles for this competition are limited to Stout (all types) and Pale Ale (all types). Fee is \$6.00 per entry with three bottles of beer required for each entry. Prizes include merchandise with at least \$50.00 worth for first and \$20.00 for second place.

For information, contest rules and entry forms, contact Bob Gammie (904) 241-8879 (RobertG211@aol.com on Internet), Chuck Cummins (904) 292-2166 or Joe Bryant (904) 399-3367 (BPNS42A on Prodigy) or write to: Brewer's Challenge, 354 Magnolia Street, Atlantic Beach, FL 32233.

End of release...

- - Folks, here's your chance to see how good that beer you make really is!
Join in the fun and win a prize! At the very least, your beer will be critiqued by an AHA certified judge and you will be able to see how your beer rates and will have a basis for bragging to your friends. I will be entering my oatmeal stout and I expect it to do well! Can you beat me?

Subject: RE: Dry hopping; secondary fermentation.

Domenick asks about dry hopping. I use only whole hops for dry hopping in the secondary (glass carboy). Hops pour in easily with paper funnel, float near the top, and do not clog my siphon at bottling. There really is no answer to the question about "typical reduction" in SG in the secondary since this is a function of when you rack. With ale I rack on day 3 or 4 when the final SG has almost been reached. If I racked earlier, obviously the SG would still be higher. With lagers brewed at lower temperatures (50!F) I rack on day 5 or 6 and usually the SG will drop a few more points in the 3 weeks before I bottle. I hope this helps.

Subject: seasonal ales: dryhopping with spices

Randy Mosher of Chicago, an admitted spice-beer addict recommends using spice "infusions" -- soak the spices in vodka for a week or two, then add a measured amount to your beer before bottling. The nice thing about this approach is that you can test the spicing level in a glass of beer before "ruining" your whole batch. Add drops with a medicine dropper (one with calibrations), then you can scale up from the volume of the glass (8 oz?) to the whole batch (5*128 oz).

From: donald oconnor <oconnor@ccwf.cc.utexas.edu>
Subject: iodophor

Sometime ago there was a rather spirited discussion about iodophors. I didn't have time to add some info at that time but it seems iodophor is again topical so I'll pass along a little bit of stuff now. Specifically, it seems clear from Kelly Jones post earlier this week that there is still confusion regarding acid and detergents in iodophor.

I spoke with Dr. Landum of National Chemical which is the producer of BTF iodophor. Dr. Landum is, like me, a Ph.D. chemist. This may be more than anyone wants to ever know about iodophor but it might help clear up some of the confusion.

There have been several types of iodophor produced over the years and the general idea behind all of them is the same: complexed molecular iodine in some material that will dissolve in water and then release the iodine to kill a bacterium or virus or yeast cell. An organic material is required to form the complex with iodine, but the organic material needs to be also soluble in water. This is characteristic of a surfactant and that's why all iodophors contain surfactants. The one in BTF is essentially a large alcohol. The surfactant in the iodophor currently under discussion is a little different according to another post on Monday's digest.

Iodophors can be generally broken down into two classes on the basis of the production process. The production process dictates in part which surfactant(s) is used, which in turn dictates other features such as the presence of acid. A "hot" process was developed in the 30's or 40's and a "cold" process was developed in the 50's. Iodophor produced by the older "hot" process does not release the iodine into water very efficiently at neutral pH but will at lower pH. Thus the need to add acid to these iodophors. Phosphoric acid has been mentioned here but several other acids have been used over the years. The newer process resulted in iodophors which did not need acid to release the iodine. BTF and BEST are examples of these.

Both types are meant to be used in industrial applications. Both have roughly the same level of iodine. The differences have to do with the surfactants and acid. The ones containing acid have particular utility to dairies because of the effect of the acid in dissolving residual milk stone from the equipment. This of course is not a consideration for breweries. This is not to say that breweries can't use the one with acid, but breweries use other cleaning procedures. The disadvantage of the iodophors which contain acid is that they lather or foam when agitated, at least more so than the newer iodophors, and this is a concern for brewery use.

There is no question that fermentation at these temperatures takes several months.

Well.....It only takes 5-7 days at the Old Dominion Brewing Company. My 1.080 Maibock fermented in 10 days.....

The real issue here is a big one in homebrewing: Enough healthy yeast (most homebrewers underpitch), enough dissolved oxygen (most homebrewers under oxygenate) and a healthy pool of fermentables in the bitter wort (usually not an issue, but the breakdown of the composition of the fermentables vs nonfermentables will invariably dictate the degree of attenuation in the finished product).

I guess the question is :how long does your *fermentation* take? ie, how long until the SG has dropped by 75%? No doubt that some continual activity/lagering will occur but when everything is done perfectly, a lager ferment in between 7-10 days.

Well, I installed a Hot liquor tank (propane water heater) and much to my delight, it works perfectly! The way to sparge with it is to barely open the hot out faucet. This makes the hot water trickle onto the grains around 163F (hottest setting on the heater). Cold city water flows in to the bottom of the heater, where the thermostat quickly fires up the burner. Within 15 minutes, the outlet temp is up to 170F! No modifications required. This even surpasses my expectations.

I also hooked up a O2 injector with a silica airstone. I bubbled at ~1 psi for 1.5-2 hours. The ferment kicked in within 4 hours, and by morning, it was as beautiful as any I have seen. The taste test will have to wait two weeks.

Good brewing,
Jim Busch

>looking for a recipe for Heather Ale and I was wondering if anyone
>knows where I can find one. Thanks again.

Well, here's another opportunity to root through my dusty tomes. The following excerpt is from a book called "The Scots Cellar". I only have xeroxed pages from this book (I don't even have the author's name right offhand). I'll check with the Library of Congress and try to get a complete citation. At any rate, here is a cottage recipe, supposedly from the Isle of Orkney, for heather ale:

"Crop the heather when it is in full bloom - a good large quantity. Put the croppings into a large-sized pot, fill up with water, set to boil. Boil for one hour. Then strain into a clean tub. Add one ounce of ground ginger, half an ounce of hops, and a pound of golden syrup for every dozen bottles. Set to boil again and boil for twenty minutes. Strain into a clean cask. Let it stand until milkwarm, then add a teacupful of good barm (brewer's yeast). Cover with a coarse cloth till next day. Skim the barm from the top and pour gently into a tub so that the barm may be left in the bottom. Bottle and cork tight. It will be ready for use in two or three days. This makes a very refreshing and wholesome drink as there is a good deal of spirit in heather."

The author suggests substituting heather honey for the "golden syrup" (which I believe is simply corn syrup). He also suggests using less ginger than the recipe specifies, as ginger tends to overpower the subtle flavor of the heather. No indication is given as to what comprises a "good large quantity" of heather, but the author suggests cropping the heather blossoms with as little stalk as possible, as the stalk tends to impart a great deal of bitterness.

I believe there is also a heather ale recipe in the book "The Curiosities of Ale & Beer" by John Bickerdyke, but my copy is on loan at the moment. If I remember correctly, Bickerdyke's recipe simply calls for adding the crushed heather blossoms to a standard beer wort before fermenting.

If anyone attempts to recreate this ancient brew (I've given some thought to it but haven't as yet), please post the results.

"From the bonny bells o' heather
They brewed a drink langsyne,
Was sweeter far than honey,
Was stronger far than wine."

Robert Louis Stevenson, "Heather Ale"

Subject: various

I will be traveing to San Francisco next weekend and would appreciate it if anyone would recommend brew pubs or microbreweries to visit. I've already been to Anchor. E-mail responses would be fine to save bandwidth. (I do not have access to list servers or archives that I can readily download!)

In response to Greg_Habel concern about his low O.G. My guess is that he did a very limited sparge, using only 3 gallons. I usually sparge with about 5 gallons of water and recirculate the first 2 gallons until it clears.

In regards to the Weix-FAQ. He did an immeasurable service to many brewers. For years I have been wanting a handy reference to yeast strains and the band-width he used was well worth it. I can't see how people complain when almost as much bandwidth was taken up on a humorous but almost worthless topic of how to pronounce "trub." Get real!

Subject: Thanks from a couple of lurkers

This is just a quick note of thanks to all the contributors to the HBD over the last several months. After reading HBD (and rec.craft.brewing) for a couple months while making our own, my partner and I decided that all grain really didn't look all that hard.

So - after digging thru the archived HBD's that I had, and reading everything that related to mash/lauter tun's, easymashers (tm), conversion, gott coolers, and a few other threads - we bought a seven gallon gott, fabricated something like the ascii picture I saw of the easymasher (tm), bought the grain, hops, et. al. and brewed. Even though we knew it was supposed to happen - conversion was just sort of amazing (I mean it really did turn sweet), and the way the wort cleared after filtering through the grain bed for a minute or so went just like it was supposed to.

To make a **long** afternoon short - there's a couple things we'd do different the next time (yes there will be a next time), and with practice it should go smoother, but most importantly, there's a carboy of beer-to-be bubbling merrily away in the basement. Thanks again for all the indirect help.

ciao,
pb

A 10 gallon mash/lauter tun is too big for such a small amount of grain. IMHO, you need a grain bed a minimum of six to eight inches deep. I have found that you will have to add sparge water very gingerly to a grain bed less than 10 or 12 inches deep. Many homebrew authors have their own opinions on this subject, but I feel the deeper the grain bed, the better. A 5 gallon vertical drink cooler would be more appropriate for the small mash you described.

A suggestion to avoid disturbing your grain bed is to use something to slow down or diffuse the water going into your mash-tun: I use a large plastic bowl with several 1/8" holes placed in the top of my converted 5 gal drink cooler mash/lauter tun. Commercial brewers typically use a sprayer head to diffuse the sparge water as it enters the lauter tun.

> Here's my question... how important is it that the grain
> bed is kept relatively undisturbed while sparging? Also, will the
> liquid turn colorless near the end of the sparge. Mine didn't.

It is very important to keep your grainbed undisturbed during the sparge, otherwise you can wash a lot of draff into your boiler. This can lead to off flavors like astringency and/or clarity problems. There should be very little sugar in your mash at the conclusion of sparging; however, if you sparge until the runoff is colorless, you may be oversparging. There are many ways to endpoint your sparging operation. I use George Fix's rule of thumb, that is use 1.25qt water/# grain for the mash and use the same amount of sparge water/# grain for sparging. This implies limiting your runoff to 2.5qts sweet wort/# grain. Another way to endpoint your sparge is to taste the wort periodically. If the runoff is no longer sweet or has an astringent flavor (like iced tea), you should terminate the runoff. I believe you are better off undersparging by a slight amount, rather than risk tannin extraction as a result of oversparging.

Subject: dry hopping question

I have a few questions regarding dry hopping.

I've brewed a dark, rich, all grain Christmas ale to which I plan to add 3-4 oz of Willamette pellets. I've never dry hopped with pellets and the talk over the net has begun to worry me. I planned to rack my beer to a clean carboy after secondary fermentation (to get it off the yeast sediment to avoid autolysis) then add the hops and dry hop for 4-6 weeks at 40 - 45 degrees F. This was recommended by a homebrewer who has since left town (ie I cannot ask him for advice regarding any pitfalls). The beer I am making is dark ale with an original gravity of 1.073 to which I want to impart a strong hop aroma.

Is this off base or can I do this without ruining 5 gallons of a good tasting ale?

Subject: Addtn to kegging FAQ/liquid-crystal thermometers/T-giving (spiced) ale

Al Richer did a good job summarizing the basics of kegging. I would like to add a bit more info. In addition to the big o-ring and the two under the dip tubes, there are also o-rings on the poppets INSIDE the connectors

(the part of the connector that is screwed onto the keg, over the diptube -- not the part of the connector that is at the end of the hose). I suggest changing these two poppets (I've yet to find poppets with replacable

o-rings). Also, there are orings on the outside of the connectors (again the part of the connectors that screw onto the keg). The gas-side oring has never been in contact with syrup, but a leak here would be a big waste

of CO2, so I suggest replacing both. Finally, there is a gasket, usually a

flat disk in the pressure relief valve. I've found some keg styles that have

a removable gasket, but have yet to find a replacement, so I just replace the

whole relief valve if possible (some styles of lids don't have a removable

relief valve). That gives a grand total of eight o-rings/gaskets. Sure, were talking about something like \$10 in parts, but it beats the heck out of

5 gallons of unintentional, rootbeer-flavored Pilsener. I've been getting

all my keg parts from Foxx Equipment Company, but I've heard recently they

are not selling retail anymore... I've just called them and they said that

they do still sell retail, but prefer to refer homebrewers to local or mailorder HB supply shops. Their Kansas City location number is 800-821-2254.

Spencer writes:

>with an even better range; maybe this is what Sheaf & Vine is selling?

The ones sold by Sheaf & Vine have a range of 40F to 80F. I think that this range should be made a bit lower for lagers and a bit higher for ales. If your ambient is 75F, then I could easily see the fermentation driving the temperature above 80F.

Mark writes:

>Am considering a Thanksgiving-type ale that would involve the addition
of
>some pumpkin pie spice (allspice, cinnamon, nutmeg, etc.). My question
(s)
>is, has anyone tried this before, (i.e., dryhopping with this stuff)?
>Should I do this after initial fermentation has terminated? Should I do
>this in conjunction with some aromatic hops? If so, what kind and how
>much? About how much of this pumpkin pie spice should be added for 5

If you add the spices directly to the brew, you will have to deal with

the particles which won't dissolve. What I did was to soak the spices in vodka for two days and then strain the liquid through a coffee filter. I added this at bottling so I could adjust to taste. I don't have my records handy, so I can't say how much I used, but it was a lot more than I initially anticipated. Maybe if I had soaked the spices in the vodka longer, more flavor would have come out of them. I suggest making up a bunch of your own extracts and then adding them to an already carbonated beer of a similar recipe that you intend to use. Once you know how much you will need, you can go ahead and brew the batch and then either add the spice extracts on a per-bottle basis or on a batch basis.

Subject: Re: hazy beer/sparging/separating wort from hops/2-gauge regulators

Bill writes:

1) I've had haze problems since I started mashing my own grains. Not chill haze, rather the beer never clarifies properly. I know the most likely source is unconverted starches. However, my mashes all passed the iodine test (sample taken from top of mash tun). Is there a better conversion test? Is there another possible source for this haze?

It could be starch haze from too hot a sparge water -- unconverted starch can be liberated from the husks if the sparge water is a lot higher than 168F. This reminds me of an interesting point I read in Beer & Brewing Volume 8, from Dave Miller's talk. We all kind of know this, but then again we don't think about it this way usually. There are three stages in conversion: 1)gelatinization, 2)liquifaction and 3)saccharification. All three are occurring at the same time... some starch is being gelatinized, which is then liquified by the Alpha-amylase and then saccharified by the Beta-amylase. Miller pointed out the danger of relying strictly on the iodine test because there could still be quite a bit of ungelatinized starch in the mash which would not be available to the iodine test. This is a common reason for low yield, in that a brewer will see a negative iodine test and mash out, leaving a lot of ungelatinized starch.

2) Sparging questions:

a) How much recirculation. "Recirculate until runoff is clear". Sounds great in print. However, for amber or darker beers this is not as obvious as it sounds. In last batch I recirculated the first 5 qts. Is this excessive?

Miller will say you can't recirculate too much (almost) but it depends on your setup. If you have a large underlet (dead space under the screen) you will have to recirculate more to set the filter bed. Some users of particular setups have reported an established filter bed after about a cup. For dark beers try a smaller vessel (like a test tube) for assessing clarity.

b) When to stop sparging. "Don't over sparge". I like this about as much as "cook until done". The three techniques I know of are 1) sparge until runoff reach certain gravity (1.010?), 2) Sparge until pH is too high (> 5.5?), 3) Sparge until boiler is full. Both Miller and Papazian give mash & sparge water quantities, but the last time I used these my final runnings were 1.020, seemed wasteful.

It was wasteful. Actually 3 can be your limiting factor, but you can always boil down some of the wort and then add more runoff. 1 is the one I use, but if your water is alkaline, you can extract a lot of tannins as the pH rises. If you do have alkaline water, you should acidify your sparge water to make sure the pH does not get too high. Actually, you need less acidification when

you start your sparge (because the grain lowers the pH of the mash) and more as later in the sparge (as the low pH wort runs out of the lauter tun).

3) Separating break material & spent hops from wort. When I siphon my cooled wort from the boiler into the fermenter, my siphon tube clogs leaving 1/2 to 1 gallon of wort/trub in the boiler. I usually pour the
<snip>

I use a hop bag for my boiling hops (whole AND pellet) and it reduces the amount of material at the bottom of the kettle significantly. I must note that I add 10% to Jackie Rager's formulas to compensate for the lower utilization I get when I use the hop bag.

Tom writes:

>closet). Now I have recently gone back to glass fermenters, 6.5 gallon >vice 5 gallon. I was wondering when light struck beer begins to be a >problem. <snip>

You should keep the fermenter in the dark too -- your beer can be light-struck while in the fermenter.

Bryan writes:

>Most of the kegging setups I've seen at shops have regulators on >the CO2 bottles with two "dials". What do the two dials read? Are >two necessary? I don't want to skimp on the regulator, but I don't >want to buy something unnecessary.

I feel that a two-gauge regulator is unnecessary -- the low-pressure gauge shows you the pressure after the regulator (the keg side) and the high-pressure regulator shows you the high-pressure side (the tank side). However, the pressure in the tank is going to be pretty much 800psi until all the liquid CO2 has turned to gas -- then it will drop like a rock. No, the only way to know how much CO2 you have left is to weigh the tank. A 20# tank means that it will hold 20 pounds of CO2. Weigh the tank with the regulator and hoses when it is empty -- write this down (the tank will be stamped with it's empty weight, but taking off the regulator periodically is not a good idea -- mess with the fittings as little as you can). When you get it back from the filler, it should weigh 20# more (or 5# if it is a 5# tank, 10#, etc.).

From: npyle@n33.stortek.com
Subject: acid bottles / CF chiller cleaning / ???

Corby asks how to treat his acid bottles before using them to brew. It reminds me of an old rhyme (the origin I do not know): The solution to pollution is dilution. The way I would treat the bottles: just add water. There should be no acid left "in the glass" when the bottle is emptied and rinsed. I might store the thing full of water for a day, empty, fill, and store for another day, to really rinse it well. Other than that I wouldn't worry.

I found out something (that I already knew!) this past weekend. Dishwashing liquid (detergent?) is very corrosive to basic metals. I knew this because a few years ago I plumbed some iron gas pipe and did the standard "bubble" test on the threaded joints. These threads rusted within a day, although not enough to cause any problems. Well, I'm here to say that it works on copper even better!

I wanted to do a great cleaning on my counterflow wort chiller before coiling it (just to make sure there was no machine oil or anything in it). I laid it out flat and snaked a wire into it. It only made it about halfway but I remembered someone on the net recommending using dishwashing liquid to lube it. The advantage, it was said, was that it was good for taking any oils out with it when it was rinsed.

So I poured a good amount in the end of the copper tubing and was able to snake the wire all the way through the tubing. I then got distracted for a couple of hours and when I came back to pull some twine through, there was a large amount of corrosion of the copper tubing already happening. I ended up pulling the twine through (with cotton balls and disposable cleaning rags) many many times before getting the tubing really clean. The bulk of this work was getting that green sludge (some sort of copper oxide?) out of the tubing. I checked it by cutting off a couple of inches of the tubing and cutting it lengthwise. The tubing is now clean but I would do things differently next time. If I was to use dishwashing liquid, I'd make sure that I rinsed it out within the hour. Or, use something else. Another lesson learned...

Patrick Weix and Chris Campanelli: Thanks for the FAQ's!

Cheers,
norm

>I know that some people use a chest freezer with some type of
>external thermostat to control the temperature. Has anyone
>ever burned out the compressor of a chest freezer due to using
>it in a way that it was not intended to be used?
I'm not sure about your particular freezer but mine just has a
normal refridg. compressor in it. As long as your temp. regulation
device "short cycle" protection for the compressor, I don't think
you are straining the hardware much more than normal use. A short
cycle protection is nothing more than a timer that prevents the
compressor from turning on until it has sat for a while. The time
length is usually at least 4 min. but could be more. The reason you
need to do this is to allow the high and low pressure sides to
balance before starting the compressor. Not allowing the high side
pressure to equalize puts excessive strain on the motor inside the
compressor.

>Does anyone
>have any experience with older chest freezers say > 10 years
>old. I worry that an older freezer may not have much life
>left in it, but then again I think that it may also be built a

Subject: Primary Fermetor question

I just started using a blowoff tube on a glass carboy for my primary. It works great! I have a 1" diameter tube for the blowoff and my current batch blew out about 1 pint of liquid.

My only question is: what should I do when I rack to the secondary? More specifically, now that the liquid level is lower than the neck, should I top it off when I rack?

I want to minimize the air exposure, right? But I am NOT convinced that adding a pint of water at this stage would have not effect.

Please respond by e-mail, I need to rack soon.

Thanks
Alex

From: Kieran O'Connor <koconnor@mailbox.syr.edu>
Subject: Fridge Costs

Some folks have been wondering about fridge costs. Here's a neat way to figure that out.

Most power companies offer free devices (you borrow, but can't keep) which will measure power consumption. The one I got is for educators (I'm a teacher) and they mail it to you and you mail it back when done. They have other stuff too--all sorts of science related gizmos. The power company here that does it is NY State Electric and Gas (a public utility), but they sent it to me where I work which is not even in their service area.

You put in the cost of your electricity/KW hour, then plug the fridge into it. It runs like a meter, but only when power is drawn through it, so it's accurate for our usage.

I used it once when it was set to 60--and I think it was like 3\$/month--at \$.11/KW/hour cost.

Good luck.

From: Drew Lynch <drew@chronologic.com>
Subject: Re: regulator question

The dial closest to the CO2 tank measures tank pressure, the other measures dispensing pressure. I have yet to empty my first 20lb cyinder, but I understand that for CO2, the first gauge moves very little if at all, until the tank is empty, then it drops like a stone. The best way to determine the remaining CO2 is to weigh the tank, and then subtract the tare (sp?) weight stamped into the metal near the neck of the tank. Only the dispensing gauge is necessary.

From: jim@n5ial.mythical.com (Jim Graham)
Subject: questions on making mead / suggestion re: exploding carboy

First, a couple of questions regarding making mead. Then, a suggestion for the guy who had the carboy explode in the closet.

After reading Papazian's comments on how good the stuff is, I'd like to try it out. Is brewing mead any different from brewing beer in a single-stage fermenter (I don't even own a carboy)? Is it basically going to be the normal approximately 7 days in the fermenter and then 15 days (minimum) aging in bottles? If not, how long should I expect it to take to ferment/age out?

Also, how much is it likely to cost to brew? Is Sam's Wholesale Club most likely to be the best (i.e., cheapest) source for the honey? Or is there a less-expensive source?

Is mead one of those things that, like champagne, is typically only for certain occasions? Or is it something that most people would just sit down and enjoy as they would any other homebrew? Does this matter? Do I care? Who knows.....

I'm thinking about using the first mead recipe in TNCJOHB, which he calls ``Antipodal Mead (Traditional)``. Does anyone have any suggestions for a mead that might be a better one to start with? Or is this a good start?

Btw, adding fruit isn't really much of an option right now, mainly for cost reasons (I'd have to buy the carboy as a secondary fermenter, plus buy the fresh fruit at a fruit stand or farmer's market somewhere, etc.). However, I'm certainly open for suggestions along this line, too---if nothing else, for future reference.

> stout exploded, taking out the carpet and most of the clothes in the
> closet).

Just a suggestion---why not wrap the carboy (whether it's outside or in your closet) in a blanket or something similar? When it's inside, it would at least keep the beer limited to making a mess on the floor, as opposed to trashing the floor, clothes, ceiling, etc.... When it's outside, it would

help prevent the problem of exposure to light. Whether it's inside or outside, it would make it far less likely for someone to be hurt (or worse) by shrapnel.....

I had a beer bottle explode once, and from that day on, I keep all beer bottles in either a case-box, in a cabinet, or under some sort of towel, blanket, etc., from the day the bottle is capped until it goes in the fridge. If another one explodes, I don't plan on cleaning up glass from all over the apartment (the one that blew sent glass *EVERYWHERE*---I'm just glad I wasn't home).

Anyways, that's it for today (or probably next week, by the time this gets posted to the digest). Later,

Subject: mini-keg question

Here is a question for all you who have used the mini-kegs that are becoming available: Is it easy (or even possible) to purge the kegs with CO2 when you are kegging? Can you put the dispenser in the keg, give it a gentle blast (talk about oxymorons) of CO2, and then fill?

Thanks in advance for your help!

Subject: Gel/Liq/Sacc

Al Korz raises a good point about mashing. One of the first books I read about all-grain was from Dave Line, who is (was) admittedly one of the more relaxed brewing authors around. He did say more than once (I believe it was in "The Big Book of Brewing") that once you hit a negative starch test you are not done. I guess he explained it a bit although I can't recall what his explanation was. Miller's explanation via Al seems right on the money: ungelatinized starch which is undetected by the iodine test. Maybe this is why many professional brewers rely more on the mash time rather than a conversion test.

cheers,

Subject: Beer & Brewing Bibliography

I was reading Bill Ridgely's post on Heather Ale in HBD #1222 and was facinated by the description of this ale. Anyway, It got me thinking about books on beer and brewing, new and old. Most of us are familiar with the recent books for homebrewers, Miller, Papazian, etc. However, there are obviously a lot of other books out there. I'm wondering about putting together some sort of annotated, bibliography. Any interest? Send me you comments and citations.

Subject: RE: All-grain

Hi All,

In HBD#1221 Greg Habel writes:

>Well, I attempted my first all grain batch this past weekend. Using
>a rectangular picnic cooler with a copper t'd manifold for mashing
>and sparging. Picnic cooler is a 10 gallon. Mashed 6lbs highly
>modified pale malt and 8 oz crystal with 6 quarts of 168F water for 1
>hour. ^^^^

Was 168F your strike temperature, or the temperature of the mash?
168F is a little high for saccharification rest, you want a mash
temperature of roughly 150F-158F, depending on how much body is desired
in the finished beer.

>Here's the part I think I screw'd
>up. When sparging with 3 gallons of 170F water, I had a very
>difficult time of not disturbing the grain bed. Most of the time it
>was very turbulent. Anyways, the OG ended up being 1.024!!!! I
>quickly went to the fridge and pounded a couple of homebrews, yeast
>and all! Here's my question... how important is it that the grain
>bed is kept relatively undisturbed while sparging?

It's fairly important that the grain bed be disturbed as little as
possible once recirculation of the initial runoff is complete and a
filter bed established. If the grain bed is disturbed, the chances of
particulate matter such as small pieces of grain or husk getting into
the brewpot are increased.

>How do you add 3 gallons of 170F sparge water without disturbing the
>grain bed? Could it be that my cooler is too large, ie the grain bed
>is not deep enough? I decided to ferment it anyways.

Try using something to diffuse the sparge water as you add it. I mash
and sparge in a cylindrical cooler with a colander mounted on top.
You might try setting a bowl or plate upside down on the grain bed, and
pouring the water slowly onto the bottom of the plate.

>Also, will the
>liquid turn colorless near the end of the sparge. Mine didn't.

The runoff will get lighter in color as the sparge progresses, but
it should not get colorless unless you oversparge.

>I'd love to give this another shot this weekend. Greg

Please do, and let us know how things worked out.

Also in HBD#1221, Bill Kitch writes:

>I went all grain several months ago and will never turn back. However,
>I've got some new problems. I'm sure you experienced all-grainers can

> I know the most likely source is unconverted starches. However, my
> mashes all passed the iodine test (sample taken from top of mash tun).
> Is there a better conversion test? Is there another possible source
for
> this haze?

Hmmm, just a hunch, but the fact that the iodine test passed after mashing yet haze appears in the runoff leads me to believe that unconverted starch is indeed the culprit, and that you have a filtration or sparging problem.

Check your grind, specifically the condition of the grain husks, they should be intact or nearly so. The more intact the grain husk, the better filtration you will get in the lauter tun. If the husks are excessively torn or in small pieces, you need to grind a little coarser. Your extraction may suffer a little bit, but this is by far the lesser of the two evils, IMHO.

Another thing to check is the temperature of the grain bed itself. I read somewhere, in one of Miller's books I believe, that granules of unconverted starch will burst when exposed to temperatures approaching 190F. This releases very fine particles of unconverted starch into the wort, which are all but impossible to filter out in the tun. Measure the temperature of the grain bed, not the sparge water or water on top of the bed, and keep it around 160F or so.

> 2) Sparging questions:
> a) How much recirculation. "Recirculate until runoff is clear".
> Sounds great in print. However, for amber or darker beers this is
> not as obvious as it sounds. In last batch I recirculated the first
> 5 qts. Is this excessive?

Different lautering setups will require different amounts of recirculation, so it's difficult to say whether a given amount of recirculation is excessive or not. I recirculate until the runoff is free of particulate matter, usually 2 to 3 quarts. The runoff is not crystal clear at this point, but it begins to run clear shortly afterwards.

I think the purpose of recirculation is to set up the filtration by the grain bed, not to increase yields. When the runoff is free of small chunks of grain, you're there. Of course, this is more difficult to determine with dark beers. When in doubt, I'll collect the runoff in a small glass, and hold it up to the light. This works for all but the darkest stouts.

> b) When to stop sparging. "Don't over sparge". I like this about as
> much as "cook until done". The three techniques I know of are 1)
> sparge until running reach certain gravity (1.010?), 2) Sparge until
> pH is too high (> 5.5?), 3) Sparge until boiler is full.

I use a combination of the hydrometer reading and my palate to determine when to stop. From experience, when I've collected 5 gallons of wort, I start taking frequent gravity readings of the runoff. When the gravity of the runoff approaches 1.020, I start tasting the sample. As soon as I detect a taste like hot tea, I stop sparging. With my equipment and procedures,

I'll have ~6.5 gallons collected at this point, and the gravity is ~1.010.

Your mileage may vary.

The problem with oversparging is excessive tannin extraction from the grain husks. This is why I use my palate to determine when to stop.

IMHO,

numbers like gravity and pH will vary according to water supply, amount and type of grain used, etc., so it's risky to rely solely on these measurements.

> 3) Separating break material & spent hops from wort. When I syphon my

> wasteful. Techniques? Equipment? (I know, Jack, I should drill a
> hole in the bottom of my boiler and install a SS screen w/tubing etc.
> I'm seriously considering this but would like to hear other
> alternatives.)

Someone else posted this idea a while ago, I can't remember who, try attaching a copper scouring pad to the end of your racking tube. These things are called "Chore Boys" in these parts, they have no soap in them, are easily sanitized by a brief boil, and cool off enough to handle a few seconds after removal from boiling water. I set the end of the racking tube directly on the surface of the break material, they do a superb job of filtering hops and trub, I get every drop of wort and have never had one clog.

Apologies for the lengthy post, I hope it helps.

Cheers,
Jim

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>
Subject: Foaming when adding priming sugar

I've noticed, at bottling time, when I add my priming sugar to the beer it tends to foam a bit. Anyone else notice this or have a theory why?

My guess would be that it is an indication of how much CO2 is dissolved in the beer -- the sugar somehow causes it to be released. So indirectly, it's an indication of how active the yeast in your beer still are, and perhaps an indication of how well your beer will carbonate.

BTW, I usually prime with 2/3 cup corn sugar dissolved in a few ounces of hot water.

Subject: Something new

Greetings,

I am an extract brewer with about 10 batches under my belt. Mainly because of time constraints, I don't think I'll be trying all-grain brewing for quite some time, but I would like to expand my brewing horizons. Other than brewing particular beers I haven't done before, are there any techniques ingredients etc. that you more experienced brewers would suggest I try? The only half-way unusual ingredient I've added yet was some milk sugar to a stout which is now fermenting. This request may seem out of left field, but

I thank you in advance for humoring me and for any suggestions.

Please respond by e-mail to :esonn1@cc.swarthmore.edu

Cheers,

Eugene

>Most of the kegging setups I've seen at shops have regulators on
>the CO2 bottles with two "dials". What do the two dials read? Are

2-dial systems usually have 1 low pressure dial (0-70 PSI or so) and
one high-pressure dial (0-2000 PSI). The high-pressure dial is the
pressure in your CO2 tank. The low-pressure dial is the pressure
maintained in your keg. I guess the only reason for having the high-
pressure dial is to help determine when your tank is nearly spent.

Subject: REGULATORS

Glenn Anderson writes:
Homebrewers desiring the use of this gas should be aware that they must use different regulators as the nitrogen is packed in under higher pressure than CO2. CO2 is normally under 800LBS pressure and CO2 gages normally top out somewhere around this. Nitrogen on the other hand is usually under around 2100LBS and require the appropriate regulator/gages.

To keep you from hooking up the low pressure CO2 regulator to the beer mix and blowing your head off, the bottles come with a different valve. It's female, part number is CGA580.

This is correct ONLY if you're filling your tank with 100% nitrogen and that definitely doesn't work for dispensing beer(you will eventually end up with flat beer because the CO2 in suspension will leave the beer under a blanket of nitrogen). The nitrogen/CO2 mixture is under 1800 lbs pressure and beer dispensing regulators are rated to be safe up to 2400 lbs(I called several regulator distributors to be sure). Also no special valve is needed for the special Beer Mix of nitrogen/CO2.

>this to pour properly. You could disconnect the CO2 and bleed off
>some of it from the kegs and dispense but it's a real pain bleeding
>off dissolved CO2 - it takes time and patience.

I'm sorry, but I must disagree. If you do the math first and then
choose your hose lengths/widths accordingly, you will not have
overcarbonation.

You just must first choose the temperature and the number of volumes you
want in the beer and then choose the pressure, hose lengths, hose
diameters

based on the formulas give in HBD back issues and in Dave Millers' very
good article in the 1992 AHA National Conference Proceedings. If your
beer is overcarbonating, the pressure is too high or (as Jack pointed
out)

the temperature may be higher than you think.

I'm sorry but I disagree. You obviously have not had any kegs on tap
for any extended length of time to notice the gradual effect of CO2
absorbtion at cold temperatures (if you don't believe this can happen
then you don't believe in the concept of forced carbonation either).
I've been kegging for ten years now and I definitely talk from
experience. Also I was the one that gave formulas in HBD back issues
on calculating pressure, hose lengths/diameters. The calculations
work great if you drink you keg within a few weeks but if you have a
stout on tap that you only drink occasionally it will over time
absorb more CO2. The alternative is the nitrogen/CO2 gas mixture
which slows down the inevitable absorbtion considerably. Someone else
mentioned that all you had to do is turn off your CO2 tank and only
turn it on when the pressure got too low. This will work if you drink
the beer within a few weeks but it will still continue to absorb the
CO2 but at a slower rate than if the gas pressure were left on. I'm
lazy, I don't want to keep turning the gas on & off so I prefer the
nitrogen/CO2 mixture for dispensing. I could also solve this problem
by drinking alot more beer(this is tough with two kegs always on tap!)
but then I drink for quality flavor enjoyment not for quantity.

Subject: replacing keg gaskets, etc.

I don't think it is totally necessary to replace all of the gaskets in a soda keg. I have one soda keg that I've used 3 or so times and the only gaskets I replaced was the lid o-ring and the poppet o-rings, for a total cost of less than \$1.00. Never had the taste of soda in any brews dispensed from the keg.

The only time I'd suggest replacing more gaskets is if they are leaking or you are extremely worried about soda flavor in your brew. In other words, Relax...

When you get a dirty keg, wash it out really well. Put boiling hot H2O with soap and shake it; let it sit over night. Rinse. Repeat, hook up the CO2 and dispense, etc. One thing nice about stainless is it cleans well.

As for a place to buy parts, I've done business w/ Foxx and BCI. I like BCI better 'cuz I can call 'em on Monday and have stuff at my house by Friday. Although on a couple of occasions, they have screwed up my order...

BCI: 800-284-9410.

Last I remember, lid o-rings were \$0.52, poppet o-rings around \$0.12, etc. Buy yourself a bunch and you don't have to sweat it for a while.

>way to endpoint your sparge is to taste the wort periodically.
>If the runoff is no longer sweet or has an astringent flavor
>(like iced tea), you should terminate the runoff. I
>believe you are better off undersparging by a slight amount,
>rather than risk tannin extraction as a result of oversparging.

I was just reading Beer and Brewing Volume 8 yesterday and ran across something in Dave Miller's talk. I believe he said that at the end of his sparge, he once tasted the runnings and they tasted like tea (and looked like tea). On his next batch, he acidified his sparge water to 5.7pH with 88% Lactic acid (he said it didn't take much) and on his following batch, the end of the sparge was nearly colorless.

Regarding Greg's low extraction (5 gal of 1024 from 10# of grain), Miller said in the same talk that the iodine test is unreliable and that because of it, some people mash out too early -- see my hazy beer post in HBD 1222.

Jeff writes he plans to dryhop his Christmas ale with 3-4oz of Willamette pellets for 4-6 weeks.

I feel that you should save the pellets for boiling and get some whole Willamette hops for dryhopping. Whole hops will float and thus it will be much easier to rack out from under them than with pellets. Also, 3-4 ounces is quite intense for a 5 gallon batch. I usually use 1/2 to 2 ounces. Finally, I feel that 4-6 weeks is too long, even at 40-45F. At 65-70F, I recommend 7 to 10 days and about two to 2.5 weeks for lagering temperatures. After a while, I feel that more hop aromatics are escaping from the beer to the air than are entering the beer from the hops. This, of course, is unless you are planning to do this in a sealed container. You should probably purge any air that you introduce during dryhopping as oxygen kills hop aroma.

Al.

From: Eric Wade <ericwade@CLASS.ORG>
Subject: CF chiller cleaning, cooler mashing, Glatt mill, etc.

COUNTER FLOW CHILLER CLEANING

I'd like a reasonable cleaning and sanitizing procedure for CF chillers. I'm considering building one but feel that merely hot water and idophor probably isn't going to keep it clean over time. On the other hand, I don't quite feel like going through the clean-in-place process outlined in the recent BT issue. What do the rest of you do?

COOLER MASHING

I've been having some trouble reaching my desired mash temp of 154F by infusing at a ratio of 1.25 qt H2O @ 175F per pound of grist. I've also tried using a ratio of 1/1 and adjusting with boiling water. When this didn't work I drew off a fraction of the liquid, boiled and returned to the mash. I used this method on a porter that came out highly phenolic. I thought this was my first experience with an infected batch but a recent post (sorry forgot who or when) suggested a link between tannins and phenols. Could boiling the dark grains cause a phenolic taste in my brew?

I don't notice other taste/mouthfeel components I associate with tannins. Also, I'm thinking of starting with hotter water and adjusting with cold water or ice if necessary. Any potential problems with starting with a too hot mash? I understand that the enzymes are not detrimentally affected by short time periods over their active temperature range, correct?

GLATT MILL

I'd like to hear from anyone who has had a chance to use the Glatt mill, both those who are pleased as well as those who are not. I think I'll ask Santa for a mill for Christmas and would like to know which one to ask for.

PUMP SOURCES

I repeat my request for sources for wort pumps. Thank you to Jeff Burton for the lead on the March Manu. pump from C & H. I got the C & H catalog but the pump isn't listed, haven't called them yet. Where did the rest of you RIMS and other pump using brewers get your pumps? Is this a secret society sort of thing; you can't be part of the club until you find a pump all by yourself?

Please post the pump sources to the Digest, I received several requests for forwards after my last post on this. Also, at the risk of a flame war, I'd like a public discussion on CF cleaning so we get the pros and cons of the various methods before I choose one. E-mail is fine for other info.

Sorry to be so long winded, its been a while. TIA.

I have to second this. I added a carefully measured quantity of the raspberry to a bottle of really good cyser and did the same using the cherry in another bottle (I had lots, so I could spare a few bottles). It was excellent, absolutely outstanding! Now I can offer the "original" cyser as well as delicious apple-raspberry and apple-cherry melomels. :-)

Also, I'm looking forward to finally making (after a long busy spell with no brewing) a blueberry-wheat beer using the blueberry extract. Some time in the future I'll report on this. The extract sure smells good!

Mark, thanks for offering these excellent products (along with your wonderful hops) to the homebrew community.

I have no connection with Mark Garetz or Hoptech other than being a very hoppy ;-) and satisfied customer.

Subject: Radlett, England pubs? / OLD bottle cleaning

Greetings!

I may be travelling for several months to Radlett, England, on business in the near future. The tasting opportunities are overwhelming, and I would really appreciate any hints, tips, or suggestions as to places to go while in the area (like Belgium, for instance ;-), and so on. Brand names would be great.

Also, what are the laws regarding hand-carrying ale&beer through UK & US customs? How much, if at all, can I bring?

- - - - -

I recently found about a dozen old clear, green, and brown beer bottles mouldering around in a barn floor. There's green stuff growing inside at least the clear ones, and I assume the rest as well. I soaked them for a couple of days in soapy water, and am planning to put them in a 5-gallon pail of bleach water for a few weeks/months. Anything besides this to try? I'd hate to use my nice bottle brush on this scuzzy stuff.

The clear bottles will be nice! Someone here (thanks, someone) posted that they use one clear bottle per batch, and use that as their last bottle - kind of a ceremonial type of thing. Well, I've got 5 or 6 of them now, so that might hold me for a while, thanks for the great idea!

Subject: Equipment

Greetings All--

I just kegged my last batch and wanted to report to all about the changes I

made in my brewing set up that made life an absolute pleasure.

I have been brewing in a 40 Quart SS stock pot for a couple of years and after fighting with configurations mash vessels etc I have hit on what I think is an excellent combination. I was given a SS keg about

a year ago and kept meaning to cut the top off or use it in some way for

brewing. I finally got it on line for this brew session. Having two large pots on line has to be the best improvement in my brewing since I started. Now I can mash in one vessel while my sparge water is heating in the other one and can begin boiling wort before the sparge

is complete. The time savings is great! Additionally, I tried something

a little different this time. Since I now have the space for large grain

bins, I mashed 17 pounds of grain and went to 10 gallon batches instead of

5 (actually this one was about 7 with a SG of 1.072). The additional work for the larger batch was 0.

I use a copper manifold in my mash kettle and after modifying slightly this time it worked better than I had expected. I designed the manifold so that I can use the standpipe as a racking cane.

I switched to a copper chore-boy this time instead of using a hop bag tied to the end of the racking cane and that also was a positive change. This was the first time I had to slow down my sparge rate to get proper cooling into my chiller instead of waiting 3-4 hours for the wort to siphon through the it. All in all the easiest brew session ever.

To all of you considering buying/making equipment I would recommend getting the biggest set up you can afford and upgrade when you can. The flexibility the larger set up gives you more than makes up for the additional expense. Also keep your eyes and ears open you can often get good equipment for little money if you try hard. I got all of my kegs(about 7 of them) free from a restaurant that was going out of business and get this 15 gallon keg from a salws rep for one of the local breweries. Keep looking it's out there.

I didn't think this was going to be this long. Sorry for the rambling
Keep brewing-

From: D S Draper <D.S.Draper@bristol.ac.uk>
Subject: Using pectin enzyme?

Hi all, I am looking for some advice on the timing of using pectin enzyme in a fruit beer. Specifics of my recipe are: basic pale ale from malt extract, 5 UK gallons, low to moderate hop rates; 1 lb frozen raspberries added to wort just after boiling and left to sit a couple hours before being strained into fermenter and pitching yeast (a pale-ale yeast cultured from Hanseatic IPA bottle-conditioned beer). I've made this before, and really liked the subtleness of the fruit flavor from this amount of raspberry, but the beer was very hazy in spite of using isinglass during secondary fermentation. For this next attempt, I want to try pectin enzyme, but I'm uncertain about when to add the enzyme: in the primary during fermentation, in the primary after fermentation, in the secondary before finings, in the secondary after finings, or what. Also, is a couple of teaspoons to a tablespoon enough for a 5-gal brew? If you wish to send email, please do so to D.S.DRAPER@BRISTOL.AC.UK because "Reply-Mail" doesn't seem to get through to me.

Many thanks, Dave

Subject: RE: When should I pick my hops

Bill Cain writes:

> I planted some cascade and nugget hops this spring and the
> Cascade's are doing great. While the nuggets have just started to form
> cones, the Cascades have cones that are between 1/2" and 3" long.
> I've picked a couple and squeezed them, and they do produce a
> pleasant scent. I'm thinking that it's time to pick them, but
> how can I know for sure? Also, what is the best way to dry and
> store them?

There is a lot of information about this in old digests, but the short
answer
is this:

When the cones start to feel "papery" rather than "spongy" it's time to
pick
them. That means that if you squeeze a cone gently and the petals seem
to be
dried out so they don't spring back to shape like they did a week
earlier, then
they are ready.

Other clues:

1. When a few of the oldest cones (the ones that came out first) begin
to turn
slightly brown at the edges.
2. When you can easily look up a cone and see the bright yellow lupulin
glands
at the base of the petals.

Hint: Wear long sleeves and light cotton gloves when harvesting hops.
The
combination of rough bines and hop oils can be extremely irritating to
the
skin.

On the subject of drying, a first year's harvest won't give you enough to
worry
about (probably not more than will fit in the cardboard box that holds a
case
of beer). So just pick them and toss them gently in a cardboard box or
two,
preferably not more than about 6 inches deep, and put them in the driest
room
of your house, protected from bright light, for a week or two until they
are
dry. It's really that simple. The fully dried weight will be about 1/8
of the
weight when they were picked.

As to storage, a good practice is to separate them into piles of about
one
ounce (dried weight) and squeeze them down to compress them, then wrap
tightly
in aluminum foil (making as good a seal as possible) and store in your
freezer
until ready to use.

You don't really know the alpha acid percentage of home grown hops, but then you don't really have to care. Buy your bittering hops from a dealer, and you will be told the percentage down to a tenth of a percent. Use your own hops as finishing hops for flavor and aroma -- the alpha acid percentage isn't very important at that point.

Subject: Hop picking time....

It's been a late wet, cold summer out here in the PNW. Anyone who went to Portland may remember the light misty rain on that Thursday. Well, here it is well past the end of August and my hops still aren't ready to pick...

It's been a rough summer for them, two freak windstorms with heavy rain snapped six of my twenty poles (Sob! whimper...), but I only completely lost four plants.

Everybody who grows hops gets excited towards picking time. Most of the books and articles advise to pick when the cones get "papery". This can be hard to judge, particularly if one is really antsy to get on with the harvest. I have taken to cutting a cone down the middle. This lets you see the size and placement of the seeds, as well as the lupulin color and amount. The surest sign of all is when some of the cones start to turn brown at the tips, but then it's too late....

Patience,

Paul.

>pellets. Also, 3-4 ounces is quite intense for a 5 gallon batch.
>I usually use 1/2 to 2 ounces. Finally, I feel tat 4-6 weeks is
>too long, even at 40-45F. At 65-70F, I recommend 7 to 10 days
>and about two to 2.5 weeks for lagering temperatures. After a
>while, I feel that more hop aromatics are escaping from the beer
>to the air than are entering the beer from the hops. This, of
>course, is unless you are planning to do this in a sealed container.
>You should probably purge any air that you introduce during dryhopping
>as oxygen kills hop aroma.

I agree with you Al, on virtually every point, and I've dry hopped a lot
of beers. The part about purging air is not an issue if you properly
time
the infusion of the dry hops. After primary fermentation has died down
but
there is still some activity, I rack into my secondary (I guess that
fermentation is about 80-90% complete). Some CO2 is still be driven off
but in very small quantities. This is when I add my dry hops (I just
throw
them into the secondary loose). The reasoning is this: there is not
enough
CO2 production to drive off a considerable amount of hop aromatics, but
there is enough to blanket the beer in a short amount of time. The
oxygen
can't hurt the hop aroma because of the CO2 blanket. This point is a
good
time to rack in general because the oxygen has little time to do its
damage
and the trub hasn't had time either (typically around 3-5 days for me).

Thankz fir thu addveisse, Miekel.

Eric mentions the clean-in-place process outlined in the recent BT for
counter-flow chillers. Could you summarize this process for the digest,
Eric?

I plan to clean my chiller "in-place", i.e. still attached to my boiler,
what
could be easier? I would like to see how other clean their CF
chillers.

Happy hopping,
norm

Brian at FF is waiting for the new harvest to come in before he buys more hops. He decided he would rather be in short supply for a while than have to sell old hops to customers once the new supply comes in. He also has a true roller mill in the back, and he will gladly grind any grains for you. He also has a JS MaltMill for customer use. Open bins of grain strike me as a terrible idea as they will absorb water from the air.

Other options are Fermentation Settlement on Deanza Blvd in San Jose, and another shop whose name escapes me on N4th in San Jose

Subject: Recommendations

I am a new homebrewer, having just bottled my first batch, and I have a couple of questions regarding my efforts. After taking my last Specific Gravity reading, I drank the beer that I had drawn for the reading. It tasted surprisingly mellow for the smell but overall I was very happy with it. My first question is: Will the taste come out more strongly when the bottles have carbonated? (I know I should just wait and find out first hand but I am an impatient first-timer) My second question is specifically about my next batch. Last weekend I was in Santa Cruz and visited the Seabright Brewery where I drank an excellent ale with a very strong, hoppy taste to it. I would like to make my next batch have more of a hopped finish as this first batch did not. Can anyone recommend an ale extract recipe that will give a strong hopped finish? Thanks and I've appreciated all of the discussion that goes on here. It's very inspiring to someone new to the craft.

Subject: Malt Liquor, Scotland brewpub, & washing old bottles

In the United States, the definition of Malt Liquor varies from state to state and is based on alcohol content. Generally high alcohol content beers are labelled as malt liquors. Texas has several "Malt Liquors" which are not considered high enough alcohol content to be labelled as such in other states.

I have been to one brewpub in Scotland -- the Rose Street Brewery in downtown Edinburgh. I highly recommend it.

To wash bottles, I simply soak them in a mixture of water, bleach, and TSP (trisodium phosphate -- available anywhere painting supplies are sold). I use 1 oz. of bleach/gallon water and follow the recommendations on the back of the box of TSP for heavy cleaning. I haven't cleaned anything that had been sitting around for years, but I have cleaned some moldy, smelly bottles simply by soaking them in this solution for a day or so (it also does a great job at removing labels), and rinsing them on the bottle washer attached to my kitchen faucet. I've cleaned 6 or 7 cases of bottles using this method and have never had to use a bottle brush.

From: John Mare <cjohnm@ccit.arizona.edu>
Subject: RE: The Celtic Lands and their ales

Bill asks about breweries and brewpubs worth visiting in Scotland, Ireland and Wales. Ireland was in my experience a barren land with no variety available in comparison with Scotland. Drink their fine stouts (Beamish, Murpheys, Guinness) and get out of there! Wales I don't really know, but Scotland holds a few precious gems. The "real ale" revolution is in full swing and all the better pubs in Edinburgh and Glasgow carry guest real ales from Scotland and England. Because of this brewpubs as we know them are rare. We only have them because real live cask (as opposed to keg) ale is impossible to find! Pubs I would highly recommend in Edinburgh (where I used to live) are Leslie's, The Malt Shovel, The Navaar (Tuesday nights especially), The Sportsmen's, and the Guildford Arms. A special treat in Edinburgh is a visit to the Caledonian Brewery, described by Michel Jackson as "a living brewery museum". Call ahead and arrange a brewery tour of this delightful gem, and enjoy the outstanding ales. My favourite is Deucher's IPA! The McEwan's Fountain Brewery is worth avoiding! They make outstanding ales, charge a hefty fee for the tour, and then show you how computers make fine beer!

If you have a car available, a drive into the countryside to Peebles will take you to the beautiful Traquair House microbrewery (supposedly the oldest house in Scotland, Bonny Prince Charlie slept there!). Another drive of about 40 miles east along the river will take you to the Belhaven brewery also well worth visiting.

Glasgow has some excellent pubs in the University area. My favourite is The Brewery Tap on Sauchiehall Street, but there are several in the area.

Use the buses wherever possible for your own safety!

One final note. If you are heading west from Glasgow to Oban and the islands by train, you will pass through a little defunct station about 20 minutes before reaching Oban. Hop off and take the next train through because the station itself is a delightful little brewpub (West Highland Brewers), and it will be well worth your while to stop and meet the proprietor, brewer, barman (all one person), and spend about three hours chatting with the locals! The ales are good, the porter abominable (but probably a bad batch!). Upon arrival in Oban you will find a number of so-so

pubs, my favourite the Oban Inn, more for its ambience than for the beer (it is a McEwans tied house). Enjoy, I envy you!

Subject: Malt liquor/Horizons/CO2 dsgrmnt/keg gaskets/Cooler mash/beginner book

Richard writes:
>Subject: What is Malt Liquor?

Malt Liquor is a name dreamed up by some neo-prohibitionist lawmaker to allegedly warn unsuspecting beer drinkers that a particular beer has an alcohol level above a certain number the lawmaker made up. It has no real meaning to brewers or homebrewers because as we know, beers should be classified by style and not by alcohol level. Some states require "Malt Liquor" others don't. There are even stupider misuses of names (such as the misuse of the word "ale" in Texas), but despite the fact that in some states Mickey's and Salvator both have "Malt Liquor" on the label, they are no more related in flavor than milk and orange juice.

Eugene writes:

>I am an extract brewer with about 10 batches under my belt. Mainly because

The

You should try adding crystal malts and dark grains to your beers. There are a lot of extract+specialty grain recipes in Charlie's book and in the Cat's Meow, available from the archives.

John Franscisco and I seem to have differing experiences with kegging and overcarbonation. You'll all be happy to read that we will be working out our differences off-line and one of us will post the resolution.

On the subject of whether or not to replace all your gaskets on a used soda keg or not, I would like to mention that there's a chance that the keg you got has not had that much use on it's gaskets (i.e. they were replaced not too long before you got it). Also, everyone's senses are different -- perhaps you are not as sensitive to the soda flavors as I am. Also, a stout is less likely to gain an off-flavor/aroma than a cream ale.

There was a disagreement a year or two ago on the HBD in which one poster insisted that NO gaskets needed replacing and that the flavor and aroma of the beer would not be affected. They went as far as sending counter-pressure filled bottles from their keg to me as well as a couple of other HBD subscribers. The person insisted that they could not detect any soda flavors in the beer they sent me. I took the beer to a Chicago Beer Society meeting and had it judged as a light ale by a handful of high-ranking BJCP-certified judges, who were not warned of the situation. Without any discussion, all noted an unusual flavor. Three of the judges, identified the off-flavor as "a mixture of soda-pop flavors," one even writing "change the gaskets on your keg."

Eric writes:

>COOLER MASHING

>I've been having some trouble reaching my desired mash temp of 154F by

>tried using a ratio of 1/1 and adjusting with boiling water. When this
>didn't work I drew off a fraction of the liquid, boiled and returned to
the

>mash. I used this method on a porter that came out highly phenolic. I

Polyphenols are indeed what's leached from husk material and then usually
thrown into the general category called "tannins." Smoked malt, wheat
malt

and old, poorly-stored malt often lend phenolic flavors to beer.

A suggestion as to why you cannot reach the proper temperature is that
too

much of your strike water is used in heating up your mash tun. Pre-heat
the mash tun and I'll bet you'll hit your 154F. I don't suggest using
boiling water to do this as it could warp the plastic of the cooler --
perhaps use 160F water, maybe while you are crushing your malt. I've
seen

some pretty distorted cooler interiors -- be careful.

PAUL writes:

>I would like to know the best book for a beginning brewer. Thank-you!

I suggest Charlie Papazian's "The Complete Joy of Homebrewing" as a good
first book. Avoid, at all cost, any book or pamphlet by Leigh P. Beadle.
Also, older books (since there have been many recent refinements in
technique

and supplies) and books from the UK (since there is a bit of a language
difference as well as references to many supplies that are not readily
available in the US) don't make good *FIRST* books. A lot can be learned
from them, but it's best left for later.

From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)
Subject: Slow sparge problems

I've recently joined the exciting world of all-grain brewing. My two full mashes have been successful, but I've been frustrated by the how slow my sparging has been. Here is my set-up: 5 gal Gott water cooler as mash/lauter tun, Phil's phalse bottom, and Phil's Mill. Both batches have used 9 or 10 lbs of grain (mostly British pale ale malt), with mash at 1 or 1.25 quarts/lb. I've been sparging with 5 gals of 170 F water while keeping the water level above the grain bed (I skip the mash-out). Both of my sparges have taken 2 hours with the valve on the cooler full open. I would like to get this down to about an hour.

Any suggestions? Perhaps I'm crushing the grain too fine-- I've been adjusting the crush to the point where all of the grains are at least partially crushed. I've been getting about 31 ppg.

Is the depth of a 10 lb grain bed in a 5 gallon cooler too large for a more rapid sparge? I don't think this is the problem, as I believe others on the digest have rapid sparges with the same set-up.

Thanks for any help.

As the Morris article in Zymurgy states, pumps are available from W.W.
Grainger and McMaster-Carr. Sorry to not have the addresses or phones
with me, but my catalogs are at home and I do news from work.

McMaster-Carr is in Santa Fe Springs, CA., call information for phone
number.

Grainger is harder. There is no central place for which you can call
and request a catalog. Catalogs come from your local office. How do
you get the number of the local office? First, look in the phone
book. If they are not listed, Email me and I will look it up in the
catalog. Give me the nearest major city to your location.

Get a jet wash. They work great, and after a good soak they can really
get
the gunk out of your bottles. It's a little brass device that hooks up
to a faucet and sprays out a high pressure stream. I can't imagine
cleaning
bottles without one.

From: Dave Smucker <TWF99@ISUVAX.IASTATE.EDU>
Subject: KEG FERMENTERS PART 1

Recently, Dmitry Vosky, ask, via email how I used Stainless Steel kegs as a fermenter. He thought my reply would be of interest to some of you on the net so here is what works for me:

I use the 1/2 barrel (15.5 gallon) Sanke type keg for a fermenter. I had the good fortune to purchase some used kegs from a used restaurant supply company. They got the kegs in some used beer coolers and were willing to sell them for \$ 20 each. I know this is more than the \$ 15 deposit that is typical but at least I have a bill of sale. In the end this may give me no legal protection from Bud or Miller but at least I have some paper.

To use this type of keg you must remove the valve and down tube assembly. THIS CAN BE VERY DANGEROUS SO PROCEED WITH GREAT CARE. IF YOU DO THIS YOU DO SO AT YOUR OWN RISK.

The danger is that the keg very likely contains pressure and even a small amount of pressure can cause you serious injury from the valve part flying out and into your face.

THE KEY IS TO MAKE VERY SURE ALL OF THE PRESSURE IS RELEASED. The way I do this is to use a large screwdriver to push down on the ball in the center of the valve assembly. When you do this you may get covered with old beer! To prevent this I wrap the screwdriver in a towel as I press down on the ball check valve.

Make damn sure you have all of the PRESSURE OUT OF THE KEG BY DOING THIS RELEASE THING SEVERAL TIMES.

If you don't detect any pressure you are doing something wrong. I have never seen a keg that doesn't have at least a little pressure and sometimes it is quite high.

Now to remove the valve and down tube you need some other tools. I use an ice pick, a small screwdriver and some needle nose pliers. What you have to do is pick the end of the spiral type snap ring and then grip it with the pliers. Once you have the end of it and pull it towards the center and up and it should come right out.

Now make sure one more time THAT YOU HAVE RELEASED ALL OF THE PRESSURE. It is now very likely that you will have to rotate the valve assembly so that its key lines up with the notch in the keg, (this is a female keyway in the rim of the keg's exit port.) To rotate the valve assembly you may need to tap it lightly with a screwdriver.

Now that you have this lined up you can lift the valve assembly out, you may need to pry it a little with your screwdriver to get it started. KEEP YOUR FACE OUT OF THE LINE OF FIRE AS YOU DO THIS.

IF YOU DON'T UNDERSTAND THE ABOVE DON'T TAKE ON A SANKE KEG. FIND SOMEONE THAT DOES!!

Subject: KEG FERMENTERS PART 2

Assuming you have read and followed part 1 of this post or already have a 15.5 gallon Sanke keg here is how I use them as a fermenter.

First you need to clean it and you will need to clean it after each fermentation use. Here it helps to be able to see inside of the keg. To do this I use a auto turn signal/parking light bulb. I soldered a set of leads to the bulb and I have a small 12 volt power supply. I think a 9 volt supply would work also, the bulb will just not be as bright. Lowering this inspection light into you kegs lets you see how clean you have gotten them. To see the inside of the top of the keg I use a small inspection mirror. You should be able to purchase one for a few dollars at a auto supply store. They are bigger than what the dentist uses but fit easily into the keg.

I used to use brushes etc. to get the keg clean but I have now gone to 100 % chemical cleaning. I use B - BRITE. Just added it to the keg, fill with water and put a # 11 stopper in the bung hole and invert it and let it sit for 24 hours. I invert it because the part that is hard to clean is the inside of the top. I then rinse several times and use iodophor sanitizer. I use only about 2 gallons of sanitizer but roll the keg around for about 4 or 5 minutes. I then rinse with about 2 gallons of very hot, (boiling) water because it is next to impossible to drain the last few drops out of the keg.

You now have clean kegs. I now use them just like they were a giant 15 1/2 carboy. Use a # 11 stopper with a hole for you blow off tube. I use a stopper with a 1/2 inch short copper tube in the stopper and 1/2 ID plastic tube for the blow off. I put this in a 1 gallon jug with about 1 qt. of water in it to act as an air lock. I set this jug on a small board set on the top rim of the keg.

Now for the only real problem with using a keg. They weigh a lot when full! About 150 pounds. This is not a problem for sliding or rolling around a concert floor but it is very difficult to lift the keg on to a stand or table for racking to another keg or to your 5 gallon cornelius kegs for storage or lagering. I solve this problem in my case by using a hoist to lift the full keg and then move a stand under it. Since I brew in my work shop I have some hoist points set up on my ceiling beams. For a hoist I use a 3/4 ton comealong, but many other hoists would also work.

I am currently looking for the right size used chest type freezer that I could mount on wheels, slide under my hoisted keg. I would then lower the keg and use the freezer for temperature control.

I hope this answers some of questions keg fermenters. Let me know if you have any questions.

Subject: Hops FAQ?

I would like to submit a request for a hops FAQ, in the style of the yeast FAQ. My reason for this goes back to recipe formulation. I have had a pretty cavalier attitude about recipe formulation in the past but I have to admit, the two best beers I've made were attempts at copying a certain beer, armed with OG's, maybe some malt info, and the variety of hops used. I could make some guesses as to the IBU's etc., and hit it pretty well with Rager's formulae.

The problem comes along when ingredients aren't available, and substitutes must be made. For me, the most obvious flavor component of a beer is the hop profile (due, in large part to the hop-head slant I put in my brews). So, the type of thing I'd like to see:

Cascade - grown in GNW USA. Has a flowery, grapefruit profile. Most often used as a finishing hop. Classic American Pale Ale hop (reference SNPA, Liberty Ale) Alpha acid range 4.5 - 5.5. Good substitute = XXX hop.

It could go into much more detail but this is the type of thing I would hope for. This could go a long way toward giving people the confidence to create more varieties in their homebrewing. Of course, I would expect IBU calculations to be part of the FAQ. I'm sure there are other things that could be added; I just can't come up with them now.

Any takers? Does the hops special edition (which I still don't have) contain all this information? Even if so, I would guess we could do a better job. I would be willing to help out on this project but I don't have the experience of some of the other HBD contributors. I also don't know my way around Internet so archiving should be left to someone else as well.

>fermenters, 6.5 gallon >vice 5 gallon. I was wondering when
>light struck beer begins to be a problem.

Al replies:

> You should keep the fermenter in the dark too -- your beer can
> be light-struck while in the fermenter.

I had my wife buy some quilted material and sew it into a cylinder
a little larger than my carboys, and about four inches taller. The
top seam was sewn over to allow insertion of parachute cord for a
drawstring. This not only protects the fermenting wort from light,
it also helps even out temperature fluctuations caused by my setback
thermostat.

Subject: Yeast FAQ is at sierra!

Hi All,

Just want to spread the word that a plain text version of the updated FAQ is now at sierra.stanford.edu/pub/homebrew/docs/Yeast.faq.Z. To all novices, note that this is a **binary** file, so type "bin" on the line before you type "get" :-) ! And .Z is for unix compress, not zip.

A postscript version is being prepared, with a few added embellishments.

Thanks to all who sent support and/or information!

Hope you find it useful.

Subject: Madden's #1 -- A Famous Prohibition Beer?

I'm wondering if anybody out there knows anything about a "famous" beer during prohibition called Madden's (sp?) #1.

I hear that a Homebrewer turned "pro" during Prohibition and marketed this beer. It appeared darker than modern commercial beer and was supposed to be popular on the East Coast. Can anybody tell me anything about this beer. A recipe would be really nice..

Thanks.

From: Ken Miller <KCMILLER%SJSUVM1.BITNET@cmsa.Berkeley.EDU>
Subject: Heather beer

As Bill Ridgely pointed out, Bickerdyke does indeed include a brief section on heather beer in The Curiosities of Ale and Beer (1889). Selections below:

<begin quoted text>

There is a tradition lingering in the northern parts of this island, that the Picts possessed the secret of making an ale from heather. Sir David Smith...mentions a large trough cut in solid rock at Kutchester, near the Roman wall. "The old peasants," he says, "have a tradition that the Romans made a beverage somewhat like beer, of the bells of heather, and that this trough was used in the process of making it."

<interesting but somewhat lengthy legend concerning Pictish heather beer deleted>

True or false, this is the legend as related in the north, and certain it is that a heather beer was made until quite recently in some parts of Scotland and Ireland. The heather, however, is used as a flavoring rather than as the actual basis for making the drink. The blossoms of the heather are carefully gathered and cleansed, and are then placed in the bottom of vessels; wort of the ordinary kind is allowed to drain through the blossoms, and gains in its passage a peculiar and agreeable flavour, which is well known to all who are familiar with heather honey.

Pennant, in his Voyage to the Hebrides, mentions heather ale, and says that the proportions were two-thirds of the plant to one of hops (hops being sometimes added); and Mr. Weld, in his Two Months in the Highlands, says that "although the art of brewing Pictish ale is lost, old grouse shooters have tasted a beverage prepared by shepherds, on the moors, principally from heather flowers, though honey or sugar, to produce fermentation, was added. In some parts of Ireland there is a tradition that the Danes possessed the knowledge of making an intoxicating liquor from heather bells....It is possible that there is some connection between this heather ale and the ale formerly made by the Swedes and flavoured with the Myrica gale....In Yorkshire...a beer is still made called "gale beer," and is flavoured with the blossoms of a species of heather found growing on the moors in that part of the country.

<end quoted text>

There you have it. Recipes for Pictish heather beer died with the last of the Pictish brewers, but late 19th century Celts apparently used heather as a flavoring for both beer and mead. The second paragraph above seems to imply using the heather blossoms in a manner similar to aroma hops (i.e., brief contact with the hot wort); but the last sentence above is open almost any interpretation. (BTW, can any botanists out there tell us the common name for Myrica gale?)

Anyway, have a happy, hoppy, and (perhaps) heathery brewing...

<Subject: My first all grain batch - a screw up.

> Mashed 6lbs highly modified pale malt and 8 oz crystal with 6 quarts
of
168F water for 1 hour.

Life is much easier if you use more water, like double that amount.

> Did the iodine test. The color was blackish but it turned to
clear when I stirred it up a bit.

If it cleared upon stirring, you were cheating and just spreading it
around.

>When sparging with 3 gallons of 170F water, I had a very
difficult time of not disturbing the grain bed.

Place a small bowl on top of the grain to disburse the water.

> Here's my question... how important is it that the grain
bed is kept relatively undisturbed while sparging?

Absolutely essential for the grain near the strainer. If the bed is
disturbed, it can not function as a filter.

> Also, will the liquid turn colorless near the end of the sparge.

Only if the filter bed is undisturbed.

> Could it be that my cooler is too large, ie the grain bed
is not deep enough?

You didn't tell us enough to determine either of the above but in my
experience the answer is no. With my equipment and process I get the
same
yields with one inch in a mini easymasher as I get on 10 gallon batches.
My
yields are consistantly over 30 and I am using the same equipment I used
on
my first batch with a yield in the low 20's. Technique has a lot more
to do
with yield than equipment.

>Subject: Re: Yeast FAQ Ruckus

>Well, I feel that since my post was the cause of all the wasted
bandwidth
(either for the FAQ itself if you agree with JS or for the flame-
fanning in
response if you don't), that I should speak my piece. To JS's credit...
.

Thanks for the credit but if you are going to personalize comments,
please

get the facts straight. You have fallen into the same trap as the rest of the gang that flamed my suggestions.

NOWHERE did I criticise "the FAQ itself" or any other FAQ or FAQ's in general. They are a great contribution to the database and those who create them and contribute to them deserve much credit.

I simply made a proposal that non-time critical articles be limited to 200 lines per day to make sure that those that are time critical do not get swamped.

I also suggested that once the FAQ is proposed and interested parties identified, it should be debugged as much as possible by email.

Both of these suggestions got lost in the public discussion because it is so much fun to flame that even when none is apparent, some excuse will be found.

> Finally, as for the results of his 10 to 1 poll, I would suggest that irritated people are 10 times more likely to respond than those who are satisfied.....

But that wasn't the point. I don't know of anyone who was irritated by the FAQ. The 10 to 1 mail was simply people agreeing with my two suggestions. Furthermore, the public comments went the other way as most of them criticized me (not my suggestions) just me.

>From: "Bill Kitch" <kitchwa@bongo.cc.utexas.edu>
>Subject: All-grain questions

> 2) Sparging questions:
a) How much recirculation. "Recirculate until runoff is clear". Sounds great in print. However, for amber or darker beers this is not as obvious as it sounds. In last batch I recirculated the first 5 qts. Is this excessive?

It depends on you mash tun. If you have a false bottom, you must at least drain away all the liquid under it and this could be gallons. With an easymasher, it's a cup or two. Your first runoff will of course be much darker than the finished beer but in a proper tun, it will run nearly as clear. I think the key word is "recirculate" and it is a bad word. It sounds like it is part of the process to clear the wort. What you are really doing is rejecting the turbid wort but instead of throwing it away you pour it back in.

> b) When to stop sparging. "Don't over sparge". I like this about as much as "cook until done"....

This one is a well spring of expert opinion and words like tanins, pH, tea, sweet .008 lurk like evil spirits ready to destroy your prize winning beer.

The bottom line is the point of deminishing returns. It become economically impracticle to boil down a gallon of wort much below 1.010 to add its contribution to to the batch. So all those other things, be damned, it is a waste of time and money to use watery wort unless you need it to lower the gravity or increase the boil time. It is also a waste of raw material to throw away runoff over 1.010.

If you planned things properly, you should have enough wort by the time you get that low. If you need a little more, the evil stuff in it will be so diluted that it won't affect the beer anyway. If it tastes ok but is not sweet, what harm can it do? If it makes you mouth pucker (most unlikely), you probably don't want to put much in your beer.

> 3) Seperating break material & spent hops from wort. When I syphon my cooled wort from the boiler into the fermenter, my syphon tube clogs leaving 1/2 to 1 gallon of wort/trub in the boiler. I usually pore the last of this glog into mason jars, allow the trub to settle and decant the wort for use as starters. One quart of glog doen't bother me but for my last triple I was left with nearly a gallon.

You can throw it away or let it settle as you did. That is just good tecnique. If you don't need it for starter, just bring it to a boil to sterilize it and add it to the fermenting beer and nothing is lost.

> (I know, Jack, I should drill a hole in the bottom of my boiler and install a SS screen w/tubing etc. I'm seriously considering this but would like to hear other alternatives.)

Instead of you plastic siphon, get a piece of copper tubing of the same diameter, and bend it into an "L" at the bottom. Put the tubular screen over the end and attach your siphon hose to the top and you have a portable easymasher... no hole.. no hassle but you still have to suck on the end.

>From: Jim Busch <busch@daacdev1.stx.com>
>Subject: lager time & hot liquor tanks/O2

>I guess the question is :how long does your *fermentation* take? ie, how long until the SG has dropped by 75%? No doubt that some continual activity/lagering will occur but when everything is done perfectly, a lager ferment in between 7-10 days.

I don't see how that statement can be made without specifying the temperature.

>From: korz@iepubj.att.com
>Subject: Addtn to kegging FAQ

>Al Richer did a good job summarizing the basics of kegging. I would like to add a bit more info. In addition to the big o-ring and the two under the dip tubes, there are also o-rings on the poppets

And now for the other side of the story. I have four 5 gallon kegs and two 10 gallon ones. I have never replaced a single "o" ring in any of them.

Admittedly, the ones with Coke in them smelled pretty bad for awhile and I even had the first batch in one come out with a detectable Coke taste but that was long ago and never happened since. I just soaked the lid rings in bleach for a few days. The ones with lemon/lime stuff lose all odor with a simple rinse.

It's good to know the parts are available but like so many things, if it aint broken, don't fix it.

>The ones sold by Sheaf & Vine have a range of 40F to 80F. I think that this range should be made a bit lower for lagers and a bit higher for ales.

Nifty gadget but I destroyed mine removing it. My problem is I ferment in the same kettles I mash and boil in so they must be removed between uses and these things can take that sort of abuse.

From: CCAMDEN@delphi.com
Subject: Cake mixes, and other half-baked ideas

I have several questions/comments and I will get right to them.

The first is a "cake mix" question. I recently received a catalog from The Home Brewery. They have a liquid malt extract that they call Yellow Dog(tm). It is 87% 2-row Klages, 12% malted wheat and 1% chocolate malt. I find myself intrigued by this product. Has anyone in HBD-land ever used Yellow Dog and if so, what are your comments?

On to another topic. All my reading of the HBD has made me think about doing a, if not all-grain batch, then at least a partial grain batch. My question is, if I have a recipe that calls for, oh, say 5 lbs of DME, and I want to try substituting 3 lbs of grain, how much DME should I then use. Now, I realize that some will say "why not go all-grain?", but I just don't have the equipment (brewpot). I can throw together a few things to experiment with small amounts of grain, but I will still need to use DME. (OK, let's see; will now I be a "cake-mix-brewer" who only uses part of the cake-mix and adds his own flour??)

No question this time, just a comment. My wife and I just got back from living in Nuernberg (umlaut-less German spelling), Germany for 3 years. I didn't brew there, there wasn't a need to; here in Huntsville, AL there is a great need. One of our favorite places to go was Cheimsee (large alpine lake about 40 miles east of Munich). Just south of Ingolstadt, we would enter a large hops growing region. We got into the habit of stopping at the same autobahn rest-stop through the summer and walking to a nearby hops field (?), where we would shoot some video. We got some great footage of the hops as they grew all summer long. So, what's the point of all this? A check of the map tells me that this was smack-dab-in-the-middle of the Hallertau region. It was a neat experience then, and learning more about these hops now, makes the memories even better.

Email replies to my questions are encouraged, unless you think that everyone would be interested in the brewing characteristics of Yellow Dog amber malt extract.

Subject: Fermentation Frenzy

Hi

This is directed to Ken Johnson who was not happy with our store. You mentioned that we do not have open bins of grains. Well you are correct.

The main reason for this is that open bins are one of the best ways to invite

a pest contamination (especially during the summer months). Having worked

as a food microbiologist and plant inspector for 5 years I know that an open

bin of a food product is not wise. If you would like a specific amount that

is not already on the shelves just ask and we will be happy to get it for you.

As for our hop selection we carry just about every hop type grown.

Sometimes

towards the end of the hop season (just before the next years hops are picked) certain hop varieties are of poor quality and we don't buy them and

resell poor quality hops. But if you really want a particular variety regardless of quality will order it for you.

I am sorry you were not impressed with our shop as we are here for our customers and what to make you impressed

Take Care and I hope you will give us another try,

Donna Lynn

Subject: FAQ's Politics and Protocols

At the risk of rendering horse flesh into micro-burger I would like to submit the following:

When someone goes to the trouble of assembling, sometimes with painstaking detail, the answers to many of the most FAQ's in a given subject, they might be best served, prior to posting their compilation on our HBD, by querying the HBD "population" as to their propriety in posting their data. In this way, the anticipation of the receipt of the "education" might whet the appetites of the "cogniscenti", and therefore silence the erstwhile loose cannons, disparagers or flame-throwers, as the case might be.

It is amazing, when someone goes to the trouble to compile massive amounts of information to distribute to the "masses", that certain of those masses, you know who you are, act as iconoclasts, ad nauseum, without even ctitiqueing the post. Bandwidth, bandwidth, bandwidth. What's the big deal? OUR TAXES PAY (gentle thanks to HP) FOR THE BANDWIDTH! Lighten up! Isn't education worth the BANDWIDTH?

I will not offer up any quasi-pardoning postures for using THE BANDWIDTH to make this statement, but hope that all of those diligent, hardworking & concientious people keep on making their posts re: FAQ's.

-blazo

From: tony@spss.com (Tony Babinec 312 329-3570)
Subject: sweet gale synonyms/request for collaboration

Here is the little I know about sweet gale.

First, the following terms are synonymous:

myrica gale
sweet gale
bog myrtle
moor myrtle

I have looked at a number of herb/wildflower catalogs, and one in particular carried a number of myrtles, but none with the above names. One myrtle, the name of which I don't recall now, was described as having seeds that produce an anise-like flavor.

Spencer Thomas kindly sent to me an old hbd posting from James Spence that mentioned a source:

old post excerpt begins here
Desjardins Herboriste
3303 Ste. Catherine St. E.
Montreal, Quebec H1W2C5
telephone: (514)-523-4860

Pierre (Rajotte) says 250 gms is \$3.56 plus shipping.
old post ends here

I phoned Desjardins Herboriste, and they were unwilling to ship outside of Canada.

Now, what I am hoping for is that some Canadian reader of this post will order the sweet gale and send it to me. Any takers? Please e-mail privately. Thanks.

From: "Rafael Busto" <SUPERVISOR@bnk1.bnkst.edu>

Subject: Strange overcarbonation

I just wanted to report something that has ruined my last three batches (2 ales and 1 lager) Everything looks fine during the whole process untill you open the first bottle after 2 weeks of bottleing. As soon as you open it a very thick foam starts to grow on the bottle itself. In a second look you can tell that this foam is created from a lot of bubbles that come from the yeast sediment.

When you pour it to the glass the foam keeps growing and stays for few minutes untill it becomes liquid.

The flavor of the beer is cidery.

Any clue?

I tried to make my beer as clean as I can. The only things I can think are:

- I need a new hose (it has been used over 7 batches)
- The fermentation was not totally completed (but 3 times in a row?)

Please let me know of similar experiences or solutions.

Thanks a lot

>rapid sparge?

No, this is not the problem, I've used 10+ pounds of grain in a 5 gallon lauter tun many times, the runoff came out as fast as I allowed it. On one occasion, I was brewing a weizen using 10 pounds of grain, half of which was wheat malt. I got distracted by something on the radio, bumped the spigot on my lauter tun to a wide open position without noticing. I had just started sparging, there was just over a gallon of wort in the boiler. When I did notice a couple of minutes later, there was over 3 gallons in the boiler, and the runoff was still flowing strong. Despite the high percentage of wheat and the extremely fast runoff rate, the sparge still did not stick. The geometry of your tun is not the problem.

Another thought, there was a thread on HBD last year from someone using a Phil's phalse bottom who was also getting slow sparges. If memory serves, (always a dangerous assumption :-)), there was something about a hose kinking and trapping air. I've never seen this device, maybe someone who has used one can comment.

I also have a question. A friend of mine who loves to tinker with gadgets built a RIMS system recently, and has run a couple of pilot brews through it. He carefully plotted the time/temperature curve while stepping from protein rest to sugar rest temperatures, it takes about 30 minutes to step up roughly 32 degrees, from 122F to 154F. The problem is that as soon as the sugar rest is achieved, the mash is already converted!

Our concern is the length of time spent in the 140F-150F range, and it's impact on the dextrin pool. I'm a BJCP judge, a taste test on both brews confirmed our fears, they were both very thin bodied, bordering on watery. Yesterday, through the judicious use of insulation, we managed to cut this time from 30 minutes to just over 15, without changing the heating element or slowing the recirculation rate.

My question: is there an optimal rate of stepping from protein rest to sugar rest temperatures? 2F per minute or some such? I can't find this information in my brewing library anywhere.

Cheers,
Jim

One gotcha to watch out for with Phil's False Bottom is the weight of the
grain
bed crushing the outlet tube. This is especially true if you are using
the
clear vinyl type tubing, because it becomes very soft at sparge water
temperatures. If this is indeed the case, try switching to the opaque
type
tubing. It is much stiffer even at boiling temperatures.

FYI, I use the PFB in a 10 gal Gott cooler with an opaque vinyl outlet
tube and
I can complete a sparge in well under thirty minutes if I so choose.

Subject: Freezers

I've read a number of posts mentioning a chest freezer used for fermentation and lagering. Is there an advantage to this type of freezer over an upright freezer, or refrigerator?

I have several soda kegs I plan to ferment in. Will I be able to fit more in a large chest freezer vs. upright?

Thanks in advance for any info,

John Marra

Subject: Fermentation Frenzy

Hi

This is directed to Ken Johnson who was not happy with our store. You mentioned that we do not have open bins of grains. Well you are correct.

The main reason for this is that open bins are one of the best ways to invite

a pest contamination (especially during the summer months). Having worked

as a food microbiologist and plant inspector for 5 years I know that an open

bin of a food product is not wise. If you would like a specific amount that

is not already on the shelves just ask and we will be happy to get it for you.

As for our hop selection we carry just about every hop type grown.

Sometimes

towards the end of the hop season (just before the next years hops are picked) certain hop varieties are of poor quality and we don't buy them and

resell poor quality hops. But if you really want a particular variety regardless of quality will order it for you.

I am sorry you were not impressed with our shop as we are here for our customers and what to make you impressed

Take Care and I hope you will give us another try,

Donna Lynn

Subject: Tarnished Wort Chiller

I made an immersion wort chiller (17 ft. of 1/4 in. copper tubing).
The wort chiller was used for the first time about a month ago.
In that time the tubing had become tarnished.

I used the wort chiller for a batch that was made this weekend.
I put the chiller in the wort during the last 15 minutes of
the boil to ensure sanitization of the chiller. Cold water was
then passed through the wort chiller for it to cool the wort.

Afterwards, I noticed that the wort chiller was only tarnished in
the places that were not immersed in the wort.

QUESTIONS:

- 1) Did the de-tarnishing that took place affect the wort?
Will it noticeably affect the flavor of the beer?
- 2) Should I de-tarnish the wort chiller prior to its next use?
- 3) How does one go about de-tarnishing a copper wort chiller?

Thanks in advance for your responses.

Subject: More Mead Questions

Subject: Time:11:13 AM
OFFICE MEMOMore Mead QuestionsDate:9/13/93
I have a few questions to add to Jim's mead questions in #1222.

I've brewed a gingered honey mead and am hoping for some suggestions on what/when to add some additional ingredients. The recipe I used (Papazian's) calls for fresh fruit to be added at the end of the boil. I have a cherry extract for winemaking that I want to use. Should I add this during fermentation or at bottling?

I would also like to add some spices to the mead when I bottle. I had planned to make a tea and add to part of the batch while bottling so I could split the batch. My question is, what spices work well (with or without the cherry) and how strong a tea should I try? Yeah, I know it's all personal taste and the amounts always vary depending on potency, process, etc., but a ballpark would be appreciated from those who already have a little (or more) experience with this.

Thanks. Tristan

From: Lee=A.=Menegoni@nectech.com
Subject: Decoction: The Thinnest 1/3

The recent discussion on wort clarity due to starch problems from too hot a sparge has caused me to revisit getting to mashout with a decoction mash.

In previous brews I would remove the thinnest 40% or so. Though quite thin it would contain a significant fraction of grain. I would boil this and add it to the mash vessel and let it mash out at 170-175 for 15 minutes. These beers would never get crystal clear. I suspect that I gelatinized some starch in the final decoction that did not get converted while the enzymes were getting deactivated in the mashout.

In future brews I will ensure that there is NO GRAIN in the final decoction even if I have add water to get the correct volume of water.

RE: Light Struck beer in fermentor. I cover my 6.5 gallon carboys with a black plastic trash bag. I have a small slit in the top for the airlock to go thru.

Subject: Lautering

Salutations!

First, sorry 'bout the poor subject headding on my last post. I'm still getting used to this VAX os...

When I toured Summit Brewery in St. Paul I was told they lauter by recirculating the wort untill it is clear [transparent, i.e. no cloudyness] and what it sounds like most all grainers here is doing is to just run the water through once. Is it ok to recirculate the wort? I would think so as Summit won Gold for their Great Northern Porter...

Wait, a porter could stand the bitterness that might result from the possible transfer of tannins fromt he husks to the wort... Well, they also make a great Pale Ale... Any comments on this?

From: Ulick Stafford <ulick@bizet.helios.nd.edu>
Subject: Sparge and .Z

In 1224 Stave Zabarnick complains of slow sparges. Assuming a holey bottom the like of a Phil's can work OK (I hated my homemade holey bucket a la Miller), which I doubt, it helps with any sparging system to restrict the flow from the get go to a trickle. There is less to recirculate before run off is clear, and the lack of compaction of the bed allows the sparge to continue steadily. I never sparge longer than 45 minutes even for 75% wheat mashes with my copper manifold 7 gallon

Gott. Try restricting the flow next time ans see if it helps.

Patrick Weix of yeast.faq fame gives a very complicated method for ftping .Z files from stanford. When I get my copy of hbd each day (my mail subscription is still not fixed after a month - Oh well), I just type get 1224, and lo and behold it uncompresses 1224.Z prior to transfer saving me the need to set up bin or uncompress it in my own directory.

So I guess gettin yeast.faq from homebrew/docs could be as trouble free.

From: U-E68316-Scott Wisler <swisler@c0431.ae.ge.com>
Subject: Mash cooler discoloration & choreboys

This past weekend I wanted to brew 2 consecutive batches and was looking into how to compress the time involved. One of the most obvious ways is to be mashing the second batch while the first is boiling. The problem is that I mash and boil in the same pot, with my sparge water held in a styrofoam cooler. I have a plastic picnic cooler that I seriously thought of using but I didn't want permently mash colored. (Besides, my wife would throttle me) So the question to all you cooler mashers is : What color did your coolers end up?

Also, the choreboy seems to be working well for many people. I haven't found one yet, but I just got my counter-flow chiller working and used whole hops for the first time. Clog! (seems like a bad B movie senerio)

I was wondering how people attached the choreboy to the drain. I guess I'd just like to know if there was a way that DIDN'T work, so I can avoid clog problems.

Thanks,

Scott

From: nfarrell@ppco.com (Norman Farrell)
Subject: Posting

I recently made a batch of steam beer and found myself with a mas temp that I thought was 4 to 5 degrees F lower than I wanted. I did not want to add more water and dilute the enzyme concentration. I removed 2 quarts of the mash in a glass measuring cup and heated in the microwave for 7 minutes. This was long enough to reach boiling. I returned the "decoction" to the main mash stirred in and removed another 2 quarts and heated.

It took 3 "decoctions" to get the bulk temperature where I wanted. 7 minutes in the microwave was required to boil each time. The resulting beer was wonderful particularly full bodied/satisfying mouthfeel. It was better in this regard than other beers I have made with infusion or step mashing.

Was the amount and heating time I used sufficient to account for the good results? Has anyone else tried this? If it is more likely that everything in the process just came together to yield a great beer (ie. my decoctions were probably of little effect), how long would I have to heat (and what % of the mash) to do some good? BTW the brew length was 5 gal. and the OG was about 1.050. Thanks for any hints/opinions.

The Boston metro area now boasts four brewpubs. The original is the Commonwealth Brewery on Portland St. by the Boston Garden (bitter and barley wine best choices here imho, but everthing pretty dang good). The Boston Beer Works is on Brookline Ave. just across from Fenway park (IPA and Hercules strong recommended). The Cambridge Brewing Company is in Kendall Square, Cambridge (great pale ale and if you're lucky a sublime high octane version of the same, Big Man's Triple). Rounding out the list is John Harvard's on Dunster St.,. Harvard Square, Cambridge (good Stout esp. if on "Cask"). The Sam Adams Brewery tour is allways worth the trip to Jamaica Plain (a borough of Boston). While you are in J.P. stop at Doyles Cafe on Washington St., for more Sam Adams limited runs (Dunklewiezen, Cranberry "Lambic", etc.), a healthy selction of taps, and ancient Boston bar atmosphere. Other recommended watering holes: Cornwall's in Kenmore Sq., The Sunset G+T(71 Taps!) on Brighton Ave. in Brighton.

From: npyle@n33.stortek.com
Subject: Lautering / Discoloration

Gene asks about lautering wrt recirculation. He assumes most all-grainers just sparge without recirculation. It is my perception that most all-grainers do recirculate the wort. FWIW, I recirculate the wort until it runs relatively clear, but I don't go to a lot of trouble. I seem to recall Micah Millspaw advocating no recirculation at all; something about giving the proteins and other hot break material a nucleation point. Contrary to the popular beliefs, he claimed clearer beer than with recirculation. Anyone tasted Micah's beer?
Is Bob Jones still on the digest?

Scott asks about discoloring his wife's cooler with wort. I haven't really worried about it since I bought the cooler especially for brewing, but I haven't noticed any real discoloration problems. I suspect one batch wouldn't do it any harm, but I would be careful to keep the temperature below about 170F. Warping of the plastic would probably bug her more than the color.

Now that lager season is here on the front range in Colorado (yesterday was first snow!), I'm thinking again about a dopplebock. Anyone with a good all-grain DB recipe? Of course, if it was to taste like Salvator I wouldn't mind ;-).

Cheers,

From: tima@wv.MENTORG.COM (Tim Anderson)
Subject: Instant carbonation

I recently had an experience that I thought was worth sharing.

I made a pretty ordinary pale ale from DME and adjunct grains. The process was the same as all my batches. I pitched a large quantity (2 liters) of actively chugging starter (Wyeast London Ale) and aerated with wild abandon. But then I always do.

Fermentation started within a few hours, which, of course, had nothing to do with my method of aeration. After 9 days, the bubbling in the air lock was getting slow, and since I had a window of opportunity to bottle, and wouldn't again for at least another week, I went ahead and did it. I primed with corn sugar. I always prime with corn sugar. I'm proud of priming with corn sugar.

Now here's the good part. The beer was fully carbonated and fairly tasty in 2 days (!). My first reaction was, "Oh shit." I braced for glass grenades. But they never came. It's been 6 weeks since bottling, and the beer is just fine. Not over-carbonated, no gushers, no off flavors. Pretty boring stuff.

I am curious why what usually takes a couple of weeks would occur in 2 days without ill-effect. My hypothesis is that I caught the yeast at just the right moment when it was effectively done with the food at hand, was sitting back with its feet up, enjoying a good cigar and snifter of brandy, but had not yet gone dormant. What's this, dessert? Corn sugar, my favorite! If so, I suppose the timing was lucky and had I bottled just a bit sooner, my closet would look like a war zone.

By the way, this is a basement closet that maintains a constant 62F.

From: korz@iepubj.att.com
Subject: Klages or not to Klages

Well, I guess it's time to eat crow... the latest issue of Brewer's Digest (Aug `93) completely contradicts my previous assertion that Klages is no longer grown in the US. It apparently is being grown in 1993 along with 12 other varieties of malting barley. The seven 6-row varieties of malting barley being grown in the US in 1993 are: Azure, B1602, B2601, Excel, Morex, Robust and Russell. The six 2-row varieties are: B1202, Crest, Crystal, Harrington, Klages and Moravian III.

Klages appears to be grown in the following states this year: Washington, Oregon, California, Idaho, Montana, Wyoming and Colorado. From the map in the article, it appears that there is little overlap between barley strains grown in the Western States (those mentioned above) and the Midwestern States (N & S Dakota, Minnesota, Wisconsin and Michigan). Excel and Morex appear to be the only ones grown in both the W and MW. Strangely, there are no 2-row varieties grown in the MW this year!

Sorry about the misinformation. I had heard from various sources, for two years in a row now, that Klages was discontinued in 1990. Unless it has just rebounded in popularity, I was given incorrect info.

Al.

Subject: Homebrew Digest #1225

>From HBD 1225:

```
|| From: CCAMDEN@delphi.com ||  
|| Subject: Cake mixes, and other half-baked ideas||
```

```
|| The first is a "cake mix" question. I recently received a ||  
|| catalog from The Home Brewery. They have a liquid malt ||  
|| extract that they call Yellow Dog(tm). It is 87% 2-row ||  
|| Klages, 12% malted wheat and 1% chocolate malt. I find ||  
|| myself intrigued by this product. Has anyone in HBD-land ||  
|| ever used Yellow Dog and if so, what are your comments? ||
```

On GENie, we used Yellow Dog as the main ingredient in the extract version of two recipes we designed online, an ale and a porter. We made up an extract version and an all-grain version, and we used the Yellow Dog for the extract version because the Home Brewery listed the ingredients, so we knew the make up.

After we each brewed our own batches, we then swapped via UPS a few samples of our efforts, and compared them. The result? The Yellow Dog is just fine, everyone's beer was good, but in the end you get so much variation in technique that the "cake mix" you use is less important than how you brew it.

I thought the Yellow Dog was fine extract, and if I had to mail order I would consider it, but I now have two local homebrew stores, and I'd rather support them. I can add my own wheat and chocolate, and I often do!

From: donald oconnor <oconnor@ccwf.cc.utexas.edu>
Subject: oring challenge results

For nearly a year now I have avoided posting the results of the oring challenge even when it seemed appropriate such as the time George Fix referred to "O'Connor's oring beer." Quite honestly I didn't want to hear another damn word about orings.

The oring challenge was never what I said. I said that the beer had been in a used keg with a used oring. I further said the keg had once held either coke or Dr. Pepper or root beer. I asked them to tell me which. In reality, the beer had never been in a keg. I spiked each 12 ounce bottle with 9 ml of Diet Coke. That's an incredible 1.35 cans of diet coke per 5 gallon batch. I simply poured from bottle to bottle to make it look as if it came from a keg, sediment free. The beer was tasted by 5 certified judges and several others. NOT A SINGLE PERSON TASTED COKE. The reason I did this was to offer a concrete example that the threshold for coke was too high to believe an oring could soak up enough syrup to be the culprit.

However, the really remarkable results came from the group of 4 certified judges in Chicago. They not only did not taste coke, they IMAGINED TASTING "GRAPE or GINGER ALE" which they surmised came from the oring. They surmised the keg had once held grape or ginger ale.

So what did the oring challenge prove?

Were these judges incompetent? Far from it. Quite impressively, the judge in N. Carolina actually picked up a sweetness that was not like malt sweetness. Another judge in the Chicago area tasted 2 bottles a month or two apart and noticed a big difference because the beer was very oxidized by the time he drank the second. Two others, not judges, noticed the rather odd dark color of the spiked beer.

All I can say with absolute certainty is that

1. 5 certified judges and several others did not taste 1.35 cans of Diet Coke in 5 gallons of pale beer even when they were looking for it.

2. 4 certified judges did IMAGINE tasting grape or ginger ale from an old oring that never existed.

People can quibble around the edges, but these two facts are indisputable.

Before you run out to change the poppet valve, I would simply ask HOW DO YOU GET MORE THAN 1.35 CANS OF DIET COKE INTO THE POPPET VALVE ORING?

Finally, I agree with Al Korzonis that some people have more flavor sensitivity than others. I would only add that some people have more imagination than others. Both are essential to the full enjoyment of beer. The trick is to have some idea where one ends and the other begins.

Subject: Yeast Washing

martin@gamma.intel.com notes :

"I have on occasion washed some yeast. The question I have is how do you tell the difference from the trub and the yeast? The yeast is usually an off-white and the trub white, do I just not worry???"

I believe the trub is heaviest, and therefore on the bottom, as what is called, in chemistry, the "precipitate". As it contains a hodge-podge of materials, it is rarely of a pure color, and tends to be darker in shade.

The yeast - the living yeast cells, not the dead cells, which are amongst the rest of the "precipitated" materials on the bottom - are in suspension, and therefore rest in the layer above the precipitate.

The fluid medium in which they both exist provides the third, top layer, and it is clear, totally transparent, and usually only lightly tinted.

The trick to separating the three is in a two-fold approach.

- (1) Add sufficient fluid to allow the three to separate.
- (2) Adjust the geometry (shape) of the container to help expedite separating the layers - IE, use tall, thin containers to separate very small amounts.

It also helps to use something like a baster (large vacumm-bulb gadget used to suck up fluid under cooking meat and recirculate it over roasts, usually used only once or twice a year, but has many other uses ... ;-) with which to carefully remove specific layers, in order or not.

Steve,
Have you been "floating" the grain on several inches of sparge water
above the false bottom as Charlie P. recommends? I was having slow
sparges (but nowhere near 2 hours), but found that the combination
of first, filling the lauter tun with sparge water about two inches
above the level of the false bottom, and second, maintaining the
sparge water level above the grain level until the sparge is
finished, dramatically decreased sparge time.

Subject: thin part boiling in decoction

Hello all,

I've just been catching up on the last two hbds.

Lee in hbd 1225 mentioned that he boils the THINNEST third during his decoction mashes, and he attributes unclear beer to boiling some grains as well.

He goes on to suggest that boiling the grains gelatinised their starches, and hence led the haze

Well, yes and no!

The accepted "industrial" procedure for decoction involves taking out the THICKEST third (ie mostly grain), heating it to conversion temperatures and then to boiling, when, indeed, the starch gelatinises, the inner structure of the grains is disrupted, and generally the starch is made more accessible to enzymes.

This boiling mixture is then returned to the main mash.

Why is the thick part boiled? Firstly because of the changes it brings about in the grains that were boiled, and secondly because most of the (heat sensitive) enzymes have dissolved in the liquor (that is the thin bit), so that if the thin bit is taken out and boiled, the enzymes are destroyed and no conversion takes place. This then leads to low yields AND starch hazes!

Therefore, in conclusion, I'd say that Lee's unclear beer was caused by NOT BOILING ENOUGH GRAINS and BOILING TOO MUCH LIQUID.

Using the above procedure I've got excellent yields of clear and NOT astringent beer.

(There are other features of the decoction system that I won't go into, but in passing, by keeping the boiled part as thick as possible no tannins are extracted during the boil either.)

Rob. Thomas

From: dstotler@cygnus.PPPL.GOV (Daren Stotler)
Subject: Dormant Yeast / Stuck Fermentation

I'm trying to brew the Bock kit sold by the Home Brewery. This is my first attempt at brewing in my fridge/freezer; I guess I've more to learn. Here goes:

I had two liquid yeast starters fail (Yeast Labs Bavarian Lager) for unknown reasons; so I decided to brew with the dry yeast (14 gm) that came with the kit. It said "European Lager" on the package; I wasn't familiar with the brand. I rehydrated the yeast (this was clearly successful) and pitched into the wort @ 65 F. Off it went into the freezer. After 12 hrs., I set the thermostat to 62 F. The next morning (24 hrs), a vigorous fermentation was evident. Over the next 12 hrs, I gradually reduced the thermostat to 52 F. This was apparently too much, as the yeast clearly pooped out and went to sleep.

In an effort to bring the yeast back, I first raised the temperature to 58 F. After a few days with no results, I raised it to 62 F and then stirred the wort up as best I could. Last night there were a few bubbles coming out of the airlock, but I suspect that they were just CO2 coming out of solution since there was no activity when I peeked in this morning.

Does anyone have suggestions for what to try next? More stirring? Yeast nutrient? Please E-mail me at dstotler@pppl.gov.

Thanks,
Daren Stotler

You say you are going to use "pure canned pumpkin" for your pumpkin brown ale. Most canned "pumpkin" I have seen in food stores is really SQUASH!

!

It even has a picture of a pumpkin on the label, but if you read the ingredients, the contents are really squash or pumpkin squash. This is what most people use to make pumpkin pie anyway and it tastes like pumpkin, but it is not the real thing.

I am long overdue to make a batch of homebrew and I eagerly await a recipe for some Halloween Pumpkin brew.

Subject: stuck fermentation?

I recently made a lager, and to keep things cool, I put the carboy in some water and threw in some ice (never enough that I had an ice-water solution, just enough to cool things down a little). After 14 days in the secondary, I went to bottle, but before I could start racking I noticed the beer was fermenting like crazy. After a couple of days, activity has subsided, but I'm puzzled as to what happened. Is it possible I lowered the temperature past some critical point that caused the fermentation to become stuck? What is this temperature for lagers? For ales?

Subject: Local brew shop?

Hi,

I have recently rediscovered my interest in homebrewing, and have found a local liquor store which sells homebrew kits. (One of which is currently bubbling in my basement!) But, they don't stock any other supplies.

I live in north/central new jersey, in between Morristown and Somerville; does anyone know of a shop that stocks homebrew supplies near this area, or is mail order my best bet?

Thanks,

Gary.

From: Lee=A.=Menegoni@nectech.com
Subject: Decoction procedure

Rob Thomas missed the point of my previous post on decoction mashing which dealt only with the final decoction required to get to mash out. I made no mention of the decoctions leading to mash temp since they are well understood

with regards to process and purpose. What I did attempt to do was better describe what Noonan's "thinnest 1/3" and its impact on the mash process.

Regardless of the number of prior "thick" decoctions one still needs to raise the temp from mash range 150sF to mash out 170F. If grain is in the final "thin" decoction it will liberate starch during boil. Since the purpose of this decoction is to raise the mash temp to deactivate enzyme activity it is quite possible for the final decoction to introduce more starch than can be converted by the remaining enzymes in the 10 minutes or so it takes for them to become deactivated.

My revised decoction procedure is:

Put 5 dead CDs in player, start.
Heat 1 quart water per lb grain to 135F.
Add grain to mash tun.
Check temp for protein rest adjust as needed.
Let mash sit for 10 minutes at protein rest temp.
Check/adjust ph in mash tun.
Kettle mash 40-50% of grain at 155 for 30 minutes, mash is very thick.
Add 1/3- 1/2 quart of water per lb grain in kettle mash, prevents scorching.
Check/adjust ph of kettle mash. (if too high boil will extract tannins)
Boil kettle mashed grain for 10 minutes.
Add slowly add half the boiled grains to mash tun, stir constantly.
Check temp of mash.
Add 1 pint of boiled grain to mash until desired temp reached.
Check/adjust mash ph.
Let remainder of boiled grains cool add to mash when temp is low enough.
Mash until complete conversion.
Remove as much liquid as possible, take NO GRAIN.
Add water to get liquid to 1/2 - 3/4 quart per lb grain.
Boil liquid.
Add boiling liquid to mash tun and stir.
Check temp of mashout, don't over shoot 170 by much, may liberate starch.
Mash out for 15 minutes.

Subject: more on decoction

Hello again all,

Firstly, thanks to Lee Menegoni for sending his post (in this digest?) to me as well, as it allows me to reply promptly, and get the matter settled quickly.

As he said above (?), I did misunderstand about his thin part description.

Therefore, let me ask another question, did you do a starch test on the beer or sweet wort to prove the cloudiness was starch?

In retrospect your conclusion about the last boil containing small amounts of grain and therefore liberating starch seems reasonable, but only if your yields are usually lowish (otherwise there wouldn't be any starch left to gelatinise). I haven't had this problem in the 8 or 9 batches I've done, even though I often (usually?) have upto a cup of solids in ca. a gallon of thin decoct.

Has anyone else got any experience with this problem (I'm getting worried),

or does everyone else who decocts carefully strain the last decoct?

Did you get any more info Lee?

Rob. Thomas

Subject: Re: lautering and clarity

In HBD 1226, Norm Pyle asks whether anyone has 'put to a test' Micah Millspaw's claim that minimal or no recirculation increased clarity of a brew.

Well, I did ask Bob Jones to clarify (sic) Micah's claim, and he said that Micah would sometimes (jokingly??) say that he would sometimes throw whole malt into the brew-kettle to increase clarity !! :-) Now, this was a joke, but Micah is quite vehement in his assertion regarding too much recirculation (and also makes some arguments regarding loss of stability with over recirculation.

Anyways, to my data point: last February a brew-partner and I made a Pilsner-Urquell clone that became known as "Pilsner from Hell". Why? Because it seemed everything that could have gone wrong in the brewing process...DID! This included a joint in the copper sparging manifold coming apart, which then proceeded to leak large amounts of grain husk material into the boiling kettle. We worried (gasp!) about it a little...but decided to place our fate into the considered opinion of Micah Millspaw.

Bottom line is that the brew was cloudy in the primary. After we fined with gelatin in secondary and bottled, we have the brightest brew either of us have produced!!

Also, in general I do little recirculation in my copper manifold sparger (on the order of a quart), and have had no problem with cloudy brews.

DON'T DO IT!

I tried making a pumpkin ale this past weekend using 3-28 fl. oz. cans of pure pumpkin. I discovered that the pumpkin will completely dissolve in the boiling wort, turning it into the consistency of pumpkin pudding when cooled. It made sparging next to impossible, even with my coarsest sparge filter. All the pumpkin ended up in the fermenter where most of it has settled out. It takes up quite a bit of space, leaving me with less beer.

If I were to do it again I'd wait for pumpkins to be in season, carve up one or two and use chunks of the meat (after cooking it a bit).

I'll be racking the beer off the pumpkin, etc. into the secondary tonight where I'll add various spices (cinnamon, allspice, vanilla, etc. -- the usual pumpkin pie things). I'm hoping I'll have this ready for Cdn. Thanksgiving next month. Not much hope of that I know, but I had no time for brewing this summer. :-(

>digest?

Hi Norm, yep I'm still here, mostly a lurking. The jest of Micah and my
contention was focused at better beer stability. The stability is
improved
if there is a higher fraction of lipids in your final packaged product.
The
lipids are low to start with in american grown grain. The lipid content
is
greatest at first runoff from the mash. Therefore it is best to take the
first runnings. The particulates in the runoff don't seem to cause any
problems with final beer clarity. They may even improve it! This being
due
to the particulates acting as nucleation sites for proteins. There is an
interesting discussion coming in the next issue of Zymurgy where this
very
issue is addressed by G. Fix G. Noonan and myself and Micah. The issue
was
raised by a letter to the Professor. I have read all the text and it does
make for interesting reading.

I'm off on a three week trip to England, Wales and Scotland, a pub
crawling.

Cheers,
Bob Jones

Subject: re o-rings and taste threshold

oconnor@ccwf.cc.utexas.edu asks:

> HOW DO YOU GET MORE THAN 1.35 CANS OF DIET COKE INTO THE
> POPPET VALVE ORING?

Simple. The problem is absorption of flavors, not absorption of total liquid. I don't know what the ratio of carbonated water to cola syrup is in fountain-mix systems (I'd guess high single digits from recollections of helping with setups) but that syrup is mostly sugar; the effect of 1.35 cans of cola could probably be matched by as little as a drop of its strongest-flavored component.

No, I don't keg. But this isn't kegging; it isn't even simple chemistry---more like bottle washing.

wrt what the judges tasted: to me, Diet Coke tastes more of the artificial sweetener than of Coca-Cola; I'm not surprised they thought of ginger ale or fruit soda when they detected the sweetness.

From: David Atkins <ATKINS@macc.wisc.edu>
Subject: Racking tube 'trubles'

Hello readers,

Being new to the world of racking tubes, I ask for some advice and experiences.
On several occasions, I've been unable to secure a steady siphon using either a carboy cap or good old fashion oral vacuation (non-phrase?). It seems that regardless of siphon hose diameter and the subsequent inclusion of a metal strip hose clamp, I cannot maintain a constant seal between the hose and racking tube (a wholly plastic affair, no copper).

Before the line fills, air gets sucked into the line where the hose and tube meet. This steals away the siphon and aerates fermenting(ed) beer. And I have tried two diameters of hose, to very little avail.

I had three very stressful goes at transferring 5 gals from a 7 gal. carboy to a 5 gal. I ended up using plain ol' hose and plain ol' sucking. What will really suck is my luck if foibled siphon attempts lead to any contamination.

I have done some experimenting with the tube and see that I must do more. Any suggestions to the list or to my email will be welcome. Bottling is just a few days away.

Thanks brewers.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Re: Tarnished wort chillers

In HBD 1225 Philip J Difalco asks about tarnished copper immersion chillers.

There are different types of "tarnish", the dull kind and the green kind. When I first used my immersion chiller I put it away with a few drops of water still on it. To my horror (I scare easily) there were green copper oxide spots on my chiller! Of course, these wiped off with a soft cloth. The green tarnish you don't want in your beer. The dull red-orange colour of the copper turns to a bright, almost pink colour when immersed in an acidic medium, such as wort. The amount of copper actually being removed from the chiller is negligible, and traces of copper are actually beneficial to yeast metabolism. My suggestion: after use, rinse the chiller under running water (or hose it down under the shower), and wipe it dry with a tea towel. Before use, give it another quick rub down to remove loose oxide.

Subject: Vienna malt and Munich malt

Will these grains convert themselves or must they have an external enzyme source?

Also, has anyone ever tried making Vienna malt using the method outlined by Dave Miller in The Complete Handbook of Home Brewing? If so, how did it turn out?

Vienna malt doesn't seem to be available in Canada except by special order.

I've had some on order now for 10 weeks and it still hasn't arrived (through my local HB supply store). When it does it will cost me about \$2

per pound! If I were to bring it in myself it would get here much faster (about 2 weeks) but cost much, much more. (The store is bundling it in with other supplies they are ordering, so the shipping and brokerage fees will be distributed over the entire shipment.)

Don't suggest using some of those wonderful Belgian malts instead. They aren't available here either and my store won't carry them unless there is a Canadian distributor they can order them from. :-(

From: mike.sadul@canrem.com (Mike Sadul)
Subject: Cooler size

Greetings fellow homebrewers!

I have been an avid reader of the HBD for some time now.
Never posted ... until now!

It is because of this digest, that I have decided to move from
extract brewing to all grain (it's cheaper, tastes better, cheaper,
tastes better ...), so you're all to blame! :)
(at least that's what I tell my wife)

I am currently in the process of buying/making equipment.

All the discussions of different techniques and different types of
equipment (and the problems and limitations of each) have made
the choices easier for me. Much better than a brewing book.

However, ... a few questions remain (otherwise I would still be in
the background :)). But first a bit of the what and why's:

Because of the time involved with all-grain, I have decided to brew
10 gallon batches. The "gallons" will probably be US gallons, since
I now keg my beer and despise having to fill 3 or 4 extra bottles
after filling the keg.
(5 Imperial gallons = 22.5L = 18L keg + a few 1-litre bottles)
This takes part of the joy out of using kegs and doesn't adhere to
the KISS rule.

The equipment list (so far):

60 quart kettle and lid from Rapids (friendly staff, great prices,
quick delivery).
60,000 BTU propane burner, with 144 little holes on the ring burner,
from a local hardware store.
50' of 3/8" OD copper tubing for an immersion chiller (easy to clean
and sanitize, hot & cold break remain in kettle after siphoning).
MaltMill (cheque's in the mail Jack :))

The copper manifold that I built (before I realized I was going to
do 10 gallon batches) for a "regular" cooler (34 quarts?) will be
dismantled and the parts used to build a manifold for a larger cooler.

Question:

What size cooler should I buy?

I want to be able to mash 15 - 25 lbs. of grain AND be able to dump
all of my sparge water into the cooler to do one of those batch
sparges (back to the KISS rule (1 kettle, 1 cooler)). I can get
either a 68 quart or a 107 quart cooler. Will the 68 quart be a
little tight? Will the 107 quart create too shallow of a grain bed?
Will I get flamed for wasting so much bandwidth for this one question?

Thanks for all of your help (so far!),

Mike

Subject: Texas ales

Howdy,

On 9/15/93, Troy asks for the lowdown on Texas legal definitions on beers.

It's really quite simply. If it's below 4% alcohol, it's beer. If it's above, it's ale. You have to have a separate permit to brew each commercially.

The permits are flat fees. So Anheuser-Busch, which brews beer in Houston, pays half of what Pierre Celis, who brews beer & ale in Austin, does in fees, even though A-B produces more in a day than Celis does in a year.

And people wonder why there isn't more happening on the beer front in Texas.

BTW, Celis can't offer samples of Grand Cru at the brewery because it's an ale.

However, they can offer unlimited samples of the others. Also, he can't sell

his beer directly to the public, only through a retailer, while A-B owns Sea World of San Antonio, which sells, by coincidence, A-B beers. The Texas

Lege made a special exemption just for them a full two years before legalizing

brew-pubs & after A-B had been selling beer for years at Whale Jail.

So you can see that even though the new brewpub laws in Texas are quite limited, we're pretty happy just to have something.

Subject: The O-ring Challenge

Don asks:

>HOW DO YOU GET MORE THAN 1.35 CANS OF DIET COKE INTO THE
>POPPET VALVE ORING?

Well, it seems to me that Don is not aware of what most Cornelius Canisters are really used for: post-mix. Few are used for what's called pre-mix. What's the difference. Pre-mix is pre-mixed at the bottling plant -- it's the same stuff as the soda in bottles and cans. Post-mix is an altogether different animal -- it's syrup! It is mixed with carbonated water by the dispenser. It is altogether conceivable that you could absorb more aromatics than are found in a case of diet coke into the 8 gaskets that are found in a standard Cornelius canister.

When I sell a reconditioned keg (which I do myself), I put the used gaskets and poppets into a 6-mil HDPE bag and tape it to the side of the keg. I do this not only to prove that I've changed all the seals, but also to give the buyer the opportunity to smell them and reassure themselves that changing them was worth the money they paid.

One time, I was expecting a customer and had no reconditioned kegs on hand. Halfway through the reconditioning, I realized that I had no poppets in stock for this type of keg. I smelled the original poppets and they smelled strongly of soda pop. "Perhaps I could boil the smell out of them?" I said to myself. 20 minutes of boiling later, the poppets still smelled of soda pop. My last resort, was to take the poppets out of my own personal kegs (which were purchased new and have never been in contact with syrup) and to give the customer a discount since they weren't getting all new seals.

Regarding the flavor of cola, try this at home: have someone give you a blind taste test between Coke and Seven-Up. Ten of us did this test and only one of us could consistently identify which was which. What does this prove? That soda pop aromas are non-descript (except for root beer, maybe) and lemon-lime doesn't taste very different from cola. The aroma of cola and the aroma of beer are definately different and, personally, I prefer to keep them separate.

Finally, that's Korzonas, not Korzonis. It's Lithuanian, not Greek. Fairer skin, blander food and better beer (right George?).

Al.

Subject: TX laws/Decoctions

Troy writes:

>Hey! Don't leave us all in suspense, out with the ugly truth. Enquiring
>minds want to know. What exactly did the Texas legislature do with
"ale"?

Texas requires a beer labeled as "ale" to have an alcohol level of at
least

a certain percentage (sorry -- someone from TX please post the
percentage).

But it's perfectly okay to have a beer below that alcohol level be called
a "bock." This is why Celis Pale Bock cannot be called what it really is,
namely, a Pale Ale (well, I think it's more of a Brown Ale, but that's
me).

Rob writes:

>The accepted "industrial" procedure for decoction involves
>taking out the THICKEST third (ie mostly grain), heating it to
>conversion temperatures and then to boiling, when, indeed, the
>starch gelatinises, the inner structure of the grains is disrupted,
>and generally the starch is made more accessible to enzymes.

Yes, but according to Noonan, this (using the thick part of the mash
for the decoctions) is only for the first two or three decoctions.
For the final decoction, the one that takes the mash up to the
mash-out temperature, Noonan recommends using the thinnest part of
the mash. I'm quite sure that this is what Lee was talking about.
It's actually important to gelatinize and burst-open the starch
granules during the first 2 or 3 decoctions, but equally important,
as Lee mentioned, to NOT gelatinize or release any additional
starch during the FINAL decoction. Any starch that gets liberated
during the final decoction will not have any "live" enzymes left in the
mash (during the mash-out) to convert them to sugar.

Subject: kegging pressure problem

I am new to kegging and have a problem which I can not figure out. I have a CO2 cylinder, regulator (purchased new from local Pepsi supplier) and a pair of used cornelius kegs (with beer). Somehow, I have overpressurized my beer.

I have the regulator set for about 15 psi. When I connect the system for an extended period of time, the low pressure side RISES to 40 psi. More confusing yet, the high pressure gauge rises from about 850 psi. to 950 psi.!

As an experiment, I have left the system connected and turned off the CO2 cylinder. Pressure has dropped to about 10 psi as of today. I think I have a leak, however, one of the kegs is new and may still be absorbing CO2.

What problem in my setup can cause the low pressure side to go from 15 psi to 40 psi? I don't have a clue.

From: tpm@wdl.loral.com (Tim P McNerney)
Subject: Using Soda Kegs for Fermentation

A couple of days ago, Dave Smucker mentioned using 1/2 barrel kegs as fermenters and I was wondering about using soda kegs, also. I usually do my primary fermentation in my brewkettle and would like to transfer directly to a keg for secondary, saving myself the trouble of transferring to a glass secondary, then a keg at racking time. It seems to me that I should just be able to flush the headspace with CO2 and then leave the relief valve open. Then I just need to wait for secondary to complete, close up and pressurize. The only problems I see with this are:

Chance of infection through the relief valve, but I don't think this would be a big problem.

Difficulty determining when secondary is done, but so what if I underestimate the time for secondary.

Does anyone see any other serious problems with this scheme? Would there be any problem sealing the valve when I first transfer and then release the pressure once a day or so (I figure this eliminates the problem of infection even more)? Does anyone else use soda kegs for secondary and if so, does anyone bother trying to attach a fermentation lock?

Thanks.

Hi Gary...

Subject: local homebrew supplies

i'm very new to all this (still shopping for equipment), but there is what seems to be a neat place in Red Bank, called Red Bank Brewing Supply.

Red Bank Brewing Supply
67 Monmouth Street
Red Bank, NJ 07701
908/842-7507

They seemed like really helpful people...explained a lot to me. They claim to actually brew stuff there as well, but I can't validate that.

I live in Freehold, work at Ft Monmouth, so they are really quite close.

Hope this helps....

Subject: o-rings again

Another way to break-in a "new" soda keg that you don't feel like replacing the gaskets on, is to fill the keg with a nice heavy stout or doppelbock.

I've also found that soaking o-rings in soapy water noticeably reduces the soda smell.

Of course, your mileage may vary;

Also, I fully agree w/ Al: everyone has different tastes. If you happen to have very sensitive tastes, overhaul your keg; if not, relax, fill it, and bottoms up!

Subject: RE: decoction mashing

Hi All,

Picking up the recent thread on decoction:

Lee and I discussed this a few days before his post, and I didn't have the information at hand. This prompted me to look through my brewing books,

it turns out both Miller and Noonan are quite explicit on the issue of grain in the final thin decoction causing haze problems.

From Miller's "Continental Pilsner", p. 52, the context is a discussion of various decoction techniques:

"Other variations are even quicker. For example, some brewers use a single-decoction mash in which the boost to saccharification is accomplished by decoction but the final boost to mash-out at 168 degrees F (75 degrees C) is done by directly heating the mash-tun. This program is arguably more sensible than the double-decoction method because starch released during the second boil may not be converted during the mash-out rest (the amylase enzymes are rapidly destroyed at such temperatures) and might cause hazes in the wort and finished beer."

From Noonan's "Brewing Lager Beer", p. 118:

"When the starch end-point has been verified, the **very thinnest** ("very thinnest" is italicized in the text) part of the mash is removed to be boiled."

"Because there are fewer starch and albuminous particles in the thinner portion, there is less risk of these being decomposed during the boiling and spoiling the runoff."

Rob Thomas writes in HBD#1227:

>In retrospect your conclusion about the last boil containing small
>amounts of grain and therefore liberating starch seems reasonable,
>but only if your yields are usually lowish (otherwise there wouldn't
>be any starch left to gelatinise).

I don't think this is the case. There is always some insoluble starch in the chunks of grain that amylase enzyme won't touch. Boiling gelatinizes this starch, releasing starch that is now soluble but not converted into the wort. Thus, the presence of unconverted starch in the wort is not necessarily a consequence of low yields.

Rob writes:

>Has anyone else got any experience with this problem (I'm getting worried),
>or does everyone else who decocts carefully strain the last decoct?

Can't speak for everyone else, I use a 10 gallon cylindrical Igloo cooler with a copper sparge manifold as a mash/lauter tun. When it's time for the

final thin decoction I simply open the spigot on the cooler, and drain the liquid from the tun. With the exception of the initial cloudy runoff, the final decoction consists of clear wort and *NO* grain. I've never had clarity problems with beers brewed using decoction mashing, in fact, I believe decoction mashing improves clarity, what with multiple boils breaking down all that protein.

My take on all of this is that including *ANY* grain in the final decoction is risky. Perhaps the amylase enzyme will convert the starch before it denatures, perhaps not. Given the time and effort involved in grain brewing and decoction mashing, I choose not to take the chance.

Comments?

Cheers,
Jim

From: bickham@msc.cornell.edu
Subject: Adding fruit to the secondary

I'll be brewing a fruit beer soon and want to add cherries to the secondary. Since they are out of season, I'll have to buy them frozen, but that's fine since a lot of people recommend freezing to set the pectins. My questions are:

1. Should crush the cherries or at least macerate the skins before I add them to the fermenter.
2. In one of the recent issues of Zymurgy, someone recommended putting the fruit in a pantyhose legging to keep the fruit from forming a surface barrier which traps the carbon dioxide. Has anyone tried this?

Thanks, Scott

Subject: Fining with gelatin

Hi -

Having passed through my "I need gallons of beer to drink...Now!" phase, and upon entering my "This beer had better be exceptional!" phase, I have need of some information...

I am planning on splitting my latest concoction between bottles and keg, and would like to ensure clarity. As well, it had, upon moving to secondary, a decidedly overly-yeasty taste, which seemed to me to be more than simple immaturity.

As a result, I am going to do some gelatin fining to yank some yeasties. The bible by Sir Charles recommends fining at bottling time. I was wondering if it was acceptable to fine for a week or so in secondary, so that I can bottle with less sedimentary concerns.

Thanks for any help,

Jack

Subject: Enzymes and Munich malt

>In HBD 1227, Bill Flowers asks whether Munich malt contains sufficient
>enzymes to convert themselves:

Last winter I tried making a Munich Dunkel using 100% munich malt. The
source of the malt claimed that the malt had sufficient enzymes to
convert
itself.

Well, to make a long story short, I ended up with a large pot of starchy
porridge..... (that I fed to the compost pile)

When I went back to the supply shop to complain/ask whether the malt
did indeed have sufficient enzyme activity they (jokingly??) asked me
if I was SURE I had not killed my enzymes. (and, as it turns out, spread
the
story to a few select members of the local brew-club when they came into
the
store after I left...) **

When I got over my apoplexy, we had a productive dialog about mashing
schedules, after which we decided I would try again with a 50/50 munich/
pale
malt mixture, and they would call their supplier (Breis??) to inquire
again
about the enzyme content of Munich.

I was vindicated! The second attempt converted nicely, and their
supplier
said the malt did NOT have sufficient enzyme activity to convert itself.
(though members of the local brew club still occasionally give me grief
about killing my enzymes...sniff...)

Although I am not SURE about this, I think a reasonable generalization is
that
domestic Munich malts do not contain sufficient enzymes to convert
themselves,
but munich malts of European source will contain sufficient enzymes.

** Just for fairness, the claims of killing enzymes were made in fun...
though

I DO still get grief for it from club members....

Subject: Decoction, Coolers

>From: Lee=A.=Menegoni@nectech.com
>Subject: Decoction procedure

>Regardless of the number of prior "thick" decoctions one still needs to raise the temp from mash range 150sF to mash out 170F.

It is my considered opinion that there is no advantage in raising a decoction mash to mash out via the decoction mode. The benefits of decoction arise from the mashing at 155F of the previously boiled decoctions. Once saccrification is complete, this last decoction(s) is superfluous. It is far simpler just to heat the whole kettle to mash out.

>From: "Bob Jones" <bjones@novax.llnl.gov>
>Subject: Recirculating mash runoff

>The lipid content is greatest at first runoff from the mash. Therefore it is best to take the first runnings.

Someone has confused two issues here. Micah was talking about sparging and the advantages of first runoff. This has little to do with re-circulating the runoff.

In the former, we are talking about running additional water (sparging) through the mash to increase the overall volume of wort which will be further processed. Micha's comments discussed the advantages of only using the wort that runs from the original mash, without sparging additional water through it.

The re-circulation discussion revolves about the oft proclaimed advantages of recirculating the original mash liquid through the filter bed BEFORE collecting it for further processing.

In a proper mash tun, the only objective is to utilize the initial runoff which is usually very turbid and full of husk material. Instead of throwing it away, it can be poured back into the mash so that then next time it passes through the filter bed it will run clear. The amount that must be recirculated depends on the design of the mash tun and the dead space under the false bottom and the flow rate. It varies from a cup or two to gallons.

Now, the problem comes from the claims that prolonged re-circulation of the

runoff before commencing the sparge, has a profound effect on extraction rate. I know of no reason for this to be true unless there is something wrong with the design of the mash tun.

>From: mike.sadul@canrem.com (Mike Sadul)
>Subject: Cooler size

>I am currently in the process of buying/making equipment.

>The equipment list (so far):
60 quart kettle and lid from Rapids (friendly staff, great prices, quick delivery).
60,000 BTU propane burner, with 144 little holes on the ring burner, from a local hardware store.
50' of 3/8" OD copper tubing for an immersion chiller (easy to clean and sanitize, hot & cold break remain in kettle after siphoning).
MaltMill (cheque's in the mail Jack :))

>The copper manifold that I built (before I realized I was going to do 10 gallon batches) for a "regular" cooler (34 quarts?) will be dismantled and the parts used to build a manifold for a larger cooler.

>Question:
>What size cooler should I buy?

Don't buy one. In the interest of International good will, I will include an EASYMASHER with your MM shipment. Install it in your kettle and you don't need any other equipment. Mash in your brew kettle, collect the wort and clean out the "mash tun" and now call it a "brew kettle". If you fall in love with the system, your next money would be best spent on another smaller kettle for mashing and another EM for it.

You can easily mash 10 gallon batches in the (\$40) enamel on steel canner but you can only boil 5 gallon batches. If you are loaded, buy the 10 or 16 gallon Rapids kettle for your mash tun.

Any of these kettles also make great fermenters. The 10 gal is a little tight for 10 gallon batches but if you lager, there is not much foam buildup.

If I had to do it over again, I would have bought two 16 gal kettles but I am stuck now with one of each. I mash and sparge in the 10, boil in the 16 and ferment in the ten. It would be nicer to ferment in the 16 but then I have to hold the wort while cleaning and sterilizing it.

Subject: RE: soda kegs as fermenters

Hi All,

In HBD#1227, Tim McNerney asks about using soda kegs for secondary:

>Does anyone see any other problems with this scheme? Would there
>be any problem sealing the valve when I first transfer and then release
>the pressure once a day or so

I exclusively use kegs for secondary fermentation, they work great! My procedure is to purge the keg with CO2, then rack from primary a day or so after the krausen has fallen. Filling the keg with CO2 helps prevent oxidation of the beer during the transfer. CO2 is considerably heavier than oxygen, if you don't tip the keg during racking, it'll pretty much stay in there for the duration of the transfer.

Once the beer is transferred, seal the keg, and purge the headspace.

Put

a small amount of pressure on the keg, enough to ensure you have a tight seal around the large o-ring. For the first day or two, open the relief valve slightly, and bleed off some of the pressure, once or twice daily. After the first day or two, you'll find very little gas is released when you open the valve, as fermentation is very nearly complete. Drop back to bleeding the pressure every 2 to 3 days.

BTW, the relief valves on my kegs are rated to open at 50-60 psi, the kegs are stamped "130 psi maximum". Provided the relief valve does not fail, there is little danger. Since the pressure is bled periodically, I don't believe there is any danger at all. I've done over 30 batches in this manner over the last 18 months, with no problems.

There is an added benefit to using kegs as secondaries. When the time comes to transfer to a serving keg, the entire batch can be transferred without siphoning. Get a length of pressure tubing, and attach a liquid hose barb to each end. Purge the receiving keg of oxygen, and make sure it is tightly sealed. Bleed all of the pressure off the full keg, then connect the two kegs via the liquid OUT fitting on each. Put 15-20 psi on the full keg, and the beer will start to flow into the receiving keg. Keep an eye on the flow, it will slow down periodically as pressure builds in the receiving keg. Use the relief valve to bleed some pressure off the receiver, and the flow will resume. The advantage to this method is that the entire batch can be transferred in about five minutes to a serving keg without worrying about starting a siphon, without oxidizing the beer by splashing during siphoning, and without exposure to airborne micro-nasties.

Cheers,
Jim

Subject: Goofy Texas laws

To add to the discussion of Texas beer laws, the word "stout" implies a strong beer to the TABC (Tx Alc Bev Comm) and so we can't get Sam Smith's Oatmeal Stout because the alcohol content is not high enough to be called stout! Also, we also have a packaging restriction relating to the alcohol content. If the brew is < 4% alcohol, then it has to be packaged in 7, 8, 12, 16, 24, 32 oz containers or in fractions of a barrel (like 3.375 gal, 7.75 gal, 15.5 gal). I think the factory breweries got a special addition of the 5 gal beerball size to the list. It cost them a fortune to schmooze and lobby our legislature.

However, if the brew is > 4%, then it can have any size package it wants, like 16.9oz (0.5L) for the German imports. This means that we can't get Anchor Steam on draught because the alc content is not high enough to be packaged in their 50L kegs. Unfortunately, Texas is such a huge market that many breweries will make special versions to get around our stupid laws.

Here's an interesting point (brought up in another forum): since beer sold here in the USA cannot have an alcoholic content labelling (to protect us from ourselves), is there a restriction on OG labelling? This is the case with the German beers that I brought back, and it helps a bit to try to duplicate the style. (I think it's part of their packaging law to have it on there....)

Subject: Cascades dying?/Building a basement brewery

Hi folks--

I have a couple of questions, one regarding the apparent death of one of my hops plants, and another regarding the construction of a basement brewery.

My Cascades plant, after growing to @ 15 ft. and putting out a small number of cones in its first year, has suddenly started to turn black and shrivel from the top down (I only had one shoot come up this year). Up to now, I have been impressed with the ruggedness of this variety, compared to my dearly-departed Mt. Hood (slugs) and Saaz (spider mites) cuttings. Now, I think something is consuming my Cascades.

If it matters, after the death of the Saaz plant, I began weekly applications of "Safer soap" to control the spider mites on the cascades. In the two months since the demise of the Saaz, the spider mites seemed to disappear. Is the plant reaching the end of its season or do I have an interloper?

Also, I will be moving at the end of the month to a house with a basement. My roommate (and owner of the house) has agreed to help me convert a corner into a "brew room". The basement has a concrete floor with brick walls and an unfinished ceiling. Putting in the framing should be inexpensive, since we have a free source for 2x4's. Can anyone recommend a cheap material to use for the walls? I'm thinking of something like the plastic used to make shower walls. The basement is fairly dusty and will also be used for a workshop and storage area, so I'd like to create a closed area that could be kept sanitary with periodic "swabbings".

For the record, I don't plan on using an open burner in the basement. My hot water source will be the house's gas-fired heater, and the boiling of the wort will take place outside. The brew room will be used for mashing, fermentation, and beer/equipment storage.

To save bandwidth, email replies are welcome.

Al is right on with this one! I use all used Pepsi Cornelius kegs and I know that they contained some of the residual syrup and the guy at the Pepsi plant told me that's what they contained before I bought them. He highly recommended that I change all my gaskets, which I did because they reaked of sweet syrup. A lot of the used kegs on the market have just been heavily rinsed and contain all the original gaskets and poppet valves - change all of them! I've had my kegs for ten years now and finally changed out all the gaskets and poppet valves again last year just as a preventative measure for possible leaks that might start forming. You can tell when the main lid gasket needs to be changed by bending it and looking for cracks starting to form in the rubber.

This sounds really strange. Even when my beer absorbs CO2 after extended periods (Al & I still have this under investigation) my pressure on my gauges remain the same as when I first hooked them up. I'm willing to guess that maybe you have a defective regulator, especially since both the high side and low side gauges are increasing. I've rebuilt my regulators and have never had the pressure change on its own.

From: Ulick Stafford <ulick@gauguin.helios.nd.edu>
Subject: Decoctions

Quite a discussion going on about decoctions. As a committed decocter of most beers I have found that decocted beers tend to be perfectly clear with no other fining. However, the one or two times I have gotten lazy and mashed out in a normal manner (let's call it Warner method), I have produced beers that presented more clearing problems - usually wheat beers and usually chill haze, than if I had used a thin decoction. It is nearly impossible to avoid grain when pulling a 40-50% thin mash. The expectation is that the starch was well gelatinized by the earlier decoction. One is necessary except for very unconverted malt that you won't find here. I have never experienced a starch haze, but the great effect that a thin decoction has on protein coagulation reduces the boil time to what is needed to extract hop acids and clarity is less of a problem. Typically, for the thick decoctions I remove grains with a sieve, and thin decoctions with a ladle (a small pot), and then return some of the grains to the rest mash with the sieve. Once or twice I set up my cooler with the false bottom in at the start of the mash, and got the most beautiful runoff for the thin decoction. However the long time that the mash was on the bottom caused it to clog and loitering was a bitch. In general I have found the following procedure to work well for most barley beers, especially stouts with the high unmalted component.

Dough in at 70-90 with .75 quarts per pound.
Add another .75 qt/lb of hot to boiling water to raise temp into protein rest range (122-131). The amount and temperature of water will depend on the heat capacity of your mash tun - in my case quite a lot with a 7 gallon Gott

Rest 15-20 min. Pull 33-40% thick decoction (using sieve and capacity marks on the inside of cooler)

Heat decoction to 145. Rest 10 minutes.

Heat decoction to 153. Rest 10 minutes.

Heat decoction to 158. Rest 10 minutes.

Heat to boiling. Boil 15 minutes.

(all heating should be done slowly to prevent hot spots and burning. constant stirring is needed while raising the temp, except for boiling, when the odd stir will do. Make sure the decoction isn't too thick)
Return to rest mash. In my experience the heat capacity of the cooler means

the temp will always be ~146, but your equipment will vary. I usually rest there for 10 minutes and then raise with either a small thick decoction or small infusion of boiling water or on the burner till

the top of my saccharification range is reached, ~153-155. Rest here for 10 minutes.

Pull loiter decoction. 40-50% of the thin mash. Boil 15-20 minutes.

Return to rest mash- mix in well. Again temp may be low of strike, thanks

to heat capacity of cooler. Dump out into boiler (yes I have heard of HSA). Heat to 170. Put sparge manifold in cooler and dump mash back in.

Start heating sparge water etc.

Subject: Viennaless Viennas?

Hello:

I am interested in brewing an Oktoberfest-type all grain beer (OK, by the time it is ready it will probably be a Decemberfest at the earliest). I was reading the article in the last Brewing Techniques about this style. For those of you who have not read it, it discusses the style

and particularly emphasizes ways in which brewers can "cheat" and still end up with a reasonable beer. For example, by not lagering (if you haven't got the facilities) or by doing a single step infusion mash (which

is the only type of mash some places are equipped to do). The article also mentions that Vienna-type malts are not necessary, and that recipes contained in G. and L. Fix's book on the style use NO Vienna/Munich malts.

This appeals to me, since I like to buy my grain (American 2-row and Crystal Malt) in bulk to save money, and would like to use what I have instead of buying small quantities of something else at higher prices. My question is, though, if you don't use these special malts, what do you use

to get the appropriate color and flavor? Crystal malt? Home-kilned mock-Munich a la Dave Miller? What? (I realize that I could solve this puzzle by buying and reading the Fix book but I don't have easy access to it and figured I would try to get the answer for free first (sorry George)). Thanks....

Dave.

From: florianb@ying.cna.tek.com
Subject: Recirculation, debunking the myths

In yesterday's hbd, cush@msc.edu says,

=>
included a joint in the copper sparging manifold coming apart, which then proceeded to leak large amounts of grain husk material into the boiling kettle. We worried (gasp!) about it a little...but decided to place our fate into the considered opinion of Micah Millspaw.

Bottom line is that the brew was cloudy in the primary. After we fined with geletin in secondary and bottled, we have the brightest brew either of us have produced!!

=>

and a second post by bjones@novax.llnl.gov,

=>
contention was focused at better beer stability. The stability is improved if there is a higher fraction of lipids in your final packaged product. The lipids are low to start with in american grown grain. The lipid content is greatest at first runoff from the mash. Therefore it is best to take the first runnings. The particulates in the runoff don't seem to cause any problems with final beer clarity. They may even improve it! This being due to the particulates acting as nucleation sites for proteins.
=>

Both these comments are in keeping with my original post about three years ago, when I claimed rights to a new method of lautering. This new method, which I stole from my brother-in-law, involves putting all the sparge water into the lautering tub at once. Only a minimal amount of recirculation is used. When I changed to this method, my beer clarity improved, particularly in the case of ales (which don't lager and thereby settle out for 4 months). At that time, I couldn't find reference to this method in any of the some 20 books I have on home brewing, nor in the hobby rags. I won over support from several brewers here on the hbd after they tried it. I highly recommend the process as it improves the beer and saves time, too.

I still plan to post a description of the method, as soon as I change my spark plugs. Too bad I have to work for a living.

From: florianb@ying.cna.tek.com
Subject: Re: racking tube 'trubles'

In hbd #1227, David Atkins asks:

=>

Before the line fills, air gets sucked into the line where the hose and tube meet. This steals away the siphon and aerates fermenting(ed) beer. And I have tried two diameters of hose, to very little avail.
=>

I'm not sure what you're seeing is air. It could be CO2 coming out of solution at the interface of the plastic racking tube and the siphon hoze. In any case, this happens often. You can eliminate it by getting the siphon going and then "thumping" it with your finger really hard at the place where the two meet and the gas is present.

If this doesn't work, then it might be air due to a poor fit of the hoze and the racking tube. Put a little glycerin on the racking tube before fitting the hoze over it.

Luck,
florian

Subject: Miller Reserve Amber Ale

Just thought I'd share this tidbit for those not brave enough to dare the Budmillours swill. Personally, I'm of the crowd that believes there is no bad beer...some are just more drinkable than others. This Amber Ale they're putting out now is definitely top of the line swill. Give it a shot. Generally I only resort to store bought stuff when I haven't been able to keep the homebrewing up with my appetite.

Anyway, this stuff isn't bad. I was shocked when I looked at who made it and took a sip.

Subject: oring blues

I make beer in 15 gallon batches. I make a session bitter to keep my wife happy. I make this beer a lot. It is very reproducable. The last time I made

it, I kegged it in 3, 5 gallon soda kegs. One, I dry-hopped and brought to

a family picnic. The second I brought out at a party. I was terribly disappointed in it. I couldn't pinpoint the taste, but blamed it on a heat-wave induced high temperature at end of fermentation. One other source I

feared was a contaminated keg. I took a sample out of the third keg. Hmm, tastes better. I brought a sample from each keg to the judge (my wife). Two different beers, I was told. I sat on the basement floor hugging keg number three and staring at number two trying to figure out what went wrong.

Then I saw it, a red oring on the liquid fitting. I had recently acquired a

number of soda kegs, but hadn't replaced all the orings (I ran out). I was a

minor doubter in the "you must replace all orings. They are evil" debate. Up

until this time, I hadn't noticed any problems with beers in these kegs (3 of

10). The orings were original. I replaced it with a new one and guess what?

The two samples tasted the same. I was happy. Better yet, the judge was happy.

This oring had enough leaching capability for my wife, a few beer friends, and

myself to notice. Just a datapoint.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
Subject: Novice mashing questions

I have just completed brewing my second all-grain beer. I now have a few questions about the procedure.

First, here are the details of the recipe:

8 lbs pale lager malt, pre-crushed
.5 lbs 40L crystal malt
1 tablespoon Irish Moss, 90 min
1 oz 5.5 alpha Cascade pellets, 30 min
.5 oz 7.7 alpha Northern Brewer pellets, 10 min
.5 oz 7.7 alpha Northern Brewer pellets, 1 min

Mash-in lager malt with 3 gallons water from the coin-op drinking water machine (to which I added .25 oz gypsum), at 60 C, in 5 gal Easymasher. Temp stabilized at 55 deg C. Protein rest for 30 minutes. Raised temp to 68 C, held for 1.5 hour conversion. Raised to 75 C, held for 10 min mash-out. Added crystal malt. Sparge with 4 gal coin-op drinking water with .25 oz. gypsum added. SG at end of sparge was 1.009, and a barely perceptible tea-like taste was present in final runnings.

Boiled 1.5 hours with above hop additions in 10 gal pot in which I installed a home-made Easymasher clone. Immersion chiller used to reduce temp to about 15 deg C. Drained into carboy using copper tube with holes in it to aerate.

Measured OG 1.054 for 5 gal. Pitched yeast, placed carboy into temp chamber mistakenly set to 5 C. Visible yeast activity after 18 hours, which increased dramatically after temp re-set to 10 C.

I got the idea for using purified water plus gypsum from G. Fix's article on Belgian Malts in Brewing Techniques.

My questions:

1) Rather than use the iodine test, I just tasted the mash. It was sweet and sticky after about 30 minutes, but I went for 1.5 hours to make sure. Any problem with this?

2) If I just add gypsum to purified water, do I really need to make pH measurements?

3) The sparge rate out of the easymasher was pretty fast, so I shut the valve down just to slow things down. Was this necessary, or could I just run it wide open and finish quicker? Runoff was clear after about 1 quart.

4) After draining the boiling pot, there was a lot of break material and hop pellet sludge remaining inside, thanks to the screen on the homemade easymasher clone. The bitter wort in the carboy was cloudy. After about 1/2 hour in the temp chamber, the cloudy wort in the carboy had cleared and precipitated a bunch more break material. My guess is that the stuff in the carboy was "cold break" or something similar, and the stuff remaining in the

boiling pot was "hot break". Sound reasonable?

5) In both of my grain brews, there has been a lot of sludge on top of the foam in the fermenter. This appears similar to the stuff that remained on top of the spent grain after sparging. Is this related to the protein rest duration and temperature? Seems like this came up recently in conversation here.

6) When I brewed from extracts in the past, I used three types of specialty grains: crystal malt for sweetness and color, roasted barley for that coffee-like bite, and black patent for blackness. Now I have become aware of a veritable plethora of specialty grains like Cara-Pils, Dextrine, Munich, Cara Vienne, Aromatic, etc.... Can someone tell me how to use all of these different types of grains?

I hope this long post is not considered a waste of bandwidth.
Thanks for your help,

Joel Birkeland

Date: Thu, 16 Sep 93 12:43:05 MDT
From: npyle@n33.stortek.com
Subject: Decoction procedure

Lee describes his decoction procedure in no less than 22 steps, the first being "Put 5 dead CDs in player, start". I would have to add step 23 if was to try this procedure: "Sign divorce papers, say goodbye to kids". Yow! If this is what it takes to do a decoction, I won't be trying a PU clone anytime soon. My infusion procedure is something like this:

Put 1 Dire Straits CD in player, start.
Heat 1 qt water per lb grain to 168F.
Add grain and water to mash tun.
Check mash temp, adjust as needed to around 154F.
Go to store or for a bike ride with the family, return.
Iodine test (wasted step?).
Add a few gallons of near boiling water to the mash, stir constantly.
Adjust mashout temp to near 170F.
Mash out for 15 minutes.
Kiss my wife.

I count 10 steps and 3 (4?) of them are unnecessary in terms of the actual brewing. Now, I'm not trying to start a flame war, nor am I trying to compare the merits of simple infusion mashing with decoction mashing. I just want to inform some of the extract brewers out there that all-graining doesn't have to be that tough. I suppose if you're really out to make a world class pils or something, that all of Lee's steps are valid, but you've used an entire day to do it. My method takes me about 6 hours now start to finish, and that includes the part about spending some time with the family. I still get "you're not going to brew beer this weekend again, are you?".

How about Lee's steps, all you decocters out there? Is all that pH adjustment necessary? Anyone like to compare procedures with his? Or mine for that matter? This is the type of thing I'd like to see discussed here, so that we can get more ideas on how to make better beer (maybe easier, too).

What about Rob's starch test idea on the finished beer? Would there be enough starch in the final beer for the iodine to pick it out? Too bad I just finished my Starch Brown Ale (boiled some brats with the last four bottles), or I would've tried this.

Mike, I think the 68 quart cooler will work fine for you for normal brews (as

you say, up to 25 lbs) but for a high gravity brew it might fall short.
The
solution to this is to do a normal sparge for the rare high gravity brew,
and
your 68 quart will be fine.

Cheers,
norm

From: npyle@n33.stortek.com
Subject: Hops FAQ Call for Papers

I have received only positive feedback on the idea of a hops FAQ, so I'm going ahead with it, partnering with Mark Garetz (mgaretz@hopstech.com). He's going to provide the technical expertise and I'm going to help out with some legwork, etc., as in this post. Never fear, naysayers, we'll try to work out all the details via email and post only relevant information to this forum.

The general form of the FAQ will be something like this:

General description of hops (Mark Garetz)

IBU formulae (anyone have Rager's formulae in a nice form? Other formulae?)

A treatise on growing hops (volunteers?)

A treatise on dry hopping (volunteers?)

A table of sorts with the following information (this will be the bulk of it):

Hop name
Area grown
Taste profile
Common useage (length of boil, type of brew)
Commercial beer examples
Alpha acid range
Good substitutes
Other?

Consider this an official request for information. I am looking for people to help fill in these areas, especially actual brewer's information on the last section. If you'd like to contribute please email the information to me: npyle@n33.stortek.com -OR- to Mark at mgaretz@hopstech.com. I should be the primary contact, but if you have trouble reaching my email address (this system is about as reliable as dry yeast), then send it on to Mark. I suggest that you don't send the same thing to both of us (except for comm problems), so we don't have to sort through it all and pick out the dupes. To make it easier on us, try to put things in this general order, but if you already have a bunch of info in a file, send it on and don't worry about it.

One more thing: we are open to suggestions about the format but we'd like to keep it simple; this is a FAQ, not a detailed research paper or book (Mark's writing that offline!). This is your chance to contribute to the digest, whether you are a relative newbie or a wise old owl! (Almost) everyone uses hops, so let's get your feedback. Hop-heads Unite!

Cheers,

From: ROB THOMAS <THOMASR@EZRZ1.vmsmail.ethz.ch>
Subject: yet more on decoction (yawn)

Hello again everyone,
I've certainly got enough info over the past couple of days to carry out a considerable number of tests at home. (maybe this weekend). One last point about the thin decoct:
in "Die Bierbrauerei" by Schuster Weinfurtner and Narziss (1992, vol. 2) they say that the thin part is 1Kg grain to 4.5 - 5 litres of liquid. Now that is definately not free of grains! So I read further. They say that returning this to the main mash gives a temperature of 75 - 77 degC, with a total of 1 Kg grains / 3 - 3.5 litres liquid. Under these conditions they claim that by the time the sweet wort reaches the kettle any starches have been hydrolysed to (soluble) dextrans by the ca. 8 percent activity alpha amylase remaining. However, as Jim Dipalma said, do we want to risk it after a whole morning's work?
Rob. Thomas

p.s. I just read further in the book, they say that the mash should be kept at 75 - 78 degC until there is a negative iodine test. Also:
"Thereby the gelatinised starch liberated during the boiling of the lautermash is also saccharified".

I test I might try is taking some of what's left in the mash tun during the last decoct and adding a boiling suspension of starch to it. Presumably I will see hydrolysis, and eventually a negative iodine test.

Cheers, and thanks all for the discussion,
rob thomas

Subject: McEwans Scotch Ale Recipe

In HBD #1227, Bob writes:

> I am in the process of trying to emulate the flavor of Ye Ole McEwans
Scotch
> Ale. I am an extract brewer that uses added grains. If there is
anyone out
> there that has had any success I would be very appreciative if you
would share
> your recipe with me.
>
I suggest the following extract based recipe to emulate McEwans Scotch
Ale:

9 lbs. light dry malt extract
1.5 lbs. dark caramel malt (90-120L) preferably English
8 oz maltodextrin powder
3 oz black malt

30 to 35 bittering units - this is 9 to 9.5 alpha acid units in a 1.088
gravity
wort boil. All bittering hops boiled for 45 minutes. no finishing hops.

use WYeast #1084 Irish Ale yeast and rack to secondary as soon as the
head falls
or as soon as possible.

In my recollection, McEwans is fairly strong (1.088 O.G.), malty
bordering on
sweet, has a pronounced diacetyl character and has big body. The color is
dark
brown.

The caramel and black malt provide caramel sweetness and a dark brown
color.
Maltodextrin powder and caramel malt provide residual sweetness, i.e.,
dextrins
and the relatively low hop rate lets the malt come through. The Irish
ale yeast
produces a high diacetyl concentration and early racking prevents the
yeast from
reducing too much diacetyl.

I have never used gelatin (or isinglass for that matter), but I have done some research on using isinglass in real ales. A pretty good micro near here is Red Feather Ale, a Peter Austin system, and they use isinglass in the secondary to drop the yeast prior to packaging. The brewer told me to "blend" the isinglass until thick and pasty and stir it in, let stand 12-24 hours prior to packaging. This is obviously not true real ale, but

First of all, Jack, mash tun != lauter tun, at least for most serious brewers who are using any system other than single infusion or your EasyWidgets. The objective of a mash tun is to convert starches to fermentable sugars and dextrins. The objective of a lauter tun is extract these fermentable sugars and dextrins without extracting tannins from the malt husks. Anyone who is "throwing away" the first runnings is wasting a lot of extract. Micah is/was of the school that does not believe in recircing, primarily due to his desire to maximize the

amount of lipids that survive into the fermenter. I believe in recircing until the wort clarifies, but still has particulate matter present. I have brewed all grain batches in 4 different systems over the past 5 years, and no matter what the size of the lauter tun, the recirc time is in the order of 10-15 minutes. I agree with concept that extract efficiency is not dependent on recirc time or quantity, provided an adequate amount of sparging is done to rinse the grains.

The swabbing of the area is most likely overkill as long as you use lots of healthy yeast and good (not necessarily anal) sanitation.

>
> For the record, I don't plan on using an open burner in the basement.
My hot
> water source will be the house's gas-fired heater, and the boiling of

> fermentation, and beer/equipment storage.
Think about physical labor requirements. How many pounds of hot wet mash are you going to lug into the backyard? Or if you lauter in the basement, how many gallons of fluid are you willin to lug upstairs? Can you do this yourself, or do you require a partner to brew?

>From Florian:
> Both these comments are in keeping with my original post about three years ago, when I claimed rights to a new method of lautering. This new method, which I stole from my brother-in-law, involves putting all the sparge water into the lautering tub at once. Only a minimal amount of recirculation

Hardly "new". Its called batch sparging and is the "other" way to sparge. Usually when this technique is used, the fluid level is allowed to drop below the grain bed, then the sparge water is dumped in to a few inches above the grain bed and lautering continues.

Good brewing,
Jim Busch

>Subject: RE: decoction mashing

> I don't think this is the case. There is always some insoluble starch in the chunks of grain that amylase enzyme won't touch. Boiling gelatinizes this starch, releasing starch that is now soluble but not converted into the wort. Thus, the presence of unconverted starch in the wort is not necessarily a consequence of low yields.

This may be a semantic point and I am not sure of your meaning because cause and effect seem to be reversed. However, unconverted starch in the wort is one the CAUSES of low yields.

>From: cush@msc.edu
>Subject: Enzymes and Munich malt

>Although I am not SURE about this, I think a reasonable generalization is that domestic Munich malts do not contain sufficient enzymes to convert themselves, but Munich malts of European source will contain sufficient enzymes.

It has been reported that The Munich malt from Belgium will convert completely by itself. This fact, along with its outstanding taste and easy availability make me wonder why anyone would use Bries.

>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)

>Raised to 75 C, held for 10 min mash-out. Added crystal malt.

I question this strategy but not knowing your reasons, I will simply state that I mix all grains together as I weigh them and then crush them together. I know of no reason to keep them separate.

>Measured OG 1.054 for 5 gal.

Nice yield. 3 cheers for the easymasher.

>1) Rather than use the iodine test, I just tasted the mash. It was sweet and sticky after about 30 minutes, but I went for 1.5 hours to make sure. Any problem with this?

Nothing other than the waste of time. Sweet and sticky however, is not good enough but 1.5 hours, no doubt is. The iodine test is far more precise than

taste but given enough time, it becomes irrelevant. If you don't want to use the test, you can just double the specified conversion times for the malt.

All malt is tested and rated for conversion time and this information is available from most sources.

>2) If I just add gypsum to purified water, do I really need to make pH measurements?

Without making the pH measurement, how do you know that you need to add gypsum? If it aint broke, dont fix it.

>3) The sparge rate out of the easymasher was pretty fast, so I shut the valve down just to slow things down. Was this necessary, or could I just run it wide open and finish quicker? Runoff was clear after about 1 quart.

It will clear faster if you slow it down but once it is clear, the rate is your option. There are those who believe that it affects the extraction rate and those who do not. I am of the later opinion.

>4) After draining the boiling pot, there was a lot of break material and hop pellet sludge remaining inside, thanks to the screen on the homemade easymasher clone. The bitter wort in the carboy was cloudy.

When using an emersion chiller, it should be perfectly clear after chilling and sitting for a reasonable amount of time. Try an extra thrity minutes after it is chilled.

The only time I get cloudy runoff is if I let it suck the kettle dry. I have a pump on mine and it will suck. It takes very little sediment to make your wort that was perfectly clear, look cloudy. Stop draining as soon as you hear the sucking sound. If the easymasher is installed correctly, this should only leave a few qts of stuff on the bottom. You can pour this into a sterile jug and add it back after settling.

> After about 1/2 hour in the temp chamber, the cloudy wort in the carboy had cleared and precipitated a bunch more break material. My guess is that the stuff in the carboy was "cold break" or something similar, and the stuff remaining in the boiling pot was "hot break". Sound reasonable?

Again, if you used an emersion chiller, what is left on the bottom is a combination of the two. What settled out later is what should have settled out in the kettle before transferring.

One other point (as you made the em yourself), the mesh size may be a factor here. It is not too critical in the mash tun but in the boiler, there is no real filter bed. For the record, I use and recommend 32 mesh screen.

>6) When I brewed from extracts in the past, I used three types of specialty grains: crystal malt for sweetness and color, roasted barley for that coffee-like bite, and black patent for blackness. Now I have become aware of a veritable plethora of specialty grains like Cara-Pils, Dextrine, Munich, Cara Vienne, Aromatic, etc.... Can someone tell me how to use all of these different types of grains?

My suggestion is for you to make a batch with none of the above to get a handle on the basic beer. Keep in mind that PU is made from a single malt and that is not a bad place to start. Many of the specialty grains are used to make extract beer taste like grain beer and offer little to the all grain brewer. The problem is sorting out the ones that are useful.

The most obvious are the color malts for obvious reasons. The next would be the roasted malts for that roasted flavor.

Beyond that, I run out of gas. I can't taste any of the others when added to by beer in the usual amounts and prefer to change the base malt. Please note that I said "I can't taste" and presume that those who can will fill in the blanks.

> munich/pale malt mixture, and they would call their supplier (Breis??)
> to inquire again about the enzyme content of Munich.

Real Munich malt (known as Dunkles Malz in Germany) contains enzymes,
and will convert itself in a 100% mash. For example, Dr. Fix has tried
the experiment with the DeWolf-Cosyns Belgian malts. The Siebel
Institute ran analyses on the D-C malts when they were importing them
(now they are imported by Schreier Malting), and as I recall, their
Munich malt had a diastatic power of about 60 degrees Lintner. (Keep in
mind that US 6 row can have 150 Lintner and 2 row Harrington, 110
Lintner.)

Munich malt is traditionally made from the highest quality, low protein,
2 row malt. By partially drying the green malt at 50-60C for 8 hours
and then raising the temperature to 100C for about 4 hours, melanoidins
(color compounds) are formed by the combination of amino acids and
simple sugars. The 100C temperature is a minimum needed to form the
melanoidins, but it is low enough, and the conditions within the malt
dry enough, that some enzymatic power is retained.

Briess "Munich" malt is not made the traditional way. It is regular US
6 row malt that has been roasted at well above 100C after drying to
produce a higher color, more akin to the way chocolate malt is made.
This high temperature roasting will destroy the enzymatic power of the
malt. It also doesn't produce the same flavors and aromas.

Your supplier should be able to get a malt analysis of any of the
products they supply, and the diastatic power (in degrees Lintner) will
tell the story.

Subject: identifying flavours

Trying to hone my judging and production skills, I am always trying to identify specific off flavours. At last week's meeting one of the club members brought a sample of diacetyl diluted in commercial beer. I think I now have a handle on what diacetyl smells and tastes like, and IMHO it is not even remotely buttery or butterscotch. However, if someone (a beer judge) tells me that a beer is buttery, I now know what sensation they are referring to, and I recognize it's contribution to the flavour profile of Yorkshire ales.

I am now trying to identify some other flavour/aroma components. There is a flavour I have come across recently in a friend's kit beer (all malt) which has a very sweet cotton-candy flavour, which I presume to be 2-3-Pentanedione. Again, this does not have a "honey" smell which is frequently linked to this compound. I have detected a "clover honey" aroma in some beers (notably Brick, when it first came out), but this did not come through in the flavour profile.

Can anyone help with these compound identification problems:

1. Does anyone else think Diacetyl (2-3-Butanedione) smells and tastes nothing like butter or butterscotch?
2. Does 2-3-Pentanedione taste like cotton candy? If not, what does?
3. What actually produces the clover honey aroma (note, this aroma is fairly specific to clover honey, not honey in general. Sniff some honey if

you don't believe me...)

Thanks.

Subject: 1993 Hop Harvest

Well, the hops are in and dried. Anyone interested in comparing notes?

My hop yield last year, their first season, was very dependent on variety. I assumed that Mt. Hood, Nugget and Willamette just needed another year to get established. However, yields for these varieties were disappointing again this year:

Dried weight (oz)	
Variety	19921993
=====	=====
Cascade	12 16
Mt. Hood	5/83/4
Nugget	3/8 1
Willamette	3/83/4
Chinook	10 1/2 5 1/2

My location is eastern PA; the hops get a lot of sun and good rich compost, but I may not have been diligent enough with the watering. The Chinook vines in particular seemed to get scorched this year, possibly explaining their low yield compared to last year. Any hints for getting yield out of the other varieties.

Also, I'm moving to Orlando next year. Can you grow hops there?

Subject: Decotion : epilogue

The recent thread on decotion mashing is a fine example of using the HBDS collected resources to better understand the details of brewing. In this case we discussed getting to mashout temp in a decotion mash: equipment, methods and potential problems. The long strange trip 23 step method to better decotion wasn't intended to scare people away from grain brewing. It was intended to show the steps involved in this advanced all grain brewing process and act as a point of reference in further discussions involving efficiency improvements in this time consuming process.

Norm fears divorce if he tries decotion mashing: Decotion mashing does take much longer. I do 3 or 4 a year in an attempt to brew a world class Pils or Fest beer, it takes about 6 hours for double decotion (strike to protein rest temp decotion 1 to mash temp 2 to mashout) and about seven for a triple which I don't do anymore. IMHO the only way to achieve the malty character of these beers is decotion mashing of under modified malts. I have tasted well brewed Pilsners that were made from highly modified US, British and Belgian lager and pils malts decocted or infused and they don't have the same character as a brew from decotion mashed under modified German pils malt.

Re: having a life + brewing
This spring I did a triple decotion Pils, one of my best efforts ever, in between steps I would attend the annual town meeting. I didn't miss a single vote and got to speak on the issue that most impacted the neighborhood I live in. Most of my other brews are single or double step mashed ales. I brew a beer called "Pride of Cucamonga" it is a not to AHA style single step US 2 row Cream Ale. It takes about 4 hours start to finish. Tastes great/filling. I also tend to intermingle brewing and household projects and do them on the weekend day that my SO works. This Saturday paint the hall + stairwell and brew some "Pride" next weekend the Dead, they're high stepin' into town.

RE: "All those PH adjustments"
These are readings, easy with a digital PH meter, more than adjustment and were included more for theoretical completeness, this net gang is a tough crowd to please. It is important to maintain a low enough PH when you boil

the grains or off flavors will be extracted. Since I add water to the thick decoction to minimize scorching and caramelization attention should be paid to the preboil PH particularly if your water can cause a significant rise in PH.

I have recently constructed an insulated mash/lauder tun, I will post the description soon. This will allow me to now:

Do an Iodine test on liquid drawn from the spigot it is less likely to contain grain chunks with ungelatinized starch that can produce false negatives.

Remove liquid only for the final decoction and eliminate the potential for starch haze as discussed previously.

Reduce a source of hot side aeration since I will not be transferring hot mash from the kettle into the lauder tun.

Subject: How much carbonation is good?

I am sure I have asked this question before, but can't find any answers in my archives. Anyway, here goes.

It seems that there are two basic options out there for serving beer:

- 1) Get the carbonation to the level you want it to be in the glass and pour gently from the bottle/keg/cask.
- 2) Overcarbonate in the bottle/keg/cask and pour more violently, pausing frequently to let the foam settle down and get a decent amount of liquid in the glass.

Now it seems most German lagers use method 2). What is the advantage to overcarbonating and then getting back to a more normal level with pouring correctly? Is it something to recommend we homebrewers try? Is it something that only benefits a few styles? Do some brewers avoid it only because they are afraid it won't be poured correctly from the bottle? Enquiring minds want to know.

Subject: Re: Pumpkin Pie Ale

I had the same experience as Bill Flowers with pumpkin from hell never getting out of the beer, but the resulting brew won a prize (OK, it was in the "weird beer" category). Make a darker ale and they can't see the pumpkin haze.

But what I figured I would do next time is "mash" the pumpkin and put it in a grain bag or somesuch and just squeeze out the "pumpkin essence". Just don't put canned pumpkin right in your wort.

Also, I used the "amount for two pies" rule and used that amount of pumpkin and that amount of spices.

Subject: Keg secondary -> bottle sanitation

While discussing bottling from a soda keg secondary one of our club members told us a sad story. He had brewed an excellent brew that was chosen to represent our club in an AHA club competition. Per usual he used a soda keg secondary and transferred it to a sanitized, air free serving keg using the process outlined by Jim Dipalma in a recent post. He then sanitized a bunch of bottles a rigid plastic tube and his tap. He added some boiled corn sugar solution to the serving keg and stuck the rigid plastic tube in the outlet of his tap and bottled. A month later he tasted a bottle, ugh contaminated. He reviewed his process which he followed many times before. Someone asked him did you soak your tap or disassemble and soak? He never knew that the picnic tap could be disassembled. That night I went home inspected one of my picnic taps, It unscrewed into two pieces and revealed possible places for contamination to develop.

Next time I bottle from a keg either counter pressure or from primed serving keg I will disassemble my picnic tap and sanitize.

>itself.
>
>Well, to make a long story short, I ended up with a large pot of starchy
>porridge..... (that I fed to the compost pile)
>
>When I went back to the supply shop to complain/ask whether the malt
>did indeed have sufficient enzyme activity they (jokingly??) asked me
>if I was SURE I had not killed my enzymes.

Those people at the supply shop should get their education and attitude
in order or they will be out of business soon. Just a few data points
that I can offer on the DeWolf-Cosyns Belgian Malts:

name	Lintner Lov		
Pale Ale	60	3.21	
Pilsner	1051.83		
Wheat	1.75		
Munich	50.2	7.83	
Aromatic	29.1	25.7	

A US 2-row, for comparison:
Schreier 1311.78

This is how it is listed in the lab tests -- all the rest of the DeWolf-
Cosyns
malts either have 0 or a blank under degrees Lintner. I'm confident that
the
Wheat does have diastatic power, but it probably was not tested for it.
The
analysis says that the Aromatic will mash itself, which means that
anything
over 29.1 degrees Lintner will mash itself. I've seen 200 degrees
Lintner
reported on some 6-row pilsner malts, but since most of us don't add too
much
flaked grains (corn, wheat, oats) I don't think that there's much to
worry
about if you have at least 50 Lintner in your base malt.

David,

This might be air but it is more likely carbon dioxide. You are probably seeing a combination of the siphon tube not being completely filled with liquid when the siphon is started, combined with CO2 coming out of solution while racking.

DA> suggestions to the list or to my email will be welcome. Bottling is

I've seen a number of people have the same problem and the solution is amazingly simple. Start your siphon by whatever method you use (I just take a good "draw" on the end of the tube. Put the end of the tube in the vessel that you're racking to and immediately grasp the tube where it is fitted on to the racking cane. About 1-2 inches from where the tubing joins the racking cane, bend the tubing up, above the level of the top of the bend in the cane. You might even slightly pinch the tubing at the top of the bend. You'll see the tubing on the cane side fill completely with liquid, pushing the air/CO2 out and up over the "hump" that you've formed. Slowly lower the "hump" down and the entire tube will fill with liquid and your siphon will proceed normally.

It sounds a lot harder than it is; it's easy to do but hard to describe. Try it once with water and you'll see how simple it is.

Subject: o-ring defunking

I don't keg and wouldn't know an o-ring from an onion ring (I thought they were the same thing). However, for those who would rather not replace their o-rings, I have a suggestion which may be helpful in eliminating unwanted odors.

Try placing the offending o-rings in an airtight container (zip-loc bag) with some balled up newspapers and leave them in the freezer overnight. The newspapers will "suck-up" the odors.

This works on those wonderful "plastic containers sold at parties" so it just might do the trick on the ol' o-rings.

Subject: FAQ's

I think the recent trend toward FAQ's is absolutely great. (Personally, I don't much care how they get hashed out in the digest. If I'm interested in the dicussion I follow it, if not, I scroll past it. The important thing is that it gets done!)

The only thing is, I've lost track of how many there are! Can somebody post a quick directory of the FAQ's and how to get them?

I remember something about all-grain equipment, the recently completed yeast FAQ, the keg FAQ in progress, and of course the Cat's Meow. Are there others?

Personally, any helpful information for the computer-illiterate would be real welcome too. I hook up to my campus VAX through my Macintosh. I "f.t.p.'d" to stanford to get the Cat's Meow about a year ago, but it didn't print out too well. I saw someone else's copy which looked absolutely beautiful, with cover art and all, but this is all kind of a mystery to me as to why the copies came out differently. I suppose it has something to do with zipping or compressing or one of those things?

Sorry to flaunt my ignorance. I eagerly await enlightenment!

Guzzling away,

Subject: Homebrew Digest #1223 (Septemb

I have recently made my first foray into mini-kegging, with those 5-liter jobs that have been available for imported beer for so long. I was told that approx 1/12 a cup corn sugar would suffice. After 4 weeks of aging, on two different batches that I bottled at the same time and turned out fine, both kegs were nearly completely flat. Luckily my friends were willing to drink flat beer, but I was wondering if anyone else had any experience in priming amounts necessary for these mini kegs.

While I'm here and dyslurking, I have another question. Other than spiritual and philosophical blessings, are there any real, tangible advantages to priming with DME or using a gyre to prime? I'm just an evil barbarian extract/dry yeast brewer at this stage in my experience and while lots of the stuff I make is quite decent, the flavors are always strong and harsh, like a Ben & Jerry's beer.

Subject: apple/cinnamon brew

Hi Folks,

Well, here in New England, Autumn is approaching us rapidly; leaves are changing, pumpkins are available by the ton, apples are ready, and hot mulled cider fills the air.

I'm interested in making an apple-cinnamon brew; seems appropriate for the season. My initial thoughts on how to brew this are below. I'd appreciate any tips/input on ways I can make this better. This will be my first brew w/ fruit.

6-7 lbs light DME
2 oz hallertauer hops
3 oz cinnamon (boil) (I'll use sticks)
3 oz cinnamon (finish)
irish moss
EDME dry-yeast

(5 gallons)

Boil 60 mins; add finishing hops when i remove the brew from the flame. Likewise for the finishing cinnamon. I'll probably rehydrate the yeast too.

Ferment for 4 days or so; after 4 days, prepare the apples; i'll cut 'em up, then pastuerize them at 170F. transfer the brew to a secondary, dump the apples in. Ferment for another 4-7 days; bottle/keg. As for priming, I was thinking of using honey - how much should I use? Is there a risk of beer bombs if i don't drink the stuff fast enough? No problem w/ the keg...

Questions:

- How much apples? I'm thinking 7-10 lbs
- Should I include the apple skins?
- More cinnamon? less? my experience tells me that the cinnamon effect disappears like hop aroma over time...

Thanks,

Subject: King Kooker mod

I did the following mod to my King Kooker this week end. It works great on the 6-8 gallons I begin to boil. No black soot on the bottom of the pot, no black soot when I turn the flame way down, seems like a more efficient burn.

I removed the brass nut that constitutes the burner. I plugged the existing hole with a sheet rock screw. I ground the head end of the screw off flush to the nut. On an adjacent nut surface I drilled a 1/16" hole. I replaced the brass nut.

Notes:

- 1) I removed about 1/8" - 1/4" from the point of the screw prior to insertion so it would not protrude thru the old hole.
- 2) I used the surface "after" the one with the original hole making it 1/8 turn tighter. I thought this better than 1/8 turn less.
- 3) 1/16" was the smallest bit I had. If all you brew is in the 5 gallon range and you are trying to improve the fuel efficiency of the Kooker a smaller hole may work. These brass nut are available in hardware stores for half a buck so I may try a smaller hole if I find a smaller bit.

Subject: fermenting with reckless abandon

Greetings in HBD land,

I am having a problem with a current all-extract wheat beer I'm making. I have made this same recipe several times, but this is only the second time I have used a liquid yeast (Wyeast Bavarian Wheat). The problem is that it's fermenting so wildly, that it blows the sanitizing solutions out of my one-way valve and then fills the valve with foam. The other time I used this yeast, it fermented quickly, but not so violently. I'm still using the cave-man equipment of a single stage fermenter made out of high grade plastic. My question is "Is there a way to slow down the fermentation a bit?". If not, is there a way I can clear out some of the foam while minimizing the risk of polluting my beer? I've been taking the valve off, pressing down on the cover so a bit of foam comes out and replacing the valve (all cleaned out and refilled with more sanitizing solution).

Should I merely relax, don't worry...?

Any help would be greatly appreciated.
Thanks in advance, Eugene

while
> lots of the stuff I make is quite decent, the flavors are always strong
and
> harsh, like a Ben & Jerry's beer.

Theory tells us that due to the differences in the way that yeast
ferments
malt and corn sugar, that there will be differences in the beer according
to the priming technique you choose: a beer primed with DME or wort will
go through both respiration and fermentation phases of yeast
metabolism. During yeast respiration, the yeast consume oxygen on their
journey to reproduction. The corn sugar primed beer will bypass the
respiration phase via the crabtree effect. Theoretically, the malt
primed beer will have better flavor stability as oxygen has been
scavenged from the bottle during the bottle fermentation.

Some unsolicited advice: If you switch to pure liquid yeast cultures,
you can make huge advances in your beer quality. Using some simple,
creative culturing techniques, you can use liquid yeast with minimal
price penalty. All you really lose is the ability to brew on a whim as
brewing good beer with liquid cultures requires the use of a yeast
starter and its associated leadtime.

From: COOK@CDHF2.GSFC.NASA.GOV (Chris Cook)
Subject: CO2 Connection Questions

A question about keggering and counter-pressure bottle fillers. How do people change fittings to CO2 systems?

I have one CO2 tank that I use for everything. That means:

- 1) Storing beer at home in the basement. Because of leaks, I usually keep the CO2 disconnected, repressurizing kegs when they need it. The best setup is one gas connection and a long hose.
- 2) Serving beer at group events. Although for smaller groups I just repressurize periodically, for larger events I try to keep CO2 connections on the popular kegs. The best setup is a string of gas connections spaced closely.
- 3) Counter-pressure bottle filling. This means one gas connection and the CP filler.

The only way I can connect and disconnect this stuff is to get the wrenches out, and I worry about the wear and tear for the connections and nylon bushings (which I usually drop at least once).

Is there an easier way to make changes? Are there quick-disconnects for the line, or some such? How do other people work with CP fillers?

From: Spencer.W.Thomas@med.umich.edu
Subject: Sweet Gale (Bog Myrtle)

Today, I was reviewing some books on brewing before taking them back to the library, to see what I might want to copy for my files, and re-encountered this passage from Odd Nordland's Brewing and Beer Tradition on Norway. I should note that the quotations come from questionnaires filled out by Norwegians about their knowledge and recollection of old brewing practices.

The important part played by the grut of Central Europe ... has already been discussed. From the fourteenth to the seventeenth century, the most important ingredient of this mixture of dried leaves

and spices was bog myrtle, *Myrica gale*, which will here also be referred to as pors [presumably the Norwegian name].

The bog myrtle was an important plant in medieval Norway, being mentioned as early as in fourteenth-century laws. ... rent for farms could be paid in bog myrtle ...

... bog myrtle occurs as one of the plants that could be used for flavouring ale: 'To add a strong flavour to the ale, and to make it heady, pors was put into it. ... It was gathered in autumn, and the leaves were also taken.' 'When this plant was used, the ale was strong. It went to one's head. They spoke of having a "Christmas head".'

... In northern Hordaland, small quantities of pors were added to the Christmas ale until the turn of the century.

... 'The ale was flavoured with hops mixed with pors. It was slightly yellowish, and had a fresh, sweet taste. It was said locally that when one drank much of it, it was strongly intoxicating, with unpleasant after-effects.'

...

That bog myrtle produces a special effect when added to ale is ... well documented in our material, and in earlier sources ... Linnaeus ... mention[s] the especially intoxicating effects ...

... Does bog myrtle possess the properties that were once ascribed to it...? ... chemical analysis has revealed no such properties. [One writer] is inclined to believe that there must be some substance in the bog myrtle that has the effect described. But he is also open to the suggestion that the belief in a special effect gave rise to an increased consumption [that] produced effects of the kind described. ... The solution of these problems would ... require a complicated analysis, and as it is of little practical value to find the cause of the alleged headaches of bygone ages, the question will probably remain unsolved.

It is not clear from this material what part(s) of the plant were used, except for the mention that "the leaves were also taken." He does refer at one point to the shape of the fruit of the plant, so we might assume that this is what was used. Certainly, Rajotte refers to the seeds as the flavoring agent in his Santa's Magic Potion. In the American herbal, the most closely related plant is the bayberry, from which the twigs and roots seem to be used (at least, that's what I can

find in herb shops around here).

Subject: Cooler size, Hop yields NOT

Thanks to all who responded to my cooler size question, both publicly and via e-mail. Many of you requested information about my equipment (price, where purchased, etc.). I responded to all, except my mailer said I provided one incorrect address (didn't tell me which one, though). If you sent me e-mail and I didn't reply, please let me know.

Re: hop yields

I purchased hop plants this year (yes, little plants, not rhizomes) VERY late in the growing season through mail-order from Richters in Goodwood, Ontario, Canada.

I received one each of Cascade, Mt. Hood and Hallertauer. I planted them on the last weekend in June about 70 miles north of Toronto.

The Hallertauer only reached a height of around 7 feet, while the Cascade grew off the end of its pole (around 12 feet). I am already preparing for next year by searching for 30 foot saplings.

The Cascade was/is my only producer, with 3 hops. :(
The hops look very sad hanging there all alone.
Perhaps I can use them in a small (1 oz. wort) test sample. :)

The Weatherman predicted ground frost last night, can hop plants handle a little cold?

Cheers,
Mike

Subject: Bass yeast/2.5 gal in a 5 gal carboy/DME priming

Bob writes:

>I want to make the Bass Ale recipe listed on page 32 of The
>Cat's Meow II & was wondering what style of Wyeast liquid yeast
>I should use??

I recommend that you use Wyeast #1028, London Ale, which is reported to be the Whiteshield strain (Whiteshield being a bottle conditioned beer made by Bass -- at least it used to be bottle conditioned -- now, I don't know).

Denis writes:

>we want to attempt to brew
>2.5 gallons of beer in a five gallon carboy (we want to brew two types
of beer
>and feel ten gallons of beer would be a little excessive :)).

>Has anyone out there done this before? Can anyone think of any possible
>problems that may occur? (Basically we are worried about oxidation)!

Don't worry, to borrow a phrase from Charlie... when you just add the wort to the carboy, you will have air in there, but that's when you want oxygen entering your wort. Later, when fermentation begins, the air will be pushed out of the carboy by the CO2 that the yeast produces (CO2 is heavier than air). See... no problem!

p.shaw writes:

>Other than
>spiritual and philosophical blessings, are there any real, tangible
>advantages to priming with DME or using a gyle to prime?

Personally, I started by using dextrose for priming. Then I went to DME because I had read so much about the "EVILS OF ADDING CORN SUGAR TO YOUR BEER." Eventually, I switched back to dextrose most because I think it's easier.

On some of my batches primed with DME, I noticed a sort of floating, "oily" scum on the top of the beer in the bottle. Some have written that this is similar to the kraeusen ring in the fermenter, but I have reason to doubt it. I think it's protein from the DME priming solution. If I'm correct in this assumption, it should be remedied by force cooling the DME priming solution so that cold break forms and is not added to the priming vessel (is left behind). See what I mean about dextrose being easier? Since switching back to dextrose priming, I have yet to see this scum in my bottles. I would test this theory myself, but since I'm having trouble finding time to brew, I would suspect it will take years for this test to reach the top of my list. Any takers?

Subject: Specialty malts at mash-out?

Jack sez:

>>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
>
>>Raised to 75 C, held for 10 min mash-out. Added crystal malt.
>
>I question this strategy but not knowing your reasons, I will simply
state
>that I mix all grains together as I weigh them and the crush them
together.
>I know of no reason to keep them separate.

I know of a couple. For crystal malt, the starch -> sugar conversion has supposedly already taken place in the process. Crystal malt is kilned at a high temperature (160F+???), causing the enzymes to convert the starch to "unfermentable" sugars. It is then dried, forming sugar crystals within the kernels, thus the name (one of several). It is not necessarily a bad thing to add this to your mash but it is likely that some of the "unfermentable" sugars in it will be broken down by the enzymes in the mash into fermentable sugars and some of the desired sweetness will be lost. Granted, this is probably a small portion of the sugar in the malt, but some sweetness will be lost.

For other specialty grains, like chocolate and black patent, I like to add them at mash-out time as well. In this case, I've noticed a harshness extracted from the dark grains if left in for the entire mash cycle. It has never appeared to me in my beers when I added the dark grains at mash out. With dark grains, the intention for me is to add some color, and roasted flavor. I can get a really smooth brown ale with my method, but I like the beer much less if the dark grains are mashed with the pale malt. I've also noticed this with at least one microbrew, although others have not. It may just be something I'm sensitive to. I've not brewed a stout, though, so I don't know how this method works in that arena.

...

Lee, sorry to be a tough crowd. I do appreciate your explanations re: the pH adjustments. Maybe I'm just jealous about your awesomely malty lagers, but I'm also fortunate that my favorite beer styles (US and UK hoppy ales) can be done with a simple infusion.

...

Fairly often someone (this time Denis Trudeau) asks about brewing small batches in a large carboy wrt oxidation. I do this virtually every time: brew 5 gallon batches in a 7 gallon carboy. This gives more surface area than, say 2.5 gallons in a 5 gallon carboy because the diameter of the 7 is larger. Anyway, I have had no discernable oxidation problems and was wondering if others have had any trouble. (This question is aside from blowoff considerations, Al!)

...

John asks about carbonation and pouring methods. Sorry, John I've got no answers, just more uncertainty. I've heard a half a dozen ways to "properly" pour beer. Here's a sample:

- 1) Pour down the side of the glass to start (to see how much carbonation is there) and finish off at the top with as much turbulence as is necessary to create a 1" head.
- 2) Pour down the middle of the glass to start and then ease off (i.e. pour down the side to achieve the magical, mythical 1" head.
- 3) Pour down the side of the glass (a good beer shouldn't need help in forming a nice head). I believe this one was from M. Jackson, but I can't swear to it.
- 4) Pour down the middle of the glass until full of head. Stop. Wait for head to drop. Repeat until you achieve the quintessential 1" head.

There are others, but I suggest: Pour it the way you like it. One of the reasons we homebrew is to do things the way we like them. Pouring should be no different.

...

Jonathan wants a FAQ for FAQs. Hmmm, are we getting high-tech or what?

...

Cheers,
Norm

Subject: rebottling

I have recently bottled (several weeks ago) an entire five gallon batch of Kolsch in Grolsch bottles (Kolsch in Grolsch ?...Hey, I'm a poet and don't know it but my feet show it cuz they're Longfellows :)).

Anyway, since then, I found that a local brewpub is sponsoring an Oktoberfest/Homebrew competition and I would really like to enter this beer for critique. Those who have submitted beers in competitions now see my dilemma - I can't enter the beer in a Grolsch bottle. So I'm considering rebottling a number of them in the required brown 12 oz. longnecks.

What is the collective wisdom on this? Should I "supercool" the beer and decant it very slowly into the longnecks so as not to disturb the brew?...Will I lose the carbonation? Anybody ever done anything like this?

Thanks,
john

Subject: someone asks about cardamom

The dictionary describes cardamom thusly: "A tropical Asiatic perennial plant, *Elettaria cardamomum*, having large, hairy leaves and capsular fruit, the seeds of which are used as a condiment and medicine." Cardamom is used as a seasoning in Asian cooking, especially Indian cooking. Specialty food stores carry cardamom seeds, while your favorite grocery store has crushed cardamom in the spice section. When fresh, cardamom has (to me) a lemon-citrus flavor note. I've used it as a "secret" ingredient in small amounts in wit and strong Belgian ale recipes. While there are lots of ways to add spices, what has worked for me is adding some in the last 10 minutes of the boil.

Subject: Re: Hop Harvest '93 & Beer of the month club

I planted my risomes (2 Cascade, 2 Chinook & 1 willamette) in late April. I live about 40 miles northeast of Boston on the NH border, so we have a decent growing season. My Chinook did great, they grew about 15 up the side of my house and I got a sandwich bag full of hops. The cascade grew well too, about 12 feet, but didn't produce any hops. The Willamette, was a disappointment, it never came up. It sent out roots, (I dug it up to check on it) but it never sent any vines. I was reassured by the people I got them from that it will do something next year, but I have my doubts. Has anyone else had a similar experience?

Regarding Beer of the Month Club, I have a subscription to one called Beer Across America, for details e-mail direct, Day@a1.tch.harvard.edu

From: gjfix@utamata.uta.edu (George J Fix)
Subject: Fusel Alcohols; Lipids

Greetings one and all!

The article I wrote on fusel alcohols that appeared in the last issue of Zymurgy had the following typographical errors:

(1) The last part of the second paragraph on page 32 was truncated. It should read as follows:

" ...widespread agreement about the implications that brewing procedures and brewing materials have on fusel alcohol levels. Some of the most important of these points will be discussed in this article."

(2) The sentence on page 33 stating that aromatic alcohols were volatile should read

" These are also non-volatile, and are characterized by the presence of aromatic rings."

(3) I have no idea where the crazy structure shown at the bottom of page 33 (first column) came from. It is certainly not Tyrsol. The correct structure can be found on page 64 of my book on brewing science.

I have received a lot of private e-mail concerning the Jones/Millspaw article that appeared in Zymurgy, and in particular about the general question of "lipid enhancement". It is well known that lipids can be used by yeast as a replacement for O₂. Turbid wort is rich in lipids, and if this is carried over to the fermenter, there is less need to aerate the wort before pitching. This has been exploited by high gravity brewers (primarily in the the UK) to lessen the O₂ demand of yeast used to ferment worts with OEs of order 18 P (1.074). My problem with this practice comes from my experience that fatty acids derived from trub are major players in beer staling. This may not be a major issue with homebrew that is afforded pristine care. However, it could be an issue for beer that is shipped (to competitions or friends), and is subject to mechanical and/or thermal abuse. In any case, it appears from my own brewing experiences that failure to properly clarify wort can be a destabilizing factor for most beers.

Subject: re Brewpubs in Utah

Mike O'Neil asked about brewpubs in Utah and Arizona.

There are three brewpubs that I know of in Utah. Squatters in Salt Lake City, Eddie McStiffs in Moab, and Ebenezers in Ogden.

Squatters is the oldest, and they produce some fine offerings. Last time I was in SLC, they had cask conditioned real ale. The stout is OK. The pale ale is lacking something, but after all, this is a 3.2% (control) state and I am sure most of their customers do not like lots and lots of beer flavor.

Ebenezers is housed in a beautiful structure in Ogden. The beer is too cold, and it does not have much beer flavor. They usually have 4 offerings, one of which is a seasonal brew.

Eddie McStiffs has a tasty stout. I was not impressed with their pale. I guess Utah is not a good place to get pale ale, unless you make your own.

Hope this helps.

From: Lee=A.=Menegoni@nectech.com
Subject: Grain at mash / DME prime /Recirculate

I agree with Al K's comments on DME priming. Unless one boils it for a half hour or so and then chills you will get potential haze. The small amount of corn sugar used to prime will not cause off flavors. Since I bottle from keg secondaries and there is a fair amount of CO2 in the brew already

I use 1/3 cup per keg with my ales. I don't provide additional carbonation to lagers with sugar I force carbonated them, I do so because it took me so long to brew (decoction) and ferment/lager I am concerned I may produce off aromas.

Grain at mash out: For dark brews I add grains at mash out it makes the iodine test easier to read. For lighter colored brews I mash all the grain.

When I sparged my recent brew I used Rob Thomas suggestion of testing for starch. When the liquid tested negative I declared this to be "clear" and began collecting wort even though the run off was some what opaque. Does the matter in suspension contain lipids mentioned in a previous post? Is clear another of those vague terms that we find in brewing references?

the
>foam while minimizing the risk of polluting my beer?

The way to slow down your fermentation is to lower the temperature -- if
this is possible with your fermentation room. If you are fermenting in
the
basement, if you patiently search around the basement with a thermometer,
you can usually find a cooler corner. Greg Lawrence, a fellow local
homebrewer, was having problems with too warm a fermentation room. His
heat plant was in there, plus the dryer, plus a refridgerator, plus the
beer itself was making a lot of heat. He solved the problem by building
a sort of foam insulation box, which insulates his fermenters from the
room -- the three uninsulated sides of the box are the cement floor and
two cement walls of the foundation. This effectively reduced the temp
a good 10 degrees (if I recall correctly).

Another method for fermenting in a cool place if you don't have a cellar
is to ferment outdoors in an insulated box with a thermostatically
controlled
heater in there -- be careful to not burn anything down! Some have used
an old refridgerator with a light bulb for the heat, but recall the light
damage that can result, so you'll have to figure out a way to get the
heat
out of the bulb without the light. Some kind of sheetmetal baffle system
painted with flat black engine (heat resistant) paint, might be the
solution.

My initial thought was (no, not the blowoff method, Norm) to suggest a
larger
fermenter, but you did mention that you were having this problem
specifically
with a *WHEAT* beer. I suspect that the fact that wheat malt is higher
in
the proteins that give good head retention is why the kraeusen may be
lasting
so long as to come out through the airlock hole. If, indeed this is why
you
are having this problem, perhaps even a lower fermentation temp may not
help.

I used to be a strong supporter of the blowoff method, but I've begun to
have

my doubts. My doubts began when I brewed my 1120 OG Lithuanian Imperial Stout. The head retention on this beer's krausen was so good that not only did the fermenter blowoff into the 1-gallon blowoff vessel (a plastic milk jug), but the krausen of the blowoff vessel foamed all over the place! I cleaned up, dumped the blowoff vessel, added fresh water and let it finish. When I went to bottle the beer, I found some blowoff behind the fermenter that had dried like a piece of styrofoam! This is when I first began to suspect that perhaps head-retaining proteins were being lost in the blowoff.

I plan to test this theory.

Despite this, if you cannot contain your krausen, I suggest that attaching a hose (the wider diameter the better -- my blowoff hoses are 1" ID!) and putting the "out-end" into a bucket or jug partially filled with water is safer than skimming or the procedure you described in your post.

Al.

Eugene,

You don't want to slow down your fermentation. You should use different equipment. Rather than using a fermentation valve, substitute a stopper with a hose that runs into a bottle of H₂O with a few campden tablets dissolved in it. The foam that is clogging your fermentation valve will pass through the tubing into the jar of water/campden solution. The system will be a closed system and will keep any airborne nasties out of your brew. When the primary fermentation has settled down, remove the stopper and replace it with a fermentation valve. I routinely use such a set up when brewing mead (which has a rather violent primary fermentation

What nylon bushings? None of the flare fittings I have have any nylon bushings and unless you are a gorilla on your wrenches, you should have no trouble with repeated coupling/uncoupling of flare fittings.

Chris> Is there an easier way to make changes? Are there
Chris> quick-disconnects for the line, or some such? How do other
Chris> people work with CP fillers?

Sure, you could use any number of different disconnects, only they will cost you in the range of \$15 to \$20 per part at wholesale prices. I just get out the wrenches every time I want to use the CP filler. No hassle at all. You could also get a distribution block which is a brass block with 6 threaded holes, one input and five output with check valves and ball valves. Hook up to your heart's content any combination of things.

From: jim@n5ial.mythical.com (Jim Graham)
Subject: Samuel Smith's Pale Ale & Oatmeal Stout

Note the Reply-To address listed in my .signature---please direct replies to me as n5ial!jim@gagme.chi.il.us. This is temporary, but for the next couple of weeks, it's very important. I'd set the actual Reply-To field, but in a digest, it would never appear anyways.....

Anyways, I was wondering if anyone had a recipe (extract or extract plus specialty grain) for a clone of either Samuel Smith's Old Brewery Pale Ale or Samuel Smith's Old Brewery Oatmeal Stout.

Alternatively, does anyone have a recipe for a good oatmeal stout? One sip from the Samuel Smith's oatmeal stout had me sold on this wonderful variant.... (I've always been a fan of the Samuel Smith's Pale Ale...at least, I have been for about 9--10 years or so.) I must say, even though I've had some pretty good stout in the past, the oatmeal stout beats all of the others, hands down.

Oh, I should add this bit---I don't have a carboy. I have a single-stage fermenter, and zero money to buy a carboy. If there is any way at all to brew either variety in a single-stage process, please gear any responses in that direction. Otherwise, I'm still interested, if nothing else, for future reference.

Thanks,
--jim

Subject: Grainmill information request

I am covered with shame, embarrassment, and residue. The richness of HBD overwhelms me and, having other interests, I plead guilty to precipitate zapping. Now, I find that my grainmill has gone south (where I foolishly sent all that HBD wisdom) and I am in need. I seem to remember that a new grainmill was announced, but heeded not. Now I quiver to know, being desirous of fine crush (almost powderlike, with intact husks) and minimal gelt requirements. Gods, do not tell me that there is a FAQ-file; do not overwhelm me with penitential test results, but respond, I beseech thee, to Bokenkam@ucs.indiana.edu.

From: Elaine Boris <EBORIS@UGA.CC.UGA.EDU>
Subject: CHERRY PORTER

Greetings & Happy Equinox,

Back in July I had asked about making a half batch of cherry stout in my 7 gal secondary. I want to thank, belatedly, everyone for their input and suggestions. They encouraged me to give it a try. I ended up making more of a porter than a stout and I was very pleased with the sample I had this weekend. The only problem is that the carbonation is low, and no head to the beer. There is enough so that you wouldn't call it flat and it stays carbonated even with a slow sipper like myself.

I used cherry extract (w/pits, unpasteurized) because several HBDers suggested it and also the available cherries looked unwholesome. I started with 8 oz that I added to the primary fermenter, but when I racked to the secondary and sampled a little, it had no cherry flavor so I added 8oz more. Now the cherry flavor is there but subtle.

INDEPENDENCE CHERRY PORTER 7/05/93
4 GALS BOTTLED 7/18/93
1LB EXTRA DARK DME (-1 CUP FOR PRIMING)
1CAN MUNTON & FISON AMBER HOPPED MALT EXTRACT (3.3LB CAN)
1LB CRYSTAL MALT (CRUSHED)
2CUPS CHOCOLATE GRAIN MALT (CRUSHED)
1CUPS BLACK PATENT GRAIN MALT (CRUSHED)
1IN BREWING LICORICE
.5 TSP SALT
.5 TSP CALSIUM CARB
2TSP GYPSUM
1OZ NORTHERN BREWERS HOPS PELLETS 60 MIN BOIL
.5 OZ NORTHERN BREWERS HOPS PELLETS 30 MIN BOIL
.5 OZ KENT GOLDING HOPS PELLETS 5 MIN BOIL
1PKT WHITBREAD LIQUID ALE YEAST (WYEAST 1098)
8OZ CHERRY EXTRACT
8OZ CHERRY EXTRACT - ADDED AFTER RACKED TO SECONDARY FERMENTER
1CUP DME FOR PRIMING

STARTING SG1.050 (BEFORE EXTRA CHERRY EXTRACT WAS ADDED)
ENDING SG1.022 (OOPS - AFTER PRIMING SUGAR WAS ADDED)

I steeped the crushed grains 45 min in 150 degree water and then sparged with warm water into my brew kettle. I had a vigorous fermentation going about 5 hours (that evening when I checked) later. I racked to the glass secondary after about 4 days, bubbling had slowed but not stopped and then bottled about 9 days after that.

From: Kieran O'Connor <koconnor@mailbox.syr.edu>
Subject: Temperature Adjustments

Awhile back I read Miller's book--and finally took one of his pieces of advice to heart. I checked the calibration of both my Thermometers and my hydrometer.

As it turned out--my hydrometer is ok--and my floating thermometer is. But my bi-metal probe type thermometer was off by 4 degrees F. It has a locking nut on it--so I boiled it in distilled water and calibrated it. At the school I work in--in Cortland NY--we are at 1000 ft elevation, so my science teacher friend said to calibrate it to 98C for boiling--given the altitude.

now my question in--if the temps we use, say for mashing (148-158F) need to be somewhat accurate--do we need to make adjustments across the board? Shoudl i now lower my mash temps 4 degrees F when I brew in Cortland?

It seems that if I did not--the if I were mashing at 154--the real temp would be 158F--a significant difference.

Any thoughts?

Subject: Silver soldering

Hi Brewers,

Wayde Nie asks about using silver solder on a SS wort boiler.

One problem that I see is that silver solder typically doesn't wet Stainless steel. You might be able to find some that specifically does work on SS, but you should be careful to avoid leaded solders and solders that melt at low temperatures. You dont want that seal coming loose in the middle of a boil. 8-). -Pete

From: npyle@n33.stortek.com
Subject: DD yeast/mash oxidation/blowoff

steveinmass asks about borrowing some yeast from Double Diamond bottles. I had a DD last night and didn't notice any yeast. Shortly after I emptied the bottle my wife poured hot frying oil in it, so if they were there they died a horrible screaming death. May we have a moment of silence...

...
I also wasn't too impressed with the pale ale but that's a different story. Am I the only one who's noticed this problem with ales from the UK: they are overcarbonated! I'm talking about the common UK ales like DD, Bass, and Watney's. Now I know they carbonate them more for the US market but this is ridiculous. I like to be able to drink more than one sip between burps and well, I can't with these beers. It also doesn't help the taste any. I much prefer a good American pale ale these days; the imports can't touch 'em, at least not the imports that I get (slow dock, slow boat, slow dock, slow warehouse, slow truck/train, etc. etc.). Of course, though I love it, SNPA is overcarbonated IMHO, too.

...
Oxidation during the mash is a potential problem area, contrary to old wisdom. When I first got into brewing, I read that hop constituents were the cause of oxidation reactions which in turn caused stability problems. Now, it is apparent that malt constituents contribute to this as well. Without getting into details of which I know little, it will suffice to say that treating a hot mash the same way you treat hot wort is wise (i.e. no splashing, dumping, etc.).

...
Al, I plan to brew a(nother) pale ale in a couple of weeks, and I would consider trying a blowoff/non-blowoff test with it. I could conceivably make about a 8 gallon batch, putting 5 in my 5 gallon carboy (blowoff) and 3 in my 7 gallon carboy (non-blowoff). The problem with this is that I couldn't then do a secondary, which is standard at my brewery. Any suggestions? Am I wasting my time?

Subject: thanks/haze/oldish starter(?)/easymasher

Hello all,

Thanks to all those folks providing advice on converting a nat. gas stove to LP.

I was fortunate to receive a slew of response with good suggestions and care for and my apartments well-being.

And now for some more advice:

I may have a haze in my extract/specialty grain beer. It was several days ago when I drew a sample to F.G. and taste. The recipe is a modification of a NCJ porter (amber extract with crushed crystal, choc, black, and toasted malts).

When we bottle tonight and the beer's clear there will be no worries, but FMI, for my information, could I inflict a starch or protein haze with specialty malts? I had pleasing hot and cold breaks. If I find off flavors w/ haze I know the verdict.

Speaking of beer, I was unable to brew this past weekend, leaving 2 cups of yeast lab american ale 'starting' in a wine bottle. Has anyone or knows of anyone who has had a starter starting for a week. Can I salvage it by adding what I already have to a couple more cups of sterile wort? Is it too late to put the bottle in 'fridge to keep? An air lock has been affixed since the get go so sanitation may not be an issue.

Speaking of starters, sometime before the end of this decade, I hope to be competent enough for all-graining. I haven't gotten any info on the mysterious easymasher. If anyone could give me some info. on the item, I'd be grateful (as in thanks, definitely not dead)

Thanks,
David

The

As far as the blowoff goes, you could attach a large, sanitized balloon
to the
top of your carboy. Remember to attach it well (I use Duct Tape), or it
will
re-distribute the foam ALL OVER THE ROOM. Also, it should be large so
that it
won't burst (mine are about a foot long un-inflated). This allows the
blowoff
to not be lost, so you keep all of the material it contains (good or bad)
while
not letting any nasties in. Once the foam has gone down, I replace the
balloon with a fermentation lock. BTW, a large mouthed fermentor won't
work
with the balloon since you can't get the balloon over the mouth. Also,
don't
use condoms, they have lubricants and poisons in them. Hope this helps.

Most silver solders contain more than 40 percent LEAD. Since we are
talking
about food related equipment (at least I assume you intend on drinking
your
homebrewed beer), using lead bearing solder does not seem like a good
idea.
There are, however, silver solders that don't contain lead, so be certain
to
check carefully the solder you use. Also, all of the non-lead solders
that
I've personally dealt with require special equipment and techniques to
use them
effectively (this has been mostly Sterling Silver wire used by audiophile
friends), and are designed for very low resistance electrical components,
not
structural/mechanical support as you intend, so I don't know if it will
hold
well. I have heard of non-silver, non-lead solders designed for food
related

From: Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU>
Subject: partial-mash question(s)

I have 27 extract brews which have at various times been under my belt, and I am thinking about making this year's Christmas Ale a partial-mash brew. I don't have the equipment for all-grain, but I'd like to experiment. I have many questions, but I'll start with just one, in the interests of "bandwidth", and also hoping that by getting responses to my questions one at a time, eventually I'll get them all answered!

So here is my first question. I have heard or thought of a couple different ways of handling the four pounds or so of grain I'll be dealing with. (1) Put all the grains in a grain bag, go through the various temperature rests, and instead of the "mashout" remove the bag and either just squeeze the liquid out of the bag by mashing (sic) it down in a colander placed across the top of the kettle or running 170F. water through the bag/colander or both. (2) Don't use a bag; at the end of the mash, dump the liquor and grains into a kettle, then pour back through the colander to catch the grains and then sparge; (3) get another plastic bucket and drill holes to make the double-bucket lautering system; (4) fabricate that portable easymasher thing with the copper tube w/ screen or choreboy attached that rises over the side of the kettle and can drain into another vessel. Which method would be considered preferable, and what are the pro's/con's of each? Is there a way I haven't thought of? Is there one of the above I should definitely NOT do? Okay, so that was four questions, give me a break.

I would vastly prefer (1) or (2) for the sake of simplicity and minimal investment of time (not fabricating things), unless I'm likely to produce off-flavors or I might get such lousy extraction that it will not have been worth the effort.

Sorry about the FAQ on FAQ's a while back. Actually, the irony was not lost on me when I posted my request, so I'm glad if some of you got a chuckle out of it!

Subject: re malt v dextrose

rhreed@icdc.delcoelect.com says

> . Theoretically, the malt primed beer will have better flavor stability as oxygen has been scavenged from the bottle during the bottle fermentation.

Has anyone tested this? Miller suggests leaving very little headspace, and not capping for a short while after filling, on the grounds that enough CO2 will evolve to flush out the oxygen; I don't know anyone who's measured this.

One method /not/ recommended for homebrewers due to messiness: at Old Dominion, the owner told us his bottling machine squirts a tiny bit of hot water into each filled bottle to make the beer foam, thus replacing O2 with CO2. (The machine fills from the bottom and is not very high-speed; I don't know whether high-speed machines produce enough foam just in handling the beer.)

Subject: Have Brew Keg - What Now?

Greetings Homebrewers,

I am new to this mail list and to homebrewing. I am on my fourth batch of Brew.

I recently aquired a 15 1/2 Gallon Brewery keg (The kind your local beverage shop sells beer in and keeps your \$50.00 deposit til you return). This Keg uses a tap that pushes down and turns. I have several questions. 1) Where can I get a tap (other than rent one and dont return it). 2) can I rig this keg to use CO2 and use it insted of bottling. 3) If I can use a regular tap, how do I get the beer carbonated since with oxygen pumped in it will go bad in a few days. I know someone out there has the scoop on these ignorant questions.

Subject: kegging/infection(?) question

First time caller - long time listener

After kegging my beer, which was malty/low bitterness/clear, it became sour and cloudy very quickly. Before kegging, I allowed the beer to condition in the secondary at 32 - 34 F for a couple of weeks and then racked to my cornelius (sp?) keg. While racking, I accidentally picked up some trub (approx. 10 - 20 mL) off of the bottom of the secondary. The corn. keg was purged with CO2 prior to racking by filling the keg with 12 ppm BTF iodophor and displacing it with low psi CO2. This prevents the beer from exposure with air. Anyway... After force carbonation with CO2, two days later the beer is bitter/sour/cloudy. I allowed it to set for a couple of weeks at 32-34 F, thinking that the stuff from the bottom of the secondary was the culprit and it needed to settle out. Well... That didn't work.

Any ideas/comments that can help?

Beer history:

All grain - 5 gallons
8# 2-row Belgian malt
1# Belgian caravienna malt
1/2 # Belgian Special B malt
Saaz/Hallertau hops
Wyeast German Ale Yeast (w/ starter)

American Double Mash (90 F -> 122 F -> 152 F)
3.25 gal mash water in 10 gal SS pot
3.25 gal sparge water (170 F) - grain bag/bucket w/spigot method

Immersion wort chiller

Glass primary and secondary
- 5 day primary at 65 F (blew out air-lock due to high activity of this yeast as discussed in previous thread)
- 10 day secondary at 60 F
- 2-week condition at 32 - 34 F
- racking as stated above

Thoughts?

Thanks
- David

From: Paul Boor <PBOOR@beach.utmb.edu>
Subject: Easy Masher

In response to the recent posting by NPyle who seems in search of streamlining methods (rather than complicating them), I submit my EASY MASHER METHODOLOGY with which I have brewed upward of 50+ brews, many of them great.

This methods owes its seemingly bizarre beginnings to the 20 year old book by C.J.J. Berry, a paperback that is still found in some homebrew stores. The method also harkens back to postings of several months ago concerning overnight mashing:

- 1) Friday night (near midnight): grind up your grain bill.
- 2) Heat lots of water to 180F; make up a THICK mash in your masher/spargatron of choice.
- 3) Stick in your preset AQUARIUM HEATER, put on the top, plug in the heater.
- 4) Sack out with your significant other, if available.
- 5) Wake up early and stir one kettle-full of near-boiling water into the masher/spargatron, bringing temp up toward 170F.
- 6) Sparge it out with 170F water.

If you insist on taking lots of temps and otherwise wasting precious time, you will get a strike of about 155F on Friday night. The masher/spargatron should be of the insulated variety so frequently discussed on the HBD. Indee, in the years before the great GOTT gave us coolers, I used "wastebin" wrapped up in blankets a la C.J.J.Berry's original description. With today's standard insulated deal, even without tinkering with an aquarium heater, your AM strike will be in the 125-135 range; the heater keeps it higher.

It is true: "all-graining doesn't have to be that tough!" This method is especially well suited to use with English (well-modified) malts and heavier beers.

Any other easy-mashers out there???

From: Lee=A.=Menegoni@nectech.com
Subject: cloning Samuel Smith beers

An important part of getting the Samuel Smith taste is by producing elevated levels of diacetyl in your fermentation process. Diacetyl production by the yeast occurs early in the fermentation process and is directly related to temperature. Diacetyl reduction by the yeast occurs later. I accidently brewed a SSPA clone from a standard Pale Ale recipe by: Pitching my starter into wort that was about 10F warmer than fermentation temp. This produced the elevated levels of diacetyl.

Racking to secondary immediately after primary fermetation ceased and then adding finings to percipitate the yeast out prematurely. This reduces the yeast population at the point at which diacetyl gets reduced. The high level produced early coupled with the small yeast population available for reduction will result in a beer with noticable levels of diacetyl.

Notes: I pitch a starter that I step up for about a week, it has about 3/8" of slurry on the bottom of a 1.5l wine bottle. I suspect this large yeast population coupled with the warm temp directly effects the amount of diacety produced. If your starter was smaller the wort would cool while its population expands and the level of diacetyl would be less.

I have also heard that excessive diacetyl is produced in under airated worts does any one have information on this?

*****
```

If there is oxygen available, then the yeast will continue from glycolysis thru TCA and ETC, regardless of what substrate you use. (DME or corn sugar)
When the oxygen is depleted then they will reduce the pyruvate from glycolysis into ethanol and CO2 via Acetaldehyde.

Subject: RE: Mailing Brew

Hi: I just joined the club and thought I'd make my debut with my \$0.02 on Rich Ryan's question 'bout sending beer through the mail.

I regularly exchange homebrew with a buddy who has lived in Florida, Oregon, and Nevada. The very first time I tried to send him brew, I very cleverly told the lady behind the counter what was in the package (they will not ask you, you have to give yourself away). She promptly pushed the package back at me and said that sending liquids in bottles via the US Mail is not something I wanted to get caught doing. So I went to another post office. I guess this means that the US Postal Service doesn't want us using them to send beer. However, I always do.

I ALWAYS send beers First Class. It costs a lot (about \$1/lb.) but the packages I sent from Long Beach, CA to Corvallis, OR got there in two or three days. For me, this short time for delivery is worth the extra cost. I like the idea that if my beer is sitting somewhere that is beer-hostile, it won't be there for long.

Zymurgy had an article not too long ago (issue?) specifically about packaging beer for sending to contests. I remember that it specifically did NOT say whether or not it is legal to send beer via UPS, US Mail, etc. The article was written by someone who has done a lot of UNpacking beer for contests and he recommended that you not get carried away with packaging. Basically, his reason for this was that over-packaged bottles were a hassle for him to deal with. If you're going to send via US Mail, I would recommend the opposite. I don't know the legal ramifications of getting beer on other people's mail and I don't want to know (at least not from a postal inspector knocking on my door). I use lots of newspaper for insulation from temp extremes, cushioning, and absorbtion (though I haven't lost one yet), and two layers of plastic for "head retention". Of course, packaging == money, but I want my beer there quickly, quietly, and safely.

I called UPS ((800) 222-8333) and they said that they do NOT handle beer. The person I spoke to acted as if she had heard this question many times (she laughed) but said that they do handle wine "in some states". This whole

thing may be trickier than I thought. Is it illegal to send alcohol across state lines, period? Is the AHA in big trouble for encouraging this sort of behaviour? Somebody MUST do this. How does Anchor send out their Xmas Ale? Or do they only ship within California? Hmm...

I do have some experiences with UPS which I think are worth sharing. First, this very friend with which I exchange beer once worked for UPS unloading trucks. According to him, UPS would prefer to suffer some breakage and compensate the customer rather than slow things down (I realize this is hearsay and other's experiences may be different). In support of this, my friend and I have exchanged only one package via UPS and it was the only time bottles arrived broken. Also, it took MUCH longer for the package to arrive (about 7 days instead of the 3 days which seems to be typical for 1st Class). I realize this is condemnation on slim evidence and the main reason I don't use UPS is the time for delivery, though I can't say for sure that spoilage has been a problem. Perhaps they offer a speedier but cheaper service similar to 1st Class.

Hopes this helps. I guess Rich's question still stands. Anyone know the legal way?

> undertaking than paying someone to weld SS.

First, I'm not sure that you could get it to effectively bond to the
stainless.

Second, if you did get it to stick, you'd run the risk of having the
solder melt from the heat you're applying to the wort.

Third, solder is composed (I believe) of tin, lead, and antimony. I
don't think I'd want to take the chance of exposing my acidic wort
to that particular composition and risk some of it dissolving in my
wort.

The welding shouldn't cost you more than \$20 if you find the
stainless pipe nipple for the welder and pre-drill the hole.

You might also check out the brass fittings at a good hardware
store. I'm sure you can find some sort of compression fitting that
will do the trick.

Better yet, offer to trade homebrew for welding. That's what I did.

Subject: wierd yeast activity

All,
I'm making an all-grain pale ale using Yeast Labs American Ale yeast (Hey, it's all I had available at the time!).

I have never seen a yeast act this peculiar. I made a starter 9/9. The yeast was relatively fresh; the good until date was the end of October. The yeast took 36 hours to start working, and then it was very subdued.

Once added to the wort (at 70 deg. F) it took 24 hours to give any evidence of working. After noticing reduced ferm. lock activity after three days, I racked to secondary.

The yeast acts like it is still in primary fermentation phase. It still is producing a "cap" of sticky bubbles after about 9 days in the secondary (at 68 deg.). If I slightly agitate the carboy the bubbles collapse into large flocculante (?) (large pieces of yeast-beastie stuff that falls to the bottom of the carboy), and then the bubbles immediately re-form into a cap. Fermentation lock activity is now at about the once every 30 seconds stage, but the bubbles persist.

I have never seen anything like this before. Has anyone used this yeast stain before or experienced this?

Chuck

Subject: Brazing vs Silver-soldering vs TIG welding

Someone asked about silver-soldering vs welding nipples onto kegs...

Be very cautious of silver solders, as most of them are about 96% tin. As others have pointed out here, tin is not compatible with hot wort.

A third option is to braze the nipple. Brazing is similar to soldering, except that higher temperatures and different alloys are used. Because of the higher temps involved, a simple propane torch will not suffice. However, I just finished brazing my nipple, (this is beginning to sound like S&M) using a combination propane/oxygen torch. This heats the SS up to bright cherry red, hot enough to braze. I believe a MAPP gas torch will also work, I think a MAPP cylinder can simply be used in place of propane on a standard propane torch for a hotter flame. The brazing rod I used was called Copper-Phosphorous. I checked the MSDS for these and there didn't seem to be anything in it that would be bad for me or my beer (note there is no cadmium or other heavy metals in these rods). All of this equipment/materials can be purchased at any good hardware store/home center, for much less than the cost of a MIG or TIG setup.

Subject: Barley diseases

In the HBD on 14 Sep 93, korz@iepubj.att.com wrote the about production of various malting barley varieties in the U.S. I have heard from two different sources now that most of the malting barley in the midwest and upper great plains (Minnesota, North & South Dakota) has been damaged/destroyed this year due to scab. Scab, or head blight, is caused by a fungus that produces several mycotoxins, among them vomitoxin, which prevents the sale of contaminated grain. One book I read says that "beer made with scabby barley takes on a 'gushy' or excessive foaming characteristic. However, because of strict grading standards, scabby barley is not used by the brewing industry today." As little as 3% scabby barley can be toxic to hogs, but other livestock do not react the same. If I remember correctly, some of the mycotoxins produced by this fungus have been implicated as potential carcinogens too. The excessive rain this spring and summer in the region is to blame for the above-normal amounts of scab. This means that malters will likely be buying grain from other areas of the country, like Washington, which do not normally produce large amounts of malting barley. I have not heard whether this is expected to affect price and/or supply.

I wouldn't go so far as to say most. Local Ag. reporters have said the
damage runs in the neighborhood of 30% recently. More worrisome is the
fact
that harvest is running **very** late around here due to excessive
moisture.
The longer drydown times have left the remainder of the unharvested small
grain crops at risk for diseases, but I haven't heard of large losses due
to this, yet.

Malting and feed barley aren't the only things effected. The wheat
crop is also suffering from scab. This has put some of the export
customers
ill at ease about purchasing wheat (cf. China).

In the upper Great Plains, the predominant varieties of malting barley
are of the 6-row type (Morex, Larker, Robust), employed primarily by the
big industrial brewers (AB, Miller, Stroh). In fact, **very** little 2-
row
is grown around here (< 5% of total), with most of the 2-row production
coming from the Northwest. If indeed maltsters are buying from other
areas,
6-row malt may be in short supply. This hasn't manifested itself in
higher
prices for malting barley (at least not around here). The homebrewing
market probably has little to worry about. However, I suspect the mega
breweries are at least somewhat nervous.

Subject: MASH TUN = LAUTER TUN

>From: Jim Busch <busch@daacdev1.stx.com>
>Subject: Tuns/Sparging

>First of all , Jack, mash tun != lauter tun, at least for most serious brewers who are using any system other than single infusion or your EasyWidgets. The objective of a mash tun is to convert starches to fermentable sugars and dextrans. The objective of a lauter tun is extract these fermentable sugars and dextrans without extracting tannins from the malt husks.

Not sure of your symbolism but if "!=" means not equal, the advent of "EasyWidgets" suggests it is time to change the definition. With an easymasher (note lower case) installed, the mash tun becomes the lauter tun simply by opening the spigot.

> I have brewed all grain batches in 4 different systems over the past 5 years, and no matter what the size of the lauter tun, the recirc time is in the order of 10-15 minutes.

Is it possible that none of those four different systems was an easymasher?
It takes less than a minute with the em. Furthermore, I do not see what time has to do with the issue. It is the volume that must be recycled that effects the characteristics that were brought up. If a cup or two has to be poured back into the tun, it would have little effect on anything and would not even qualify for calling it "recirculating". If 5 gallons have to be recirculated, it is a different ball game.

I hate to always sound like I am trying to sell something when this subject comes up but the fact is, the easymasher has revolutionised home brewing as anyone who has ever used one will testify to. Few of the age old problems and concerns apply to it.

Someone asked what an easymasher is and I waited a discreet amount of time hoping someone else would respond but as no one did, here is a brief description. Please note that this device can be easily made from hardware store stuff and whether you make one or buy one makes little difference to me. That is the reason for the lower case/upper case business.

The following is taken from my article on kettle mashing and anyone wishing the whole article can receive same via email.

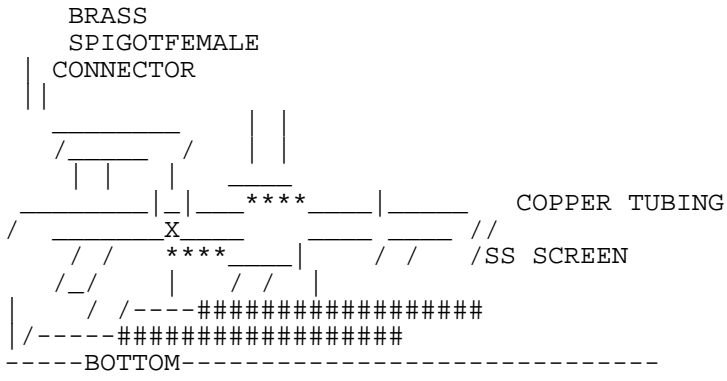

FIG. 1

Fig. 1 shows an exploded view of the spigot and strainer. The strainer is simply a 2 x 6 inch piece of screen, rolled into a six inch tube and clamped to the copper tube. The last half inch is bent over itself to seal it off.

The copper tube has a double bend in it to allow it to be rotated so that the end is right on the bottom leaving almost no wort behind. It is easily removed for cleaning.

The spigot passes through a clearance hole drilled in the kettle and is retained by the female connector and a washer to take up the treads and make a tight fit.

In the spirit of "There are no stupid questions":

All of the hop oils in the lupulin glands of boiling hops are boiled away during a 60 minute boil. The hop oils are the source of hop flavor and aroma, so there should be no hop flavor or aroma contributed by the boiling hops. Therefore, one ounce of Northern Brewer @ 10% alpha could be substituted for two ounces of Willamette @ 5% alpha. The same bitterness would be achieved and there would be no perceptable difference in taste. Right? Probably not. Where is the flaw in my thinking?

A little knowledge is a dangerous thing.

Subject: Soldering/brazing, etc.

To add my couple of pence worth to the soldering discussion:

Those who suggest that brazing is the way to go are on the right track. Soldering is a much lower temperature process and doesn't provide nearly the strength that brazing does.

I've successfully brazed fittings on SS pots using "Safety-Silv 1200" rod.

The manufacturer, J. W. Harris, says its suitable for food processing equipment. The exact metallurgic composition escapes me, but the major components are silver and copper, with a small amount of zinc and a tiny bit of tin. I've never experienced haze problems or metallic off-flavors

in beers brewed in the pots with this braze. Flux is boric acid, I believe, and comes off with hot water and scrubbing with a wire brush.

I've used Safety-Silv 1200 to braze numerous bicycle frames, without a joint failure, so it provides a fairly strong joint. I use either Mapp gas with a Turbo head or one of those propane/oxygen setups from the h/w store. As you probably can guess the brazing rod melts in the 1200 deg F range. I've read that prolonged heating of SS above 1200-1400 degrees can cause it to become brittle, so be careful. I'd suggest practicing on the portion of the keg you've cut off.

Whatever brazing rod you choose, make sure it has no lead and *** NO CADMIUM ***. Cadmium fumes will kill quicker than you can say "Rheinheitsgebot".

One last thing, I wouldn't trust a brazed joint to be "sanitary" in the same sense that professionally welded and ground would be, so I wouldn't use this method on fermenters and the like. Just on Hot liquor tanks, mash-tuns and boilers.

One final thing, Silver braze flows like water when it reaches liquidus, and won't fill gaps of more than .001 or so, in my experience. Make sure you have a good tight joint before lighting up that torch...

Subject: Keg Forced Carbonation Confusion

Boy, am I confused. I setup my keggling system about a week and a half ago and had problems getting enough carbonation/head. I used the method outlined in Cliff Tanner's Braukunst catalog and after 3 days, my beer seemed to be carbonated OK but had little or no head. Since then, I have researched this further and found that there is no consistency whatsoever regarding the temperatures and pressures needed for both force carbonating and dispensing. Can anyone shed some light on this? Here are the various methods I've uncovered.....

Braukunst Method:

Chill beer to your liking (40 degrees), determine how carbonated you want it (2.25 atmospheres for ales, 2.75 atm for lagers), look up your beer temp and carbonation (in atm) on the big chart and determine the saturation pressure needed to carbonate (my Red Ale came out to 9.5 psi at 40 degrees), pressurize to that pressure and let sit for 2-3 days, dispense at 2-3 psi GREATER than the carbonating pressure.

Charlie P. Method (from TNCJOHB):

Chill beer (40 degrees), pressurize to 25-30 psi, let sit for two days (or shake vigorously for 5-10 min), then dispense at 5 psi.

Williams Brewing Supply method (from mail order catalog):

Chill beer (no temp specified), pressurize (no pressure specified) and wait FIVE days, no dispense pressure specified

Bob Clark's Method (from HBD Archives 6/7/93):

Chill beer (no temp specified), pressurize to 30 psi, wait 3-4 days. Then dispense at 8-10 psi.

Mark Parshall's method (from HBD Archives 6/3/93):

Chill beer (40 degrees), pressurize to 25-30 psi, let sit for 3-5 days, lower regulator to 10 psi to dispense (he says this generates too much head).

Mark Parshall's friend's method (from HBD Archives 6/3/93):

Chill beer (40 degrees), pressurize to 40-50 psi, shake vigorously for 15 minutes, no dispense pressure specified.

HELP! What's a kegger to do?

From: Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU>
Subject: campden/cranberries/oatmeal stout

I'm a couple of days behind in my digest reading. I suppose you could say that I am suffering from indigestion.

Anyway, in #1231 Aaron Morris recommends Campden tablets in the blowoff bucket. What does the campden do? I've never heard of this.

In this same issue, Robert Kaye asks about cranberry ale. I have a recipe at home which I haven't tried yet, but it was posted to the HBD a year or so ago I think. The author recommended putting frozen cranberries in the pot at the end of the boil - incidentally, helping the cooling along - and letting them sit for awhile, then racking the wort off the berries and break material. Anyone else tried this?

And finally, Jim Graham asks about Oatmeal Stout. Jim, if you are an extract brewer, try William's Oatmeal Dark extract. I used it once and was real pleased with it. If you're not an extract brewer, well, then you certainly don't want MY advice! I usually follow Al K.'s advice and just do single stage for ales, especially dark ones, unless I am dry-hopping.

From: pjd@craycos.com (Phil Duclos)
Subject: silver solder

Let's get one thing straight, silver solder is not your typical plumbing or electrical solder. It does not contain lead, although it may contain other undesirable metals, and it melts at ~1100 F. It does not contain tin either. It is used for refrigeration, precious metals, etc..

where strength is required. It comes in many melting points and mixtures and is more like brazing than soldering. It requires significant heat, and on stainless, that means an oxy/acetylene torch. Joints are strong, but tend to be brittle and because of that it may be unsuitable for the roughhouse brewery environment. It does not meet sanitation requirement per typical health codes. The technique is difficult to get right so its not for a beginner to welding. All that said, it is cheaper than TIG and may be a good choice for someone properly equipped and trained. A nice TIG job on a brew kettle should only cost \$10->20 so, its not unreasonable to have a really nice job. Trading for beer might be possible too. I plan to add a sight tube and thermometer to my hot liquor tank and I expect to pay almost as much for the fittings as the welding job. Its not all that cheap, but it sure looks nice!

Subject: Fuller's water treatment

A while ago I sent out some requests to a few English Ale Brewers, most notably Fuller Smith & Turner P.L.C., for information about their water treatments. Hey, it was worth a shot. Fuller's Brewing Director, R.H. Drury, responded thusly:

"I am not able to tell you the mineral content of our Brewing water for commercial reasons. Suffice to say it is not the typical London analysis which is too high in carbonates and is therefore "burtonised" to some extent."

In light of the most recent issue of Brewing Techniques and Karl King's article on water treatment which shows that "burtonized" water is much higher in carbonates than London water:

Ca CO3 SO4 Mg Na Cl

Burton 275 260 450 40 25 35
London 90 125 40 5 15 20

What is Mr. Drury talking about? Does he mean that Fuller's water is "...therefore "burtonised" to some extent" or does he mean London water? It may be important to note that Fuller's Brewery is in London, and perhaps he is switching names (Burton <==> London). On the other hand, in Fuller's Cask Conditioned ESB I detect a front of the tongue and behind the teeth sharpness, a tang, almost a mild "furriness". High sulfate?

Am I making too much of water treatment?

Since I mentioned the most recent issue of Brewing Techniques, I'd just like to say that I'm very impressed with the publication. I actually found 3 out of 4 of the features and articles of compelling and immediate interest (at this time I'm not charged up about rye), even so I found the rye article well written and full of good information. (This contrasts greatly with articles about labels). I am particularly looking forward to the next issue's "Practical Guidelines for Cask Conditioning

Sure, switch to a 1" ID plastic hose and move the bucket of water to a height about 2 feet above the top of the carboy. Most of the beer kicked out during the blow-off period can't make it out and falls back into the carboy. I use this system for any beer with an OG of at least 1.050. Lower strength beers tend not to kick out as much fluid.

Cheers,
Andy A

 Subject: Usage of Silver Solder Alloys

Hey Group,

I noticed the post on using Silver based Brazing (soldering) alloys. This is a good alternative to welding of fittings. In addition, it allows the use of copper tubing and fittings into the stainless steel tanks. There is the potential for some galvanic corrosion of the copper in preference to the silver. While I cannot predict the rate, I think it will be quite small; small cathode, big anode, etc. Be sure to use a flux for Stainless Steel before attempting to braze or it won't stick. Use a slightly reducing flame and type 3A flux. Silver Solder does not contain lead, but some of the alloys contain Cadmium, which is worse. I don't know if it will leach out, but if it does, it will cause heavy metal poisoning. The American Welding Society alloy designations are listed below, don't use the alloys containing Cadmium. Here's the table.

Table of Silver-based brazing (soldering) alloys

From: Wayde Nie <u9106857@mcmail.cis.mcmaster.ca>
Subject: Keg system setup

In HBD 1232, Cecil Clontz Sez:

<I recently aquired a 15 1/2 Gallon Brewery keg (The kind your local beverage
<shop sells beer in and keeps your \$50.00 deposit til you return). This
Keg
<uses a tap that pushes down and turns. I have several questions.

My housemates and I have been using a CO2 charged, brewers retail style keggng system for almost a year now and don't know how we ever got along without it. This sounds, from your description, to be exactly what you want. We like this setup as opposed to the cornelius (SP?) one mainly because it can be used for homebrew and we can dispense commercial swill for our parties. This leaves our precious brew for us!

First of all, for your homebrew, I'd find a more suitable sized keg. Here in Canada, Brewer's Retail offers a "cylinder" (22 liters) which is roughly 5 Gal for \$20 deposit. We have found this size to be great for our single batches. Save your 15 1/2 Gal keg to make a good brew kettle. (As per any of the suggestions in the HBD archives)

<1) Where can I get a tap (other than rent one and don't return it).

All of our equipment came from a co called Johnson Enterprises in Illinois. They were very helpful and supplied us with exactly what we needed to convert an old fridge. (I have no affiliation with Johnson, just

a satisfied customer, BlahBlahBlahBlah....)

for a basic fridge conversion you will need:

i) A CO2 cylinder, ours is a 20lb tank and thats PLENTY.

It has been on line for almost a year and is still quite full.

ii) A CO2 regulator, IMHO a 2 gauge reg. is comforting and really only a few bucks more. (one gauge for tank presure (optional) the other is for line presure (a must)).

iii) A "Sankey" coupler. (the twist and push down type) this is what connects to your keg. It has two threaded connectors, one for beer out :-) and the other for CO2 in.

iv) Faucet assembly. This is the actual tap with all the necessary hardware for mounting. (fridge door, under the bar, beside your bed, etc...8*)

v) Proper pressure hoses and clamps to hook the whole thing together.

Except for the CO2 tank and fridge, we got the entire setup UPS'ed across the border and to our front door in about a week for less than \$200

Canadian. (Worth *EVERY* penny).

<2) can I rig this keg to use CO2 and use it instead of bottling.

Yep, we do this routinely! Inside the "beer out" hole of the sankey you'll find a small rubber "pea" with acts as a backflow valve. If you carefully poke this pea out (remember, it has to go back in later!) you

can siphon your beer into the keg through this hole. The connectors on the Sankey seem to have odd threads (at least we can't seem to find a match locally). Therefore, we'd recommend buying an extra female beer line connector to hook your siphoning hose to the sankey. To carbonate, put the full keg under about 30 - 40 lbs of pressure from your CO2 tank and shake like mad (the keg, not you) for about 1-2 min. Repeat this in another couple of hours and let the keg sit over night under this pressure. The next day, bleed off the excess keg pressure, reduce your CO2 reg. to about 10-15 lbs, and enjoy a *Sediment free* draught homebrew! (**This requires NO extra sugar at kegging time**) Don't be distressed if the first few draws are mostly foam, this is normal. If the foaming continues, play with the reg pressure. This is an outline of our process, others may have slightly different ones, but this works well for us.

<3) If I can use a regular tap, how do I get the beer carbonated since with <oxygen pumped in it will go bad in a few days.

This setup uses CO2 and a properly cared for keg will last for quite some time. (Can't give you solid dates, ours are always gone within a couple weeks...(Hick!) Hope all this helps, if you want us to clarify anything then feel free to EMail us back directly.

PS. here's there phone number.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)
Subject: Temperature Adjustments

Kieran O'Connor asks about whether he should change his mashing temperature due to problems in measuring the temperature. I'm not quite sure which of the following questions he was asking, so I'll answer both.

1. "I checked the calibration of both my Thermometers ... my bi-metal probe type thermometer was off by 4 degrees F."

For this case you do need to mash with the corrected temperature. For instance, if your thermometer reads 4 degrees high and you want to mash at 154 F, then you should make sure that your thermometer reads 158 F. In other words, you should correct the temperature from your thermometer to get the real temperature.

2. "I boiled it in distilled water and calibrated it. At the school I work in--in Cortland NY--we are at 1000 ft elevation, so my science teacher friend said to calibrate it to 98C for boiling -- given the altitude."

I'm a little more familiar with this one, since I live at 7300 ft! If you're not boiling the water, then the temperature you want doesn't change. In other words, if you want to mash at 154 F, you heat the water until your corrected thermometer reading is 154 F, regardless of altitude. The difference with altitude comes in when you boil. Since you're boiling at a lower temperature, you might want to boil longer to get the same effect. Our boiling temperature is around 198 F, so there's quite a difference here.

Hope this helps,

Subject: Re: Mailing Beer/ UPS

I have found that as far a UPS is concerned, as long as they don't know it's beer, they don't care. Even if they find out that it's beer they really don't care. My mother (being totally without a clue that she shouldn't do this) sent my brother in Kentucky a case of Sam Adams via UPS. When he got it, he called to thank her and ask why she bothered to repack it and why was one bottle missing. It turns out that a bottle broke during shipment and UPS repackaged it and sent it on it's merry way, no questions asked.

Oh well...

Pam

Wayde> install the fittings into to base of a converted keg style boiler.
I
Wayde> would think that soldering would be less of an undertaking than
Wayde> paying someone to weld SS.

Wayde Nie, u9106857@McMail.CIS.McMaster.CA

Having done this, I can testify with some authority. Silver soldering SS works, but is **EXTREMELY** difficult to do correctly. The **MINIMUM** amount of heat possible to get the solder to flow should be used. Heat should not be applied for more than about 1 minute at a time, after which the area should be cooled **IMMEDIATELY** with a sopping wet rag. The best flux to use is the white paste kind which comes in the white 3" diam. plastic jar with a blue top (I forget the name). Use the flux sparingly. If you see that your solder is flowing in one place, but not all the places which you are trying to solder, you have oxidized that non-flowing area. **DO NOT APPLY MORE HEAT** to that area, cause that is our normal reaction when we see lack of flow. This is exactly the wrong thing to do. Stop, cool it off, clean it off well and start over again. If you overheat SS, it will become brittle.

I know about all of what I say since I did all the wrong things. When I was done, the joints between the keg and the pipe nipple were strong, but they still leaked. Well, so we went to clean things up and in the process of melting off the excess solder, a piece of keg as big as my little finger nail dropped out of the keg wall. It had cracked and now I had a large hole to fill in as well. Finally changed over to bronze brazing rod and got the job redone and no leaks.

Bottom line, get it welded. Don't be cheap and foolish. Also, when you get it welded, make sure the welder cools it immediately. If you do the welding and leave it to cool naturally, it will heat the surrounding area for more than the critical 5 minutes and you will get brittle SS again.

Subject: Silver Solder

Silver solder can be nasty to solder and can be hazardous to your health if you get the wrong stuff. For your health's sake, get the kind that is cadmium free, for your yeast's health get low, low lead content. The simplest flux is plain old borax, the chemical not the soap :-). You can get the solder and the flux at your local welding supply, consult them about the solder for food preparation vessels, melt point of at least 1200 degreesF. The flux you can get at hardware stores, drug stores (sometimes), and your local supplier of chemicals for school science labs. The actual soldering is tricky, burnish the stainless steel parts, mix the borax powder with water and apply to the joint, bring entire joint up to temperature, the borax will melt. Don't get the joint too hot (easier said than done, with stainless steel), too hot and the solder will ball up and roll right off. Some old timers will wrap the solder wire around the joint and heat indirectly until the solder sweats into the joint making a very nice fillet. The key is to not oxidize the surface that the flux has cleaned, direct heat from a flame WILL oxidize.

P.S. A welder with mig or tig capabilities will take about 10 minutes to weld the joint with Stainless but will probably charge an hour minimum, typically \$30 to \$40 per hour.

Regards,
Mac

I did just that with my rig. I was able to assemble my mash/lauter tun, kettle and hot liquor tanks using brass fittings and silver bearing solder. I was able to do it using a regular blow torch.

A couple of things to know:

1. Make sure whatever solder you use is FOOD GRADE!
2. Silver braze (e.g. 15% or so silver) is very strong and harder to use. Silver bearing solder (3-5% silver) is easier to use but much weaker.
3. Get the right kind of flux - ask a welding shop for help. As I found out there are different temperatures and compatibilities to deal with.
4. In short, brass and SS are incompatible with Silver Solder and you will

probably be frustrated in getting a solid, watertight, durable connection.

The problem is that the copper in the brass dissolves into the silver solder and makes it very brittle. As your joint cools it will crack. You are getting shafted not only by the presence of copper, but the differential expansion between brass and SS.

If you can get SS fittings for at least the bulkhead (where you would be silver soldering to the keg) your job should be much easier. One possibility, that I have not explored yet, would be to get some threaded SS pipe (say 1/2" npt), bore a hole in your keg and just solder the nipple in place. Then you could attach your (cheap) brass fittings on either side. If you can get some sort of SS fitting with a flange, all the better.

Just in case you are wondering: yes all my joints leak a tad. Now that I have several brews behind me the cracks have filled with caramelized sugar (at least on the kettle)... :-(

Subject: Mailing brew

Scott Kaczorowski comments in HBD 1232:

```
|| Zymurgy had an article not too long ago (issue?) specifically ||  
|| about packaging beer for sending to contests. I remember ||  
|| that it specifically did NOT say whether or not it is legal ||  
|| to send beer via UPS, US Mail, etc. The article ||
```

On GENie we began having regular brew swaps about a year ago. When we first decided to do this, someone called around to the USPS, UPS and Bureau of Alcohol, Tobacco and Firearms (hey, ask _everyone_) about the legality of shipping beer. Basically, ATF doesn't care as long as it's not whiskey. USPS said it is AGAINST the LAW to ship alcoholic bevs through the mail (first class or otherwise).

UPS folks will give you varying answers. I've had them reject a package of framed photos because I used glass (they prefer plexi). However, unless you tell them "liquid in glass" they won't know and might not care; that amount of caring is what varies from counter to counter. I usually write on the UPS slip "yeast samples" or "brewing samples." Never questioned.

This week I shipped to a fellow brewer in Canada, so I had to deal with a customs form as well. Since I had to be honest on the customs form ("two (2) bottles homemade beer, value \$1 each"), I pretty much had to be honest on the UPS papers too, so I said "Homemade beer samples for judging." (I know that many winemakers ship samples via UPS) Flew right through, and he reported getting my beer today (four days from WV to Ontario).

The bottom line is that UPS is not a gov't agency, not the law, and the worst they can do is reject your package.

Subject: RE: Mailing Homebrew

Rich Ryan asks about mailing beer.....

Our group of folks on GENie regularly mail beer to each other for our Swap/Tastings held on-line on Saturday nights. It is true that the US Postal Service frowns 8^(very heavily on shipping alcoholic beverages by mail. I think it is again BATF regulations. You can ship by UPS though. This is what we do. We just label the boxes as Brewing Supplies and leave it like that. We have had no problems to date.

I have not tested this but I use Miller's suggestion mostly for convenience. I fill all my bottles and set a cap on each one as I fill it. When all the bottles are filled, then I go and fasten the cap on each one. As I said, this is mostly for convenience because I don't need to worry about keeping the bottling wand sanitized or worry about it leaking or worry about keeping the siphon primed while I am capping. That said, as I get about 1/2 - 3/4 of the way through bottling, the bottles that were filled first have started to "burp" as the air is pushed out by the CO2 produced by the yeasties.

One item that is critical for the success of this method is that my 2 & 4 year old helpers are asleep.

From: COOK@CDHF2.GSFC.NASA.GOV (Chris Cook)
Subject: Purging Keg Headspace

John McCaffrey <johnmc@brooktree.com> wrote on keg-forced carbonation confusion (love that phrase) and discussed several major techniques.

One minor thought that may help. When I carbonate my kegs, I found out (the hard way, of course) that it is important to completely purge the air from the headspace.

A while ago I kegged a batch and forgot to purge, just ran the pressure up.

Normally when I force-carbonate I can hear the CO2 going to work, and every time I shake the key, more CO2 pours into the key. This time, nothing. Days later it hadn't carbonated at all, despite having way too much pressure for dispensing. Thinking on this, sudden memory struck and I started purging. I emptied the headspace from the gas disconnect, charged it and emptied it, and charged it again up to carbonation pressure. This time the beer took some CO2, although still not that much. After a day of middling carbonation and overpressurization, I tried two more empty/refill cycles and suddenly everything was working OK.

This raises a question: what procedures are people using for purging keg headspaces? My usual practice when I don't have amnesia is to hook up the gas supply with the keg lid ajar, open the gas valve halfway and let the CO2 run into the tank second or two, then pull the lid shut.

When people say "purge the headspace," what procedures are you following?

In regards to the question of if the actual variety of hop really matters for bittering purposes:

I am also interested in the general net opinion on this issue. I have always wondered about this ever since I read the "Hops" special issue of Zymurgy which describes how one guy set out to brew every style of beer known. He used Chinook hops as the base bittering hop for every style. The rationale was that bitterness is bitterness and Chinook hops have the most %AA per dollar.

So how about it? Am I wasting big money using lots of Czech Saaz for bittering pilsners?

Subject: Austin Stuff, Celis

Hey out there in HBD land, I just went to the Celis brewery for the first time a few days ago and I had a great tour. The tour info was primarily historical (the story of Pierre Celis and his coming to Texas and getting the brew kettles) and an intro to the brew process for those who are not initiated. The best part of the tour, of course, was the beer samples - *fresh* from the tap, brewed within 6 weeks, words don't do the taste justice. Anyway - the sum total of all of this is - if you are in the Austin/Central Texas area and haven't gone, you should go. If you are coming into the Austin area from out of town - make time for the trip, the brewery is no more than a 30 minute drive from anywhere in Austin (its actually about 5-10 minutes from I35 and 290). While on Austin, anyone know details on the upcoming Austin Brew Ha-Ha Competition?

While I'm here - I want to make a spiced beer for holidays and have decided that the spiced liquour (sp!) is the way to go for me. Anyone know where I can get some Gloegg or other kind of spice concentrate for use in such a beer? If not I'll resort to making my own and wing it.

Hope you people up north are enjoying your fall - it'll be 98 again here today and no chance of any turning leaves...

Chris

Subject: Re: Keg Forced Carbonation Confusion

I keep my kegs at room temp and run the beer line into a small fridge that has a cold plate in it. I cool my beer on demand. Being at room temp, I have to run my kegs at 30 psi for it to have 2.5 volumes (NOT atmospheres - atmospheres is a unit of pressure) of CO2. All I do is pressurize the keg and shake it until I don't hear any more CO2 being absorbed by the brew and then I know the beer is saturated and ready to go. This takes 10 to 15 minutes.

The following table has been posted to HBD in the past and is very useful.

formula:

$$P = -16.6999 - 0.0101059 T + 0.00116512 T^2 + 0.173354 T V + 4.24267 V - 0.0684226 V^2$$

Here's a table that that function generates:

	Volumes of CO2 desired										
Temp	2.0	2.1	2.2	2.3	2.4	2.5	2.6	2.7	2.8	2.9	3.0
32F	3.5	4.4	5.4	6.3	7.3	8.2	9.2	10.1	11.0	12.0	12.9

Subject: Re: Force Carbonation

John McCaffery has asked for some information about force carbonation, so here goes (I'm sure this will be just one post among many):

Carbonation is the process of dissolving CO2 in water to form carbonic acid.

Gasses are more soluble at lower temperature, though they get forced out of solution just before freezing. This is what makes the bubbles in ice cubes. CO2 is pretty soluble, but not instantly so. Nor does it diffuse rapidly through the beer. The dissolving takes place only at the gas/liquid interface, so the amount of surface area is important.

There are several implications to these facts.

- 1) Pressure does not equal carbonation. It is possible for a keg to be under high pressure and not have the beer well carbonated.
- 2) As the pressure/temp/vol CO2 tables imply, as temperature rises (or falls) the pressure necessary for a certain degree of carbonation rises (or falls).
- 3) An upright motionless keg presents the least surface area and thus provides the worst conditions for carbonation.

Keeping these things in mind, here's how I handle my carbonation--

Sanitize the keg. Purge it of air by pressurizing to 15 psi and venting it off several times. Open the safety release on the lid and then open the lid just enough to slip in the racking hose. Bleed CO2 into the *open* keg at very low regulator setting (2-3 psi). This is anti-oxidation voodoo. Rack the beer into the keg.

Seal the lid, pressurize to 35 psi. Check for leaks and a good seal. Shake the keg repeatedly until no more gas will flow at 35 psi. Put the keg in the fridge overnight. When the keg is chilled, hook it back up to the CO2 at 35 psi and lay the keg on its side with the gas inlet uppermost. I don't have a check (one way) valve on my regulator, but I do have a long (6') clear hose. I will occasionally get a few drops of beer moving into the gas line, but it has never been a problem, just some cleaning after I'm done. With the keg horizontal (to expose more surface area) rock and slosh the keg until the regulator stops hissing. Set the keg upright. Take a break. Repeat until no gas is drawn into the key when shaking.

At this point the keg is over pressurized and undercarbonated. The pressure is 35 psi. If the pressure is vented to dispensing range, the beer will have large coarse bubbles, foam a lot and go flat quickly. Now I put the beer back into the fridge. As more gas dissolves, the pressure will drop. Over the next day or so, it will drop to 15-20 psi. At this point, I keep the keg at dispensing/equilibrium pressure (for me this is 12-15 psi at 47F, your taste may vary). Depending on which tap and lines I use, I may have to lower or raise the dispensing pressure to get the right head.

Something odd happens as the storage time increases. The bubbles get smaller, the beading (trails of bubbles) improves, and the carbonation

lasts longer in the glass. I suspect this is due to the CO2 bonding (slowly) to things other than water, but you can't prove it by me. This improvement in the quality of carbonation over time is puzzling, but pleasant.

I hope this helps out John and others. I arrived at the process empirically, 'cause the instructions I had (like his) didn't seem to work properly. Shake it up!

agitatedly,

Paul.

Subject: Portable taps

For some time, I've been dissatisfied with my "cobra head" portable tap. It seems like the hose is too short, too fat. The tap causes a lot of turbulence. I have arrived at the conclusion that these things are just a kluge. If I have time, I now remove a tap and line from my dispensing fridge, but this is both a hassle and a compromise.

Does anyone know of a source for a better hand-tap for field use? I don't want to go to the expense of a cold plate or jockey box setup. I just want a tap that has a smaller i.d. hose and a tap that was designed for beer, rather than coffee. Any help out there?

Paul.

I do kind of a hybrid of 1 and 2. I essentially do the mash in a SS pot
that
I put in a picnic cooler for temperature control. When it comes time to
sparge, I line a plastic colander with my grain bag and pour the mash
into
it. After recycling the first runnings through the grain bed thus
created, I
run my 168F water through the grain. My colander has holes that are too
large
for this purpose, so my water goes through too fast, but I seem to get
pretty
good extraction this way. I use 2-2.5 gal of water and 2.5 to 3# of
grain for
this process.

I intend to fabricate one of those double bucket systems some year when I
get
a few minutes of free time.

Subject: Mash Oxidation

Norm writes:

>Oxidation during the mash is a potential problem area, contrary to old wisdom.

I agree. Coincidentally, I was re-reading Noonan last night, in preparation for re-taking the BJCP exam, and in the section on "Why Decoction?" he says that the boiling of the decoctions helps to de-oxygenate the wort which leads to the grain bed settling in "layers" at lautering time Noonan claims this makes for a better filter bed. I have no experience with this, but thought it might be of general interest.

For the record, when kettle mashing, I scoop the mash into the lauter tun with a small pot and try to do this as gently as possible to avoid oxidation. In general, oxidation is a bad thing -- offhand the only positive oxidation I can think of at this minute is the protective oxidation on aluminum and stainless steel.

Subject: yeast behavior

HBDites:

As I am drinking some of the last of the summer's extract-brewed weissen batches I thought I would report some variation in the results, almost certainly due to the yeast.

I brewed four 5 gallon batches, dark then light, and light then dark. I pitched the 'dregs' from the fermenter, shaken up, from the first dark batch into the next light batch. I started over for the next two batches, also pitching from the first (light) into the second (dark). The boiling times, 60 min., were the same for all batches. The fermentation temperatures were also approximately the same (~70 F), as were the temperatures when I pitched (~75 F). Both light brews and both dark brews had the same rather simple recipes:

6.6 lbs. NorthWestern Weissen extract
1.5 oz. Saaz (3/4 in boil, the rest at the end)
22 oz. Yeast Lab W51 Bavarian Weizen, primed for the first of each pair of brews

=====
>From yeast FAQ:
Yeast Lab W51 Bavarian Weizen
This strain produces a classic German style wheat beer, with moderately high, spicy phenolic overtones reminiscent of cloves. Medium attenuation, moderately flocculent.
=====

The two dark batches had, at the usual reboil stage:

1/2 lb. chocolate malt
1/4 lb. crystal malt

The finished brews made with the fresh yeast were almost overwhelming in mostly clovelike phenolics while the brews made with the "repitched" yeast had much more balanced phenolics (some vanilla) and esters (banana), like commercial weissens, only more intense (and delicious in my opinion). The 'overly' clovelike brews have mellowed with age, but their weissen character is still not close to the pleasant balance between phenols and esters found in the other brews and in store-bought European wheat beers.

Regarding this, I can find no illuminating material in Warner's great monograph on german wheat beer, except that the overall level of phenolic substances is higher when the entire fermentation is carried out at higher temperatures. My working hypotheses are that some change in the yeast or some substance(s) in the sediment contribute to the (better) character of the second batches. Any comments? Any advice on how I can acheive second-batch results from the getgo?

>bitterness would be achieved and there would be no perceptable
>difference in taste. Right? Probably not. Where is the flaw in my
>thinking?

Firstly, not *all* of the oils are boiled away (*most* are though and some are changed into oxidation products, also with aroma). But enough survive into the beer to have subtle impacts on the beer's flavor. Also, the "oil" is not a single compound but contains upwards of 300 compounds that occur in differing proportions depending on the variety. Also, there is the question of the "bitter flavor" that comes from the alpha acids and their oxidation products. The proportions of the alpha acids (which is variety dependent) has an effect on the quality of the bitter flavor. The best documented example of this is the cohumulone level. It is suspected that high cohumulone levels lead to a harsher bitterness. It so happens that usually "aroma" hops have a low proportion of cohumulone, and the high alpha hops tend to have higher proportions.

Back to the oils: So here's what happens. When you put in a low alpha hop for bittering, you are usually adding a lot more aroma compounds to the beer because you are adding a lot more ounces of hops to get the alpha acid content right. Conversely, when you use a "high alpha" hop, you add less oils. Now I say "usually" because some of the high alpha varieties also have high oils, but the noble aroma hops (that the studies have been done with that I am basing my comments on) also have fairly high oil contents but low alphas.

A lot also depends on the beer style. The aroma compounds left over from the bittering hops is a lot more likely to be noticed in a well-made lager than it would be in a pale ale that would typically have more finishing hops or a stout/heavy beer where lots of flavors will mask the hop subtleties. All of the commercial studies on this subject have been done with lagers. They have been trying to answer the age-old question "Does

using noble and/or aroma hops for bittering make a difference in the beer's taste?" The answer seems to be "Yes." But again, they are concerned with lagers. So, it's not a stupid question. The pros have been at it for years.

Mark

> falls back into the carboy. I use this system for any beer with an
> OG of at least 1.050. Lower strength beers tend not to kick out
> as much fluid.

Aren't you risking a siphon of potentially contaminated water (or sanitizer) back into your fermenter?

blowoff hose

A is the level of the wort in the fermenter. C is the level of the liquid in your blowoff bucket. B is the point at which the wort is forced up to during heavy fermentation. When the fermentation slows, since the mass of the liquid in the left side of the tube is greater than the mass of the liquid in the right side of the tube, the direction of motion of the liquid is now left (pulling liquid from the blowoff bucket). No?

RE: HOPS FAQ, progress is slow, mostly because of the underwhelming response to my request for information. I am currently looking for commercial examples and flavor/aroma profiles for the following hops:

Hallertau Hersbrucker
Hallertau Mittelfruh
Liberty

Mt. Hood
Styrian Goldings
Willamette
Bullion
Centennial
Chinook
Cluster
Galena
Nugget
Perle
Pride of Ringwood

Yes, I realize this is practically a list of every hop ever known to (modern) man. The point is that for this FAQ to work I need input from you brewers. I haven't tried a lot of these hops and even some of the ones I did try, I didn't take notes on hop flavor profile, etc. As far as the flavor profiles, your own adjectives are what I'm after (i.e. citric, flowery, funky, strong, non-descript, etc.) Also, commercial examples of a particular hop would be quite welcome, but I'd prefer not to get things like "I've heard they use Mt. Hood in XYZ beer". If its a rumour it probably doesn't belong in the FAQ. Part of the reason for me doing this FAQ is selfish; I want the information. If it was solely for that purpose, though, I wouldn't be putting in the kind of time I'm spending. The extra effort is for the digest participants; I'm just asking for a little input. Is that too much to ask?

As always, we thank you for your support,
norm

From: Philip J Difalco <sxupjd@anubis.fnma.COM>
Subject: Vigorous fermentation (non tarred)

Sorry about the tar-corrupted file - I only have a slight idea how that may have happened, but it's too mundane to elaborate.

Basically, I brewed a Scottish Ale (recipe taken from pg. 9-6 of Cats Meow), brewed using standard extract procedures. I used Wyeast #1056 (American Ale yeast), made a starter, and added it to the wort.

I racked to a secondary (carboy) after 9 days. Today (day 12) the brew is still actively fermenting (one bubble from airlock about every minute, and tiny bubbles regularly rise to the beer's surface - as noticed through the carboy). My basement temp. ranges between 67°F to 70°F (where the beer's fermenting). Additional Note: My tarnished Wort Chiller became de-tarnished after the wort chilling phase for this brew.

QUESTIONS/CONCERNS:

Is this long of a fermentation period abnormal (for #1056)?
How long a fermentation period can I observe before I become worried?

Any/all responses/observations welcome.

Looking through the 1992 HOMEBREW Digest Index (1992.index) I noticed some articles referencing "Problems with long ferments for WYeast 1056" - however, I don't have direct ftp access to sierra.stanford.edu, and therefore am unable to view those HB Digests (Digest #'s: 835, 837, 969->972, 1011, 1012).

(if you want the awk script I used to do the HB Digest Index search, let me know and I'll email it - usage: searchFor searchString indexFileNames).

Subject: next partial-mash question

I've had this partial-mash question partially answered from someone already in private e-mail, but since it's next on my list I'll go ahead and post it to the think tank anyway.

When partial-mashing, to what extent might it be beneficial to (1) measure & adjust the ph of the water (2) use the iodine test for conversion?

It sounds to me like most partial-grain people pretty much fly by the seat of the pants on these matters.

Opinions?

>with everything else but after reading the postings about
>fruit additives to beer I'm totally confused. Now I'm
>thinking of adding the juice right at the end just before
>bottling. I would appreciate any suggestions.

It's not a good idea to add the juice early in the boil because boiling will boil-off many aromatics from the juice and about all you'll get is alcohol out of the juice's sugars. The flavor is in the aromatics!

Also, it's not a good idea to add the juice at bottling because it has sugars in it and you'll get overcarbonated beer.

In addition to the two suggested cherry juice additions there are at least two more:

1. add the juice in the last 1 minute of the boil, and
2. pasteurize the juice by heating it to 160F for 10 minutes, cool it, and add it after the primary fermentation is over.

Suggestion 1) is more likely to set the pectins (I think your homemade juice has pectins in it) which will make your beer cloudy.

Suggestion 2) is the best because adding the cherry juice (or any fruit) at pitching time is that the fermentation of the malt sugars and fruit sugars will produce a lot of CO2 which will scrub the cherry aromatics out of the beer.

I think that 4 cups may be an un-noticeable amount of cherry flavor for a 5 gallon batch. I'm about to make a cherry beer and am thinking about using between 6 and 8 pounds of cherries under 3.5 gallons of beer. I've used 13 pounds in a batch of pKriek and the cherry flavor was quite intense.

I've looked through many grocery stores looking for 100% cherry juice, but no luck -- they are always (in order on the label): water, corn syrup, white grape juice, cherry juice, preservatives. That's not what I want in my beer. If you can't find more real cherry juice, it would be a shame

to waste the 4 cups you have. Here's what I suggest:

- * Brew up the batch of beer.
- * When it's done, siphon one gallon onto the four cups of PASTEURIZED juice in a sanitized, two-gallon container.
- * Bottle the other four gallons.
- * Wait till the cherry sub-batch is done, bottle that.

Al.

From: KONSTANTINE@delphi.com
Subject: Silver solder

I've been following the discussion on silver soldering and decided to pull out The Complete Metalsmith by Tim McCreight and look up silver solder alloys. Here's what I found.

AgCuZnCdMelt. Pt.

"IT" 8016 4 01490

HARD 7621 3 01425

MEDIUM 702010 01390

EASY 602515 01325

EASY-FLO 501515201270

If there are any questions, Ag=silver, Cu=copper, Zn=Zinc, and Cd=Cadmium. The Melting Point is degrees fahrenheit.

These are all high temperature alloys and from personal experience they will solder stainless. Keep close tolerances and the joint will be stronger than the items you are bonding. As the chart indicates, stay away from Easy-Flo for food grade applications because Cadmium is very toxic.

Later,
Konstantine.

Subject: Hops! (and more hops)

Hi All!

Just thought I would throw in my \$0.02 on this year's hop harvest. With three brand new rhisomes put in the ground ~mid-May, I was able to get enough hops to distribute freely among friends and family. We planted three varieties: Cascade, Hallertau, and Tett. The Hallertau was the early-on favorite but in the end, pooped out before putting out many cones. Total? Well, maybe 12-15 cones. That's right, CONES, not ounces. :(The cascade, on the other hand, did a bang-up job. The hop vines reminded me of grape vines, there were so many cones! Yikes! We have a standard grocery bag which has about a 4" layer of cones. This is verrrrry promising. The Tett? Well, it was a shy plant. Total vine length was about 12". Yup, that's right, 12". Oh well, I'll get 'em next year!

Looking forward to brewing with home-grown hops ...

D.

Subject: Cherry Juice

Hi All,

In today's HBD there was a discussion (sorry, no quotes or sources) about using cherry juice instead of whole cherries. One respondent mentioned that he couldn't find 100% cherry juice. Many health food stores carry Knudeson's (sp?) and they make a 100% cherry juice. They also make a variety of other pure, juices (anyone for a kiwi-papaya weiss?!?).

I've used the cherry juice twice. The first time was in a light ale. The stuff had a real metallic edge to it and wasn't very drinkable (I just dumped out the last gallon of it yesterday - over a year old!). It actually turned out to be passable if consumed on the rocks! I later made a cherry stout which was much better. In both brews, I used about 3 quarts of the stuff.

Personally, I'm not wild about fruit in my beers. I did my part as a homebrewer and experimented, and now I'm happily back to malt, hops, water, and yeast!

From: Bob_McIlvaine@keyfile.com
Subject: Solder And Brazing

A welder with mig or tig capabilities will take about 10 minutes to weld a keg type joint with Stainless, and charge an hour minimum, typically \$30 to \$40 per hour. Make sure the guy knows how to do stainless and can handle liquid tight joints. Get all your holes and fittings ready to weld and he can probably do all your joints in an hour. If your lucky, you'll find a welder who will do the job for several pints of good home brew.

Silver solder can be nasty to solder and can be hazardous to your health if you get the wrong stuff. For your health's sake, get the kind that is cadmium free, for your yeast's health get low, low lead content. The simplest flux is plain old borax, the chemical not the soap :-). You can get the solder and the flux at your local welding supply, consult them about the solder for food preparation vessels, melt point of at least 1200 degreesF. The flux you can get at hardware stores, drug stores (sometimes), and your local supplier of chemicals for school science labs. The actual soldering is tricky, burnish the stainless steel parts, mix the borax powder with water and apply to the joint, bring entire joint up to temperature, the borax will melt. Don't get the joint too hot (easier said than done, with stainless steel), too hot and the solder will ball up and roll right off. Some old timers will wrap the solder wire around the joint and heat indirectly until the solder sweats into the joint making a very nice fillet. The key is to not oxidize the surface that the flux has cleaned, direct heat from a flame WILL oxidize.

Regards,
Mac

From: tmr@fjtdl.att.com
Subject: Re: Purging Keg Headspace

Although Chris Cook writes about purging kegs with CO₂, I have been doing this with my secondary fermenter to eliminate any risk of wort oxidation. Before racking from the primary to the secondary, I fill my 5 gallon glass carboy with CO₂ using a small 2 or 3 inch long CO₂ "charger" used in making carbonated water. I place the cartridge into the empty water container, tighten the cartridge to puncture it and then squeeze the lever on the bottle to release all the CO₂ into the secondary. With a carboy I use a rubber or vinyl tube long enough to reach the bottom of the carboy. Since the CO₂ is denser than air it should fill up from the bottom upwards, displacing the air on top as it fills. Then when racking, the wort is transferred into the secondary under a blanket of CO₂ avoiding any contact with air.

I also use this technique when adding priming sugar/DME. I purge whatever air I can out of the primary plastic pail with the CO₂ bottle. In this case I don't need any tube. Just fire the CO₂ into the secondary starting all the way at the bottom. I don't know how well this works since I can't see the CO₂ in the fermenters, but it seems like it should work. Maybe I'll lower a match or candle into the CO₂ filled pail and see at what level the flame goes out.

From: Kelly Jones <k-jones@ee.utah.edu>
Subject: Troubleshoot my dry hopping!

Recently, I tried my first dry hop, and I'm not entirely pleased with the results. In brief, the brew was half of a 10gal batch of American Pale Ale. When secondary was almost complete, I added 1 oz of homegrown cascade, in a weighted nylon stocking, to the carboy. Sunday, after 10 days dryhop, I bottled. I tasted the brew at bottling time, and found a very pronounced excess bitterness. I compared this to the other half of the batch, which had not been dry hopped, and which did not have this bitterness. So, the bitterness was a result of the dryhopping.

Questions:

Is this simply a temporary bitterness that will soon mellow? Or can dry hopping really add noticeable bitterness? Did I over dryhop? How many IBU's can/should dry hops introduce?

By the way, the hop aromatics in the dry-hopped batch are great, so I'd prefer not to reduce the amount of dry hops, but I'm afraid this bitterness may have spoiled an otherwise great ale.

Thanks,

Kelly

Subject: Wedding Bells

I've been brewing like a madman, the kegs have aged up, and the bride and groom

have tasted and decided which two kegs they want to have at the wedding.

Now

my problem is: How do I set it up at the wedding?

I noticed several earlier posting about beer for weddings, so anyone with experience please let me know how it went; specifically:

- 1) transport:: I was going to haul it over a couple of hours before but is this enough time?
- 2) temperature:: THIS could be a problem. I was planning on having the kegs in a tub with a little ice on the bottom and cover the whole thing with a rug or something. I don't want it too cold, etc.
- 3) Tank:: I'll tape the 5lb CO2 tank to the outside of the tub, I guess, and cover the regulator to protect it.

Basically I have the standard 5gal kegs, a 5lb tank, and a regular regulator.

Any advise appreciated,

paul boor

>

blowoff bucket

>

>

> fermenter

> ...

If you did it this way, you'd have a bigger problem than sanitizer suck-back.

You'd probably blow most of your batch out the hose! The hose goes just into

top of the carboy thusly:

blowoff hose

B _____ /__foam__/
 // //

/-|-|/

|

blowoff bucket

fermenter

I agree with raising the effluent bucket above the carboy. I put mine on a

shelf well above the carboy. In fact, I intend to get a longer hose

(maybe

8 feet) so I can put it way up there. Most of the foul goo sticks to the

inside of the hose and never makes to the bucket anyway, and I'm hoping I

can get back most of the magic liquid that rides along with the foam.

Added note: 1" ID hose jammed right into the carboy neck is the only way to go. (But jam it in just a little!)

A data point for the cherry juice:

Some months back I made a wheat ale with Wyeast Belgian and primed with pure cherry juice. It was just some commercial bottled stuff from a local "natural food" store (no added sugar, preservatives, or camel snot)

I didn't have a clue how much to use. It wasn't very sweet, so I used 2 quarts to a 5 gallon batch. Didn't boil, heat, or otherwise incant; Just dumped it in. The carbonation came slowly but in the end was over-carbonated. The result was tasty and surprisingly kriek-like. Were I to do it again, I would use only a quart and resign myself to less cherry flavor.

From: bliss@pixel.convex.com (Brian Bliss)
Subject: CO2 / mead

Chris Cook (cook@cdhf2.gsfc.nasa.gov) writes:
>When people say "purge the headspace," what procedures are you following?

Being totally anal, blanketing the keg with CO2 before you siphon into it, pressurizing the headspace to 15 PSI and releasing the gas at least 3 times, once with the keg stright up, once tilted to the side (so that the "IN" gas fitting is on top), and once swirling the beer in the keg, to make damn sure you got every last little bit of air out of the headspace.

You should at least be this anal if you are going to force carbonate the beer by agitating it - any O2 in the headspace is going to making into solution, and you can easily oxidize 5 gal of beer overnight if you're not careful (If it doesn't taste as good the next morning as it did the night before when you carbonated it, then you did something wrong :-).

If you just crank up the pressure and let sit undisturbed for a few days, it's not a big factor...

- - - - -

Paul dArmond <paulf@henson.cc.wvu.edu> writes:
>At this point the keg is over pressurized and undercarbonated. The
>pressure is 35 psi. If the pressure is vented to dispensing range, the
>beer will have large coarse bubbles, foam a lot and go flat quickly.
>...
>Something odd happens as the storage time increases. The bubbles get
>smaller, the beading (trails of bubbles) improves, and the carbonation
>lasts longer in the glass. I suspect this is due to the CO2 bonding
>(slowly) to things other than water, but you can't prove it by me. This
>improvement in the quality of carbonation over time is puzzling, but
pleasant.

I have definitely noticed this, also. I kind of like the "foamy head, but little CO2 in the beer" effect that happens just after force carbonation via agitation (for dry stouts). It makes for more of a Guinness-like taste. certainly not appropriate in most brews, though.

- - - - -

Keith Hill <khill@eecs.wsu.edu> writes:
>I was wondering if anyone wout there has mad mead using fruit? If so
>I would like some hints for future batches or help on the following
>problem, how to avoid.

If you use watermelon, beware that the pith will not dissolve during fermentation; rather, it will float on top, forming a sponge-like layer that easily clogs blowoff apparati. It also has a red-fireworks effect (much better than anything you've seen on the 4th of july) when the pressure is released. If you figure the carpet cleaning in with the price

of the batch, the cost is prohibitive. On the + side, what's left
tastes great :-)

Subject: Keg aging

Greetings:

I have a relatively new keg set up, and I am working on getting a system that works well for me. I have read the recent postings on forced carbonation with interest, but I have an additional question. Everyone suggests shaking vigorously to get the CO2 into solution. However, this would appear to be at odds with another objective, getting the beer to clear. In other words, one is also stirring up sediment when shaking. So, once the keg is carbonated, how long does it need to sit to get a good clear final product? While I try to rack carefully, some stuff invariably comes along for the ride, particularly if I dry hop. Also, will chill haze eventually settle out if I store the kegs cold? How long does this take? Help.

Dave Rose.

Subject: Mash temperature drop

I have seen little about acceptable temperature drops during mashing. There is much about target and strike temps, however I'm looking for an indication of how much of a temperature drop is acceptable over the course of a mash. So, for a single step infusion with a target of 153F what is an acceptable temperature drop over an hour? Can one average the temp over the mash and then assume that the conversion characteristics are actually those found with a mash of the average temp. For example, if I start at 156F, and drop to 150F over an hour is it safe to assume that I would have gotten the same result with a constant 153F?

From: COYOTE <SLK6P@cc.usu.edu>
Subject: Utah Brewpubs

There are four brewpubs in the land of 3.2 beer and the Osmond family :(

The biggest in Wasatch brewery in Park City. About 1/2-1hr up from Salt Lake. Worth the visit just to see the location. Beautiful! They have a number of brews. I would recommend the Slickrock. Light, hoppy, hazy. Good afternoon brew. Ale. Usually pretty good. Recently has been excellent. Malty. Slightly browned amber. Good heady/hoppy. Stout. I used to love this stuff till I started making better stouts Used to seem very thick and creamy. Now...I've had ones I could walk on top of. This would be a swimmer! Seasonals...You may still catch the Raspberry. I think it's slickrock with raspberry extract added. Pretty good though. Holiday ales, christmass ale, fall bock...depends on what they are up to at the time. There is a Light beer now. Watered down slickrock is my guess. ugh. I have not known them to have the "best quality control" but hey....it's a brewpub not Miller! It is the only bottler you could take with you from Utah.

Squatter. Salt Lake City. Mostly a restaurant which brews too. Hop vines on the patie. Good selection of styles. I don't know what they have going now. They've had a cask-conditioned ale which was quite true to style. Light ales, cream stouts, ambers...Generally nice beer. More adventurous and willing to bring out the flavors of a style, rather than catering to "american beer" style consumers. That's a very good thing! (ps. that should read SQUATTERS)

Ebeneezers. Ogden Utah. An hour north of salt lake. A wonderfully built log cabin housing a classy restaurant. Oh by the way, they brew beer upstairs too. Haven't tried the food, but the 4 beers we sampled were...well...played pretty safe. Their setup looks very nice and clean...but being the extreme hop-head I am, I felt the brews were lacking. The pub has only been open a couple of years, and I hit it early on so maybe things have changed. A worthy place to visit all in all. They had a light, amber, stout...and a specialty, which changes. That may all have changed by now. (oh..it was a lager at the time)

????Can't remember the name. In Price Ut. A few hours south of Salt Lake. Never been there. Never had their beer. Seen the label on a bottle. Looked nice. Don't know what the inside was like. But I liked the homebrew toot refilled it with!

And finally for the more adventurous... The Coyote Brewery in Logan UT. Run my....none other than.... The Wyllie-Man himself. Fresh brewed beer on tap in a senic basement lounge decorated in the fashion of the Lambic breweries. All spiders intact. Even the aggressive house spiders! An ever changing array of tastes to delight. IPA's, Malty ambers, hoppy bitters, Creamy stouts, Potable Porters... and the occasional experimental adventures... Fruits, spices, one of the latest being a Pepper Cardamon corrupted Scotch Ale (90 shilling).

The Pumpkin Mash will begin it's life with the full moon!

(really...if you're passing through northern Ut. drop me a line.
We have the biggest vendor of Wasatch beers (other than their home)
here in town, the White Owl tavern. Nothing like an Owl burger on the
deck
friday afternoon with a Big Dog of Ale. Summers gone, the trees are
alive!)

**** PS: I don't have any affiliation with any of the breweries, except
my own! And sharing the kinship of the many other mini breweries found
in basements and closets all over this little valley!!! *****

Subject: Smoked Porter

I would like to make a Smoked Porter similar to the wonderful stuff put out by the Alaskan Beer Co. and Greg Noonan's brewery. I would like to smoke my own grain, but I have heard or read widely varied recipes on how to do this. TCJOHB recommends 1 lb. of smoked 2-row for their Smokey the Beer recipe, and suggests doing it on a brass screen on the BBQ. I seem to remember a winning recipe from the national AHA convention that used 4-5 lbs. of smoked grain for a 5 gallon batch. Any experiences out there? I guess the plan for now is to use 2 lbs. of 2-row, fire up the Weber, add some Alder chips (that seems to be the smoker's wood of choice here in the Pacific NW), place the grain on a screen or cookie sheet, cover and wait until deep roasted color prevails. Any advice?

I once got a hold of a Cornelius keg which I was told was legal, but in retrospect, I'm quite sure wasn't. The source was a guy from one of the homebrew clubs who said he got a dozen kegs from an aluminum recycler and that they had been released by the owners. The kegs still had the: "WARNING: PROPERTY OF PEPSI COLA BOTTLERS OF ILLINOIS" or some such statment.

I tried removing this label by pulling, but that's not a good way. Then, I thought, hey, why don't I burn it off with a propane torch? The label burned off quite nicely, but in the process, the SS glowed red-hot. Upon cooling, the metal was dark brown and rough. On the inside of the keg, there was a rainbow colored area, right where I had been heating. I never ended up using that keg and I think it just started to rust in that heated area.

The bottom line is that I think that it's possible to ruin a SS keg by overheating, even with a simple propane torch (no oxygen other than that in the air).

In response to John McCafferey's keg carbonation/dispensing pressure confusion:

John "Cisco" and I are still working this issue. We'll report shortly on our findings.

Johnathan writes:

>Anyway, in #1231 Aaron Morris recommends Campden tablets in the blowoff

>bucket. What does the campden do? I've never heard of this.

The campden tablets sanitize the water in the blowoff bucket. I believe they are Sodium or Potassium Metabisulfite. I'm quite sure the intent is to sanitize the water in case the cooling of the wort sucks blowoff water up the blowoff tube into the fermenter. Since I've switched to 1.25" OD, 1" ID blowoff hoses, there's no fear of this happening, so I just use plain water. You could just as well use boiling water in the blowoff bucket if you wish since after 24 hours, the gas that the campden tablets make (I forget which it is -- some sulfur-compound) has fizzled-out

and anything that wants to live in your bucket can, so boiling water would

work just as well and is cheaper. I strongly recommend that you use an

oversized tube for blowoff (ideally, 1" ID) to avoid clogging and explosions.

I might also add, that I'm still debating (with myself) on whether to use blowoff or not anymore (fear of lost head-retaining proteins).

Al.

following?
>

I purge the keg prior to racking into it by filling the keg with CO2
and opening the vent in the lid. I repeat this several times. Then
I rack into the keg with gas still attached to receiving keg (2-3 psi) to
ward off the demons of beer oxidation. One can also rack into the keg
using the liquid out connector with the appropriate fittings. You will
have to bleed the gas out of the receiving keg as it fills with beer.
When complete, I pressurize the keg to 10-15 psi, vent and re-pressurize
and repeat 3 or 4 times. *Another* useful technique to exorcise the
demons
of beer oxidation is to use the two-hole (orange) carboy cap at racking
and force LOW pressure CO2 into one hole (the side hole) to start the
siphon.
After the siphon has started, loosen the carboy cap and maintain a low
flow rate of CO2 to keep a blanket of CO2 on the beer until you're done
racking.

Subject: decoction (not again!), SN Pale Bock

Hello all,

I've been an HBD reader for a few months now, but this is my first writing adventure. I know the decoction discussion has come and gone, but it did inspire my buddy and I to try it. Although slightly intimidated by the 23 step process, possible divorces, etc., we leapt right in. It all started yesterday...

We started just as we would for a temperature controlled mash. Infuse about 10 quarts 135 F water with 10.5 pounds grain (9 # Belgian Pilsener Malt, 1 # Belgian Munich Malt, and 1/2 # Crystal Malt (30 L)) into a 10 gallon cooler equipped with a copper sparge manifold. We hit our protein rest temperature of about 125 F. We held this for about thirty minutes then pulled our first decoction (about 1/3 of the total volume, mostly grains). Our plan was to slowly heat this on our propane cooker to about 155 F. It was then we realized that the words "slowly heat" and "propane cooker" do not go together well. After an almost instantaneous local boil, we moved the decoction inside to the stove. Here we were somewhere between 140 F and 160 F for about 30 minutes.

Figuring this would be okay, we proceeded to boil for about 20 minutes. We slowly added this back to our mash.

Our mash came to a temperature of about 140 F and stayed firmly there. After a few boiling water infusions and another small decoction, we managed to get all the way to 152 F. Cautiously optimistic, we let it mash for about an hour and a half. Our iodine tests never showed complete conversion (maybe because of grain particles in the sample?). We pulled our final decoction (all liquid, about 2 gallons) and heated it to boil quickly on the propane torch. Once added back, we began our sparge with about 4.5

gallons of water. This went fine (sparged till runnings were about 1.010), as did the boil. We cooled the wort using an immersion chiller and racked off some brilliantly clear wort. Total time was about 8 hours.

Our original gravity was 1.044. This gives an extraction of about 21 pts/lb/gal (I think). This is a bit lower than my typical extraction for a temperature controlled mash (about 25 pts/lb/gal).

My questions are these:

1. Was my extraction so low because of incomplete conversion or some other reason?
2. Was my temperature control a factor? If so, how do others out there control temperatures more precisely?
3. Should my first decoction have been bigger?
4. Does anyone out there have a good recipe to duplicate the Sierra Nevada Pale Bock? My wife really likes it and since she gave me no grief about this decoction mess...

Sorry about the length and TIA for the info.

>js
Ok ok. We all have our opinions. Jack your approach reminds me of a
brewing friend here who won't budge from his tried and true methods.
Despite all the renovations and improvements my brewery has gone through
much in part due to major learning/ideas/creations developed from net
knowledge. His brews are all made from the basics:

Pale malt, crystal malt, the three dark malts (choco/roast/black)
He basically rotates between: Pale, golden, amber, stout.
It works for him. He likes his beer.

Me...I adventure. I've tried most anything, from pumkin to pepper, to
vast arrays of fruits and spices. Plus...a number of specialty malts.
Yes they add color and flavor. They can give an extract brewer a
grainier
taste. But many of them will perform best in the presence of mashing
enzymes. to an extractor they may just lead to starch and haze.

Here's some examples of ones I use and why (I've been all-graining for
about 4 years now, so I've tried a couple along the way...)

Basics: Pale malts, 2 row, 6 row. Basic mashing enzyme power-
fermentables

Vienna 2 row. A slightly darker maltier base malt. Good for ambers
Munich malt. 2 or 6 row, depending on supplier (see discussions)
A bit darker still, has enzymes. Good in strong lagers styles.

Crystals. The whole shlew of lovibond ratings. Use em all. 10-120.
Don't just settle for generic "crystal". Get the rating, try high and
low. I don't think I've ever made a beer w/o crystal. The higher
end add a particularly nice heavier maltiness to mid-color brews.

Specialties worth trying (IMHO of course) Use .5-3 #/5 gallons

Victory. Adds a nutty/roasty flavor, but MUCH more subtle than
the dark malts. Great for a nut brown, or vienna

Dextrine. Want the full body mouth feel in your stouts? That sweet
chewy kind of character you find in a good full porter.

Wheat. Go 50/50 for a real wheat beer, or just a touch to add some
serious head retention. I usually toss in a few cups for fun.

Rye. A bit more unusual. Not for everyone. Adds a red tone.
Try some DARK crystal with about 30% rye in a golden/amber brew.
It has an unusual flavor. Sort of "bitey" , tart almost.

Hard to describe by a nice change of pace. One taster swears by it

Dark malts

Chocolate, Roasted, Black Patent. (These should almost be in the basics!) I love chocolate. I bought 30 #'s so I'd NEVER run out. Get to know them separately or in combinations. The battle over which belongs in porter may never end- black or roast?!!!! Try a full pound, or just toss in a handful to a "light" beer and see what happens. Wonderful things come to life. Dark grains are NOT only for dark beers. A subtle roast taste can do wonders for a pale.

How to get to know specialty malts...Thoughts to ponder.

So many variables, so much beer, so much tasting, and brewing... Make a lighter beer with just pale and crystal as the base. Add a slightly oversized amount of the specialty malt. Say 3 or 4 pounds. see how it really tastes. Then use it in smaller quantities to your liking. Do this SEPARATELY with different batches and different malts,

then start to mix and match.

Look to style recipes for what is "appropriate" for a particular style and go for it. Alternate combinations. Use victory and munich, then munich and dextrine, then victory and dextrine.

I have gotten to a point where I don't formulate a recipe ahead of time. I decide on degree of color, and go to my grain room and mix and match letting the grains speak to me and call out who wants to give their all to this particular batch. I try to add several but NOT ALL types in each batch. I've had brews with as much as 10 different types of malt. The resulting flavors can be very complex and perform dances of ecstasy on the taste buds and "brew senses". Then there is the whole world of hop varieties to play with, but that's another story.

I know there are many other types of malts out there. Belgian and all, which I have yet to sample. There are certainly differences between american 2 row and english 2 row, or lager malts. Worth the prices to try for that special holiday ferment, or all the time!

NOW A QUESTION: Hot side aeration.

I have not seen Fix's article on this, I was wondering if anyone could summarize the crux of it for me. The concern is over adding air to a mash once it's brought up to mashing temp, and then upon sparging and splashing.

I made a copper manifold/rectangular cooler lauter tun (I love it!) I added a tube that extends upward at the side away from the spigot. I can run water through the tubing and sprinkle sparge water gently on top of the mash with NO disturbance of the grain bed. One idea which came up was that I could use this tube to set the grain bed. I begin the mash in my brew pot, get it well mixed then add hot water to bring the temp up and dump the shlew into the cooler. I can then blow air into the tube at the top side to mix the contents, allowing the heavier pieces of husk to settle quickly while any powder rises to the top. I've had excellent sparges using this. I've even run the tun dry (got distracted) before finishing the sparge, so I added more water (underlet) and reset the grain bed by blowing air in. The bubbles rise from below- stirring all the grain and bits upward. As they re-settle the heavies drop first and the bed is re-set. With this setup I don't see how I could ever have a stuck

sparge.

But what damage can be caused by bubbling air through a mash? I know that boiled hot wort is subject to oxidation reactions, but we're talking about a fair few degrees cooler here. Do other mashers out there take efforts to avoid splashing the wort upon sparging? I stick a spoon in the line of flow to let the wort travel down the spoon rather than through the air splashing into the collecting vessel.

Any knowledgable info on this, or personal experiences would be welcomed. Thanks in advance. Good brew to you all.

From: edo@marcam.com (Ed Oriordan)
Subject: First All Grain

I am slowly preparing for my first all grain batch, and would like to ask a few questions on my proposed recipe. I am going for a kind of Pete's Wicked or dark pale ale (this is somewhat of a conversion of my standard extract brew). 5 gal batch size.

8 lbs 2-Row American
1/2 lb Crystal
1/2 lb Cara-Pils
1/4 lb Chocolate malt
1 oz Norther Brewer (bittering)
1 oz Cascade (finishing)
1056 WYeast American

Q1 - I am planning a single step infusion. Is 2-Row American the grain I should be using? If not, what and why?
Q2 - Should I be using more than 8 lbs? Should I use 9 lbs?
Q3 - I have used crystal and chocolate in the past, but never Cara-Pils. Is there anything I need to know? I am using it for body (is this a waste for a single step infusion?) Should I use more than 1/2 lb?
Q4 - Do all four grains require the same grind? I have my own mill so I can adjust it? Are they all about the same grain size?
Q5 - I am planning on mashing the Cara-Pils and 2-Row and adding the crystal and chocolate at mashout time, is this correct?

If anybody could give me a hand I'd appreciate it.

Later I'll post what I am planning for the actual brewing procedure if that's OK.

Thanks

Subject: PVC/DWC Tubing - Food Grade?

To date, I have conducted my mashes in a cylindrical insulated water cooler (the big orange type) with a false bottom. The system works well as far as holding a constant temperature, but I have always found it difficult to stir the mash in a deep and narrow container. Therefore, I plan to convert a large rectangular picnic cooler into a mash tun for easier stirring/mixing. Rather than using slotted copper tubing for drainage, I am considering using either black or white PVC/DWC tubing that is sealed with either the yellow PVC cement employed in plumbing procedures, or with silicon sealant (the aquarium type). Now the question:

Is PVC tubing safe for this type of food application?? What about the yellow sealant? All comments appreciated. Take care.

drose@husc.harvard.edu asks:

> Everyone suggests shaking vigorously to get the CO2 into solution.
> However, this would appear to be at odds with another objective,
getting
> the beer to clear. In other words, one is also stirring up sediment
when
> shaking. So, once the keg is carbonated, how long does it need to sit.
.....

I age the beer in a glass carboy and transfer it to the keg when the beer
is perfectly clear. Pressurize the keg, shake it to force carbonate and
it's ready to serve - immediately. If, during the final racking you do
introduce some sediment, the amount is rarely enough to be a factor.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Bottle carbonation/mash temp/blowoff tubes

Chris asks:

>Does this imply that bottled beer would carbonate faster if placed
>on its side rather than upright? Anyone have a data point?

When bottle conditioning, the CO2 is being generated in the beer itself, and comes out of solution to enter the headspace. In a keg, the CO2 is in the headspace and has to dissolve into the beer. Two opposite scenarios. In the bottle, the dissolved CO2 and the headspace gas will tend to find their own equilibrium. In the keg, you start with a low dissolved CO2 and high head space CO2 partial pressure. If you want your keg carbonation to mimic bottle carbonation, attach a plastic hose from your CO2 dip tube down to the bottom of the keg, clamp it at the end, and punch it full of a million pin holes. Then, start at about 5 psi, upping the pressure by about 1psi/day for a week. Of course, it's faster just to shake the kegs....

Domenick Venezia asks:

>I have seen little about acceptable temperature drops during mashing.
>There is much about target and strike temps, however I'm looking for
>an indication of how much of a temperature drop is acceptable over the
>course of a mash. So, for a single step infusion with a target of
>153F what is an acceptable temperature drop over an hour? Can one
average
>the temp over the mash and then assume that the conversion
characteristics
>are actually those found with a mash of the average temp. For example,
>if I start at 156F, and drop to 150F over an hour is it safe to assume
>that I would have gotten the same result with a constant 153F?

I think that if you are trying to maintain a specific temperature, you're acceptable temperature fluctuation is the precision tolerance of your thermometer. That said, I think we all have temperature variation in the mash, and do our damndest to minimize it, unless it is specifically desired. I tend to pre-heat my oven to 200°F, then turn it off and put in the mash tun. I get almost no heat loss over a two hour mash that way. Even this way, though, at the time I put the tun in the oven the bottom and middle of the mash may be a few degrees warmer than the top and sides. To answer your question specifically, if your mash drops from 156 to 150 over an hour, *record* it as a drop of 156 to 150 over an hour. If you want a mash of 153, either find a way of better insulating the tun, or give it extra heat boosts every now and again. Sometimes accuracy requires a little extra work. But then, sometimes you can just pop it in the oven.
..

On the subject of blowoff tubes:

Recently I have started following Miller's suggestion, racking off the trub a little while after pitching the yeast, but before primary fermentation

gets going. This can be tricky, because a good healthy yeast starter will get going before the trub gets to settle out. What I do is this: My immersion chiller (planispiral) cools the wort rapidly to under 100°F, but then slows down, as the temperature differential is decreased. I take the temperature down to about 80°F, then rack into a carboy (I use the ventury tube aeration here). I let it cool a further few hours, then pitch the yeast. I wait another few hours, and rack it off the trub while transferring to the primary, a 23L carboy, again aerating the wort. When the kraeusen forms, it is birght, clean, and white. No brown gunge at all. It rises into the extra headspace the 23L carboy offers, and falls back in, retaining all those lovely heading proteins. Moral: The brown gunge is from the trub, and is not a product of the kraeusen. Get to the source of the problem instead of employing bandaid solutions. If you use blowoff because you like to ferment in carboys, get a bigger carboy. I you use a blowoff to remove bitterness, rack off the trub instead. Of course, if you're happy with your beer, ignore this.

I made a sweet stout recently and primed with M&F light DME. I noticed
a ring around the bottle after 1 1/2 weeks or so. I figured I had
infected
the whole batch, but it all turned out excellent! Thanks for posting
this
message, Al. Now I have a better feel about that ring. There was also
oily scum in the beer after the head drops :(after 5 mins or so. I
brewed
a four gallon batch in a five gallon carboy - little blowoff. But now
I
suspect the DME was the culprit, rather than unexpelled krausen.

I did the same thing with my first full mash Pale Ale. I added 1oz of Willamette to the fermenter, it came out with a great hop aroma, but also an unbelievable bitterness. BTW I just threw the hops in on top of the fermenting wort. It took a long time for my bitterness to go away, and by that time I didn't think the beer was very good. (couldn't tell if wasn't very good to start with too much bitterness)

No because when you are force carbonating the keg, you need the extra CO2 beer contact. When the bottle is carbonating the yeast are producing CO2 in the beer.

Subject: more cherry juice stuff...

Chris and Al talk about the difficulties in finding and using cherry juice for beer. I too have used the Knudsen's cherry juice, added in the secondary. I used two quarts and the result was only a slight cherry aftertaste. The beer was good, but I was disappointed with the low level of cherry flavor (no metallic taste though!). Adding the cherry juice kicked off a very strong fermentation and, if I were to do it again, I would use more juice (or the concentrated version) and reduce the temp of the secondary to slow down the extra fermentation caused by the new sugars.

This having been said, however, I don't think I'll be trying the juice anymore. The last cherry ale I made was done using HopTech's cherry flavoring, and I was very pleased. One tbspc in the keg resulted in a wonderful cherry flavor. The beer was a 30% wheat base and hopped using US Saaz at about 1/2 my usual rate. Incidentally, this beer was very popular with my non-HBing friends.

Of course, the usual disclaimers about associations with HopTech apply. Just a happy customer...

BTW, for those interested in finding the pure cherry juice, check out Whole Foods. That was the only place I could find it.

Subject: Pete's Wicked Ale Extract Recipe

Ingredients for 5 gallons:

6 lb bag of William's nut brown extract: "includes a blend of pale, victory, crystal, chocolate, dextrin, and other malts" from Williams Brewing 1-800-759-6025
6 oz of crushed chocolate malt. (Lovibond 350)
1 & 1/3 ounce cascade hops.
1 cup of corn sugar for priming.

Yeast: "Wyeast American/Chico Ale"

Total boiling time: 70 minutes

Hops added : "Cascade" State: "Whole 1992 4.6%" Amount: 0.95oz Boiled for: 70

Hops added : "Cascade" State: "Whole 1992 4.6%" Amount: 0.30oz Boiled for: 10

Initial gravity: 1.043 Final gravity: 1.012

Prepare the chocolate malt in a separate boiling pot containing at least a gallon of water. Add the chocolate malt to cold water. Raise the temperature to 170 F. Pour the hot liquid through a strainer into the main brew pot to remove spent grains.

You probably could substitute a simple pale ale extract with some crystal malt for the William's nut brown extract.

Tasting Notes: In a side-by-side comparison with Pete's Wicked Ale, the two beers were nearly identical. The homebrew was preferred because the roasted-coffee-like flavor component was slightly stronger and much more persistent in the homebrew. This was probably due to the freshness of the homebrew. (Who knows how long the Pete's Wicked Ale has been sitting on a shelf!)

Subject: Portsmouth, New Hampshire Brewers Festival

(Apologies if this has already been posted, or for the late date if it hasn't)

The Strawberry Banke Grande Olde Portsmouth Fall Brewers Festival will be held

on Saturday Oct 2, at Strawberry Banke, in Portsmouth New Hampshire, starting at 10 am.

Portsmouth is about 1 hour North of Boston and 1 hour South of Portland, on I-95. Just take the Portsmouth downtown exit and follow the signs to Strawberry Banke.

Events include a home brew contest (non-AHA sanctioned), demonstrations by local suppliers, and samples from the areas micro breweries. There will be historic re-enactments, family activities and games, and shows including a Victorian era magician and a recreation of a Women's Temperance League rally.

Admission is \$5 for adults, \$3 for children 7-17, and children under 6 are free.

For more information call Strawberry Banke at 603-433-1100

Information for this posting was taken from an article in the Exeter News Letter, Exeter New Hampshire.

From: reeves@lanl.gov (Geoff Reeves)
Subject: Yeast Hydration

Remember a while back we had a discussion about the best liquids for hydrating yeasts and for starters? The candidates seemed to be wort, sugar water, or plain water. Does anyone have a copy of those discussions. I know I can search through old digests but it will save me a lot of time if someone kept that thread.

My brother-in-law wants to do a research project on beer yeast and thought he might investigate this question. Are there any other suggestions you all have for beer yeast research (at the early graduate student level).

Thanks
Geoff

I have seen this subject asked before, but I have not yet read of a workable, ie. inexpensive, solution. The main problem I see is that you can not attach anything to the hydrometer itself. This would effect the weight/calibration of the hydrometer. The weight could be compensated for by recalibrating, but the friction of your proposed "slide wire" resistor might be enough to cause the hydrometer to stick and provide false readings. A possible solution to this would be to use a series of photo receptors that would be uncovered as the hydrometer sinks into the fermenting beer. This would require a light source opposie the photo receptors. The resolution would depend on the number of photo receptors that could be attached to a 3" vertical strip, the average length of the hydrometer drop from 1.000 to 1.060.

Just a suggestion, for what it's worth.

Subject: shipping beer

I work at UPS and have rewrapped damaged boxes containing Homebrew
About four years ago a box containing wine broke open and a supervisor
went to check if UPS could ship alcohol. I was told it was ok and the
only
time regulations applied is when it is being sold mail order. If its
being sold
the purchaser has to be of age and the seller licensed. No
restrictions on pe
rson to person.

The best thing to pack it in, in my opinion, is a box lined with one inch
thick
styrofoam insulation. Its ridgid so it adds strength to the box wont
shift
around, and its cheap and easy to find. Styrofoam popcorn shifts so does
balled
newspaper and your bottles wind up against the bottom of the box.
Pack it right - Dont bother writing fragile on the box we dont have time
to
read it.

From: Owen Plowman <owen@ca.oracle.com>
Subject: Problems with carbonation

Hello! We are using this account as guests to ask the following questions:

1. We are a couple of new brewers in Toronto and we are experiencing some difficulties in getting our beer to carbonate properly. So far we have made three batches of beer (all from kits available at the local "Brew Your Own" store) and have had mixed success. Our first batch was a simple "kit" lager which went four days in primary and thirteen days in secondary. While not totally flat this beer did not carbonate fully and was somewhat disappointing. The store suggested that we should siphon off our beer before adding the carbonation sugar to ensure that all the sugar would be fully mixed and not fall into the bottom sludge that never gets into the bottles.

Batch number two was the same "kit" lager, with 6 1/2 lbs of fresh raspberries added to create a fruity summer beer. The beer fermented four days in primary and seventeen days in secondary (with very vigorous fermentation going on all the time). The result was great with lots of carbonation and a super taste.

Batch number three was an English Bitter brewed using a bitter "kit" with a mixture of grains and hops added to improve the taste. Primary lasted four days and secondary fifteen. Carbonation this time was poor with the beer being nearly flat.

In all three cases we used malt sugar (between 2/3 and 1 cup) for eighteen litres of beer. The actual taste of all our beers is quite good and we have had no problems with contamination at all. We suspect that our problem is related to the life cycle of the yeast and that for some reason there is not enough left at bottling time to create carbonation. Can some of you more experienced brewers offer any ideas on what we are doing wrong and how to improve for future batches? Should we be bottling sooner and how can we judge when the time is right?

It's probably best if you reply directly to the mail id we are using ("owen@ca.oracle.com") for this question, and then we will summarize to the list.

2. Is there anybody on the list who is familiar with the Widmer Brewing Co. in Portland Oregon? They produce a Hefeweizen and we would very much appreciate any recipes that closely mimic this beer if somebody has one.

3. We read Bill Flowers note on Hoptech's fruit extracts and are interested in finding out more about these. Where is Hoptech located and do you know if these same extracts are available in Toronto?

Thanks very much

Doug and Brian

This struck a chord in me. I'd just like to point out that your hop utilization is going to change dramatically when you go from a partion boil extract brewing process to a full boil mashing process. I discovered when I changed over that I needed about half as much hops as I had been using in extract beers.

The reason is that if you boil 6 pounds of extract in a gallon and a half of water, the gravity of that wort is well over 1.100, and probably somewhere near 1.125. High gravity worts don't take up much iso alpha acids from the hops. When you switch to all grain, and therefore full wort boils, your gravity will be more like 1.050, and you'll get a lot more bitterness out of your hops.

From: LeRoy S. Strohl <lstrohl@s850.mwc.edu>
Subject: article on Maine brew pubs and micros

In the October 1993 issue of -Down East- magazine appears an article entitled The Ultimate Pub Crawl by Al Diamon. According to the article **Maine currently ranks fourth in the nation in number of breweries per, one for every 136,000 of us.** If his notes on the tastings are accurate, there are some good brews to look forward to if one were to visit Maine. The article finishes with a Where to Find Maine's Breweries list:

Acadia Brewing, 30 Rodick St., Bar Harbor, 288-9513
Andrews Brewing, Box 4975, Lincolnville, 763-3305
Bar Harbor Brewing, 22 Fore St, Bar Harbor, 288-4592
D.L.Geary Brewing, 38 Evergreen Drive, Portland, 878-2337
Gritty McDuff's Brew Pub, 396 Fore St, Portland, 772-2739
Kennebunkport Brewing, 8 Western Ave, Kennebunk, 967-4311
Lake St. George Brewing, RR 1, Box 2505, Liberty, 589-4180
Sea Dog Brewing, 43 Mechanic Street, Camden, 236-6863
Sunday River Brewing, 1 Sunday River Road, Bethel, 824-3541

Three summers ago because the weather had turned foul while vacationing with friends in Rhode Island, we took a drive up to Portland. We spent far too long in Gritty McDuff's that afternoon and evening. The beer seemed just right for the day, against all of our better judgment we stayed overnight in a Holiday Inn, went back for more excellent beer and food for lunch the next day before returning to Rhode Island.

| in the promoter's car"
|-Spinal Tap

saccharification rest. This process of releasing additional soluble starch during the boil, then allowing the amylase enzyme a second phase of conversion, is the cause of the higher extraction rates achieved through decoction mashing.

Pulling the thickest 40%-50% should be roughly 2 - 2.5 gallons of mash by volume. This fits easily in a 4 or 5 gallon pot. Heat the mash on the stove slowly, monitoring the temperature. When the desired mash temperature is reached, find some way of stabilizing it. I use a cheap plastic picnic cooler with a trivet in the bottom to avoid melting the plastic. Hold for 30 minutes. Don't worry about the iodine test at this point, as the boil will re-introduce soluble starch into the decocted mash.

After 30 minutes, add the decoction back to main mash as described above.

>Here we were somewhere between 140 F and 160 F for about 30 minutes

It's really important to exercise better control over the mash temperature, if you ever expect to attain any consistent results from your recipes.

>Sorry about the length

No problem, like I said, one of my favorite brewing topics.

Cheers,
Jim

Subject: Pumpkin reciplease

Fellow Brewers,

I subscribed to HBD a few months ago and have only recently started reading the info consistently. Therefore, please be lenient with me if I breach any protocol or etiquette(I have witnessed some of the more serious 'discussions'). Anyway, I have seen people mentioning pumpkin brews on occasion and my mouth is beginning to water and my mash tun is twitching! I tasted a friend's Frambroise(raspberry brew) and it was such a treat that I think this fall warrants a pumpkin brew! If anyone has recipes or suggestions for brewing with pumpkin PLEASE respond before my taste buds rebel. Also, this will be my first batch made with fruit or vegetable so any advice is always welcome. I switch back and forth between all-grain and partial mashes so any type of recipe will be appreciated.

TIA,
JOE

From: Ulick Stafford <ulick@bizet.helios.nd.edu>
Subject: Trub racking, Bottles on side, decoction

Ed Hitchcock comments on the Miller suggestion of racking off trub. I did this for a while, but a few very slow takeoffs convinced me that I left most of my yeast behind. If one has consistent yeast habits, it's OK, but mine are so variable. Last night I brewed a wheat beer, pitched at 66F with German Ale yeast slurry top-cropped from my last use of that yeast and had the characteristic Kraeusen from hell by 8 this morning, despite the cold <60F in the basement. Hard to predict when to rack when other yeast takes up to 18 hours or more.

Ed also comments on use of blowoffs - or actually non use. I actually reverted back to a plastic bucket for ales and skim - not to remove brown muck-

I don't believe it causes problems but to top crop yeast. I suppose I could use blowoffs in the Burton Union method, but for my boiler 5 gallon carboys are too small and 6.5 are too big. But I guess I could dilute at pitching for my weaker beers (15B is really a bit high for the wheat Kolsch I made yesterday - and I'll dilute at bottling anyway). I guess I could shell out for a 6 gallon carboy.

Charles Anderson comments that it won't help carbonation to turn a bottle on its side. I won't comment either way, but I did read a published source recommending this procedure for a few days at warmer temperatures immediately after bottling. I presumed the advantage was to have more yeast sediment close to all the beer, and to improve natural convection patterns that would seem pretty lousy in a bottle. I just bottled beer last night and will turn a few bottles on their side when I get home and see if there is any difference. The patch was primed with wort. I'll report in a week or two.

Decoctions again. Last night I brewed a beer with 8lb wheat, 2lb Pale ale (only basic malt I had) and 1lb Cara-pils. I doughed in with cold water, and then added hot to reach a temperature of 100 with 16 qt total. Heated on the burner to 122 and held, and then did the decoction in reverse, i.e. poured the thin stuff into the mashtun. The resulting decoction was huge ~ 60% of the mash. Heated normally and then returned over 5 minutes allowing some of the thick mash to cool before adding it. I rose the small rest mash and the cooler from 117 or so to 155 with little difficulty. I also assume that I boiled more grains than usual and so got a more effective decoction, but also a little more liquid reducing the amount of enzyme in the rest mash. Could the latter be a problem? Otherwise the extra big decoction seems to be a good solution to the problem of doing decoctions on a small scale - i.e. heat loss during returns.

Subject: Hidebound Brewers, HSA

>From: COYOTE <SLK6P@cc.usu.edu>
>Subject: Specialty Malts/Hot Side aeration-oxidation

>Ok ok. We all have our opinions. Jack your approach reminds me of a brewing friend here who won't budge from his tried and true methods. Despite all the renovations and improvements my brewery has gone through much in part due to major learning/ideas/creations developed from net knowledge. His brews are all made from the basics:

Just for the record, Pilsener Urquel is made from pale malt only and might be considered basic beer although, a very highly regarded one.

My recommendation is that, until one can consistently produce such a beer, there is no point in throwing in a dozen other variables that swamp the learning process. It has nothing to do with stiffling creativity.

> But what damage can be caused by bubbling air through a mash?

Hot Side Aeration. Exactly what the new wave brewers are cursing.

> Do other mashers out there take efforts to avoid splashing the wort upon sparging?

I am not sure to what extent HSA is a real problem in small batches but I took one simple measure that cost nothing after reading the Fix article.

My sweet wort travels from the kitchen to the boiling area at basement level via plastic tubing which passes through the floor. It was free-falling the last foot or so into the brew kettle. I added several feet of copper tubing at the end so it can deposit the wort at the bottom of the kettle without aeration.

I do indeed change my process as rational new ideas are presented.

From: Lee=A.=Menegoni@nectech.com
Subject: Decoction / low extraction

In a recent post someone tried the 23 step long strange trip decoction method
I posted and had a couple problems. I had similar problems when I did my first decoctions.

Slow + propane don't mix... instant boil.. mashed 30 minutes boiled 20.
Even if you nuked the enzymes with heat the remaining grains have enough conversion power to convert the starch to sugar, Belgian Pils malt is high in conversion power. The boil will liberate starch that will improve extraction and aid in wort clarity.

Remove 1/3 kettle mash boil add to main mash temp is about 140.
This is a problem with the Noonan decoction method. You need to kettle mash and boil 40% to 50% in order to get the temp in the 150s otherwise you end up with a rest at 140s and a thin bodied beer. This is especially a problem with highly modified grain like the Belgian stuff since it will convert so quickly. Using under modified malts and two kettle mash steps results in most of the grain being converted at high 150s in the kettle mashes and the final fraction in the 140s.

Add boiling water to get to desired mash temp, mash for 1.5 hours, do iodine test still negative, sparge anyway .. get clear wort extraction about 22points per lb.

I'm guessing but you may have thinned the the mash too much and not converted all the starch to sugar. You also may have severely reduced the enzymes in the brief boil while kettle mashing. This could have resulted in all the enzymes for sugar reduction coming from 2/3 of your grain.

Bottom (2) Line(s): If doing a decoction with a single kettle mash step.
Kettle mash and boil about 50% of the grains.

<Subject: Good Receipes Please :-)

<Hi, I know some of you out there have some really good receipes
<for beer. Could some of them either be put into this news letter or
<sent directly to me.

I was meaning to post this anyway:

Pale Ale

2 row american *breiss* base malt, target OG 1.063 (total)
CaraVienna (DeWolf-Cosyns) 12% of grist
Munich(DeWolf-Cosyns) 6% of grist
Aromatic (DeWolf-Cosyns) 4% of grist
Biscuit (DeWolf-Cosyns) <1% of grist
Gypsum in mash
US Whole Perle, ~8% alpha in Kettle-60 min
Goldings Pellets ~5% 30 min
Goldings Pellets10 and 2 min
Saazer Whole Plugs ~3% 2 min
Saazer Whole Plugs ~3% dry hopped

Add ~1 qt per lb hot water, gypsum and malt. Hold 20 min at
144F. Raise to 152-154, hold 45-60 min, raise to 172, lauter.
Boil, hop.....
Counter flow chill,
add ~10% boiled water to dilute to ~1.050
force oxygen, pitch thick Dominion Ale Yeast

FG 1.008, 5.3% ABV

Notes: Since this is the time of year that I run out of
whole hops (mostly cascade and centennial), I was using up some
inventory of Perle (good kettle hop) and goldings (great flavor
hop). A brewer friend of mine had a 5oz pack of saazer plugs
that he asked me to use (tough situation), so I brewed up the
above recipe. I had just made an IPA of 1.060 gravity, so when
this batch ended up at 1.063, I decided to continue my experiments
with pre ferment dilution. I had already convinced myself prior
to this that I could water down a batch considerably with no
great impact on flavor, so I went for it here. I am using a
counterflow pipeline to run my wort from the brewery to the
conditioning room, so I merely hooked up the hot liquor tank to
the counterflow pipeline and let 170F water enter the pipeline,
chilling and rinsing the line somewhat. After topping up the
fermenter, I added O2 and yeast.

Tasting: A good amber color, almost no detectable biscuit character,
but this may change with more yeast dropping out. The goldings
flavor comes through real well but not too strong. The finish
of saazer and goldings adds a bit of complexity to the otherwise
dominant saazer dry hopping. I had never dry hopped with saaz before,
and it is a great change from the norm.

Malt notes: Despite the well known limitations of american 2 row malt, I use it without difficulty. The key is to tailor your recipe so that there are abundant flavoring malts/caramel malts to give the body/dextrins/color desired. By adjusting the munich and caramel malts, a very full bodied beer can be brewed with a terminal gravity as low as 1.008.

Good brewing,
Jim Busch

Subject: Maize/Cornstarch/CherryJuice

Since my wife prefers light bodied and light colored brews, but doesn't mind a little alcohol, I have been considering using either maize flakes or cornstarch as an adjunct to an all-grain ale. (You know how it goes, brew something the wife likes so she doesn't complain so much when you brew something you like.) I have seen numerous references to using maize flakes on this digest. I have seen a recipe in TNCJOHB that uses cornstarch. However, does this differ substantially from just throwing in a pound of so of corn suger before the boil? It seems to me that the sugars obtained from mashing cornstarch would be -- corn sugar. Using sugar would make the mash a bit smaller, but would also remove some of the satisfaction of making my own. What's the collective wisdom on this?

On another note, I have read with interest the recent posts concerning the brewing of fruit beers through the addition of pure juice. I just tried that. I added three quarts of 100% pure unsweetened cherry juice to the secondary in a recent batch of pale ale. It started another ferment, which completed normally. Although the juice had a very strong cherry flavor, there was absolutely NO cherry flavor in the resulting beer. There is a strange (but not unpleasant) fruity flavor. However, I couldn't tell you if it was cherry, apple, or diet coke. (This beer has the stickiest head I've ever seen. It is actually difficult to wash out of the glass.) I think I may turn this batch into my "holiday beer" by making a "tea" made by steeping spices, e.g. cinnamon, cloves, and allspice, in a quart or so of water, then adding this "tea" to the keg. How well will that work?

Cheers,

Don

Subject: wort chiller

Since I've been reading this list (not more than two months) there have been several items on wort chillers but I didn't see anything on the lines of *why* a wort chiller. As a new brewer this was not clear to me. Perhaps other newbies are wondering also.

The scales have fallen. I used to add about 2 gallons of cold water to 3 gallons of wort and wait six hours for it to cool to pitching temp (80F)

Now I made a simple immersion chiller. It went in the wort 10 minutes before the end of the boil. It cut cooling time from six+ hours to nine minutes!

Well worth the \$32 cost of tubing and connectors, I'd say.

Chris

From: Alan B. Carlson <alanc@adb.gu.se>
Subject: Xmas ale

I am planning on doing a Xmas ale (a bit late to start, perhaps).
Situated
in Sweden, I don't have access to spruce, but spruce is a pine tree and
there's plenty of pine trees in Sweden. Last spring I collected some
sprigs
and dumped them into a gallon-sized ziplock bag which was subsequently
stowed in the freezer. My first question is how much sprigs should I use
and should I boil them first (separately) or add them to the boil as one
does hops? I usually do 23-26 liter batches (between 6-7 gallons) My
second
question is should I hop the wort as I normally do or should I go a bit
lighter - in case the sprigs impart some bitterness of their own? What I
would like to do is come close to last year's Anchor Xmas Ale - btw, has
anyone heard what kind of spice profile Anchor will have this year?

Subject: Mash temperatures for Scotch Ale

I'm not particularly fond of Scotch Ale, at least if bottled McEwan's is a good example of it. So, not wishing to experiment any more than absolutely necessary, I'm curious about how much of what I would refer to as the overpowering "malty sweetness" of McEwan's owes itself to mashing at somewhat higher temperatures?

I often use British 2-row and typical mash ales between 150-153 degrees F.

>From those that may have some practical experience in this matter, what characteristics of a good sweet malt flavor can be derived from mashing highly modified malt at these somewhat higher mash temperatures (ie. presumably in the 158-160 deg. F range.)?

I'd welcome any input on this matter. I'm not necessarily looking to brew a McEwan's clone but would like get a better feel for how much effect higher temps might have on the development of non-fermentable sugars and this flavor characteristic.

Thanks,

Ben

> Jim, my e-mail to you bounced.

Either your site didn't use the Reply-To: address (n5ial!jim@gagme.chi.il.us)
I included, or it didn't like the bang-path (there are sites that can't handle bang-paths). Oh well, mail to me at my real address, jim@n5ial.mythical.com, *SHOULD* be ok by the time this hits the digest.

> William's Brewing is a big mail-order outfit in San LEandro CA. Their malt/
> oat extract syrup, Oatmeal Dark, is one I used with great success last year.
> You can add more specialty grain or extract if you want (I did) but I imagine
> it's pretty good just by itself too. (I have no finacial or other [...])

Does anyone have an address, or better yet, a phone number (1-800 number if possible) for these folks? I've got to do an oatmeal stout, and at least for now, an extract brew is the only way it'll happen. But oatmeal stout is just too good as an after-dinner/late-night treat to pass up!

Next subject.... I've noticed that different beer mugs I have will make various beers appear to taste better/worse. For example, I have a mug that I got in San Antonio, TX one time that's basically a giant ceramic coffee mug (probably around 18 oz). I've noticed that it's better, by far, for darker brews (e.g., stout, bock, etc.), but not for pale ales and such. I also have a very, very nice stoneware mug that my mom brought back from one of her trips to Germany (it was West Germany at the time, if that means anything). This is the best for the lighter ales, lagers, etc., but is just ``ok'' for the very dark brews. I have plain glass mugs, too, that are ok (but not anything special) for everything (except for the batch I'm about to bring up in a second)....

Last night, I discovered that a pewter mug that my mom brought back from a trip to England seems to mask a slight off taste in a batch that I posted questions about here several months ago (it was very cidery at the time)

.
In any other mug, there is still a slight hint of a cidery taste on at least the first few sips of each fresh beer. From the pewter mug, however, it's just d*mned good beer with no off tastes at all.

Does anyone have any idea what causes this? Btw, I'm not the only one who has noticed it. When I took some of the bock (I posted an article about that here, too) to the local homebrew shop for them to try, they also

noticed the difference between the San Antonio ceramic mug and their plain glass mug. So I know I'm not imagining things....

Is it just the texture of the mug that changes one's perception of the flavor? Or is there some magical property of different types of glass (or pewter) that actually does change the flavor in some way?

From: D S Draper <D.S.Draper@bristol.ac.uk>
Subject: Help with yeast culturing

Hello all, please help me with a problem I'm having in culturing yeast from bottle-conditioned beers. My goal was to get better flavor than what

is possible using Edme ale yeast, which is all that I can get locally (liquid yeasts are not sold in the UK). I'm sorry to make such a long message, but I am desperate--I've made 14 gallons of undrinkable beer in the past three weeks. Here is the history:

Attempt #1: Took a (275ml) bottle of Worthington White Shield, decanted most of the beer, added a couple heaping spoons of dried malt extract and one of glucose. Shook it up, put a wad of sterile cotton in the top. After several days, it was quite vigorously active. Pitched a batch of beer that is designed to mimic WWS (from Dave Line's recipe). After quick startup, the main foamy yeast mat subsided after about 36 hours to be replaced by a mat with a distinctly different look--the bubbles were much larger, and had little tendril-like things on the surfaces. The bubbles gave the surface of the mat a sort of "tensile cohesion" (for lack of a better term) that is totally unlike anything I've seen using Edme. It also had a very strange smell unlike anything encountered before. After it subsided (took about a week), racked to secondary. Tasted awful, like cough syrup, with a woody, medicinal flavor--it was the taste equivalent of the smell noted above. After a few days in the secondary, with no improvement in flavor, I concluded it was infected and dumped it out. I reckoned that because I had pitched a pretty small volume of active yeast, something else must have gotten in. Alternatively, I obviously did next to nothing with respect to sanitation in this attempt.

Attempt #2: A raspberry ale using a yeast cultured from Hanseatic IPA. This time, I sterilized a wine bottle rigorously; boiled the malt extract + sugar and then cooled it. I covered the neck of the wine bottle with some plastic food wrap and a rubber band (the rubber stopper for the airlock I'd gotten didn't fit). I sterilized everything in sight this time, including wiping the neck of the bottle with alcohol prior to pouring the starter solution into the wort. This time, again very rapid takeoff, and everything looked perfectly normal. Smelled fine too... until the last day or two in the primary, when that same smell was present in small amounts. Racked to the secondary, and the smell was more noticeable while I was cleaning the primary afterwards. After a couple of days, when I added pectin enzyme (just dumped in the powder) and finings, the sample I removed had that same damn taste. I let it sit in the secondary for about 10 days, then bottled--the taste was still there, and stronger. That was 9 days ago, and last night I tried one, and it tasted like bloody cough syrup again. There is no aroma as in #1 though.

Attempt #3 (started before I realized what was happening in #2). Keg bitter using 7.5 lbs of Boots unhopped malt extract syrup, some grains, hops etc. Yeast cultured from King & Barnes Festive Ale. This time I used a 1-liter plastic Volvic water bottle, whose neck could accept the rubber stopper for my airlock. Sterilized everything in sight, boiled the

proto-wort as before, got vigorous action in a few days. Once again, very rapid takeoff, but this time we had a repeat of #1 in terms of appearance: the ordinary fluffy mat was overtaken by that slimy-looking, stiffer, larger-bubbled mat. I tasted it at several points, but "that taste" from #1,2 was definitely not present. 48 hrs after racking to the secondary, when I added finings, the sample had a different unpleasant taste: it is almost bread-like, in fact sourdough bread is what comes to mind. Plodding gamely on, I transferred to my pressure barrel three days ago, and a sample last night had the sourdough taste even more pronounced.

Aaaaaaaaaaaaaagggggggggghhhhhhhhh! 14 gallons of bad beer. What am I doing wrong??? After Attempt #1 I've been extra anal about sterility. All my beers (53 batches counting these three) have been done with the same techniques, and I never had the slightest hint of contamination before. In reading the net for the past 4 months or so, the conventional wisdom is that it's child's play to culture from bottles. Is the problem with #2 that I capped the starter bottle only with plastic wrap? Is the problem with #3 that I used a plastic starter bottle? I assumed that because it was a drinking-water bottle that it would be food-grade. In both #2 and #3, I tasted the starter solution before pitching it, and it was not unpleasant. My next step is to order a pure culture from Brewlab here in the UK (thanks to Pete Hammond for providing their address) with a proper glass flask and try that--but we're talking about a 10 quid outlay for that, and I'm on too tight a budget to spend that much for 5 more gallons of bad beer.

Once again sorry for using all the bandwidth, I eagerly await your replies. Posting is fine, but if you want to email me direct, do so at d.s.draper@bristol.ac.uk because "reply mail" doesn't seem to get to me. Many many thanks, Dave in Bristol

Subject: Automatic Hydrometer

A while back I moonlighted and wrote a manual for an automatic battery monitoring system for diesel submarines. One part of it was an automatic hydrometer.

Basically, it worked similar to a battery tester with the little colored balls. Each colored ball has a known specific gravity. The device could

either have enough photo-receptors for each ball, or the operator could start out with the starting gravity and simply count the balls as they rise. The more finely spaced the balls are the more precise the measurements. Using a computer and calculating the slope, a fairly good representation of the rate of change should be determined.

How to find a supply of calibrated balls?? I'll leave that to the net.

I brew a decent all grain Scotch Ale. I use a fair amount of dextrin
and crystal malts in the mash and I mash it at 158 degrees F with a
single step, stovetop infusion mash. This comes out fairly malty and
sweet. I would not be surprised if some of McEwan's sweetness came from
added sugars (e.g. treacle), though, because mine is malty but not as
'syrupy'.

Subject: CO2 on wort -- infections?

Salutations!

I've just had the thought that perhaps even the food grade CO2 isn't filtered and thus has the possibility of containing 'nasties' in the form of wild yeast or bacteria. I was thinking of this when I read some of us purge our kegs with CO2. Am I missing something? I know most bugs need O2 to live, but what about some kind of hybernation sort of thing? It's not an uncommon thing to find animals that will lay dormant until the needed resources about i.e. those fish that lay in the dried mud until it rains, fungi and bacteria that can freeze and then live. Just a thought.

I have used cornstarch in Pale Ale's - <15% of the total mash - and have
not
experienced the cidery flavor often obtained with adding corn sugar.
Perhaps, the method of commercial preparation of corn sugar introduces
something that results in a cidery flavor. I believe that ultimately,
the
amount of adjuncts - corn or other - that you add has the largest impact
on
flavor.

Use of a small amount of corn starch is quite simple: I add it during the
starch conversion rest. Initially, the mash thickens up like gravy and
as the
enzymes begin conversion, the viscosity of the mash returns to normal.

In Greg Noonan's recent book, Scotch Ale, the 120 and 140 shilling
Wee Heavy recipes call for a very high mash temperature - 158F - and
fairly low bittering rates on the order of 30 to 40 bittering units.
These two parameters create beer with big mouth feel, body and malt
sweetness. I believe the diacetyl also enhances the perception of
sweetness in McEwan's Scotch Ale.

The glass or mug can certainly make a difference in how a beverage tastes. Composition, shape, and texture all have an impact on how we perceive flavor.

You wondered specifically about the texture/material. Try "drinking" out of empty glass, ceramic, and pewter cups. They will all "taste" different -- I always thought pewter had a kind of tang to it that could, IMHO, mask slight imperfections in a beer. And a ceramic mug will, to me, lend a "fullness" of texture to the tongue that I don't get from glass.

Also, the vessel's shape can make a big difference. Different shapes will concentrate the aroma differently, and smell is a huge part of taste. That's why Trappist ale glasses are bowl shaped, weizen glasses are tall and vase-like, and pilsner glasses are tall and narrow. In (northern) Europe, they realize this, and you almost always get served a beer in a correctly shaped glass.

Serious wine drinkers have known this for years as well. You can buy different wine glasses for reislings, chardonnays, cabernet sauvignons, etc. I once read a newspaper article about a guy who makes hand-blown glassware (at \$80 a pop) for drinking only certain types of wine.

Subject: Hot-Side Aeration

> NOW A QUESTION: Hot side aeration.
> I have not seen Fix's article on this, I was wondering if anyone
could
> summarize the crux of it for me. The concern is over adding air to a
mash
> once it's brought up to mashing temp, and then upon sparging and
splashing.

The crux of Fix's article on hot side aeration ("HSA") (without going
into the chemistry that I won't pretend to understand) is:

- It should be considered in the process from the beginning
of the mash through mash-out. Avoid a lot of oxygenating
(splashing, etc.) as much as possible when transferring the
wort from the lauter tun to the boiling kettle. He states
that some theorize that the introduction of a raking
mechanism in many American breweries that ungently mixed the
mash to even the temperature in the tun may have contributed
to the demise of our brew industry, perhaps as much as
Prohibition, due to the "hot-side" aeration off-flavors that
were introduced by such action.
- A vigorous boil in the kettle is desirable for a good hot break,
but wort should be handled gingerly when cooling until below
about 86 F. Of course aeration is desired when cooled to
re-oxygenate for the yeast prior to fermentation.
- Hot-side aeration is more of a concern for high gravity worts.
- Also, due to scale considerations (sfc. area vs. volume), "HSA"
should be more of a problem the smaller the batch size - hence,
beware homebrewers.

In the same issue of Zymurgy, another author or authors contend that
recirculating wort prior to sparging is not a good idea as the potential
for "HSA" exists, and that it doesn't really do much for wort clarity.
They contend (I'm not emotionally involved here) that if yield is the
issue, just add another pound of grain or so to the mash and forget
the recirculation.

From: korz@iepubj.att.com
Subject: Re: Problems with carbonation

Doug and Brian write about problems with carbonation (edited):
"Brew Your Own" store) and have had mixed success. Our first batch was a simple "kit" lager which went four days in primary and thirteen days in secondary. While not totally flat this beer did not carbonate fully and was somewhat disappointing. The store suggested that we should siphon off our beer before adding the carbonation sugar to ensure that all the sugar would be fully mixed and not fall into the botom sludge that never gets into the bottles.

First off, what you made was an ale -- given that it fermented out in 17 days, I suspect that you fermented somewhere between 65F and 70F (around 20C). This will make an ale since lagers are really brewed in the high-40's or in the 50's (Farenheit). Secondly, it's recommended to rack (siphon) to a different container for adding the priming sugar not so much because your priming sugar will stay in the fermenter, but rather because you will inevitably stir up some of the gunk in the bottom of the fermenter and get it in your bottles.

Batch number two was the same "kit" lager, with 6 1/2 lbs of fresh raspberries added to create a fruity summer beer. The beer fermented four days in primary and seventeen days in secondary (with very vigorous fermentation going on all the time). The result was great with lots of carbonation and a super taste.

You probably got a lot of carbonation here, either because you bottled a bit too soon or because the raspberries had some more attenuative wild yeast or perhaps some bacteria on them.

Batch number three was an English Bitter...
...Carbonation this time was poor with the beer being nearly flat.

In all three cases we used malt sugar (between 2/3 and 1 cup) for eighteen litres of beer...

Well, there's your problem. If you prime with malt extract, you need to use more than if you prime with corn sugar (dextrose). Malt extract, BY WEIGHT, is only about 80% as fermentable as dextrose which is 100% fermentable, so 3/4 cup corn sugar is about the same as 1.25 cups of malt extract. I recommend that you switch to corn sugar for priming since it is cheaper, does not

contain proteins (which could give your beer an unpleasant, but benign ring around the collar) and dissolves easier in your priming solution. Also, another reason you may feel that your beer is undercarbonated is because most major North American beers are way overcarbonated. If you want to get a carbonation level like Miller or Molson, you will have to use 1 cup of corn sugar or 1.5 cups of malt extract and then use anti foaming agents so your beers don't gush all over the place. Either that or you will have to filter your beers so you remove all head-retaining proteins. My advice: try 3/4 cup of corn sugar and get used to the slightly lower level of carbonation -- it fights less for attention in your mouth with the real flavor of the beer.

I wrote this in a bit of a hurry, so if it sounds like I'm flaming you, I appologize -- I didn't mean to.

Al.

From: gjfix@utam.uta.edu (George J Fix)
Subject: Yeast pitching rates

It has been my experience that underpitching yeast is a common problem with some homebrewers, and selected micros as well. There appears to be general agreement in the professional literature that the proper pitching rate for cold fermented lagers is

12-16 million viable cells per ml wort.

I have found this to be the case with my beers as well. It should be noted that with ales fermented around 20C (68F), half this rate is satisfactory. Wort gravity is another issue, and I have found that the proper pitching rate should increase with it. To cite an extreme example, I have been playing around with several formulations for pre-prohibition Stock Ale. The OGs range from 1.070 to 1.085, and best results were obtained when the ale yeast was pitched at lager rates.

As for as practical brewing is concerned, the key is to find ways of getting good estimates for the number of cells actually pitched as well as estimates of their viability. Rodney Morris has come up with a straightforward staining procedure for estimating % viability. It is discussed in detail in my article that appeared in "Just Brew It" (1992, BP).

The most accurate elementary way to count yeast cells is with a hemocytometer. Since many homebrewers do not have access to such a device, pitching by volumes can be used as an alternative. I have found (using a hemocytometer) that there are approximately

4.5 billion cells per ml. yeast solids.

This means e.g. to pitch 18 million cells per ml. we need 1 volume of yeast solids per

$$4.5 \times 1000 / 18 = 250$$

volumes of wort. Thus, for a 5 gallon = 640 oz. batch one needs

$$640 / 250 = 2.56 \text{ oz.}$$

of yeast solids. If these are at least 67% viable, then this would be satisfactory for lagers. Half that would be ok for ales with a standard OG. If the % viability were below 67%, we would be underpitching, something that would be evident from a longer than desirable lag and/or higher than normal FG.

With yeast starters or yeast propagated from slants, we will have to estimate the amount of solids from a solution that is a mixture of yeast and liquid. Fortunately, the range for proper cells additions is rather wide, so we have some margin for error here. One can decant off the solution, and then pitch

the proper volume of yeast solids. This should be done, however, under nearly sterile conditions. I have found with some practice one can get pretty good at estimating yeast solids in solution, and this avoids the need for decanting.

For all of the yeast strains I have worked with I have found that saturating chilled wort with O₂ gives the best results. Direct DO measurements indicate that it is possible to dissolve 6-8 mg/l liter in standard gravity wort at 15 C. This decreases as either temperature or wort gravity increases. The O₂ fraction of atmospheric air is ~21% which goes up to ~32% for air dissolved in wort. This means that saturating wort with air will lead to a ~third less O₂ than direct O₂ injection. This may or may not be a problem depending on the yeast strain used. It should be emphasized that all the O₂ in the world will not help if the cell count is below the proper levels. Private discussion with Jack Schmedling has indicated to me that this was a factor in his interesting experiment on wort aeration.

Too much O₂ is toxic to yeast, but this will happen only when O₂ levels reach 20 mg/l or higher. I have found, and there is confirmation of this in the professional literature, that it is impossible to dissolve even half this amount in wort even at 0 C. Those who have read the book Belgian Ales will note that I am in disagreement with the results reported there regarding O₂ levels. The results are also in conflict with results in the professional literature.

Subject: GABF

My wife and I will be attending the GABF, and we would be interested in comparing notes with other homebrewers concerning the beers that are represented there. Both Laurie and I will be on the professional panel, so I have no idea how good a condition our palates will be in either Fri or Sat. nights. Nevertheless, there are a lot of new micros that will have beers there, and the reaction to these by other brewers would be of great interest. Look us up if interested.

Subject: Pumpkin Mash- recipe

I did a Pumpkin beer last year that was a variation on the CATS EYE from the Cats Meow. I did a mash from the grains below and pulled one gallon off and added the goop mix, pasteurized and fermented in a gallon jug. I named the whole beer "Cats Eye" and the gallon batch "Pumpkin Mash". Cats Eye was kegged, and the mash bottled w/ cute labels.

We had a huge party at the house- live bands, costumes..the works on Halloween and served up both (and a bit more) and had ourselves a jolly 'ol time. Then the cops wanted to reclaim the cities flashing light/ baracades. Put a slight damper on things- but they do make good party decorations ;)^

So...being as how we are to experience a full moon tonight...and october is about to begin, the time is right for pumpkin tonight!

First- last year's recipe for the 7 gal Cats Eye, and 1 gal PumpKin Mash

10# 2 row Pale Malt
2 # 40L Crystal
1 # Wheat Malt
.5 # Chocolate
4 cups (1.5#) Cooked brown rice (ah what the hell!!!)

Boil 2 oz Tettnager- flake
1 oz Saaz
Finish 1 oz Cascade

Gypsum in the mash. Irish moss in the boil.
I won't bother with the full mash routine. A step up to mash temp- 60 deg C then 65, then mashout at 70. Sparge, pull of 1 gal for pumpkin experiment.

Pumpkin Mash:

13 # pumpkin - degooped. Take orange flesh, separate out seeds (Originally I thought of getting seeds- grinding and mashing. anyone have an idea whether that would work? Gotta have starches!)
2 tbsp cinnamon
1 tsp nutmeg
handful of chopped cilantro
.5 tbsp pickling spice (includes cloves and stuff....)

This was steeped for 1 min in 1 gal of the boiled wort mix. Tossed the cascade in here for more steeping.

Both were very yummy and well received. The cats eye had a hoppy nose, good head- fresh of the tap- and a deep amber to brown color. Malty full mouth feel, but not heavy. It was intended to be on the lighter side for public consumption. The Pumpkin Mash had a creamy mouth feel, and a spicy aftertaste. I couldn't really identify the cilantro, but there was an unusual- but pleasant unique flavor. It was a very nice blend of flavors. It was hazy. Maybe I'll try fining this time. I wouldn't go overboard on the spices- but I don't know if you really could get a "pumpkin flavor",I think it added more of a fullness and feel.

I wouldn't boil the pumkin- treat it like fruit. It smelled wonderful when it was steeping.

-oh. I used Wyeast's german alt yeast culture for both.

Now this year: Same yeast...but I'm going to do a double batch (10gal)
Half will be pumpkin, the other half - peach.

MASH:

10 # 2 row pale malt

4 # Vienna 2 row

1 # 120 L Xtal

1 # 60 L Xtal

2 # Unmalted Wheat

2 # Victory

.25 # Chocolate (yeah I know everythings changed. It's a new year! Only the pumpkin remains the same!)

I think I'll use some fresh cascade hops (my big producer this year!) and some Centennial for bittering. Maybe something diff. in the peach. Got some year old Kent Goldings from william's. May be just the thing for a lambic style! (I've got a raspberry brown ale going now. Yum!)

The peaches have been stoned, and frozen. I've got about a 1/3 bushel. The rest is meading away! Smells awfully sulfury. But I digress...

Pumpkin Mash:

A big sized pumpkin (about 1 foot across) and several small ones from my garden. Gutted- and deseeded the guts.

(since I'm scaling up this year to 5 gallons)

5 tbsp cinnamon

2 tsp nutmeg

a bunch of cilantro, and a palmful of ground coriander seed.

1 tbsp pickling spice

This will be steeped as before, and the pumpkin goop strained out before it's placed in the primary. Rinse the goop with hot H2O. Should keep me busy tonight. I usually brew sat afternoons, but I'll be busy playing rock and roll this weekend, and besides- the carma of a full moon can't be beat (well, and rainy day is real nice too!).

On an off note- I just saw Michael Hedges last night! INCREDIBLE!

ok ok. sorry for all the excess band width. I banter. Let me know if any one tries any variations of these. I'd love to know how they come out. If anyone want to swap a pumpkin brau- drop me a line!

RE: Cornstarch in the mash. I'd think something serving like corn flakes,
or rice would add sugar w/o much body, but I'd also be inclined to think that the enzymes would not necessarily break down all the starch all the way to the equivalent of corn sugar. It is much more refined, and part of the process of mashing leaves fully converted and partially converted products- adding to the fullness of a brew.

Brew on Ye Brethren of Bee, Barley, and Vine. Happy Hoppiness!

Subject: Smaller Batches

I have a friend who is interested in becoming a homebrewer. The biggest obstacle that he sees confronting him, is the fact that he is not what you would call a "quaffer". He is interested in variety, and quality, but not quantity. When he posed the question of smaller batches to me, I responded with "I dont see why not", after which he mentioned that receipes cannot always be simply cut in half to make a half a batch. Well, I'm a quaffer, and perfer the larger size batches, so I thought I would through this question out to the knowledgeable folks on the net. Can the receipes simply be proportionatly cut down? Has anyone tried a 1 or 2 gallon batch? Good points? Bad points? Anything?
Happy brewing
Bret

BOSTON WORT PROCESSORS HOLD KLUB KRUSH-OFF
by Patrick Sobalvarro

To the delicate strains of German "oompah" bands playing Trinklieder, the Boston Wort Processors held the long-awaited Klub Krush-off on September 12 at Tim and Heidi's beautiful home in North Reading. Club members began arriving with their mills at 2:00 p.m., and hijinks galore ensued as they attempted to fasten them to the tables thoughtfully provided by their hosts.

Represented were six different mills: a customized Marcato grain mill, a slightly modified 1989 Corona flour mill, an original 1925 Corona flour mill, a Schmidling adjustable MaltMill, a Listermann Malt Mill, and a Glatt Malt Mill.

The intention of the club in holding the Krush-Off was to evaluate these mills for ease of use and quality of workmanship, as well as to subjectively evaluate the quality of the crush they provided. We say "subjectively" here because graduated screens were not used; the crush was evaluated in each case by a group of experienced brewers in the club who closely examined the crushed grains.

The malt that was used for the crush-off was M&F 2-row pale ale malt. The operators of each mill received half a pound with which to adjust the mill; then two more pounds were run through each mill in the actual test. The crushed grains themselves were used later that day in brewing an all-grain

demonstration batch for the benefit of the extract brewers in the club.

Some of the mills were run motorized; most of those that were used a well-worn 2.3 amp 3/8" electric hand drill. In some cases, mills were run both motorized and by hand; where mills were run by hand, we made an attempt to evaluate the rate at which the operators cranked them.

We must say first that there was no clear hands-down winner among the mills brought to the Krush-off, and that the Boston Wort Processors do not endorse the purchase of any particular mill. In each case the mills produced crushed grain that should be adequate to the needs of a demanding homebrewer. That said, we did notice considerable differences between the mills, and our detailed descriptions of the results for each entrant follow.

Mill: Customized Marcato Owner/Operator: Jay Hersh
Approximate cost: \$65 (new) + tax.

The Marcato is an Italian grain mill with stainless steel knurled rollers. It may be driven with a roller or motorized with a hand drill; in the latter case an adaptor of the sort used to drive Italian pasta extruders is connected to the drive.

The customization in this case consisted of the addition of lengthwise grooves along the rollers to help them pull grains in; additionally, a plastic soda bottle was taped to the mill as a hopper. This hopper held exactly two pounds of grain.

The mill was operated by electric power during the test. A 2.9 amp electric hand drill was used for this. This mill was noticeably noisier than the others, but this may be because a different drill was used for it than for the others. The motorized mill took 2:28 (two minutes and twenty-eight seconds) to crush two pounds of grain.

The crush committee had the following comments: all kernels were opened; about half of the husks were cut in half perpendicular to the long axis; the flour content was "not bad," which is to say, less flour was produced with this mill than with the modified Corona or the Schmidling MaltMill, but there was a little more flour than with the other mills. The committee felt, however, that the crush was of very good quality, and that good extraction rates could be expected.

The workmanship of the Marcato mill itself was considered good. The clamping system used to secure it to the table appeared to be a little inconvenient, but the stainless steel rollers quite made up for it. The mill was easily adjustable simply by turning a knob, but small motions of the knob led to large variations in the roller spacing. The soda-bottle hopper, secured as it was with tape and cardboard, was deemed "kludgey, but serviceable."

Mill: 1989 modified Corona Owner: Randy Zeitvogel
Approximate Cost: \$45 (new) + tax Operator: Dan Hall

The Corona is a flour mill, made in Latin America, and generally the cheapest of the available mills. One round plate a few inches in diameter rotates against a fixed plate of the same size; both have radially-grooved surfaces. The modification in this case consisted of extra spacing between the two plates via the insertion of steel washers.

The mill clamps to a table or counter with a built-in clamp. The hopper held two and a half pounds of grain. When run with a 2.3 amp electric drill, the mill was less noisy than the Marcato (this may be because a different drill was used). The mill took only 24 seconds to crush the two pounds of grain.

The crush committee had the following comments: Every kernel was opened. The sizes of the broken pieces of kernel varied more widely than for the Marcato, but the range was considered acceptable. Two members of the crush committee felt that the amount of powder produced by this mill was greater than the amount of powder produced by the Marcato mill; but a third member felt that the amount of powder produced was slightly less (Gorman and Keohane vs. Slack). The husks were shredded more than by the Marcato; between 80% and 90% were adjudged to be cut in half perpendicular to the long axis. The crush committee nonetheless felt that the crush was of good quality and that a high extraction rate could be expected.

The workmanship of this mill, with its all-metal construction, was excellent. It was easy to adjust and appeared to be very durable.

Mill: 1925 unmodified Corona Owner: Sarah White
Approximate Cost: Priceless! Operators: CSMC

This instrument was clearly well-loved by its operators. They were quick to point out its many features: how it operated in near silence; how its long handle nearly ground the grains itself, the turning effort was so low; how the owner's cat likes it.

The mill was clamped to the table with a "moby C-clamp." The mill was operated by hand during the test. The operator was clocked at 100 rpm. Only three-quarters of a pound were ground, in 1:38 (one minute and thirty-eight seconds).

The operators chose to adjust the mill to minimize the flour resulting from crushing. The crush committee noted that there was very little powder in the resulting crushed malt, but that about 15% of the kernels remained unopened. The pieces of kernel that were crushed were about the same size as those from the modified Corona. All the crushed husks seen were cut in half perpendicular to the long axis. The committee expected lower extraction rates from the crushed malt in this test than in any of the others.

What are we to say of the workmanship of this mill? This beautiful instrument, older than most Worts' parents, with its black-enameled wooden

handle and its metallic body hinting of tales, tales it could tell of long nights making tortillas in some Northern Mexican village, a dream landscape of desert and night sky and mountains and moonrise, this instrument was of excellent construction. By all evidence durable, as well.

Mill: Schmidling Adjustable MaltMill Owner/operator: Chris McDermott
Approximate Cost: \$129 (retail) + shipping.
 (the non-adjustable model is \$99 + shipping)

The Schmidling MaltMill is a two-roller malt mill with 10" steel rollers, finely grooved lengthwise. The roller spacing can be adjusted at one end of one roller, so that the rollers are not exactly parallel; the operator said that this was not a problem, however. The mill has a 2.25-pound hopper made of fiberboard, and a fiberboard base made to fit over the top of a grain bucket. It was tested twice: once hand-cranked and once motorized. In both tests the mill had to be held to the bucket by hand. The rollers were at their factory setting of 0.055".

The unmotorized test came first. The mill was very quiet when cranked by hand; the operator was timed at approximately 120 rpm. Two pounds of grain were crushed in 44 seconds.

When evaluating the hand-cranked crush, the crush committee said that the crushed kernel pieces were on average finer than those produced by Coronas, and the variation of sizes was smaller. Every kernel was opened, and only a small percentage were cut in half; most were split lengthwise. The amount of powder produced appeared to be about the same as the unmodified Corona. The committee expected good extraction rates from this crushed malt.

The motorized test used a 2.3 amp electric drill. Two pounds of grain were crushed in only 21 seconds, for the day's record. The crush committee felt, however, that the crushed grain was not of the same quality as when the mill was operated by hand. Approximately 20% of the husks were damaged, and there was considerably more powder.

The workmanship of the Schmidling mill was considered quite good. The long rollers gave it a high rate of crushing, and the construction, although large parts of it were fiber- or particle-board, was solid. Some club members felt that it was more difficult to adjust the spacing on this mill than on other mills. Others mentioned that it occasionally proves necessary to replace the O-rings used in the drive mechanism.

Mill: Listermann Malt Mill Operator: Pete Langlois
Owner: unidentified

The Listermann Mill, also known as the PhilMill, is a single-roller adjustable malt mill that crushes grain against a fixed plate. A 2.5-lb. plastic-bottle hopper can be affixed to the top. It is attached to a table with two large screw-hooks.

We had trouble with the Listermann Mill during the Krush-off, and we are not sure that it was operating correctly. The mill was run motorized, with the same 2.3-amp electric hand drill as in other tests. However, the crushing rate was extremely low -- about one pound per ten minutes.

The mill has no bearings, and so the roller is secured in the metal body with two steel circlips, one on each side of the body. When the mill was operated during our test, one of the circlips ground against the metal body, producing a fine metal powder that soaked up the lubricant. As a result, the mill began to make loud metal-on-metal noises, and the test was stopped prematurely, after fifteen minutes and thirty seconds. The body of the mill became noticeably hot during the test. The rate of crushing, as noted above, was approximately one pound per ten minutes, which most of the Worts present deemed unacceptably slow.

Notwithstanding these considerable problems, the crush committee felt that the Listermann Mill produced the highest-quality crush of all. No whole kernels were found; the husks were in good shape; the crushed kernel pieces were of nearly uniform size, and there was very little powder. A very high extraction rate was expected.

The workmanship of the Listermann Mill was not considered very good. The hopper, while serviceable, was considered "kludgey," and the screw-hooks for attachment to the table proved difficult to use and not very secure. The very low rate of crushing, and the means of securing the roller in the body, with its attendant problems, were noted with some distress by those present.

Mill: Glatt Malt Mill Owner: Patrick Sobalvarro
Operator: Bob Gorman

The Glatt Malt Mill, from Glatt Machining, is a two-roller all-metal mill with 4-inch steel rollers, with wide, shallow, lengthwise grooves. Both ends of one roller are adjustable with a semi-circular vernier scale to allow one to repeat settings. The rollers are mounted in Delrin bearings. The drive is geared, and the mill is built so that the lands of one roller and the grooves of the other face each other at the crushing surface. The mill has a 2.5-lb. hopper, and is intended to be mounted on a table using two 3/8" bolts. A chute carries the crushed grain from the bottom of the rollers into the grain container.

The Glatt Mill was evaluated both hand-cranked and motorized. In both cases the rollers were left at their factory-set spacing. In the hand-cranked test, the operator was timed at approximately 150 rpm, for the most frenetic hand-cranking of the day. Two pounds were crushed in 1:06 (one minute and six seconds). In earlier testing, the mill proved very easy to crank by hand, because of the mechanical advantage afforded by the gearing.

When motorized, with a 2.3-amp electric hand drill, the Glatt Mill crushed two pounds of grain in 0:45 (45 seconds).

The crush committee found no differences between the two crush samples (from the hand-cranked and motorized tests) when they were examined side by side. Both had slightly less powder than the hand-cranked Schmidling mill. The granule size was uniform. The condition of the husks was considered to be the same or "maybe 5% better" than the hand-cranked Schmidling mill.

The workmanship of the Glatt Malt Mill was considered excellent. The metal construction and heavy enamel paint appeared very durable. The ease of adjustment and ease of cranking were both noted favorably.

It was noted during the test that some grain pieces sticking to the Glatt Mill's rear roller were ejected from the back; this amounted to a negligible amount when two pounds were crushed, but it was messy all the same. Greg Glatt has said that he is modifying the chute to entirely cover the rear roller for this reason.

- - - - -

We enjoyed the Krush-off, and for many of us, it was our first opportunity to see some of the mills we've heard about, and also to see them in action. It was good fun, and the beer prepared from the crushed grain will be enjoyed at a future meeting.

Many Worts helped in the Krush-off, and space does not allow us to list them all. Tim and Heidi of course deserve all our gratitude for being such excellent hosts. Tim Madigan, the gentleman who timed the hand-crankers, has my appreciation. The crush evaluation committee, consisting of Scott Keohane, Bill Slack, Bob "El Presidente Exigente" Gorman, and various others whom I have no doubt forgotten, as well as the owners and operators of all the mills all deserve kudos for making the Krush-off possible.

Subject: Pumpkin Ale recipe

In HBD #1237 JMGARNETT@ATCSD.ESS.HARRIS.COM (JIM) writes:

> pumpkin brew! If anyone has recipes or suggestions for brewing with
> pumpkin PLEASE respond before my taste buds rebel. Also, this will
> be my first batch made with fruit or vegetable so any advice is
> always welcome. I switch back and forth between all-grain and

I won 3rd place in the Novelty Beer category at the 1992 Dixie Cup Homebrew Competition with this recipe. To give credit where it is due, I based this recipe largely on an extract recipe that was printed in Barley Malt & Vine's (West Roxbury, Mass) store newsletter a few year's back. I added 1 lb. light crystal malt and substituted Chico Ale Wyeast #1056(aka American Ale) for the dried yeast they recommended. I also modified (increased!) the spices used.

6 # Northwestern Golden malt extract
1 # British crystal malt
2 # sliced up pumpkin (NOT the gross seedy junk, the stuff you carve!)
1.5 oz Fuggles hops for 60 minutes
1 tsp Nutmeg
1 tsp Allspice
1 tsp Cinnamon
1 oz fresh grated Ginger root
Wyeast #1056 (American Ale, allegedly the same yeast used by SNBC)

Add all the spices (including Ginger root) for the last 10 minutes of the boil.

OK, now there is some controversey over exactly WHEN to add the pumpkin: the original newsletter said to add 2 inch cubes of pumpkin to the brew-kettle 10 MINUTES before the end of the boil, and to "ferment on" the pumpkin cubes. In the batch I made for the Dixie Cup, I put the pumpkin cubes into the brew-kettle 30 minutes before the end of the boil. I'm not sure this was a good idea - I think I boiled off some pumpkin crud ("crud" is a technical term) that got into the final product. With the batch I just brewed, I am going to add mashed-up pumpkin to the secondary carboy, and rack the contents of the primary on top of it. I used this method with excellent results on a raspberry wheat beer recently.

I also used a very different hopping schedule in my most recent batch:
60 minutes - 3/4 oz Willamette (4.5% alpha)
30 minutes - 1/4 oz Willamette
1/2 oz Cascades (5.5% alpha)
5 minutes - 1 1/2 oz Cascades

The original recipe said to add finings to clear. I added 1 teaspoon of Irish Moss at 60, 30 and 10 minutes before the end of the boil. I am also considering finings or some other clarification agent in the secondary (pumpkin has got some CLOUDY JUNK in it!).

Subject: chill concentrated wort?

Hello fellow homebrewers,

I have been an HBD subscriber for about a month and an extract brewer for about nine months. During that time I have brewed about a dozen batches. My usual practice is to transfer the concentrated wort (about 1.5 gallons) to a carboy containing about 3.5 gallons of cold water to make up a five gallon batch. I have heard and read about the value of quickly cooling the wort to yeast-pitching temperatures. I am wondering if I would be better or worse off if I chilled the concentrated wort before adding it to the cold water in the carboy. I would very much appreciate any comments.

John

bjw@techsun1.cray.com (Benjamin Woodliff) writes:

>I'm not particularly fond of Scotch Ale, at least if bottled McEwan's
>is a good example of it.

it's not.

>I'm curious about how much of what I would refer
>to as the overpowering "malty sweetness" of McEwan's owes itself to
>mashing at somewhat higher temperatures?

McEwan's Scotch Ale is sweetened with lactose after fermentation.

On the other hand, McEwan's Export IPA is not, and is a very good example
of a (mild) scotch ale (but it's not an IPA). Alternatively, MacAndrew's
(strong scotch ale, or wee-heavy) is quite nice, but lacks smokey
character and has too much hop flavor for a scotch ale (but it's yummy).
Traquair House is the definitive example, at \$5 a bottle.

Don't get turned off to scotch ales because of McEwan's Scotch Ale...

I am involved with an upcoming beer festival and am looking for some nice trophies/plaques/whatever to give the winners in the homebrew competition.

I am soliciting recommendations for mail-order or local suppliers. My requirements are a good catalog, quality merchandise and timely delivery.

The New England Brewers Fall Festival is on October 23rd in Boston. It will be the largest beer festival on the east coast. We are expecting over 100 breweries from New England, the US and the world to attend plus such luminaries as Michael Jackson, Fred Eckhardt and Bert Grant.

If you would like more information about the event, send a request for "event info" to nebff@synchro.com. If you would like information about volunteering to work at the event, send a request for "volunteer info" to nebff@synchro.com.

Subject: Lactic Acid

In Dallas we have very soft water. In order to avoid an astringent quality in my beer, I have been more carefully adjusting the PH of the sparge water. My "acidifying" agent has been Calcium Sulphate (Gypsum). Problem is with the amount of Gypsum I have to add to get the PH down, I am adding a lot of Calcium.

A brewing friend suggested using Lactic Acid. Got a bottle of Kent brand 88% Lactic Acid. I could use a suggestion from you Brewing Chemist types....

Any guess on how much of this 88% Lactic Acid I might use to adjust the PH in 5 gallons? You know something like: "1 tsp of 88% Lactic acid should lower 5 gallons of liquid by .4 PH degrees". I could use trial and error but I've got a hunch that someone out there may have the answer or be familiar with this stuff.

From: Steve Christiansen <steven@sequent.com>
Subject: cold plates

A number of times, in this forum and elsewhere, I've heard of homebrewers who use cold plates to chill kegged beer to drinking temperature on the way to the tap. Sometimes this is done with ice on the cold plate. In other cases the cold plate is placed in a fridge or freezer.

Now this sounded great to me because I have a fridge space shortage, and it would be easier to find room for a cold plate than a keg. But when I asked the guy in the draft department of the local homebrew shop about cold plates, he told me I wouldn't be happy using one in that way. He said I'd have to start with the keg chilled somewhat to end up with beer that's cold enough. He gave me the impression that these things drop the temperature only a few degrees. I'm inclined to believe the guy because he could have sold me an expensive cold plate if he had kept his mouth shut, but before I give up on the idea, I thought I'd gather more data.

If you use a cold plate to chill beer, how well does it work for you? Do you need to keep the cold plate at 32F or below to work well? Are some cold plates better than others? (recommendations welcome) Or should I forget about the idea?

Thanks for any info.

From: Jim Grady <grady@hpangrt.an.hp.com>
Subject: Oatmeal Stout, William's Brewing

First of all, here are the numbers for William's Brewing:

William's Brewing
P.O. Box 2195
San Leandro, CA 94577

Orders: 1.800.759.6025
FAX Orders: 1.800.283.2745
Advice: 1.510.895.2744
Other: 1.510.895.2793

<insert standard disclaimer here>

Here is a recipe for an "oatmeal stout" I made using their extracts. I am quite pleased with it.

Oatmeal Stout

6# William's Oatmeal Dark Extract
1# William's American Dark DME
1# William's Weizenmalt DME (60% wheat, 40% barley)
6 oz. Amber Crystal Malt (60^L)
3 oz. Dark Crystal Malt (120^L)

7.5 HBU Northern Brewer Hop Plugs (1 oz. @ 7.5 %alpha) - 60 min boil
2.5 HBU E.K. Goldings Hops (whole) (1/2 oz, don't really remember the alpha content) - 60 min boil

1/2 tsp Irish Moss - 20 min boil

Wyeast Irish Ale yeast.

1. For the crystal malt, I crushed the malt and put in a straining bag & put that in 6.5 gal of water at 120^F.
2. Heated the water to 170^F & removed the heat.
3. Let steep at 170^F for 15 min.
4. Remove grains, bring pot to boil.
5. Remove heat, add malt extracts.
6. Bring to boil, add hops & boil for 60 min. Add Irish moss 20 min from end.
7. etc, etc, etc,

For the new brewers out there, it took me a while to realize that I needed to do the first part of step 5. I used to add the extracts while the heat was applied and no matter how well I tried to stir, I would scorch some malt onto the bottom of the pan. Also, it should be obvious that this is a full-boil. If you only boil 2-3 gal, you'll have to increase the amount of hops you use.

Subject: Brewski (tm.) it's official!

According to an article on page 66 in the 11 October issue of -Forbe's- "Brewski" is now a trademark. The guy that brought you those wonderful LA Gear products has gone into the beer business. "The label on Sandy Saemann's bottles, currently rolling out nationwide, says 'The Greatest Name in Beer.' The slogan is 'Brewski, ask for it by name.'"... The article goes on to talk about the growth of the microbrewery business. Apparently the guy sees this new venture as a 'lifestyle' marketing vehicle. "To be blunt about it, Saemann hopes to use suds to sell socks. His Brewski Brewing Co. plans to market jackets, caps, socks, - even director's chairs and barbecue sauce - with the winged Brewski logo." "Brewski catlogs will offer gift packs containing a bottle of beer, two pilsner glasses and a cap all bearing the Brewski logo. Brewski sells for about \$5 a six pack, versus \$4 for Bud and \$7 to \$8 for other microbrews. Brewski will be the only microbrew in cans, anotherway of identifying the beer as a product for people who want to act bluecollar." The contract for production will be done by G.Heileman, in small batches.

Arrgggggh!

A couple of days ago I posted the notice about the demise of Miller Clear. I had thought about dusting off the old H.L. Mencken quote that goes something like-

"No one ever lost money underestimating the taste of the American people."

Somehow, it seems more appropriate to apply it this piece about Brewski.

I guess it would have been too much to expect that this guy might have wanted to talk about the quality of his beer first, and then delve into the fun of marketing a bunch of tie-ins.

As for me I think I'll have a "homebrewski." I have reason to believe that it will be better than Saemann's/Heileman's stuff.

Subject: Corona Motorization

Hi:

I have used a corona mill for grinding for the last couple of years and am pretty satisfied. I am sure there are nicer mills out there, but cost is a factor and I am not interested in investing in a new one at the present time. However, I recently acquired a variable speed hand drill, and was anxious to make the small advance of motorizing my present mill. Sometime ago I ordered, from Northeast Brewer's Supply, for the price of \$1.00, a fitting to allow one to hook up a drill to the Corona. I had been planning on buying a bolt of the appropriate size and cutting the head off, but as it was only \$1.00, and as I was feeling a little guilty about the skimpiness of the rest of the order I was making, I got one. When it arrived, I was somewhat chagrined to find that it consisted of a bolt with the head cut off. But no matter. I attached it to my Corona, chucked on the drill, and set to work.

I was attempting to approximate the speed of my usual cranking (which is in the neighborhood of 8 lbs in 12 minutes). However, the variable speedness of the drill notwithstanding, I could only attain two states. State one consisted of no radial movement, and assorted nasty sounds and smells emanating from the drill. State Two consisted of rapid spinning of the grinder plaste, and an accompanying shower of crushed grains all over my kitchen. After alternating between states one and two for several minutes, I began to fear for both the mechanical integrity of my drill, and the cleanliness of my kitchen, and I gave up.

So, what is the deal here. Do I need a more powerful drill? Or, am I simply trying to grind too slow. Perhaps full speed grinding is required, along with some sort of backup shield to guide the grains to their appropriate destination. Finally, maybe I just need more practice to attain an intermediate speed. Any info would be appreciated.

Dave.

From: COOK@CDHF2.GSFC.NASA.GOV (Chris Cook)
Subject: Small Batches

[Bret (MSMAIL.DOWDB@TSOD.lmig.com> asked about brewing smaller batches. A couple of years ago I started a similar thread, but I never got around to posting any obvious results.

In my case, I was trying to make sense of the (then new) Belgian malts. Aromatic, biscuit and the others all sounded fascinating, but I didn't have the slightest idea how to use them. I figured to make a series of small beer batches, where each was a basic beer with a lot of one specialty malt.

I brewed about 7 or 8 all-grain 1-gallon batches before I ran out of steam. It was actually a lot of fun. When you've used to 5 gallon brewing, these little one-gallon mashes were so easy I'd have three or more going at a time. Suddenly my kitchen stove was actually hot enough, my regular pots and pans were the right size, and I didn't strain my back humping 6-gallon pots.

I started by scrounging a raft of 1-gallon glass jugs. I bought a few to start off, but so many juices and ciders come in 1-gallon glass that you and your friends can finish the supply pretty easily. I ended up with 6, I think.

I didn't get fancy with mashing, limiting myself to simple infusion mashes. Jack's EASYMASHER or some variation would have been perfect, but I was just messing around using general kitchen stuff, so I rigged a mash/lauter-tun by putting a screen in the bottom of an old 1-gallon water thermos, which worked amazingly well. I wasn't trying for accurate measurements, but I think I was getting close to 30 points per pound (per gallon, obviously)

. Later I changed to a two-gallon cylindrical cooler, and that allowed me to add all the sparge water at once, which also helped. I was worried that maintaining temperatures with the small mashes would be difficult, but with the thermos, and mashing in the middle-150s, there wasn't a problem.

In cooking, one way to really understand how a specific spice tastes is to use too much, and that was my aim for these beers. My first batch was just the base beer with no additions. I think I used just under 2 pounds of Pale, but, like most people, I don't have my notes with me at work. The second batch used somewhat less Pale and a pound of Carapils. In the next set I brewed another control beer, one with Caravienne and another with Caramunich, and so on. All were hopped with what I though was a middling amount of Cascades.

For each set of batches I made up a quart of yeast starter with some neutral ale yeast. When the batches were cooled, I would split this

starter between the batches, and fermentation always started quickly.

The little batches turned out quite interestingly, although not what I'd expected. I don't know whether the hops utilization was quite different or my scales were simply inaccurate, but the beers were all very hoppy, with strong, although pleasant, bitterness and a great hop aroma. On the up side, I found I liked the beers with 'left coast' hop levels. The down side was that the high hop levels overshadowed the differences in malts.

I know that my hops scale (a postal scale, actually) isn't that accurate for my 5-gallon batches - it barely registered for the 1-gallon amounts.

I tried measuring the hops by volume by measuring 4 ounces, then interpolating, but I was still only using a large teaspoon or so of pellets per patch. I tried crushing the pellets in the mortar and pestle so that I could measure more accurately, but it still wasn't very accurate.

That was the only serious problem I had. If you can find a way to accurately measure the hops for these small batches, I recommend going for it. It was fun and easy.

One other hint. I did this before the thread about adding specialty malts at mashout, so I just mashed all the grains. If I do this again, I'll make a larger batch of the base beer and perform smaller mashouts with each specialty malt. You'd still have to perform separate lauters, but it would cut out a lot of the running around I did for simultaneous mashes. Another option would be to get a lauter tun bigger than 1 gallon and play around with first and second runnings.

Or play around with the different kinds of hops, or different fermenting temperatures. Have a ball.

From: David Atkins <ATKINS@macc.wisc.edu>
Subject: yeast query & bottled experience

Hello readers,

Two queries if I may...

YeastLabs American Ale:

I recall someone asking for any experiences or reactions to this strain. I have 5 gals of pale ale (og 40) in a secondary and the yeast head has yet to drop. I racked from underneath the primary's yeast head and a new one grew in the secondary carboy. It has diminished some but this is my first experience w/ the yeast and since it has been fermenting for a week, I just want to know what might be happening. This batch got off on a rollicking start...I had signs o' fermentation within 3 hours and a yeast top-layer in about 7-8 hours (the power of aeration and 4 cups starter). In sunny Madison, the tilt of the earth has lower the ambient temp. of my basement to 60-63 F. Could the lower temp result in such a slowing of fermentation. Before I could ferment for 1 week to 9 days and have clear beer to bottle....but that was before this yeast and temp change and recipe.

Bottles:

Has anyone used the 1 pint 6oz Sapporo or Kirin beer bottles for home brew. They don't appear to be as thick as returnable long necks but their generous size and easy access make them a tempting container. How would they hold up to bottle conditioning....3/4 cup corn sugar or 1 1/4 cup malt extract... don't need to carb. anymore than that.

Thanks,
David Atkins

Subject: Now, why don't they make it in an ale? ;)

SOFIA (UPI) - One of the largest breweries is beginning production of a special beer which would help against radioactive contamination, press reports said Friday.

The beer, called Lulin Special Light Laer, is supposed to help people cleanse themselves from radioactive strontium-85 particles, which enter the body through the air and various foods, and are deposited in the bones, reports the daily 24 Chasa.

Sofia newspapers carried pictures of members of the Defense Ministry's Civil Defense Department drinking the Pilsen type beer Thursday.

Lt. Colonel Valentin Angelov, scientific secretary of the ministry's Scientific Development Council, told United Press International that work on the project had begun two years ago.

``After the Chernobyl incident, we began intensive work on foodstuffs and beverages which could help the human body fight radioactive contamination,'' said Angelov.

On April 26, 1986, the nuclear power plant in Chernobyl, 80 miles (128 km) north of Kiev, Ukraine, was damaged. Radioactive contamination spread across eastern and northern Europe.

Angelov said that the special effect of the beer was due to an ingredient called Kanta-tonic, which contained some 40 Bulgarian herbs and was developed jointly by the country's Academy of Sciences and the Central Laboratory on Radiobiology and Toxicology at the Military Medical Academy.

``All our experiments have shown that the lager greatly promotes the decomposition of strontium-85,'' said Angelov.

According to the managing director of the Lulin brewery, Ivan Mihov, it is for the first time in the world that such a beverage was being produced.

He said great interest had already been shown towards the beer from abroad, notably from the the United States and Japan.

Subject: Cooking with beer recipes

From: Graham Truelove on Fri, Oct 1, 1993 2:05 PM
Subject: Cooking with beer recipes
To: Homebrew Digest

FYI: This month's Gourmet magazine, October 1993, gives several new recipes for cooking with beer - microbrewed or mass-produced (or for that matter homebrewed). The article states "The hearty and savory dishes that emerged from our test kitchens highlighted beer's versatility as an ingredient, its most notable properties being a subtle bittersweet taste and, for meats, a tenderizing effect. It's also worth noting that most preparations made with beer are best accompanied by a tall glass of their most salient ingredient."
Sounds good to me.

Mussels steamed in spiced beer
Beer-braised brisket with root vegetables
Onion and Garlic Beer Soup
Chile con queso y cerveza (Cheese and chili beer dip)
Beer, sun-dried tomato, and olive quick bread
Deep-fried broccoli and carrots in scallion and caper beer batter
Pork chops in beer teriyaki marinade
Stout spice cake with lemon glaze

All the recipes but the last call for pale, light-bodied beers and discourage the substitution of stronger flavored beers. I haven't tried any yet but the stout spice cake and the beer-braised brisket both look tempting.

Subject: RE: Drinking Containers

Hi!

Gene in Laramie asked if Corning Outlets still carry Yard glasses, the answer is yes! At least in New Hampshire they do. Yards run about \$30.00, 1/2 Yards about \$22.00 and Foots are \$15.00. The 1/2 Yards are tough to get because they sell out quickly, but they've always had the others in stock when I've been in there. \$30.00 is a great price for Yards with a stand, especially when I saw the exact same one at The Boston Brewer's Festival for \$65.00. (Even more especially when one's cat sacrifices one's yard to the radiator!)

Cheers!

Pam

Subject: cinnamon in apple cider

Greetings all on the HBD. I'm a newcomer (been reading the digest for a couple of months) and have found the info very helpful). Now I have a question of my own.

I recently made a hard apple cider with a friend of mine and it looks great. It's almost ready for bottling and we have a few questions about that.

1) Which bottles would be better for bottling--beer bottles or wine bottles? We think we want to use wine bottles, but is there any problem with this?

2) We have also considered adding a stick of cinnamon to each bottle. Has anybody done this? Would this affect the flavor in a bad way (i.e., off flavors due to microorganisms on the cinnamon, too much cinnamon flavor, etc.)

Any input at all would be most helpful.
Thanks,
Sean Taylor

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Pitching Rate

>From: gjfix@utamata.uta.edu (George J Fix)

>It has been my experience that underpitching yeast is a common problem with some homebrewers, and selected micros as well.

I am sure George's reputation doesn't hang on my corroboration but my recent experience leads me to concur emphatically. I don't know about it being a "problem" but it certainly is a significant factor in lag time.

After pondering all the responses to my wort aeration experiment, I conducted one more experiment which makes the connection between aeration and lag time even more tenuous.

To pre-empt more of the same irrelevant discussion, please keep in mind that the experimental objective was ONLY to measure lag time as a function of aeration and had nothing to do with the well accepted need for oxygenated wort for unrelated reasons.

I normally pitch about 500 ml of active wort built up from a slant culture. The first step is to cover the slant with wort so the entire culture is available to start the starter. The slant culture is discarded after one use.

I typically spend about 5 days building up the starter doubling the volume ever 24 hrs. It typically takes about 48 hours before any sign of fermentation is apparent in ten gallons of wort at 40F and 8 to 24 hrs for ales at room temp.

On my most recent batch, I built the starter up to 3 liters and fermentation was obvious in about 6 hours at 40F.

My point is not to champion the advantages of fast startup because I don't know anymore than what I have read and I doubt that my last batch will taste noticeably different from previous ones.

I am simply pointing out that pitching rates have such a profound affect on lag time compared to aeration that any attempt to measure the later effect will be swamped by error cause by small variations in the pitching rate.

js

p.s. It also seem obvious that pitching liquid yeast in the convenient starter package as supplied by one manufacturer, is not a very sensible way to get a beer off an running.

From: Jim Grady <grady@hpangrt.an.hp.com>
Subject: Christmas Ale Recipe

For those who might be looking for a Christmas Ale recipe, here is one that Curt Freeman and I made 2 weeks ago and I just bottled my share this afternoon. We took the spice list from Phil Fleming's Christmas Ale recipe that Kinney Baughman posted here 2 years ago. Since we had had a lot of fun with our first all-grain batch a week or so earlier we decided to do a partial mash (so we each would get 5 gal) and change it from a stout base to an amber base. Anyhow, here is the recipe:

Christmas Ale for 10 gal

9# Pale Malt Mash at 156°F for 90 min
0.75# Dark Crystal Malt (120°L)-+
0.5# Caramunich Belgian Malt (60-80°L) +-- add at mash out
1# German Dark Crystal Malt (20°L) -+
10# Munton & Fison Light Malt Extract Syrup

2 oz (15 AAU) Northern Brewer Hop plugs (10 gal remember) - 60 min

1 oz Hallertauer Hop plugs (steep 10 min)
1.5# Honey-----+
10 cinnamon sticks (3") |
12 oz grated ginger root |
zest from 12 oranges+-- Simmer 45 min; then add to wort (after
4 Tbs Allspice (whole) | the boil and steep with Hallertauer
2 Tbs Cloves (whole)-----+ hops

Wyeast German Ale yeast (1007)

We added the crystal malts at mash out in an attempt to retain some body. The combination we used was based partly on what I had left over from previous batches. We used a rectangular picnic cooler for the mash/lauter tun. It did not hold the heat very well compared to the insulated box method that we used on our all-grain but we feared that there was too much grain to use the tried & true method.

O.G. 1.056
F.G. 1.010
Fermented at 60°F

At bottling time, it is very good. The cloves and allspice are more pronounced over previous batches (I've made Phil's version for the past 2 years) but that may be due to finally following the directions!

>process. I discovered when I changed over that I needed about  
>half as much hops as I had been using in extract beers.  
>  
>The reason is that if you boil 6 pounds of extract in a gallon and  
>a half of water, the gravity of that wort is well over 1.100, and  
>probably somewhere near 1.125. High gravity worts don't take up  
>much iso alpha acids from the hops. When you switch to all grain,  
>and therefore full wort boils, your gravity will be more like  
>1.050, and you'll get a lot more bitterness out of your hops.
```

I had the same experience when I went to all-grain and I should have noticed this. Shortly thereafter I started basing my hop schedule on IBUs and have no problems since. The IBU formulae consider the OG (although the details of utilization are debatable) and avoid the problem of overhopping with full boils.

Subject: Carboys/Yards

For those interested and living in the Northern Illinois area, the Corning Factory Store has the following to offer:

5 gallon glass carboys.....\$8.99 (ask for cardboard packing)
Yard of Ale Glasses (w/stands)....\$29.99
1/2 Yards (w/stands).....\$19.99
Foot of Ale Glasses (w/stands).....\$14.99

The yards are cheaper than I have seen before. It is not something for which I would immediately jump at at, but some would.

They are located in the Piano Factory Mall in St.Charles w/ telephone number of (708)377-5460. The mall additionally has a housewares outlet store with other things of interest to homebrewers (canning jars etc...)

.

Good Luck

From: brewerbob@aol.com
Subject: Mailing/shipping home brew

I have checked it all out and I have been the "victim" of the US Postal Service as well. Here is the real skinny on at least two methods of shipping alcoholic beverages:

The U.S. Postal Service has regulations forbidding the shipment of any alcoholic beverage via USPS. (As well as about 100 other items such as explosives, drugs, toxic materials, etc, etc...) That's all there is to that!

I had a package that I sent (or tried to send) to the state of Washington that was dropped/hit/crushed/mishandled/etc in spite of the labels on all six sides stating it was fragile. I received a form stating that I had been a bad boy and my package was sent straight to Hell (I think that may be the other Washington!) and I could not even get my postage back!

Shipping by UPS is legal! However, to avoid any hassle with some low paid and low trained clerk that could easily occur if you identify it as beer, the best thing to do is identify the contents as "Non-parishable food products" or "Hobby parts including glass and metal" or something along those lines. If you must, call it "Live yeast cultures" and the driver may be more careful with the handling of the box.

I do strongly recommend, however, that you do NOT send it in a beer carton! I sent a case of twenty sixteen ounces to Texas in a Tucher box (after all, they were originally Tucher bottles) along with a second box which was a plain brown box containing about ten assorted bottles of home brews. The two were sent at the very same time. The second one arrived just fine, the first one never arrived. I just hope the driver appreciated my home brew. It was a Shiner style Bock beer.

I did put in a claim and UPS paid me \$100 plus the \$11.xx shipping cost. I split the money with the intended recipient and told him to buy a case or two of good beer with it!

Good luck with your shipments.

BrewerBob@aol.com

P.S. By the way, when I ship beer to the AHA competition, I always include a couple of extra labeled bottles for the crew and I pack the beer bottles in fresh popcorn so they have something to eat with all that beer. I enclose a

note telling them that the popcorn was popped as the box was being prepared for shipment so it is fresh. The whole thing starts in a plastic bag inside the box which is sealed before the box is closed.

From: Jack Thompson <jct@reed.edu>

Subject: Old brew/Babylon

just reading through Carl S. Pederson's Microbiology of Food Fermentations, the AVI Publishing Co., Inc, Connecticut, 1971, when I came across this item on p. 211:

"The first evidence of beer manufacture has been traced to to ancient Babylonia, possibly dating back as far as 5000 to 7000 B.C....Some 18 varieties of beer, called bousa, were said to have been prepared in Babylonia as long ago as 2200 B.C.

...At some time barley was moistened and when germination began, it was crushed with a pestle, roughly ground, and made into loaves with sour dough or leaven. They were baked sufficiently to form a crust without cooking the interior. When beer was required, the loaves were broken, mixed with water, and allowed to ferment. the liquid was pressed, separated from the dough, and when fermentation was completed, the resulting acid-alcoholic beverage was called boozah or bousa.

Booze? Babylonian?

Beer=high tech?

Just another data point.

From: SMITH@EPVAX.MSFC.NASA.GOV (The Ice-9-man Cometh)
Subject: re: cold plates

Regarding chilling beer with a cold plate in a freezer: This would probably work for one or two glasses of non-warm beer. But the thermal mass of the cold plate is a lot lower than that of the beer going through it. A little heat transfer:

Assume an aluminum cold plate at 255K (0 F), 5 gal of beer weighing 19 kg at 290K (62 F), and perfect heat transfer. No heat transfer to the freezer during dispensing (worst case, but not by much). No temperature change due to CO2 coming out of solution (not sure how much this matters)

Dispensing temperature to be 278K (40 F).

Specific heat of Al alloy: 820 J/kg/K
Specific heat of water (beer): 4184 J/kg/K
Equation: $mp * C_{pp} * (T_{out} - T_p) = mb * C_{pb} * (T_b - T_{out})$
where p=plate, b=beer, T_{out} =dispensing temp.
Solve for mp, mass of plate:

$mp = (19 \text{ kg}) * (4184 \text{ J/kg/K}) * (290\text{K} - 278\text{K}) / (820 \text{ J/kg/K}) / (278\text{K} - 255\text{K}) = 51 \text{ kg}$
This means you'd need a 110 lb aluminum cold plate to dispense a whole keg of beer. Of course, it's all more complicated than that, because you get a lot of temperature variation in the output of the plate as it warms.

One way to help this problem would be to put your cold plate in a pan of antifreeze solution (like what you put in your car). The bigger the better, but don't ruin your freezer; water is heavy....

>Sometimes this is done with ice on the cold plate.
In other cases the cold plate is placed in a fridge or freezer.

I have used a cold plate for years and assure you that they are totally adequate for serving beer when used with ice. I have noted people using them in a fridge but can not imagine how that could work very well. The difference in heat transfer between ice water to aluminum vs refrigerator or even freezer air is orders of magnitude. A freezer might work for one glass but that would be about it. If that is all you want, it might be ok.

>I had been planning on buying a bolt of the appropriate size and cutting the head off, but as it was only \$1.00, and as I was feeling a little guilty about the skimpiness of the rest of the order I was making, I got one. When it arrived, I was somewhat chagrined to find that it consisted of a bolt with the head cut off.

This is a constant frustration for manufacturers who get accused of ripping off customers for things that seem trivial. Most people simply do not understand the costs of manufacturing which must include purchasing, inventory, interest, labor, overhead, markup for retail, taxes, shipping, packaging, warranty... the list is endless. Just what would you charge to supply me with a bolt with the head cut off? You got a bargain.

> After alternating between states one and two for several minutes, I began to fear for both the mechanical integrity of my drill, and the cleanliness of my kitchen, and I gave up. So, what is the deal here. Do I need a more powerful drill?...

You are simply experiencing the limitations of the so-called variable speed drills on the market today. They have very little torque at low speeds and are pretty useless for your purpose. I would suggest getting it to run at the proper speed before filling the hopper and then adding grain only as fast as it will take it. This unfortunately may not maintain enough pressure on the plates for a consistent grind but sow's ears do not make silk purses.

If you can afford a new drill, I highly recommend getting a geared-down version of a 1/2" drill. The power or size of the drill is not as important and the gear ratio. The higher ratio allows the motor to operate at higher speed and produce much greater torque.

You will, BTW, destroy you drill shortly after you smell smoke, if you continue.

Subject: dryhopping rate

Yesterday I bought (and drank) a bottle of Young's Special London Ale. This beer had the most vegetal hop character that I've ever encountered in a bottled beer. I have no idea how fresh it was (don't know how to read the date code -- does anyone know if the "beer date decoder" works on this label?), but it sure tasted fresh.

This stuff's got a LOT of dry hops in it. It tastes about the same as my IPA with 2 oz E.Kent Goldings hop plugs in 5 gallons, except fresher! (I did make the IPA back in the spring, I guess.)

If you're wondering about dry hop rates, you should try this beer.

Subject: Barley Wine fermentation schedule?

My latest brew is an all-grain barley wine, on the weak side. The OG was around 1.085 (boiled for many many hours!). I was trying to get the OG higher, but that is another story (I now know why many people do partial mash barley wines!).

Anyway, I used a 1 pint starter from Wyeast London Ale yeast, which was possibly a bit past high krauesen, in a 5 gallon batch. The start of obvious fermentation took over 24 hours, so I suspect I underpitched considerably. Aeration was done with a venturi tube apparatus, using the falling cooled wort (new CF chiller worked great!) to suck air into it. It had a nice 3 inches or more of foam on the top of the fermenter, so I think aeration was adequate (maybe not?, read on...).

The krauesen reached a couple of inches in about 3-4 days, and slowly levelled off and went down to a 1/4 inch layer of foam after that. After a week, I sneaked a taste in the primary. No off flavors, but very sweet. I didn't take a gravity reading. After another week, 2 weeks total in the primary, I did a gravity reading and subsequent tasting. The gravity was 1.055!!! The taste was (obviously) still very sweet. I racked into my secondary, where the beer will stay for a while, but for how long? Am I looking at a 6 month ferment here? Is this normal for a high OG beer? The strongest beer I've made before was OG 1.057 and it acted quite normal (2 weeks to 1.015 or so).

I know this sounds like the standard "how long till I bottle" question, but it pertains to the high gravity end of it. I'm in no rush, but this could take forever. If this is not normal (which I suspect) should I aerate at this point, add more yeast, nutrient, what? Next time (there will be a next time) should I work extra hard (compared to "standard gravity" ales) at increasing yeast population and oxygen content?

Thanks,
norm

Subject: Krush-off / help

Hi all,

First, thanks to Patrick Sobalvarro and the Boston Wort Processors for the Krush-off info. I now know which mill I will buy when the time comes. On to the question. I am currently extract brewing, and am attempting my first lager. It is based on the Pilsner Urquell clone on page 2-7 of the Cat's Meow (2nd ed.) with variations due to on my local supplier's advice and stock. This is what I used:

5# Briess light malt syrup
1.75# Briess Gold dry malt extract
15.5 AAU Saaz
Wyeast #2007 into 26 oz. ~1.040 starter 48 hours before pitching

Added 1/3 of the hops at 60, 30, and 10 minutes. Chilled the concentrated wort (2 gallons) to 70F, added to 2.5 gal. of 70F water, pitched entire starter (made from more of the Breiss Gold) and topped off to 5 gal. with more 70F water. Swirled to mix. O.G. 1.026, when I expected closer to 1.050. This is the first time I have used a hydrometer (out of five batches). I did correct for temperature. What am I missing here?

From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)
Subject: Novice all-grainer's comments

Now that I have three all-grain batches under my belt (not literally, yet!), I thought I should pass on a couple of the problems I've encountered and solved for the benefit for other new all-grainers.

On my first two batches I encountered significant cooling (>5 degrees over 1.5 hours) during mashing in a 5 gallon Gott cooler. On my last batch I encountered no cooling during a one hour mash. The trick is to preheat the mash tun; I did this by filling the tun with hot tap water while heating up the mash water (I do a single infusion mash). Also, I used US 2-row Klages for the last batch and experienced much faster conversion (<45 mins) than my other two batches which used English Pale Ale malt, presumably due to the higher enzymatic activity of the Klages malt. (Has anyone encountered any flavor differences between these grains?)

I also experienced very slow sparges (2 hours for 5 gallons) during my first two batches. On this last batch, the sparge slowed to a trickle so drastic action was called for. I dumped the mash out of my combined mash/lauter tun (the above Gott cooler with Phil's false bottom), and discovered that the mash had gotten under the false bottom. After removing the mash from under the false bottom and dumping it back in the tun, I was able to run the sparge as fast as I wanted. I believe the mash was getting under the false bottom during the intense stirring of mash-in. To solve this problem I may use a separate cooler for mashing and transfer the mash into the lauter tun at the end of conversion.

Hope this helps prevent someone else from encountering these problems.

From: Robert Pulliam <Robert_Pulliam@rand.org>
Subject: Chillers, Yeast, and Stout

Greetings,

Just wanted to drop a note of thanks and ask a couple of questions. First of all thanks to all who gave me info on counterflow chillers a couple of months ago. I finally got around to building one last weekend and it worked great in the test (boiling water) run. It is 30 ft of counterflow with an additional 15 ft immersed in ice water. The water was siphoned and the whole 5 gal took approximately 33 minutes (any way to speed that up?) I left a small amount of flame on the burner to ensure that the water continued to simmer throughout the entire process. It took the boiling water down to 55 degrees (great for lagers I guess.) I plan to try it without the ice bath to see what the temp change is. Anyway, thanks again. Secondly, a question or two. I plan on brewing a pale ale this weekend and a stout next weekend. I would like (read only enough money allotted by the wife) to generate a starter from a WYeast packet that would work well for both brews. Any suggestions? Also, I am looking for an all grain recipe for a Murphy's stout. Anyone? Class, class. Anyone?

From: Mark Garetz <mgaretz@hopstech.com>
Subject: Two Hop Topics

There has been a bit of discussion here lately about two hop topics: gravity vs. utilization and dry hop bitterness.

Gravity vs. Utilization:

In the research for my book, I have tried to verify the common homebrew wisdom that high gravity **boils** make a difference in the hop utilization by attempting to find references in the commercial brewing literature. I have not been able to find **any** mention that wort **boil** gravity makes any difference in hop utilization. The gravity at the start of **fermentation** does make a difference, meaning that low gravity beers get better utilization than high gravity beers. Note that this is a fermentation effect, not a boil gravity effect, and varies depending on the fermentation technique. Anyway, the **volume** of the boil **will** make a difference, which may explain Norm's comments about needing less hops when switching to all grain (full volume) boils.

I asked Gail Nickerson this question ("Does boil gravity affect utilization?") and she said (paraphrasing), "No. Not unless you were boiling a syrup or something of that consistency. And if it did, it would be known because the big boys are all using high gravity brewing techniques these days."

To summarize, then, it appears that low boil volume (regardless of the SG) gives less utilization, but **boil** gravity has no effect. But as the gravity of the **fermenting** wort increases, utilization decreases - the amount depends on your fermenting methods.

Bitterness from Dry Hopping

I am at loss on this one. I, for one, have never noticed it. A lot of brewers report a pronounced **astringency** but not bitterness. This will go away in few weeks. It is possible that some of the alpha acids in the hops had been converted to iso-alphas, but I think this is unlikely. The hops would have gone "cheesy" long before there was significant conversion from ambient heat, etc. It is also possible that oxidized beta acids are the culprit. They are bitter, but again, I would think that the alphas too would have oxidized along with the betas, and we would be back in cheese city. They're also not very soluble.

But here's the real issue: Brewer's report a **great deal** of bitterness and they have used 1 oz (or less) of an aroma hop, in a process without heat or agitation. If they used the same amount of hops in the boil, would it have contributed the same amount of "undrinkable" bitterness? I think not. (you have to get way up there to get "undrinkable" IBUs).

So what's going on? Obviously something is happening because we have to assume the brewers with the dry hop bitterness are telling the truth and that they're not imagining it. Are they mistaking astringency for bitterness? OTOH, those that report this bitter effect are a minority - a lot of brewers dry hop all the time and never have this effect, not to mention Anchor Liberty and Sam Adams Boston Lager, both of which are dry-hopped. Many, many barrels of these two brews are produced annually with none of these problems.

Still, it would be nice to get to the bottom of it.

Suggestions?

Mark

From: Conn Copas <C.V.Copas@lut.ac.uk>
Subject: Re : Bitterness from Dry Hopping

If we accept that there is a difference between hop flavour and aroma, then my experience is that prolonged dry hopping (as in leaving hops in a pressure barrel) has a relatively short-lived, intense effect upon aroma, but a long-lived effect on flavour. I personally love the aroma of English Goldings, but not so much the flavour, which is why I am of the school of thought which limits dry-hop contact time to less than 2 weeks. As for bitterness, isn't there a theory that alcohol is an alternative to heat as a means of isomerisation? Presumably, any effect would also be enhanced by increasing the contact between the hops and the brew, as with the use of shredded hops or pellets.

From: rmm@apollo.hp.com
Subject: Beer filtering...

Hi, I have seen a couple of references to filtering beer in the digest and I have some questions:

1. How fine a filter do you use?
2. Where do you find the filters?
3. When in the brewing process do you filter?
4. How much difference does it make? Can you really clarify beer by sending it through a filter once (at the end of secondary)?

I have a couple of cornelius kegs and a CO2 setup and would guess that I should use a counter-pressure fill from one keg to the other with a filter in between.

Any tips, comments or details of personal experience will be greatly appreciated. Thanks.

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Wort Processors Mill Evaluation

Sounds like a fun time was had by all and the context and tone of the report indicate that it does not require much serious debate. However, there are a few points that I would like to mention (surprise, surprise) just for clarification.

First of all, the MM used in the evaluation does not represent current design which will indeed crush one lb of malt in under 14 seconds with a hand crank and 5 lbs per minute with a motor is like falling off a log.

>The Schmidling MaltMill is a two-roller malt mill with 10" steel rollers, finely grooved lengthwise.

The current design uses a much coarser texture on the rollers that has a profound effect on the efficiency of feeding the grain through the rollers.

> In both tests the mill had to be held to the bucket by hand.

The MM is supplied on a base with rubber feet for locating it on a plastic bucket. This does not imply that this is the ideal way of using the mill in all cases and in particularly when speed tests are being run. It is far more convenient and easy to use if it is clamped to the edge of a work table with a simple C-clamp.

>The unmotorized test came first. The mill was very quiet when cranked by hand; the operator was timed at approximately 120 rpm. Two pounds of grain were crushed in 44 seconds.

The current design will crush a pound of grain in less than 14 seconds at that cranking rate.

>The motorized test used a 2.3 amp electric drill. Two pounds of grain were crushed in only 21 seconds, for the day's record.

This figure would be substantially improved with a current design but not knowing the RPM I can't even guess.

> Others mentioned that it occasionally proves necessary to replace the O-rings used in the drive mechanism.

Although a fairly trivial task to replace, the current design, does not

require the O-ring to drive the passive roller. We went from two O-rings to one and now have eliminated it's need entirely.

>The Corona is a flour mill..... When run with a 2.3 amp electric drill, the mill was less noisy than the Marcato (this may be because a different drill was used). The mill took only 24 seconds to crush the two pounds of grain.

I have real problems with this one because it implies that the Corona is almost as fast as the MM and this is not consistant with my experience.

According to my measurements, it takes 93 revolutions of a correctly adjusted Corona to process one pound of grain. This compares to 30 revolutions on the MM. This is the obvious advantage of the 10" long rollers. For the Corona to process grain in roughly the same time, it would have to run 3 times faster. Granted, no RPM's were stated for the drill operated tests, but this must be known for a rational evaluation. If the MM were run 3 times faster it would process 9 times more grain then the Corona in a given time.

By extrapolating the results of the hand cranked Corona....

>The operator was clocked at 100 rpm. Only three-quarters of a pound were ground, in 1:38 (one minute and thirty-eight seconds).

It would have to run at about 1200 RPM to process 2 lbs in 24 seconds. Theoretically, the MM would crush 40 lbs per minute at that speed.

I would also point out that, not having any bearings, the Corona would not last very long at that speed.

Finally, a note on crush quality....

The most misunderstood aspect of the grist resulting from milling of malt for brewing is the bogymen known variously as flour, dust, fine particles, powder etc. I would rank the need for unscathed husks as number two. The emphasis on both of these results from the problems created by crude grain grinders combined with poorly designed and/or operated mash/lauter tuns.

The perfect grist for mashing would be molecule sized particles of malt from which all the husk has been removed. It would wet perfectly, dissolve instantly and produce 100% yield of crystal clear wort.

In the real world, some of the starch is not converted or dissolved and it is impossible to prevent some of the husk from getting into the grist. This creates the need to filter the mashed wort and in this hypothetical case, it

could be run through a submicron filter and produce a nice clear wort with very high extraction yield. The bad news is that mechanical filtration at that level is expensive, time consuming and messy. The good news is, Mother Nature has provided a simple and free filter that when properly utilized, is just as good.

By allowing the husks to remain in the grist and providing the proper environment for them to settle and layer in the lauter tun, they will filter the wort just about as well as a mechanical filter and cost nothing.

I suppose most of us know all this but what seems to get lost in these types of subjective studies of grist from various mills is that the flour bogymen is a ghost from the days of flour mills, coffee grinders and poorly designed lauter tuns. A mill that doesn't pulverize the husks, if supported by a proper lauter tun can and SHOULD produce a significant amount of very fine grist. That is what makes the difference between acceptable and maximum extract efficiency.

To worry about husks that are broken in half as opposed to remaining whole is to miss the whole point. A husk in two pieces provides more filter pores than a whole husk. Likewise with ten, twenty or a hundred pieces. The problem arises not from chopping it up into small pieces but from pulverizing it into dust. A roller mill with two or more counter-rotating rollers is inherently incapable of pulverizing husks and whatever is done to the husks is not likely to create problems. Grinders and single roller mills are candidates for pulverizing husks and must be carefully adjusted to minimize this effect.

As an aside, I have not seen the Glatt but from descriptions, it sounds like the intermeshing grooves on the rollers might pose such a problem.

The sieve tests used by commercial breweries are quantitative and very repeatable but are designed to predict or explain problems in very large batches and are virtually meaningless for small homebrew sized batches. It's fun to say that one's mill produces text book quality grist but if in the final analysis, the beer is no different from that made from grist that has a different stastical spread of particle size, what does it prove?

I think the bottom line is that a homebrewer can use a roller mill with confidence that any problems in processing can probably be looked for elsewhere. Other types of mills require much more judgement and experience to get them to do what they were not intended to do.

From: Kelly Jones <k-jones@ee.utah.edu>
Subject: Update on troubleshoot my Dryhopping

A week ago I posted a request for help with my dryhopping. I had noticed a pronounced excess bitterness in a batch of brew which had been dryhopped 10 days on fresh homegrown cascade. (This was definitely dryhop bitterness, as it was not present in a second portion of the batch which had not yet been dryhopped.) Anyway, thanks to all who responded with help/suggestions.

Second, an update: I sampled this beer again last night, after 8 days of bottle conditioning. The bitterness is (almost) completely gone. I believe I still detect a bit more bitterness than in the undryhopped batch, but it is certainly not excessive, and works just fine for the style. Whatever this bitterness was, it was present immediately after removing the hop leaves, but gone after 8 days of conditioning.

Third, I was reading yesterday's comments by Mark Garetz on this subject. One suggestion of his is that what many report as 'bitterness' may actually be 'astringency'. I cannot speak for others, but as a lover of big red wines, my palate can easily recognize astringency. What I tasted was bitter, not astringent.

Enjoyin' my brew,

Kelly

Subject: Re: Dryhopping bitterness

Could this mysterious bitterness from dryhopping be due to infection?
Dumping unsanitized hops into fermented beer may introduce some bizarre
microorganism that produces bitter byproducts. Maybe this organism tends
to
live on hop flowers?

Just some wild speculation....

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Yeast Viability

I have been asked if there are alternative methods for estimating yeast viability that do not require the use of a microscope. I have been told that the need for a scope in the Morris procedure effectively eliminates it as an option for most.

Many moons ago I devised an iodine test to estimate % viability. It is described on pages 144-145 of BEER and BREWING, Vol.6, 1987, Br. Publ. It is based on the fact that glycogen will stain with iodine, and that yeast with high glycogen reserves tend to display high % viabilities. This test is trivial to do, and is not unlike the iodine test used in mashing.

Yeast whose viability exceeds 90% (a highly desirable condition) will stain with iodine pretty much in the same way as a corn starch solution. At the other extreme, yeast with viabilities below 50% (an unacceptable condition) will not stain at all. The problem with the procedure is that does not provide reliable info for the intermediate cases. Rodney's test is far more reliable in this regard. I still use the iodine test, but only to get initial rough estimates. It also should be noted that Rodney's procedure can be done at 200-400X. Hence, only an elementary "student scope" is needed.

<around 1.085 (boiled for many many hours!)

<Anyway, I used a 1 pint starter from Wyeast London Ale yeast, which was
<possibly a bit past high krausen, in a 5 gallon batch. The start of
<obvious
<fermentation took over 24 hours, so I suspect I underpitched
<considerably.
<Thanks,
<norm

A timely post since I just finished my first BW (fourth edition of
Woblin'
Goblin' Barley Wine) that actually fermented down to 4 degrees Plato! IT
is
also timely in that there is a pretty good article in the latest New
Brewer
by J. Maier of the Rogue Brewery in Newport, OR on just this subject. You
might recall that John is known for his BW, and makes a darn good version
called Old Crustaceon. Basically, John points out that he max's out his
mash tun to get the highest OG, oxygenates well, pitches *THREE* times
his normal amount of yeast, and ferments 10F higher (70F) than his
regular
ales. Primary for him is 2 weeks, followed by one in secondary and crash
cooling to drop yeast, and kegging with the residual yeast. I basically
did the same thing. I maxed out my mash and lauter tuns, actually
exceeding
their capacity, adding the extra mashed grains once i pulled some wort
off,
and the bed began to compact (be careful not to compact too much). I
reduced my yield by about 15% into the fermenter as a method of keeping
the OG up, but still *only* achieved 1.092 (~23 P). I also continued
to sparge the grains, yielding a Bitter of 1.043. I counterflowed
chilled
the BW to about 70F, hooked up a airstone to bottled O2 and let the
oxygen
bubble through the wort for a few hours. I pitched lots and lots, 2lbs?
?
of really healthy Dominion Ale Yeast slurry at the start of filling the
fermenter. The ensuing fermentation was impressive, blowing lots of
thick
krausen out the lid of my open fermenter, despite the 15% extra head
space
than normal. I was expecting a quick ferment (for a BW), but on day 4
the SG was around 1.045. The ferment was still quite active, but had
lost its high krausen mode. Just to be sure, I added another 1/2 lb or
so of yeast slurry on day 6 and left town for some Dead shows and brew-
pubbin' in Boston. Upon my return, on day 10, the SG was around 1.025
and the yeast was still in suspension and active. I waited until day 13
to keg, and the SG had dropped to around 1.016/4P. This can be compared
to a 4 day ferment of an ordinary ale (1.052-1.012). I did measure my
ferment temp during high krausen and it was 80F!! This is really too
high, and I am looking into a chilled water unit to attemperate the

ferments, but I have found that enough hops can mask some of the high temp ferment problems. Two of the kegs were cask hopped with one oz each of Centennial (same that John used).

None of my previous BWs have finished below 1.024/6P. I feel the O2 and the quantity of yeast is the difference.

Norm, I have let Bws sit in the secondary for 6 months, shaking the carboy to rouse the yeast. I also had a BW that I had to kick start with a single cell culture of Red Star Champagne yeast, and it worked. Good luck,

Jim Busch

Subject: chilling wort

(John Pavao writes in HBD#1239:)

> (snip)

> I am wondering if I would be better or worse off if I chilled the
> concentrated wort before adding it to the cold water in the carboy.

I would say chill your concentrate first since it will be easier to do. For my first several batches I added the hot partial wort to the cold water in the fermenter a la Papazian, but in view of the recent warnings about HSA I went for chilling the partial boil (in my case about 2 gallons) to pitching temperature before adding it to the carboy for my latest batch. This took placing my kettle in a sink full of cold water and changing the water three times over 45 minutes. On adding hot concentrate it took seven hours for the batch to cool to pitching temp on its own, and a kitchen sink full of cold water had no noticeable effect. An immersion chiller would likely be more effective, but I have not yet made one. BTW, I tried sending this by private email but it bounced.

From: Domenick Venezia <venezia@zgi.com>
Subject: Dry hop "bitterness", Fermentation hop utilization

I also have experienced the dry hop "bitterness" in some of my pale ales as both Kelly Jones and Darryl Richman noted. In my tasting notes I described it as an "astringent harshness" not really a bitterness, and in going over my brewing records I find a correlation between this dry hop harshness and the sulfate content of my brewing water. In both cases, I had hit the gypsum and/or epsom rather hard. The good news is that in all cases this harshness was gone with 4-6 weeks bottle conditioning. An interesting "powdery" palate is imparted (I think) by the high sulfates. It's a front of the mouth "roughness" vaguely similar to the mouthfeel of spinach.

Mark Garetz writes in #1240 that hop utilization rates are related not to the boil gravity but to the starting fermentation gravity. What? I don't quite understand what is meant by "fermentation utilization". Boiling hops is an extraction technique, I assume that "fermentation utilization" refers to a breakdown effect. Mark if you could clarify this I would appreciate it. Also, maybe you could speculate on why boiling volume affects utilization rate (saturated solution of alpha acids?).

Thanks.

>Aeration was done with a venturi tube apperatus...
<snip>
>After another week, 2 weeks total in the primary, I did a gravity reading and subsequent tasting. The gravity was 1.055!!! The taste was (obviously) still very sweet...

I had a similar experience with Wyeast London Ale (#1028), but my OG was 1120 and my FG was 1050. When I serve this undercarbonated, too-sweet but still very potent Imperial Stout, I boast that the FG of this beer is higher than the OG of Budweiser! I'm afraid I can't answer Norm's question, but I have a few more points to add to the discussion. I hope that someone who has sucessfully gotten a high-gravity ferment to *complete* with London Ale yeast will post. My datapoints:

1. I believe that the Best-of-Show beer at the 1992 BOSS Competition was Brian and Linda North's Barleywine (if not, it was runner up for BOS). I judged Barleywines and really liked the flavor and balance of this beer, so much so, that I wrote down the yeast they used: Wyeast London Ale.
No mention of other yeasts, like Pasteur Champagne (available from Wyeast in liquid form also, by the way).
2. I'm quite sure that my Imperial Stout's OG was quite a bit higher than Brian and Linda's, so perhaps I was foolish for trying to get it to ferment out without help from a more alcohol-tolerant yeast like Pasteur Champagne.
1120 -> 1050 is 58% apparent attenuation, which is nowhere near the expected apparent attenuation of London Ale yeast (73-77%). This is why I suspect that the alcohol killed most of the yeast. At high kraeusen, this batch foamed a good 3 quarts of beer out of the fermenter, so it seems like the activity was quite a bit greater than Norm's batch. The fermentation temp was about 68-70F and lasted about three weeks.
3. I've read that alcohol-tolerance is related to oxygenation, but Norm seems to have covered that area quite well, so that's not the problem -- also, Norm's was an allgrain batch (mine was extract+specialty), so I'm quite sure there were plenty of nutrients in his Barleywine wort.

I'd really like to find out how to get London Ale yeast to do high-gravity brews -- I'll definately ask Brian or Linda when I see them next. Perhaps a incremental-feeding starter (where you start with a low-gravity starter, but then step-up to higher and higher gravity worts)?

>wort (2 gallons) to 70F, added to 2.5 gal. of 70F water, pitched entire
>starter (made from more of the Breiss Gold) and topped off to 5 gal.
with
>more 70F water. Swirled to mix. O.G. 1.026, when I expected closer to
>1.050. This is the first time I have used a hydrometer (out of five
>batches). I did correct for temperature. What am I missing here?

You didn't swirl enough. The heavy, high-OG wort sank to the bottom
and it will take a lot of swirling to mix it up. Don't worry, the
yeast will do it for you, but you can throw out that 1026 OG reading.

Another comment is on the use of Wyeast #2007 in trying to make a Pilsner
Urquell clone. Despite the fact that it's called "Pilsen" lager, it's
really "St. Louis" lager (as in Bud)! What you might try next time, is
Wyeast #2278, "Czech" lager, which should be available in about three
weeks.

Subject: Hop utilization VS. Boil gravity

Mark writes:

>To summarize, then, it appears that low boil volume (regardless
>of the SG) gives less utilization, but *boil* gravity has no effect.

WRONG! PERIOD!

I have a two brewing logbooks (with my respective tasting notes) and a
file
folder full of BJCP judges' comments that contradict Mark's contention.
I've
been using a slight variation on Jackie Rager's article in the Hops
Special
Issue of Zymurgy (adding 10% for leaf hops and another 10% for a hop
boiling
bag) and my IBU levels appear to be right on target. Hundreds of BJCP
judges
agree. If only I could control my maltiness with the same precision I
control
my bitterness!

> Suggestions?

Yes. I suggest you shelve your book project till you have more than
TWO years of brewing experience.

From: mwithers@hannibal.ATL.GE.COM (W. Mark Witherspoon)
Subject: HELP!!

HELP!!!

I have a problem that came up about a brew I just started. Here is the recipe:

2 lbs of pale malt
1 lbs of flaked corn
1 lbs of crystal malt (about 50 l)
4 lbs of Alexanders Pale Malt

1 oz of Tettanger Hops (3.8%) (boil @ 45 min)
1 oz of Liberty Hops (3.2%) (half and half boil/finish)

Whitbread ale yeast

OG = 1.052

I am attempting to make a "Rusty Cream Ale". But here is the problem. I was following the "directions" by Dave Miller in his book - he recommended 8-12 hours after pitching to rack to a secondary. I couldn't do it that soon. So I did rack at about 24 hours. Almost immediately the head foamed up and blew the airlock off the carboy. Since I was there to watch it. I quickly hot water rinsed the original fermenting bucket out (it was full of spent hops and trub) and resiphoned it back into it. With in 10 minutes of doing this the head was just about a thick as it was before I started originally.

Question: Have I just killed this brew...???? I expected problems since this was my first attempt at using grains (partial mash).

Comment: The hardest part of doing this was knowing when to stop sparging the mash. The mash water was the sweetest thing that I had ever tasted - that wasn't pure sugar. I watched my mash temp very carefully, not to get it over 150 F and let it go about 2 hours since I wasn't sure about my grinding technique.

Please send replies by e-mail since our our news feed of r.c.b. and r.c.w. have been cut off.

Subject: Spice/pumpkin flavors & yeast reuse ????

I must admit all this talk of pumpkin beer had me making funny faces.
But, after trying a glass at Boston Beer Works saturday night I am
impressed.
I'm getting ready to make a batch for a Thanksgiving/Christmas ale.

Now for the ?????

Being as cheap as I am I reuse my favorite yeast slurry (Wyeast 1056
american)
I generally rack to the secondary when the primary starts to slow down,
usually
2-3 days after pitching. Then reuse the yeast slurry from the secondary
in my
future batches.

Seeing how this pumpkin ale will have so many unusuall ingredients
and
spices in it. I was wondering if anyone has had any of these flovors
carry
over to future batches reusing the yeast??? Esp- if I taste at racking
to
the secondary and decide to add more pumkin &/or spices to the
secondary.

Thanks for any/all input.

From: Peter Maxwell <peterm@aoraki.dtc.hp.com>
Subject: yeast pitching rates

In HBD 1238 George Fix gives numbers for recommended pitching rates. The calculations in terms of weight of yeast solids is interesting, but I would like ballpark figures to go on, rather than go to all the trouble of separating and weighing starters.

If I start with a packet of WYEAST, what is the weight/cell count of the resulting sludge if I put it into (a) one pint and (b) one quart of 1.020 wort and let it ferment to completion?

In other words, how much build-up do I really need?

Further to the "use once" approach, if I put the WYEAST into a quart of wort, let it ferment out, split this 3 ways for storage, then take one of the thirds and put IT into a pint of wort, letting it ferment out, what yeast population/weight do I end up with? This is my current procedure and I get reasonable starts, but I'd like to know if I'm really underpitching.

Subject: Chillhaze/Proteins/Tannins

A while ago, there was this question:

>This conversation between Al and Scott has me confused. They talk about chill
>haze and tannins as being related. I thought tannins were to be avoided
>because of an astringent flavor component, rather than anything to do with
>haze. Are tannins protein based? I too have had a chill haze problem with
>a recent batch and was surprised to hear talk about acidifying sparge water
>as a cure.

Chill haze and tannins *are* related. Chill haze is caused by the interaction of tannins and large proteins which stay in solution at warmer temperatures, but precipitate into a haze at cooler temperature... hence: chill haze.

How to avoid chill haze? Well, there are many ways to do this. Note that almost all of this applies to extract brewers as well as allgrain brewers, just use the parts that make sense in your procedure. I suggest that you try all the easy (procedural) ones first and then try the clarifying agents if you still have chillhaze.

1. IN THE MASH

In the mash, you should make sure that your pH is not too high (not too alkaline) so that you minimize tannin extraction from the grain husks. If you are using less-modified grain or something with a lot of protein in it, like wheat malt or raw wheat, you should use a protein rest to break the big proteins down to amino acids and small proteins. These small proteins are essential to head retention and body. The amino acids are used by the yeast for nutrition.

2. AT MASHOUT

Make sure your mashout temperature doesn't go too much over 168F to again minimize tannin extraction from the grain husks. I believe the 168F temperature is related more to ungelatinized starch extraction, but reducing tannin extraction is another reason to avoid too high a mashout temperature.

3. SPARGING

Don't use too hot a sparge water (see #2) or let the pH of the sparge water get too high (see #1). You should treat your sparge water the same way you treated your mash (Gypsum, Lactic acid, etc.) -- it's going to the same grain bed and will be similarly acidified by the grain, so I think it's better to use a proportionally equivalent acidification of your sparge water rather than to simply acidify your sparge water to a particular pH.

4. BOIL

Make sure you have a good rolling boil for at least an hour so you get a good hot break. Hot break is basically cooked proteins. You can also use 1/4 to 1/2 teaspoon of Irish Moss in the boil (flaked appears to be the best), but too much Irish Moss can *increase* chill haze (see Beer and Brewing 1989 or 1990, I forget which). Also, I've found empirically, that too much Irish Moss can take out much of the smaller proteins, thereby reducing head retention.

5. CHILLING

Chill as suddenly as you can -- the more sudden the cooling, the better the cold break (again, coagulated proteins). Note that counterflow or plate chillers cause a more sudden chilling than immersion chillers (but I still favor immersion chillers for a variety of other reasons).

6. AFTER FERMENTATION BUT BEFORE BOTTLING

There are a number of things you can do after fermentation is over, but before you bottle:

lager - lagering (long storage at cold temperatures) will cause the chillhaze to form and settle out. Lagering a beer made with ale yeast can kill it leading to difficulty in bottle carbonation.

add papain - papain, an enzyme made from papaya, can be added to break down bigger proteins that have made it to the fermenter; I'm not sure, but there's chance that papain could reduce head retention and body, since small proteins are primarily what give beer head retention and body.

PVP (Polyclar AT) - PVP, trade name Polyclar AT, is a plastic which when added to the fermenter, will electrostatically attract tannins as it sinks down to the bottom of the fermenter, only to be left behind at bottling with the dead yeast and break.

silica gel - silica gel, not currently available to homebrewers, but used commercially to work similarly to PVP, but it operates on proteins instead. Just as with papain, it could reduce head retention and body.

bentonite - works similarly to silica gel. Same (head retention & body) warning applies.

gelatin - primarily works to speed the settling out of yeast, but also works similarly to silica gel in settling out proteins. Same warning applies.

isinglass - as far as I know, does little for protein or tannin reduction, but noted here for completeness -- added to the fermenter or to the keg to speed the yeast settling. I'd like to add the Greg Noonan says that isinglass should not be used for lagers, but doesn't explain why -- I don't see any reason why it can't be used for lagers as effectively as for ales.

filtering - cold filtering, to be exact. Cold filtering reduces chillhaze by first creating the chillhaze (the cooling) and then filtering out the coagulated protein/tannin chains.

Filtering out chillhaze but leaving some head retention and body is difficult. There's a lot of debate on what the correct pore size is and you can easily overfilter your beer.

7. AFTER BOTTLING

If you've already bottled a beer and it exhibits chillhaze, you can completely eliminate chillhaze at serving time by utilizing a non-transparent drinking vessel.

So there you have it. You don't have to do all these things to avoid getting chillhaze. As I said before, first try the procedural ways and then move on to the clarifying agents if you still have chillhaze. If you must resort to clarifying agents, first try PVP since it leaves those essential proteins in your beer. Personally, I would rather tolerate a little haze rather than filter my beer, but that's me.

From: Eric Wade <ericwade@CLASS.ORG>
Subject: Legality of mailing homebrew

U.S. Postal Service Domestic Mail Manual (DMM) section C021.2.0
INTOXICATING LIQUORS reads: "Potable beverages of .5% or more alcoholic
content by weight, which are taxable under Chapter 51, Internal Revenue
Service Code, are nonmailable. If the product conforms to applicable
requirements of the Internal Revenue Service and Food and Drug
Administration and is neither an alcoholic beverage, poisonous, nor
flammable, it may be mailed."

Under Chapter 51 of the Internal Revenue Code (26 U.S.C. sec. 5053(e))
"Beer for personal or family use" is tax exempt (up to certain volume
limitations).

It is my belief that the Postal Service has yet to catch up with the law
that made homebrewing legal which essentially freed the homebrewer from
the tax burden placed on commercial brewers. My interpretation of the
first sentence of C021.20 is that we can mail homebrew because it is not
subject to taxation. However the second sentence contradicts the first.
The "product" does conform to IRS requirements but is still an alcoholic
beverage. I don't know whom to contact regarding this apparent
contradiction in the USPS rules although an address for comments on the
DMM is provided:

Mailing Standards
US Postal Service
475 L'Enfant Plaza SW, RM 8430
Washington DC 20260-2419

On another note, I'm heading off for a weekend on the Mendocino coast.
Between home and the coast I know of both the Hopland (Mendocino) Brewery
and Anderson Valley in Boonville. Any recommendations along the coast, I
thought there was something in the town of Mendocino would be
appreciated.
Looking for quality beery spots of all type (pubs, brewpubs, etc) TIA.

OBTW, I'm a librarian (and homebrewer, of course), not a lawyer, so
please
don't take my interpretations of laws and regulations as legal advice, I
don't give legal advice.

Subject: Thanks & Smokey Mnts.

Thanks to all the respondents of my Sapporo bottle and yankee yeast queries.
Got some good advice and am looking forward to less & less bottling.

To the fortunate person who is to trave the hills of my home, I hope you have a great trip through the Smokeys. In reference to you requests for beer in the Appalachian highlands, I know of only one place close to a brew pub. Sorry to say I have vever been to this place and I don't know if it is still open or standing. North of Gatlinburg TN, in Cosby TN there is/was a place some buddies of mine called Fort Marx...Two double wides pushed together with a gravel parking lot. Inside you'd find Herr & Frau Marx and their brew-trailer-diner. Herr Marx brews beer and distills liquors and Frau Marx works wonders with potatoes and sausages. I don't know how long the've been in Cosby much less the US but everytime I hear a Fort Marx story, the place grows more and more surreal.

Asheville, NC may have some unique places...can't say from experience. I do know of some good places in my old stomp of Knoxville, TN. If you are traveling that far west out of the mountains I could give you some particulars on Knoxville or some other places you may be looking into.

Tennessee may have alcohol/beer licensing laws similar to Texas. Depending on how near to a town you are, you may have to settle for McDonalds & Bud. And there are still dry towns & counties around. You may wish to stock up for your trip.

Let me know if I can be of any help & happy trails,

David Atkins

Subject: 5 Ltr Mini Kegs
To: homebrew@hpfcmi.fc.hp.com

I'm looking for some feedback on the pros and cons of using 5 liter "mini kegs", as opposed to bottling. I can get them empty for ~\$5 at my local homebrew supply store (or buy them full of Dinkelacker or Grolsch and drink that first) and buy a CO2 tap for ~\$35 to use with them.

Anyone have any good/bad experiences with these mini kegs? I intend some day to step up to 5 gallon Cornelius kegs, but currently:
(1) I don't have another refrigerator to dedicate to brewing and
(2) The total costs for fridge, CO2 tank and connections, and kegs are prohibitive. Is this interim step worthwhile? It seems to be convenient by saving time and space at minimal initial cost.

Any and all input is appreciated!

Subject: Lambic Beers and U.S. Microbreweries

I've got a couple questions, hopefully someone out there knows the answer to these questions:

- 1) Is there any U.S. brewery producing a true lambic beer (besides the Cranberry Lambic from the Boston Brewing Co)? If not, why not?
- 2) I've read before that the various yeasts and bacteria needed for lambic beers are available in the US, but where is a good commercial source (or free source) of these microorganisms?
- 3) Has anyone tried making a homebrewed lambic in small batches. If you have I would really like to talk to you about the process, as Kriek Lambic is my favorite beer and I would like to duplicate the sour bite found only in lambic beers.
- 4) Are there any good publications about microbreweries? Particularly I'm interested in getting some start up information for an Entrepreneurial Business class at school.
- 5) Finally, in this long list of questions, does anyone have the number for the Celis brewery in Texas that makes Belgian style beers?

Thanks for your help in advance. Please send responses to me at mcel@cornell.edu. Thanks and happy brewing!!!

I'm one of those who believe it is important to cool the wort ASAP after boiling is complete (limit DMS). Keeping this in mind, I add two large blocks of ice. This quickly brings the temperature down for pitching the yeast (yes, ice at 32F will provide more cooling than water at 32F). If you believe adding tap water does not create a problem, then ice blocks made of tap water will not cause a problem and will cool even faster. The important thing in making the ice blocks is not to introduce any wild yeasts. In other words, the water which is to become ice should be placed in a previously sanitized container which can be completely CLOSED from the environment (the freezer is teeming with nasty guys that like to spoil beer). I use one gallon plastic milk containers and fill them half way (just below the handle). They are easily cut with a knife and the ice block extracted. If you are one of those concerned with using tap water, then pre-boil the water first (and remember, boiled water will freeze faster than unboiled water ... less O2). I think the addition of ice blocks is a better technique than using an immersion chiller when doing high gravity boils (which are diluted to final volume after the boil). The immersion chiller is the correct choice for full volume boils, since you do not want to dilute the wort of a full volume boil.

From: Jim Busch <busch@daacdev1.stx.com>
Subject: RE: crush off/hop util/S. Adams

I read with interest the ongoing comparisons between mills. I am more interested in the comparisons of extract efficiency from the test brews. I know that my extract went down when I switched from pre ground Briess to corona ground, then the extract returned to the preground equivalent with the adjustable MaltMill. Any results from the test, or were they all the same in the end??

With respect to Mark's comments on hop utilization and the lack of professional journals reports on the subject, I believe it is covered in Malting & Brewing Science, by Hough et al (not sure as I dont own this excellent set) but it is certainly covered in the German literature by Dr. Narziss, of the Weihenstephan institute, in Freising. At any rate, the correlation between high OG and hop utilization is well known and accepted by the pro brewers I hang out with.

A while back I posted a bit about Mr. Kochs Jamaica Plains brewery but had not actually been there. I was there the Saturday before last, and the Sudhaus is indeed impressive, dual 15 BBl decoction kettles, each with a grain feed, and water spray. The guides were a bit annoying, especially with respect to comments like "everyone knows no good hops are grown in the US" . I just couldnt let this one pass, so I pointed out that if one sampled a Petes Wicked Lager, the US grown Liberty hops could be compared to the German equivalent. Needless to say, they were not pleased to hear the words "Petes.." spoken in the hallowed grounds of Sam Adams.....:-)

Good brewing,

From: David Atkins <ATKINS@macc.wisc.edu>
Subject: chilling extract brew

I too do that extract brew. Here's how I chill.

My method involves a carboy primary--5, 6.5 or 7 gal size.

My primary is a 7 gal carboy...I don't know if I'll ever use a bucket again.

I chill the boil pot in a sink of cold water for a few minutes...ice and those refreezable faux-ice packets work well in the bath. Placing about 1.5 gals of cold water into the carboy, I funnel my extract into the container then fill up to 5 gals with a heady stream of cold water. I find that the heady stream 1) aid aeration and 2) cools wort not just by heat exchange with the water but with heat exchange with the air...get's real frothy.

Once filled, I bung the carboy shut and for 10 - 20 minutes I prop carboy on edge of sink and gentle wash the carboy with cold water. If you don't have one of those built in sink spray nozzles (like me) use those cheap faucet-shower attachment hoses you can find at a drug or discount store (a 2-3 feet length of rubber hose with an exceedingly simple adapter on one end and a shower head on the other; the shower head is removeable) I use the hose in cleaning as well as wort chilling and carboy filling--remember to sanitize though.

While chilling the carboy, rotating it slightly from time to time, I take the opportunity to shake the container, further aerating the wort. From the start of chill to the yeast pitch takes 20-30 minutes.

If you would like info on finding 6-7 gals carboys let me know. I do business with a good supplier. They don't know me, just my credit card number (read as disclaimer).

Take care,
David Atkins

% From: Mark Garetz <mgaretz@hoptech.com>
% Subject: Two Hop Topics

%
% There has been a bit of discussion here lately about two hop
% topics: gravity vs. utilization and dry hop bitterness.

% Gravity vs. Utilization:

%
% In the research for my book, I have tried to verify the common
% homebrew wisdom that high gravity *boils* make a difference in
% the hop utilization by attempting to find references in the
% commercial brewing literature. I have not been able to find *any*
% mention that wort *boil* gravity makes any difference in hop
% utilization. The gravity at the start of *fermentation* does make
% a difference, meaning that low gravity beers get better utilization
% than high gravity beers. Note that this is a fermentation effect,
% not a boil gravity effect, and varies depending on the fermentation
% technique. Anyway, the *volume* of the boil *will* make a
% difference, which may explain Norm's comments about needing less
% hops when switching to all grain (full volume) boils.

I suggest you get a copy of Malting and Brewing Science by JS Hough and
read
the hop chapter and the wort boiling chapters. Then I think you will see
that
indeed wort gravity does affect hop utilization.

%
% I asked Gail Nickerson this question ("Does boil gravity affect
% utilization?") and she said (paraphrasing), "No. Not unless you
% were boiling a syrup or something of that consistency. And if it
% did, it would be known because the big boys are all using high
% gravity brewing techniques these days."

%
Can she provide a reasearch reference for this statement? As we say in
rearch
land "If it isn't published it didn't happen"

% To summarize, then, it appears that low boil volume (regardless
% of the SG) gives less utilization, but *boil* gravity has no effect.

Wrong!

% But as the gravity of the *fermenting* wort increases, utilization
% decreases - the amount depends on your fermenting methods.

What does volume have to do with it? If alpha acids are in to high a
concentration then utilization goes down due to solubility issues. But
rather
than quote chapter and verse from M and B Science I suggest you read it
and
then repost.

Subject: SPGRAV: program to perform hydrometer corrections at any base

This polynomial is much better than the previous one that was posted. However, why not just go to the source? The CRC Handbook of Chemistry and Physics lists the S.G. of water at various temperatures, and these correspond exactly to the correction factors that come with the hydrometer, except they go up to 100C. Of course, there's still the complicating factor of the sugar in solution to contend with, but I haven't found any source for this. A quick experiment I did with some 1.032 sugar solution found that the table was still correct, within the resolution of my hydrometer, anyway. (Does anyone know of a source of S.G. tables for sugar solutions at various concentrations and temperatures?)

For those of us who don't have a computer sitting in our brewhouse, here's a table to print out and keep handy. The correction is computed by subtracting the table value for a given temperature from the table value for 15C (which is what MY hydrometer is calibrated for) and rounded to the nearest "SG point".

Temp C Correction Table SG

0	-1	999.87
5	-1	999.99
10	-1	999.73
150		999.13
201		998.23
252		997.07
303		995.67
355		994.06
407		992.24
459		990.25
50	11	988.07
55	13	985.73
60	16	983.24
65	19	980.59
70	21	977.81
75	24	974.89
80	27	971.83
85	30	968.65
90	34	965.34

How do you think I got the polynomial. SPGRAV works with very high accuracy from 00C to 1000C... The polynomial is needed instead of the table because most people make temperature measurements with greater than 50C accuracy...

From: "John C. Post" <jpost@llnl.gov>
Subject: Comments on Molasses

A few notes on Molasses in Beer...

1) DON'T use sulphured molasses. Yuck!

2) Molasses takes a *long* time to ferment out completely, not as long as honey, but much longer than malt.

3) If you have time to wait until 2) is complete, it can be a wonderful accoutrement (College Word!) to the right recipe...I like it best with some zippy hops, such as Saazer or a nice fresh Cascade.

You might try some Black Treacle for an interesting flavour kick. You can usually get it at those expensive gourmet stores (Williams-Sonoma comes to mind...)

Bing, bing, bing. You win the \$64,000 question. Your very slow (and possibly incomplete) fermentation is almost certainly a result of underpitching. A one-pint starter (presumably stepped up only once from the Wyeast package) is OK (tho not great) for a "normal" OG, but high gravity worts require WAY more yeast. It's not out of the question at this point for you to make a quickie batch of more normal ale, collect a couple of pints of furiously fermenting wort, and bung that into your barleywine. It worked for me years ago, although it was a little earlier in the barleywine's life.

As a datapoint, your text research bears out my own experience with hopping rates. High gravity worts generally require higher hopping rates, but it's because they need higher bitterness levels to balance the greater body and sweetness of the beer.

> think this is unlikely. The hops would have gone "cheesy" long
> before there was significant conversion from ambient heat, etc.

I have never experienced either effect in one of my dry-hopped beers. I leave the hops in the kegs for many weeks without getting any "cheesy" quality -- probably because cheesiness is a property of oxidation -- and I've never noticed any additional bitterness even though I dry-hop pretty heavily.

On the other hand: I was present at a tasting at UC Davis, of various

beers that had been hopped at varying times. You should talk to Michael Lewis about this, since he ran the program, but he, his students and those of us in the class who were actually brewers, were all surprised at the discernible bitterness in the one beer that had only been dry-hopped -- NO bittering hops or aroma hops in the boil. And, believe me, in case you don't know Michael Lewis, the QC around this issue was very high and the hopping rates were pretty damn low.

Me, I have to assume the problems homebrewers are having is Pilot Error, and has almost nothing to do with dry-hopping. Just a guess.

Subject: First all grain: the procedure

I am preparing for my first all grain attempt in the next couple of weekends. This is what I am planning on doing. At the end I have some questions, that I would appreciate if anybody could respond to.

Also, if anything looks strange, and you are wondering why I'm doing it, I probably don't know, so let me know.

My equipment for brewing will be as follows

36 qt cooler
1/2" Slotted copper pipe manifold sparger to 3/8" reducer
10 gallon enamel pot
gas cooker burner type thing
chiller
7 gallon glass primary fermenter with blow-off
5 gallon glass secondary fermenter with air lock

- 1) Grind grains the night before.
- 2) Heat 1 qt water per lb grain to 168F. Add some gypsum (2 Tbl.?) to lower pH.
- 3) Preheat Cooler with hot water.
- 4) Add grain and water to mash tun (cooler) on top of manifold. Stir.
- 5) Check mash temp, adjust as needed to around 154F.
- 6) Close cooler for 1 hour.
- 7) Open cooler do Iodine test for conversion. If not converted close up longer.
- 8) Add crystal, chocolate and cara-pils (all specialty grains).
- 9) Raise temp to 170F (mashout) by adding near boiling (200F) water.
- 10) Stir till 170F is hit. Close cooler let sit 15 minutes.
- 11) Hook 3/8" clear tubing to manifold. Backflush with some near boiling water
- 12) Sprinkle 4 galons 180F sparge water (add gypsum to get pH 5 - 5.5) in cooler.
- 13) Start siphon, keep putting liquid back in cooler till get clear run off.
Siphon into brew kettle. Try for no aeration.
- 14) From here on I assume it is same as extract, but with more volume (note: I already use a cooling coil).

Q1 - Equip - Is 36 qt cooler ok for size (5 gallon batches)? 11.25 lbs grain.

Q2 - Step 7 - If not converted and temp is lower than 154F should I adjust it back up? Should I check every 15 minutes or leave closed?

Q3 - Step 8 - Is this the correct time to add specialty grains? Why?

Q4 - Step 10 - Is it ok to stir? Is 15 minutes good?

Q5 - Step 12 - Should I sprinkle it all in at once or just enough to cover

grain bed and then continue adding so that I maintain a level 2 inches above

the bed? I have a feeling the latter is correct, why? Stuck sparge?

Q6 - Step 13 - I am nervous about the sparge, I hear stories of it taking a

long time. Using the manifold will I get a continuous siphon or will I have to restart it periodically? How fast should I siphon? Will I have to slow the siphon down? This step is somewhat of a mystery as to how it actually will go so some help would be appreciated? I know I'm washing the sugars off the grain. What about astringency? How do I know when I've gone long enough? How long will this step take (approximately)?
Q7 - All this talk of oxidation. Where do I have to worry about it? In the past the only place I have airated was going into the primary, and the only place I have specifically not airated is after the yeast kicks in through bottling.

Thanks a lot

Ed O'

Subject: Re: Krush-Off

Phil Miller asks if the crush evaluation was blind at the Boston Wort Processor Krush-Off.

No, each crush was identified to the Krush Kommittee. A quart jar was filled from each crush and was used for evaluation. Evaluations were made as the crush became available. All samples were kept and referred to by the committee when establishing relative quality of crush. I far as I know, no one on the committee had any favorite mill or predetermined expectations. I use a Corona, Bob Gorman ordered a Glatt Mill (don't know if this was before or after the test) and I don't know what Scott Keohane uses. We all watched the various tests as they took place. It was all pretty open and there were lots of opinions expressed by all present. In my opinion, the tests and evaluations were conducted in a fair and complete manner. A lot of people put in a lot of effort to pull this off and I think they succeeded.

Subject: Milling about

Gang--

Before another flame war ensues regarding commercialism on the HBD, I'd like to say that Jack has done homebrewing a great service in providing an affordable (to most) alternative to the Corona and for doing a great deal of research on the crushing of grain. I've seen no less than 8 different designs of MaltMills, each design (usually) better than the last. He has shown me grain crushed by various designs and asked me to choose which samples appeared to be the best crush. I'm told he has used my opinions as well as the evaluations of other homebrewers and experts at the Siebel Institute of Brewing to improve the design of the MaltMill. His mill has set a high standard for other mills that have followed. Granted, Jack has a financial interest in having his mill represented well in the HBD, but then again, if you re-read his latest post, you'll see that there is a lot of good, mill-independent information in there. I, for one, appreciate him sharing this information openly.

Al.

Disclaimer: I own a retail store and currently sell three of the mills in the Krush-off and plan to sell one more of them soon. I've done evaluations myself of all but the antique mill in the Krush-off and have only chosen to not stock one of them due to what I deemed a poor crush (this was NOT one of the mills that is commercially built as a homebrewing malt mill).

Subject: NO POPCORN, PLEASE!

In HBD #1240, brewerbob@aol.com wrote about using *real* popcorn as packing material for shipping homebrew to competitions. Please cease and desist! Don't send popcorn unless you're shipping to a friend who doesn't mind receiving it!

When the 1st Round AHA Nats were held in Boston, I was one of the lucky unpackers. Over the four sessions, I found *all* sorts of packing material, including -- oh, ye gods and little fishes! -- *battered*, *salted* popcorn, which greased up the bottles, the labels, the entry forms, the checks, and my hands. It was really gross, kiddies. And if it wasn't salted and buttered, at least the popcorn was stale and at worst it was moldy. NO WAY was I about to ingest any of the stuff. I'm glad I didn't find any bugs or rodents in the boxes!

I only wanted to get the bottles unpacked, tagged, and sorted so I could dig into the goodies Bill Murphy (site coordinator) had bought -- with his own funds, since the AHA wasn't reimbursing. And even parsimonious and uncooperative Smadams let us have draft brew. I hear Anchor is more generous.

If you want to be kind to the unpackers, use shredded newspaper. It doesn't have the static electricity problems like styrofoam "popcorn". After that, make sure your bottles are blank, with the proper labels attached by rubber bands, with blacked out caps, and without incised lettering; then make sure your entry forms and payment are included, and have the box blessed so the UPS box gremlins don't screw it up.

Subject: Mash out necessary?

After drilling into my right knee, steeping my feet in hot wort, melting the kitchen floor, and nearly removing the tip of my left index and middle

fingers (I am NOT a klutz), I have decided to set aside my "Zap-pap" food bucket lauter tun and try sparging with a copper manifold. The situation is this: I have a 10 gallon stainless brew kettle and any number

of plastic food buckets, and good warm boxes. If I mash in a food bucket in a warm box then I can preheat the sparge water in the brew kettle, but then have no way to mash out without transferring water and mash all over the place. Now, Miller (TCBoHB) is adamant that mash out is absolutely necessary. Others are less certain. Hey, it's going to be boiling in a few minutes anyway. What are the opinions from HBD land? Is it more of a

factor with lauter tun sparges rather than manifold sparges?

Thanks in advance.

Many thanks to the Boston Wort Processors et al for the interesting post on mills. Just a quick question: was it a blind judging? (I.e., did the judges know which mill ground the grains they were judging?)

The judging was not blind; the judges did know which mill ground the grains they were judging. In fact, they watched the grinding take place, and some of them even went so far as to make fun of the operators of the mills. And, frankly, I noticed that a couple of them drank a pretty fair amount of beer as the afternoon wore on. They're kind of shifty characters to begin with, actually.

Subject: Pumpkin Ale Recipe

Because of the number of requests for Pumpkin Ale I have seen on the HBD recently, here is one that I particularly enjoy:

Barefoot Pumpkin Ale

Bring to a boil 1qt water. Add 1 29oz can of pumpkin (I recommend Libby's because it is 100% pumpkin. So are most other brands, but make sure before you use it.) Stir. Add 1 3.3 lb can of DMS Malt extract. Stir. The temp should come to about 152 F. Hold at this temp for 40 mins. While this is going on you can get the rest of the ingredients to a boil in your brewpot:

1 gallon water
3.3 lbs NW (Briess) Amber malt

Add pumpkin mash (mush?) to the brewpot and bring to a boil. Add 1 oz German Hallertauer pellets and 1 oz Hersbrucker plugs. Boil 45 mins. Add 1 oz Hallertauer pellets, 2 cinnamon sticks (about 2-2.5 inches long), 1 tsp ground cardamom, 2 tsp whole cloves, 1 tsp + 1 shake of nutmeg, 1 tsp ground allspice, 1 tbsp ground ginger, and 1 Tbsp Irish Moss flakes. Let boil 10 mins. Add 0.5 oz Saaz pellets. Reduce (turn off heat) and cover brewpot and let steep for 5 mins.

As I recall, sparging this mess to the fermenter was a problem because the pumpkin is a real fine mush. I think I just added all of it to my primary and topped it off to about 5 or 5.5 gals, let it cool and racked away from the mush that settled out. This leaves a lot behind. When I make this again, I will do a full volume boil and use a wort chiller and this should cause most of the stuff to drop out.

Yeast: Whitbread Ale Yeast
OG = 1.040
Racked to secondary @ 1.010
FG = ca. 1.006-8

Tasting notes: Real nice spice/hops balance. Good color and very clear. I would enter this in a contest, but I bottled it entirely into large bottles. :)

Comments/suggestions/criticisms(constructive) should be emailed direct to:

Subject: Re: Chilling Wort

I don't bother trying to chill my wort, instead I make sure that the water in the fermenter is as cold as I can possibly get it. I either put it in a spare refrigerator (alas a luxury) the night before I brew or in the winter I put it out on the porch until it's cold. Depending upon how cold the water in the primary is, after I pour boiling wort into it, it's down to anywhere between 65-80F immediately. If I wind up having to wait to pitch, it's usually less than an hour.

Good Luck!

Subject: spiced beer

Hi all.. I'm contemplating a spiced X-mas ale for this weekend and would like some opinions on the quantities and procedures for adding spices. My recipe is as follows for 5 gal

10 lbs Hugh-Baird pale malt
1 lb Hugh-Baird 80L Crystal mash at 158 for 60 min
1 oz Kent Goldings (60 min
1/2 oz Centenials (20 min
Wyeast 1098 (expecting SG of 1060.. no clue where it might finish
spices ?? cinomon, nutmeg, vanilla

Does using whole vs powdered spices like cinomon and nutmeg make a difference
What about vanilla extract vs. beans.
When to add them ? at the end of the boil or with priming sugar
Quantities of each spice. I'm also asuming no finishing hops as that would interfere with spice flavors. Any and all opinioons appreciated.

Don't anthropomorphize computers... They don't like it.

Subject: Hops (what else?)

Domenick Venezia asked me to clarify my comments on "fermentation utilization" and says something to the effect of "huh? this is an extraction technique". (Forgive me for not being able to pull the comments directly, but I'm not on a system for the next two weeks that allows that.)

The extraction of hop alpha acids and their subsequent conversion into iso-alpha acids is only one part of the equation. There are many post boil events that affect the final amount of iso-alphas in the finished beer. Some are: Yeast type and flocculation characteristics, fermentation time and temperature, wort gravity, how much the wort pH drops as it ferments, fermentation methods, lagering or not, filtration or not, and more. All of these can combine to make big differences in the amount of iso-alpha acids left in the beer by the time it reaches your lips, as opposed to simply the amount extracted by the boil into the sweet wort.

I also noticed when reading my own post, that I said something like "as the gravity of the fermenting wort rises..." and I realized that some might have thought that I was implying that wort gravity rises as it ferments. Of course it drops, but I should have said "the higher the starting gravity of the wort is at the time you begin fermentation, the lower your utilization will be."

Interesting to note that Kelly Jones reported that his bitterness has gone away almost entirely, as I had reported that other brewers had noted.

Finally, I'll deal with Al's comments off-line.

End of HOMEBREW Digest #1242, 10/07/93

Date: Thu, 7 Oct 93 10:35:34 BST
From: Conn Copas <C.V.Copas@lut.ac.uk>
Subject: A couple of proposed experiments

Here's some easy experiments for some intrepid soul to perform in order to sort out two current controversies:

On the 'dry hopping causing bitterness' thing, I occasionally make test brews that involve pouring boiling water onto a mixture of extract and pellets in a 1L, pre-heated glass bottle. This mix is then fermented, naturally enough with the hops left in, and definitely turns out bitter. The hot wort spends about 10 mins cooling down from something like 85C to 60C, which theoretically should cause little isomerisation. Experiment - do the same, but filter the hops out prior to fermentation, and note the difference.

Experiment 2:

> The perfect grist for mashing would be molecule sized particles of malt from
> which all the husk has been removed. It would wet perfectly, dissolve
> instantly and produce 100% yield of crystal clear wort.

Get hold of some wheat malt (which is husk-free) and pulverise it to flour. Use this exclusively in the mash, and note its suitability.

Subject: Re: chill concentrated wort

Sorry to take so long to get back to this but in HBD #1239 (Monday's issue) John Pavao asks whether it is worthwhile to chill concentrated wort before diluting it with a carboy of 3.5 gal of cold water.

I brewed for a couple of years this way before going to full batch boils and I personally liked it. For me it took out the worry of oxidation and the task of getting the cold water cold enough that I would be sure that the mixture would be at yeast pitching temps. In addition, transferring chilled wort is a great opportunity to aerate the wort rather than worry about oxidation.

I made an immersion chiller from 50' of copper tubing and some siphon tubing and some random fittings all for about \$30. I used 50' because some of the plans I had seen called for 40' and 50' was cheaper than 40'. Furthermore, I had no idea what else I would use the extra 10' for and figured it could only help. I know that there have been great debates on the optimal length and I have reached no conclusion myself.

Subject: Oxidation Problems

Hello all,

I recently entered my first Homebrew competition (the Mid-South Fair in Memphis, TN). I entered an extract based dry stout. It finished second with a score of 32. The main problem that the judges noted was that it had an oxidized aroma. I'm trying to figure out where this oxidation came from. Since this was an extract brew we did nothing I can think of which would introduce HSA. Our brewing procedure was as follows:

1. Put 8 gallon pot on burner, fill with about 6 gallons of water.
2. Started burner and add specialty grains (in grain bag).
3. Remove grain bag when the water is at about 180 or 190 F.
4. When water boils, add the extract (Briess liquid) and the hops.
5. Boil for 45-60 minutes. Insert immersion chiller for the last 5 minutes.
6. Cool to about 75-80 F.
7. Rack the cool wort into the carboy.
8. Shake the **** out of it to aerate it.
9. Pitch the yeast.
10. After about a week, rack it to the secondary (being careful not to splash).
11. For bottling, rack it to a bottling bucket, add priming sugar and bottle.

Our bottle filler is one of those clear plastic tubes with the spring loaded white thingy on the end (another version of the clear tube with the spring loaded orange thingy on the end, I guess). This thing does cause the beer to foam a little on it's way into the bottle.

My questions are these:

1. Is my bottle filler the culprit in my oxidation problems? If so, is there something better out there?
2. Has anyone out there ever used those oxygen absorbing bottle caps?
3. Is it possible that some extract manufacturers have HSA problems in the manufacture of the extracts?

TIA,
Brian Moore

Subject: Lambic Beers and U.S. Microbreweries

Matthew Evans writes:

> 1) Is there any U.S. brewery producing a true lambic beer (besides
the
> Cranberry Lambic from the Boston Brewing Co)? If not, why not?

No, because the only way to produce a true lambic beer is to do it in
the right part of Belgium. The local microflora(fauna?) just aren't
right anywhere else in the world. Now, Jackson mentions a few
breweries who have experimented with "spontaneously fermented" beers
in the Lambic chapters of The Great Beers of Belgium and The Beer
Companion, but I don't at the moment recall if any are in the U.S.
One was in Britain.

> 2) I've read before that the various yeasts and bacteria needed for
lambic
> beers are available in the US, but where is a good commercial source
(or
> free source) of these microorganisms?

Yes, no, maybe. The *Brettanomyces* cultures are available from G.W.
Kent, which is a wholesaler, so you have to get your local HB supplier
to order them. Sheaf & Vine (email to Al Korzonas
(korz@iepubj.att.com)) also has some cultures (Brett and Pedio).
Nobody seems to have the appropriate *Lactobacillus* cultures, unless
you can get it from a fellower HBer.

For doing it yourself, the first thing you should do is to run out and
buy a copy of Lambic from the Classic Beer Styles series. If it's
not at your local HB store, pick up any issue of *Zymurgy*, you'll find
a publications catalog in the center.

> 4) Are there any good publications about microbreweries? Particularly
I'm
> interested in getting some start up information for an Entrepreneurial
> Business class at school.

Call the AAB (Association of Brewers). They have a number of
publications directed at microbrewers (for a fee, of course). Also
listed in the catalog in *Zymurgy*.

From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)
Subject: AHA Styles and Reality

I've recently gotten hold of the Zymurgy Special Issue on Traditional Beer Styles, and I've got a couple of questions or comments or something. 8-)

I like to make a brown ale, patterned after Pete's. I've made three batches, #2 being the most successful, so far as taste is concerned. The grist was as follows:

7#	DeWolf Ale	8L	56L
1#	DeWolf Munich	3L	3L
1#	CaraVienne	22L	22L
1#	CaraMunich	72L	72L
6oz	Chocolate	498L	174L

	327L	/	5.75 gallons = 56.9L

In a 5.75 gallon batch, the color is 57L. Note that the Chocolate is about 3.5% of the grist, and provides about half of the color. The OG = 1060. It seems to me that this brew was indeed a lot like Pete's.

The AHA style guideline says OG 1040 - 1055, and color 15 - 22 SRM. My understanding is that SRM approximately equals Lovibond. In the text describing the American Brown Ale style, it says that up to 5% of the grist can be Chocolate. Well folks, if you do that, you'll blow the color every time. Observe:

10#	DeWolf Ale	8L	80L
.1#	Chocolate	498L	50L (1%)

	130L	/	5.75 gallons = 23L

That's as light as I can make it, there's no crystal, and it's still too dark for the guidelines (OK, just barely, but I think the point is made). I don't think this brew would be very much like any American Brown Ale I've ever tried. If you use 5% Chocolate, you'll end up quite dark at 57L, but you'll still not have any crystal.

In the back of the same special issue, there are recipes for the competition winners. I made a rough calculation of the color the Brown Ale category winner came out, and I came up with 35L, too dark for the style guidelines. His OG was reported as 1062. So, here we have a national competition *winner* falling well outside the guidelines. What gives?? Are the AHA guidelines reliable? And if you can win an AHA competition without coming particularly close to the guidelines, why have them in the first place?

Part of my reason for asking is that I might like to enter competitions

myself, and I may also be interested in the AHA BJCP. But observations like this make me wonder whether it would be worthwhile. If the goal of the competition is to demonstrate brewing prowess, independent of whether the brew actually pleases anyone, well, then the style parameters make some sense. But in that case, you wouldn't even classify a beer into a category when its missed color, gravity, or IBUs specified for the category. In other words, the competition coordinator looks at the stated parameters and says "this can't be considered Brown Ale, so it won't even be entered into competition." and the judges would never taste it (no matter how good it might be). In an ideal world, the physical characteristics would actually be measured at the competition site, but I guess its hard to borrow an HPLC from the lab for the weekend 8-)

If the point is to look for the beer that is most pleasing, then I think the distinctions are too fine, and the parameters too narrow. If there's a third possibility, I'm not sure what it would be. Anyway, what I'm getting at is the guidelines and the brew that won (in that category, that year) seem to be at odds. And I'm sure that if I look, I'll find more examples. Can we generate some discussion on this topic? I think it'd be very helpful...

From: "Moore, Brian" <Moorebw@hvsmtpl.mdc.com>
Subject: Really Cool Cooling

Well here goes,

I've been reading the cooling debate in the previous few HBD's with much interest. Everyone seems to be on the wort chiller path. Has anyone ever tried just dropping a chunk (golf-ball sized maybe?) of dry ice into their hot wort? I've never tried it but have often contemplated it. There seems to be a veritable plethora of benefits:

1. Quick cooling
2. Cheap
3. All natural CO2 (?)
4. If it works anything like dry ice does in punch, maybe all of the break material would freeze into a big ball around the dry ice and you could just lift it out.

Obviously you would want to aerate the wort with an airstone or something to get oxygen back in for the yeast. Is commercial dry ice pure CO2 or are there other nasties in there? On the surface, this seems to be a neat idea so please don't flame me too badly. I'd like to try this but I'm afraid to ruin a batch of beer. Maybe if somebody else already has, they could stop me.

Thanks,
Brian Moore

Subject: Beer Bennies/Pyramid Yeast?

The following was reported in the Seattle Times, entitled "Beer Bennies":

"Oh, to work for Hale's Ales. The company, with breweries in Kirkland and Spokane, is preparing to take all its employees on three week "education tours" of European suds makers.

This Mother of All Bennies marks the firm's 10th anniversary. Mike Hale produced his first ale in Colville, and he now markets 13 draft ales throughout Washington.

The firm will take two groups of seven employees on tours of English, Belgian and German breweries. One stop: Gales Ales in Horndean, England, where Hale worked in 1982 before starting his business.

Of course, the trip coincides with Munich's Oktoberfest. Hale dryly notes in a press release that the tours `won't be work.'"

By the way, Hale's makes excellent products, especially their rich, biting

"Moss Bay Extra." They also have a great T-shirt with their mallard duck logo.

On another Northwest related subject, Pyramid Ales of Kalama, Washington, perhaps best known for its "Wheaten (tm) Ale," makes a large number of other superior beers including a double-yeasted Hefeweisen. One of my favorites is their "Wheaten Bock Ale" (O.G. 1.061) which is made with five

malted grains and Mt. Hood Hops. I am going to try a clone and through some rather involved reconnaissance have managed to come up with a close approximation of the grain mix.

My missing link is the yeast. Pyramid claims to use the same "proprietary" ale yeast on all of their brews (the Hefeweisen is filtered before undergoing a secondary fermentation with a Danish lager yeast, which settles in the bottle). My initial impulse was to try Wyeast chico/american (1056) or german alt (1007).

I recall reading "net lore" that Sierra Nevada probably got their yeast from Anchor, that Pete's probably got their yeast from Sierra Nevada, etc.

Does anyone know about the source of the Pyramid strain or have an educated guess as to a suitable substitute? Replies by private e-mail or postings both OK.

John Brooks

From: Paul deArmond <paulf@henson.cc.wvu.edu>
Subject: Re: Victorian Ales

Victorian Ales flourished during the last century, rising to prominence in the 1830's and dying off in 1900, when they were replaced by the Edwardian Ales (a much rowdier and less inhibited ale.) The Victorian Ales maintained a world-wide Empire. Indeed, it was said that the sun never set on a Victorian Ale. Two of the largest Imperial colonies, India and Canada, developed their own ales. Several other areas under the influence of Victorian Ales were quite important to trade, but never established their own brewing recognition. Two of the most notable brewing failures were Crimean Ale (very bitter and with an indecisive finish, but notable for the Charge of the Light Beergade, of which it was said, "It's magnificent, but it's not beer.") and the First and Second Afghan Brews (of which the first was a complete disaster.)

One of the notable and lasting characteristics of the Victorian Ales was their curious moral double-standard. While being very ostentatious in church-going, psalm-singing, founding societies for the reformation of fallen brews, establishing the Boy Stouts, and declaiming on the "Pale Ale's Burden", the Victorian Ales were not above mistreating natives (leading in India to the Carboy Rebellion), visiting child brothels or being whipped to a frothy head with birches.

The original Victorian Ale was blended with the lesser known Albertian Ale, which was of German origin. One of the results of this marriage was the Edwardian Ale mentioned above. The Albertian Ales never really caught on, but their influence may be seen in the current British Lagers.

for more information on the Victorian Ales, refer to the Flashman books by George MacDonald Fraser....

Subject: Re: Krush-Off extract

Jim Busch asks about the extract efficiency from the various mills at the Krush-Off:

Unfortunately, the crushes were not individually mashed. About 16 pounds of the Krush-Off residue was mashed in one batch with 2# crystal and 1# Cra-Pils and after a 75 minute infusion at 154F, a fifteen minute mashout and a normal sparge, it yielded an eleven gallon wort of 1.048 starting gravity. So I guess you could figure the_average_ extract efficiency. ;-)

Doing a club brew-in from the contest remains was as much fun as the contest itself. We made three batches using Young's ale yeast, a Weihenstephan Alt yeast and some of the new, improved Red Star (one gallon test batch). Haven't tasted them yet.

YES! ROO-ROO-ROO. Stand back! Make Way! Spread out! Free-
thinker comin' through here!

I hereby nominate Mr. Domenick Venezia to be considered for
acceptance into the Brotherhood Of Question Authority Types. It's
heartening to see someone question The Word.

It is my personal opinion that there are WAY too many homebrewing
books, written by fornicating self-proclaimed experts, and not
enough . . . oh never mind. Suffice to say I'm one homebrewer who
has yet to be convinced that mashing-out is necessary. In fact, I
think that mash-outs are an unnecessary step.

Oh sure, I here the sniveling arguments of the imprisoned. They
usually fall into one of two categories: "You have to stop enzyme
activity" -or- "it allows you to obtain consistent results".

Oh PUH-leez. If you skip mash-out, how much extra starch
conversion actually takes place while you sparge? Is it
noticeable? And if this additional conversion IS noticeable then
wouldn't you welcome the extra extract? Consistent results? Huh?
Just how does mashing-out produce consistent results.

Go ahead and throw stones. Me and Dom think the Emperor's new
clothes suck. We're standing-up and farting in the general
direction of homebrewing dogma. Well, at least I am. Dom?

From: arf@genesis.mcs.com (Jack Schmidling)
Subject: Crushoff/Extraction Rate

More on bodymen.....

Jim Bush suggests that it would be nice to know the extraction rates of the various test brews and I suggest that it may be nice but not terribly useful unless they were conducted under controlled conditions.

He also points out that his rate of extraction went down when he switched from commercially milled grain to a Corona and back up again when he started using a MM.

That warms the cockles of my heart but I have long felt that extraction rate has far more to do with the equipment and process following milling than with the milling itself.

I am in the midst of running controlled experiments to once again test extraction efficiency as a function of the grist. It has always been my opinion that a properly designed mill with fixed roller spacing will provide the same extract efficiency as an adjustable one set up to produce an industry standard type of grist. I offer an adjustable mill as an option because people think they need it. I don't doubt that, in large commercial batches, with the equipment they are stuck with using, that grist will have an effect on yield but on small batches the difference falls within the measurement error.

I run these tests on my one gallon pilot system and when using one lb of malt, the gravity for one gallon reads directly in pts/lb/gal.

The three tests just concluded, used 1 lb of Belgian Pils malt and the following mash schedule:

doughin 2000 ml water at 110F for 15 minutes
mash at 155F for 45 min
mashout at 170F for 10 min
sparge to one gallon with 180F water

The first two tests were on a fixed mill and an adjustable, set to provide industry standard grist.

The results were within the measurement error. The fixed mill sample read 1.031 and the adjustable may have been 1 point higher but on a hydrometer

with a resolution of 2 points per division, I would call it a draw.

The next test was inspired by Jim's comments on the Corona and I ran a test

on the grist from my Corona. However, ignoring all the wisdom of the Corona

fans, I set the mill to produce flour. The rotating plate pressed against

the fixed plate hard enough to require considerable force to turn with no

grain in the mill. It required a great deal of effort to crank with grain in

it and I am glad I only had to do one pound. The grist looked like coarse

flour with some recognizable husk material but it was just random slivers.

I ran the sample through the same process as above and got exactly the same

results. 31 pts/lb/gal. This did not surprise me but I had to do it to prove

the point to the skeptical. What did surprise me, was the fact that, of the

three jugs of wort produced, the Corona produced the most transparent. The

very fine husk material, did indeed do a better job of filtering.

So, whence the bogymen?

It is my contention that the bogymen is in the mash/lauter tun and not the

grain mill. Fortunately, I also sell the mash/lauter tun that makes all this

possible.

But back to mills, buy the one that turns you on, forget the "crush-offs" and

give some serious thought to pushing beyond the traditional plastic buckets

and picnic coolers.

From: chips@coleslaw.me.utexas.edu (Chris Pencis)
Subject: cleaning tips repost

Just a quick note relating responses to my cleaning tips question, here are a few ideas which may help some of you make your brewing (cleaning) process a little more painless (note, these are ideas used by those who submitted them, not just crazy ramblings)

- one idea: use plastic buckets for primary and rack off the trub into a carboy for the secondary - this leaves most of the gunk in an easy to reach place.

- use an immersible pump to drive sanitizing solution into bottles with a hose, use same pump out of water to drive air in...use low concentration iodophor which need not be rinsed

- put clean bottles in dishwasher for *sterilization*, use a little bleach and heat drying (I assume rinsing in the dishwasher will get rid of the bleach), Also, open dishwasher and bottle on the door, all spillage goes in the washer (note: this is not to remove labels etc.)

- one reply suggested the popular spray bottle washers available, or the construction of a homemade carboy washer from a plugged up section of garden hose with holes punched in the end near the plug (use bolt as plug)

- when draining bottles and carboys, turn the container over and give a little clockwise twirl and the water will drain out in a vortex, allowing air in and giving a faster drain (assumes northern hemisphere :))

Thanks to Jack, Drew, Norm, and Chris for their responses, any others who wish to add their \$.02 are greatly encouraged to do so to the address below.

Subject: Lambic beers & U.S. Microbreweries

- ----- Begin Included Message -----

Matthew Evans <matt@cadif.cornell.edu> writes:
> Subject: Lambic Beers and U.S. Microbreweries
>
> I've got a couple questions, hopefully someone out there knows the
answer
> to these questions:
Content-Length: 3703

In general, the best place for lambic questions is the lambic digest.
Subscription requests can be sent to:
lambic-request@longs.lance.colostate.edu

> 1) Is there any U.S. brewery producing a true lambic beer (besides the
> Cranberry Lambic from the Boston Brewing Co)?

To the best of my knowledge no U.S. brewery is producing anything
close to a traditional lambic.

I have just started to work with a very well known/respected pub brewer
on making a pseudo-lambic as a specialty beer. Don't expect to see it
anytime soon. Also, don't bother asking me who 'cause I'm not going to
say until he announces the batch publicly.

> Why not?

Assuming for a minute that you mean a pseudo-lambic (real lambics can
only be made just outside of Belgium due to the necessary wild
fermentation),

the first reasons that come to mind are:

- o lambics are made using wild yeasts and bacterias that
will most likely cause endless problems with 'regular'
batches
- o lambics must be aged for considerably long periods of time
resulting in high cost and low throughput
- o most pub-goers are content to drink whatever piss flows out
of the tap as it is (though there are some very good pubs
there are a few in my geographic area that amaze me as far as their
ability to stay in business for so long with such sh*t products)
so why waste time & money on an expensive and difficult style
when you can cut corners, and make sh*t and money at the same
time? (no, I'm not naming names, but I bet some can guess)
- o nobody really knows how to make a lambic outside of Brussels.
everything done by the readership of the lambic digest is just
experimentation and has hardly scratched the surface of the
knowledge necessary to brew such a beer commercially with
any guarantee of success and repeatability.
- o lambics require (traditionally) cooperage & thats not cheap
- o lots of other issues I'll just let pass so this isn't a whole
digest in itself.

> 2) I've read before that the various yeasts and bacteria needed for
lambic

> beers are available in the US, but where is a good commercial source
(or

> free source) of these microorganisms?

Cultures are easiest to find by special order from G.W.Kent through your local retailer. You must be patient when ordering, there are occasionally cycles [like now] when the cultures are backordered.

> 3) Has anyone tried making a homebrewed lambic in small batches. If you
> have I would really like to talk to you about the process, as Kriek Lambic is
> my favorite beer and I would like to duplicate the sour bite found only in
> lambic beers.

See the comment on the lambic digest above, "Lambic" by J-X Guinard (Classic Beer Styles #3), and the paper Martin Lodahl & I wrote for Beer+Brewing for the Milwaukee Conference (sorry, don't remember the volume #).

> 4) Are there any good publications about microbreweries? Particularly I'm
> interested in getting some start up information for an Entrepreneurial
> Business class at school.

>
> 5) Finally, in this long list of questions, does anyone have the number for
> the Celis brewery in Texas that makes Belgian style beers?
These two have me confused... Are you trying to open a lambic pub/micro brewery?

If so we should talk off line 'cause you need a reality check with respect to markets and how quickly you'll be out of business. (yes, I know that sounds harsh, but better to hear it now than find out later)

If you're really just confused about lambics vs. Belgian Wits (Celis) than you should get onto the lambic mailing list because we're having a discussion about Belgian Wits right now.

--Mike (your friendly lambic digest coordinator/founder)

>How many IBU's can/should dry hops introduce?

I read that your batch mellowed (lost bitterness) in 8 days. My batch did not. I dry hopped a batch of pale ale with Hallertau hops (actually I added the hops immediately at the end of the boil after turning off the fire). The result is the first batch of beer in 15 years of brewing that is so bad that I am actually pouring it down the drain. (I should save the drain and pour it directly into the sewer.) It is severely bitter and, frankly, the aroma is not all that great. The hops were allowed to remain in the wort for 7 days.

Don't overlook the Cat's Meow recipes, especially the one that I have copied below. I substituted 1 oz of Hallertau Hops for the extra hops in the recipe; also I added an ADDITIONAL 1 teaspoon of GROUND Cinnamon, and I used only 3 cloves in all. This recipe turned out to be superb! I made it 4 weeks ago for Thanksgiving, and it is half gone already. Note that it makes only 4-5 six-packs of ale.

From: djt2@po.cwru.edu (Dennis J. Templeton)
Subject: Dry Ice cooling NOT!

Someone asked about using dry ice for cooling their wort.

Since dry ice liberates humungous amounts of gas you had better be prepared for a huge overflow of sticky bubbling (and still hot) wort, like a krausen from hell.

I have tried this for other purposes and it was **definitely** not worth the trouble. Note that those of you who put dry ice in your college punch had a more controlled reaction since the punch was not boiling hot.

Try a cooling coil.

From: Montgomery_John@lanmail.ncsc.navy.mil
Subject: India Pale Ale request

This question is directed in particular to kindred brewers in the beautiful Pacific Northwest.

I recently spent an extended amount of time in the Seattle area - particularly Silverdale/Poulsbo. While there, my buddy and I ran across a little place that harbored some 30 microbrewed beers on their tap wall. Now, coming from a "microbrew" wasteland (panhandle Fl) I was awestruck (but that's another soapbox).

This place had an India Pale Ale on tap at the time that I was quite impressed with. I think the brewer was Deschutes(sp?). Is anyone familiar with this beer and, if so, do you have any all-grain recipes that attempt to clone this fine brew? I would love to produce some of that Pac.N.W. finery here in the Southeast.

Thanks a million,

From: wood@ranger.rtsg.mot.com (Dan Wood)
Subject: Removing Foil Labels, Bottle Filling

I'm setting up a homebrewing "kit" for a friend for Christmas, including two cases of M*ller longnecks in the waxed cardboard cases. I'd like to minimize the time/effort in removing the foil labels. In the past I've tried a variety of solvents, boiling water, wire brush, razor blade, etc. but never found a combination that worked well. Anyone have any tricks for this? Please don't suggest other bottle types, I already have the empties, and I'm a big fan of clear bottles.

I used the spring type bottle filler for many batches until I tried a simple hose clamp. I bought one of the 69 cent white plastic clamps, the kind with the ratcheting latch. I bent the teeth of the latch out of the way, and simply use hand pressure to shutoff the flow between bottles. It is faster, cleaner (no foaming), and probably minimizes aeration. Try it, you'll like it.

PS: Anyone tried making a grape mead? I've had good luck with cherry and cranberry juice, but I'm leery of making alcoholic grape koolaid. I've got a gallon of concentrated juice from homegrown grapes (big and blue, concord maybe?) that I figure would flavor about 4 gallons of mead. However, the wife would kill me if the mead didn't turn out: she wants to waste it on jam. Any thoughts or experiences are appreciated.

Worry if you must, but by all means, have a homebrew!

Subject: Hop substitutions

Domenick asks about hop substitutions:

>I'm still trying to perfect that Fuller's clone and I am looking for a
good
>substitution for British Northdown hops. I've used Cluster in the past
>but I'm underwhelmed by the flavor contribution of Cluster.
>
>How about Styrian Goldings, or Pride of Ringwood? Both of which are
>available locally (Seattle). Kent Goldings? Fuggles/Willamette?
>
>How about substitutions for Challenger and Target too?
>
>Since I have never encountered Northdown, Challenger, or Target I'm
>working in the dark on substitutions. Can anyone recommend a good book
>on hop characteristics. Gardening info is wasted pages.

Domenick, I've been working on the hops faq and I'm starting to come to
the
conclusion that there are no hop substitutions. There are many hops
grown to
be genetically similar (Hallertau Mittelfruh being the most copied), and
some
of the "copies" are good, and some are bad. I suppose these copies can
be
called substitutes, but its a personal choice. There is also very little
(read
"zero") literature describing flavor profiles of hops. Unfortunately, we
are
all working in the dark until we taste/smell the actual hops, which is
why I'm
looking for commercial examples of each hop for the faq (its a tough job
but
someone has to do it; I'm hoping this weekends GABF will help!). BTW,
many of
the hops you mention are fairly rare in the US (Northdown, POR) so even
less
information is available on them. So, the news is bad, but I'll wish you
good
luck in your search. Keep us informed.

Cheers,
Norm

From: "Dennis Lewis" <DLEWIS%jscdh6@jesnic.jsc.nasa.gov>
Subject: Mashing out

Thanks, chris and Dom for the refreshing look at what's really necessary. For those of you who require the opinion of published brewing experts, Terry Foster Pale Ales says that a mash out is unnecessary for most ales. Great news for the mash/lauter tun crowd. He says the only reasons you need to do a mashout is for a high viscosity wort or for a mash that has been decocted and some of the filtering properties fo the husks is diminished. The higher "mash-out" temps will get the sweet liquor to flow better thru a less than ideal grain bed.

As far as I recall, there was no mention of denaturing enzymes, completing reactions, etc. I'm going to try it today with my new mash/lauter.

>in such a slowing of fermentation. Before I could ferment for 1 week to 9 days
>and have clear beer to bottle....but that was before this yeast and temp change
>and recipe.

This is the first time I used this yeast. My OG is about 55. The main thing I noticed about this strain is its creaminess. With other yeasts, I usually had a lot of bubbles, that died down relatively quickly. With this yeast the krausen was dense, creamy, and still there when I racked to the carboy. The head built up somewhat in the carboy, but is now dying down.

Time in primary: 4 days
Time in carboy: 5 days so far

I'm fermenting at about 68F, and I'd say that the fermentation is going more slowly than I typically see.

BTW, my supplier now only carries Yeast Lab liquid yeasts. Is the American Ale yeast the same as the Wyeast??

Subject: IMPERIAL STOUT

Bitterness in stout comes from two sources: the hops, and the dark grains. There are a number of things you can do to reduce it:

1. Cut down the hopping rate. (Most likely cause of overbitterness.)
2. Use less dark malt.
3. Don't heat your dark grains to boiling (and DON'T boil them), just steep them for 30 minutes in 160F water, then strain the liquid into your boiling pot.

You can also add unfermentable sugars, which will make the beer sweeter and reduce its apparent bitterness by:

1. Add more crystal malt. Again, steep it in a sufficient quantity of 160F water (2 quarts water/lb of grain).
2. Add lactose. I've never done this, so I can't recommend amounts.

That all said, Imperial Stout is a fairly bitter style. I think a typical one will come in at about 50-80IBUs. It's also very sweet. Try Samuel Smith's for a classic example.

Subject: Is Mashing out necessary

Stellar responses from Chris Campenelli re: mashing out and is it necessary. By golly I don't do it either! For that matter I don't even adjust my hydrometer readings for temperature variances. I can't imagine the havoc being played with thoses OG's being off by a point or 2. Come to think of it, I don't always use a secondary fermentation. Nor will I bow to the ever gracious concept that one must recirculate for clear wort. Won't decoct, protein rest, or upward step infuse, either. Use a Corona not a roller mill and add an extra handful of grain to make up for the lost extraction. Sparge by dumping the water on the grain bed, not sprinkled with delicate droplets, each 0.25ML in size. X:-O

I get 33 Points extraction, consistantly, from Domestic 2 row, and my beer is consistantly very good based on the lineup consistantly at the door!

Then again, if you enjoy doing all these things, brew away!!!

>oxidized aroma. I'm trying to figure out where this oxidation came from.

<procedure deleted, looked fine to me>

>Our bottle filler is one of those clear plastic tubes with the spring
loaded
>white thingy on the end (another version of the clear tube with the
spring
>loaded orange thingy on the end, I guess). This thing does cause the
beer to
>foam a little on it's way into the bottle.

1. Is my bottle filler the culprit in my oxidation problems? If so, is there something better out there?

This could be the problem, you could try raising up the bottle to just below the level of the beer in the priming tank so your siphon runs slower until the tip of the filler is covered in beer. That's what I do.

2. Has anyone out there ever used those oxygen absorbing bottle caps?

Yes, but I've only noticed them increasing the life of my hop nose and increasing the general shelf-live of the beer.

3. Is it possible that some extract manufacturers have HSA problems in the manufacture of the extracts?

Yes, but it could also be the age of the extract and the storage temperature.

I know that extract syrup tends to darken as it ages and I'll bet that this is partly caused by oxidation.

>might be). In an ideal world, the physical characteristics would
actually be
>measured at the competition site, but I guess its hard to borrow an HPLC
from
>the lab for the weekend 8-)

I have never been involved in a competition (nor would I ever tolerate
one)
in which beers were excluded from judging. This just doesn't happen. As
far as I know, there are only two reasons for recipe forms:

1. publication of winning recipes, as in the case of the AHA Nationals,
and
2. to try to prevent ringers, i.e. if an entry appears to have been a
re-packaged commercial beer, the competition organizers could check to
see
if perhaps the recipe proves that the beer should be disqualified -- an
expert
brewer can tell if a recipe and a beer really could match or not. This
is
not an easy task and I've yet to see anyone attempt it at a competition.

Chris writes:

>conversion actually takes place while you sparge? Is it
>noticeable? And if this additional conversion IS noticeable then
>wouldn't you welcome the extra extract? Consistent results? Huh?
>Just how does mashing-out produce consistent results.

There, now that Chris and Dom's vapors have dissipated, we can get
on with the mash at hand. Chris mentioned one of the benefits
of mashout (the debated one), but failed to mention the one on which
most of us agree, namely mashing out raises the temperature of the
mash much quicker than simply pouring sparge water and therefore
more quickly decreases the viscosity of the runnings. Runnier runnings
mean faster sparging (without a loss of extract efficiency), less chance
of a set mash (stuck runoff) and more efficient extraction of sugars.
Remember, warm honey pours easier than cold honey.

Jack writes:

It is my contention that the bogyman is in the mash/lauter tun and not
the
grain mill. Fortunately, I also sell the mash/lauter tun that makes all
this
possible.

I think you mean boogyman, but in any event, I must agree that the crush
and the lautering system are interrelated. If you have a very fine
lautering
screen (like the [Eelasy[Mmlasher]), a finer grist is better, whereas if
you

have a coarse lautering screen (like the Zapap) you need something more like the "textbook" crush. The "textbook" crush (which has been posted here before) has a wide distribution of particle sizes. Actually, I feel that only the husk pieces need to be of various size, that the starch particles of the grain can be of a consistent (and small) size. Remember that with a fine lautering screen, you don't really need to rely on the husks to create your filter bed. With a coarse lautering screen, the filter bed must first be established (before which you would be recirculating your runnings). The establishment of the filter bed is basically the setting up of a network of husk particles where the large ones (the ones that do not fit through the lautering screen) are at the bottom, and on top of this lattice of large husks you trap the smaller husks.

So why then not use a very small screen and crush the dickens out of the malt? There's one piece of information that is missing, namely that Jack uses a very thin mash. This is important because a stiff (thick) mash would just sit there and not make it through the lautering screen. You can carry porridge in a sieve, right?

So why not just use a thin mash all the time? Well, this is up for debate. In some cases, it's not possible due to equipment constraints (high-gravity beers, etc.). I've read (in Noonan, I believe) that a stiffer mash favors Beta over Alpha Amylase (could someone check this - I might have it backwards).

Finally, a fine lautering screen would increase the importance of breaking down the really gummy components of some mashes (like all the beta-glucans in an Oatmeal Stout, for example). If you don't do the protein rest correctly, you can try to make a really thin oatmeal-containing mash, but still have a glob of barley-flavored oatmeal with some amber water on top, that will sit in your lauter tun till it turns to cement.

Mike writes:

> o nobody really knows how to make a lambic outside of Brussels.

Woah Mike, surely you mean outside the Zenne Valley! Frank Boon brews some very traditional lambieks in the town of Lembeek.

Subject: Fermentables/volume, what is reasonable?

Can anyone give me some advice concerning brewing from high gravity worts.
I prefer like to brew full bodied brew and have been brewing extract/
small scale mash beer. If I were to brew using 8 lbs of Light Syrup and a mash of 3 lbs of Pale Malt, 1/2 lb of Dextrine Malt, 1 lb of Amber Crystal Malt and 1 lb of Dark Crystal Malt, fermented with Wyeast's Chico/California Ale Yeast for 5 gallons would I run into problems with off-flavors from too much fermentable sugar or "other problems".

What are the some good parameters for brewing 5 gallon batches in terms of the amount of fermentables for use with Ale yeasts?

Please reply by e-mail to me directly or via HBD. THANKS

Subject: STRAINING YOUR BREW

I have one of those handy brew kits you get for Christmas with the 6 gal. carboy. I realized after my 1st batch that I was getting a lot of haze in my beer so I thought I might strain it prior to bottling. What I came up with has

been REALLY NICE! I used one of those reusable GOLD plated coffee filters (you can get them at any fancy coffee shop). I setup my 2nd carboy underneath the 1st and placed the filter inside of a funnel (perfect fit) and drained off the beer from the top, up to the last inch of trub. The filter is coarse enough that the beer gets through but fine enough that it catches all the crud that's still floating about. Since I've gone to this, I have truly had nothing but crystal clear beer!

>Subject: AHA Styles and Reality

>Part of my reason for asking is that I might like to enter competitions myself, and I may also be interested in the AHA BJCP. But observations like this make me wonder whether it would be worthwhile.

Your comments provide the incentive to post my observations on the same subject. Last weekend, my wife and I had the pleasure of serving as apprentice judges in a local competition. I went with an attitude inclined toward becoming a qualified judge and wanted to learn what it was all about. We came home totally convinced that it is not our cup of tea for two reasons.

First of all, it demands a great deal of time, is a lot of work, most of which is very boring and unenlightening. We did however, gain a very healthy sense of gratitude for those dedicated individuals who are far less selfish of their time and make competitions possible.

The real objection however, is based on the program and not the people or the results of the judging.

It is preposterous to think that one can become a qualified judge of the very large number of official styles, with the time and qualifications required by the current program. It is designed to create Jacks of all Trades and Masters of none.

The only way one should be qualified to act as a judge of other people's beers is if he or she is truly an expert in the style. The only way one can become an expert in a style is to live with it for a significant period of time. Brew it, taste a wide range of commercial and homebrew versions and essentially do nothing else for months. At that point, the candidate should be evaluated by another qualified expert in that style and this should include the ability to identify a recognized sample of that style in a blind tasting of mixed/similar styles. Only then should that person be certified to judge that style and only that style.

This may sound like a lot of trouble and hassle but I humbly suggest that it would be much more personally satisfying. I would far rather be recognized as an expert in a style than have the dubious honor of being a certified

judge. I suspect many judges have done what I suggested but one never knows who they are because they are all treated equally.

It may also create problems with judging styles for which no qualified judge happens to be present but the fallback position would be noting that point on the score sheet.

Like I said earlier, it's not the people or the results that bother me. Our light lager came in 2nd place and 4th best of show. The problem is I don't know what it means. Last year we came in first, in the same category with a much inferior beer.

I agree that the reasons you quoted are not very rational reasons for doing a mashout but there is one reason that I think is a good one. By raising the whole mash 20 degrees or so, you stand a far better chance of keeping it in the optimum range during the lautering process.

It's easy enough to do for those who kettle mash but it is probably not worth the trouble for the bucket infusers.

I of course would welcome acceptance into the esteemed BOQAT, but really, I feel the nomination is honor enough. And I would like to state here, while

I have your attention and the pulpit, that although I have worked hard though the years questioning what little authority I did not ignore, I am at heart just a little person, a regular guy, who has no wish to become a cultural icon and no wish to find the Emperor and/or his/her minions on my

doorstep late some rainy night in Seattle. Also, my father is "Mr." Domenick Venezia, I'm just Domenick, Dom, Demonick, or Wop-man.

> Go ahead and throw stones. Me and Dom think the Emperor's new
> clothes suck. We're standing-up and farting in the general
> direction of homebrewing dogma. Well, at least I am. Dom?

In all modesty I must admit to being an accomplished stone thrower myself, and in my time have let rip with a world-class fart or two, though not in mixed company, and certainly, as far as I could control it, not in anyone's general direction, and never, never, never into the wind. My fashion sense, much to my parent's chagrin, leans toward the jeans and a tee-shirt look (kinda Joe Coolish B-), so I wouldn't feign to comment on the Emperor's new clothes except to say that s/he seems to like them and a lot of people follow her/his lead. Really, I just want to brew a Fuller's ESB clone, the easiest way possible and if that means no mash out, then by god, that's what I'll do. Or rather not do. Mash out I mean. Not do one.

And a heartfelt thanks to Chris Campanelli (Happy Columbus Day, Paisano) for the nomination, and without whom none of this would have been possible.

And finally, while looking up "feign" I came across -- well, anyone have a recipe for farkleberry beer?

Should I apologize about the bandwidth?

Subject: smash the mash balderdash

Hoorah for Domenick Venezia and Chris Campanelli (is this an Italian thing?)!!

I agree the Emperor's butt is showing; we have accessible now such nice grains

that anyone can go to Kmart, buy themselves a cooler (mein GOTT!) and mash.

And they can omit about 24 of the 28 steps proposed by the Emperor's. The point to get across to extract brewers is that it's really pretty easy; sure

it's magical (rather than scientific, which it ain't), but that don't make it difficult.

Subject: Science and Hops Utilization 1/2

I realize this is a lot of post, but its only 1 day. Can't be that much of a problem.

Use of Design-of-Experiments Techniques to Determine Controlling Factors Affecting Hops Utilization and Resulting Charactor.

- - - - -

Fellow Brewing Scientists:

The recent discussions concerning which factors are most significant to the final Hop Charactor of the beer and how they can be manipulated by the homebrewer has brought to mind a company sponsered class I took recently, "Design of Experiments" (DOE). The methods taught in this class are used by industry and researchers to better define a process, by isolating and ranking the controlling factors that make up the process. These methods can also identify significant interactions between factors, such as Time and Temperature acceleration. The beauty of using DOE is that it allows significance and relationships of process factors to be determined with far fewer experiments than standard experimentation and scientific method. For example, let's say a process was made up of 4 variables and 2 values of each variable were to be tested. This would require 2 to-the 4th power or 16 experiments to examine each possibility. Using DOE, as many as 7 variables at two values could be examined simultaneously with only 8 experiments! Statistics allows the significance and relationships of the variables to be determined.

What I propose to do here is list the methods and tables necessary to perform 3 sets of DOE:

1. Determine factors for Alpha Acid Utilization during the Boil.
2. Determine factors that affect Alpha Acids during Fermentation.
3. Determine factors for Hop Oil Utilization during Dry Hopping in the Secondary.

The data measured from these experiments would be the parts per million (ppm) of the Alpha Acids or Hop Oils as determined by Liquid/Gas Chromatography. Since this equipment is not readily available, this work would need to be carried out at a University with the participation of an enthusiastic Homebrew club. Perhaps Michael Lewis' class(es) at UC Davis would be interested.

DOE #1 - Utilization Factors During the Boil

- - - - -

Factors to be evaluated:

- A. Wort Gravity
- B. Wort Volume
- C. Time of Boil
- D. Wort pH
- E. % Alpha Acids of Hop
- F. Amount of Hop
- G. Interaction of Wort Gravity to Wort Volume

Two values would be tested for each of these factors. The test table will look like this (below) where Experiment Number is on the left, and Factors are across the top. The plus 1, minus 1 indicate which value (high or low) for that factor will be used in that test. The table is rigid, interchange anything and it will throw the statistical analysis off. The Factor Columns are identified by the letters given to the Factors listed above.

	A	B	G	C	E	F	D
1)	-1	-1	1	-1	1	1	-1
2)	-1	-1	1	1	-1	-1	1
3)	-1	1	-1	-1	1	-1	1
4)	-1	1	-1	1	-1	1	-1
5)	1	-1	-1	-1	-1	1	1
6)	1	-1	-1	1	1	-1	-1
7)	1	1	1	-1	-1	-1	-1
8)	1	1	1	1	1	1	1

Part I- Process Mean

Each test batch will be concocted by using a high or low level of the factor as the table dictates. Once the data (Alpha Acid ppm) is collected for each test, the data is averaged in the following manner:

1. Each Test that used the (low) value of Factor (A) would be averaged together to yield (Aavg(-1)). In this case, the data for Tests 1-4 would be used. Likewise, each Test that used the (high) value of factor (A) would be averaged to yield (Aavg(+1)). This would be tests 5-8. The other Factors would be averaged the same way. Ex. (Cavg(+1)) would be tests 2, 4, 6 and 8.
2. If two (or more) samples are tested from each batch, all of that data would be accounted for in the average. Ex. If three samples are analyzed from each Test Run (batch), then those values for Test run (7) would be averaged, i.e. $((7a + 7b + 7c) / 3)$ and that average would be used to determine the overall average for that factor(value), as described in Step 1.
3. Also, determine the Total data average for all the test runs. EVERYTHINGavg This will be used in the prediction equation later.
4. Next, for each factor, determine the DELTA between the averages of the High value and the Low value. Ex. $(Aavg(+1)) - (Aavg(-1)) = \Delta$. Include the negative sign if High minus Low gives a negative number. Calculate deltas for the other Factors, also. This info would be used later in the Prediction Equation in Part III.
5. OPTIONAL STEP: Divide those deltas by two. This permits easier analysis if the numbers are large, that's all. It doesn't change the analysis results and may not be necessary depending on your numbers.

Example:

run	ABCM1M2Mavg
1	-1 -11203025
21	-1 -19 1110
3	-11 -1262425
411115	510
Mavg(+)	10 17.5 17.5
Mavg(-)	25 17.5 17.5
Delta	1500
Delta/2	7.5 00

6. Next, the Averages for each Factor(value) will be plotted as below. This allows the analyst to determine relative significance. I will plot a generic example, since we don't have any real numbers and the last example doesn't use enough factors. I WILL use this plot later to illustrate the analysis.

```

100 !#Plot 1#
    !
    !*
    ! /
    !   * *
50  !/
    ! * /
    ! / *---*/(first rate
    ! * / plot, eh?)
    ! *
0   !
    A-  A+  B-  B+  C-  C+  D-  D+  etc...

```

What this tells the analyst is that the data average moved positively for an increase to Factor A; negatively for Factor B; unchanged for Factor C; and very positively for Factor D. Factor C would seem to be insignificant to the process.

 Subject: Science and Hops Utilization 2/2

Use of Design-of-Experiments Techniques to Determine
 Controlling Factors Affecting Hops Utilization and Resulting
 Character.

 Part II- Process Variability.

The next part of the analysis determines the Factors influence
 on Variability. The plot above, of course, looks at influence
 on Mean.

To perform the variability analysis, several trials of each
 experiment run would need to be performed, the data averaged,
 and a standard deviation for those trials of that run
 calculated. In this project, the extra data could be obtained
 by measuring several samples of the same batch of wort, or by
 preparing a few batches of each test run and testing each. The
 latter would be more statistically significant.

Here is an example data table for 3 factors tested at two
 values. M# refers to Measurement result. S is standard
 deviation of M1 and M2 of that run. Remember, the plus 1, minus
 1 only indicates whether a high or low value for that factor
 was tested.

run	A	B	C	M1	M2	Mavg	S
1	-1	-1	1	20	30	25	7.071
21	-1	-1	9	11	10	1.414	
3	-1	1	-1	26	24	25	1.414
41	1	1	15	5	10	7.071	

1. For each factor, the natural log of the standard deviation
 will be used in the following equation. A value will be
 calculated for each Factor(value) by using each run where that
 Factor(value) was used.

$$2. \text{Avg ln}(S A(+1)) = [\ln(S \text{ run}2) + \ln(S \text{ run}4)] / 2$$

$$= [\ln(1.414) + \ln(7.071)] / 2 = 1.15$$

$$\text{Avg ln}(S A(-1)) = [\ln(S \text{ run}1) + \ln(S \text{ run}3)] / 2$$

$$= [\ln(7.071) + \ln(1.414)] / 2 = 1.15$$

(the simplicity and symmetry of the numbers of this example make this
 confusing, but bear with me)

3. Do this calculation for the other Factor(values) and
 generate the following table: where Avg Delta = Avg ln(S A(+1))
 - Avg ln(S A(-1))

A	B	C
Avg (+)	1.15	1.15
Avg (-)	1.15	1.15
Avg Delta	0	0.6

4. These results tell the analyst that Factors A and B have no
 effect on process variability, but that Factor C does have a
 significant effect. In other cases, Avg Delta for A and B may
 have been small- 0.2 and 0.6, let's say. Factor C would still
 be dominant at 1.6, but Factor B may also be significant to the
 process variability at 0.6.

5. IMPORTANT: If a factor's Mean analysis shows no significance

(as in Factor C of Plot 1, a horizontal line) or small significance, it still may have High significance to process variability. Therefore, when optimizing the process, the value of that factor which gave the least variability should be used. In the case of the table above, (for Factor C) the Avg(-) value should be used, as it is the smaller number (smaller deviation) of the two for that factor. Thus Factor C should be utilized at the lower value in the process.

Part III - Prediction Equation.

The prediction equation allows you to predict the response of the process from a given combination of factors and values. Only the factors that have been shown to be significant (either process Mean or Variability) are used. Values for the Factors can be chosen to either Minimize, Maximize or Target the response of the process.

Let's say we want to Maximize the response, get the best utilization from the boil. Going back to Part I, chose the values of the factors that gave the highest data average. In this case: A+, B-, D+, etc. Furthermore, let's assume that after doing the analysis per Part II, that Factor C (of the example in Part I) was shown to be significant to process variability and that value for least variability was C+. This would also be used in the following Prediction Equation. (use the hypothetical Mean values of Plot 1: A+ = 40, B+ = 60, C+ = 32, D+ = 60; A- = 20, B- = 80, C- = 29, D- = 10) (Also note that for math example neatness, Factor C (line) is no longer horizontal, but slightly positive.)

$$\begin{aligned}
 & \text{Aavg}(+) - \text{Aavg}(-) \\
 \text{Best} = & \text{EVERYTHINGavg} + \frac{\text{Aavg}(+) - \text{Aavg}(-)}{2} [\text{A+/-}] + \\
 & \frac{\text{Aavg}(+) - \text{Aavg}(-)}{22} [\text{B+/-}] + \frac{\text{Aavg}(+) - \text{Aavg}(-)}{22} [\text{C+/-}] + \\
 & \frac{\text{Aavg}(+) - \text{Aavg}(-)}{2} [\text{D+/-}] = 41.25 + \frac{40 - 20}{2} [1] + \frac{60 - 80}{2} [-1] \\
 & + \frac{32 - 29}{22} [1] + \frac{60 - 10}{22} [1] = \\
 = & 41.25 + 10[1] + (-10)[-1] + 1.5[1] + 25[1] = 87.75 \quad *DONE*
 \end{aligned}$$

FINAL NOTE:

Design of Experiments is rather complicated. What I have presented here is a basic use of the system. In the interest of bandwidth, I will not present the other two experiments for Primary and Secondary Fermentations. What would be done after all three phases of investigation were completed; each phase of Utilization- Boil, Primary and Secondary, would be compared to determine greatest significance to overall hop character. Indeed, another DOE could be run at that point to determine that relationship. If any Homebrew Clubs are up to the challenge, you can contact me by email for the rest of the info. Furthermore, I will enlist the help of the guy that actually taught the class, so that all your questions about applying DOE to this much debated problem can be better answered and investigated. Thank you for your patience, John

Subject: calculating beer color

In a recent hbd, Tom Leith made a number of points on brewing to style. I want to comment on one aspect of his comments, namely, calculating the color of beer. To wit: the linear math that we use to calculate the "expected" color of beer is wrong. This point is made by George Fix in George and Laurie Fix's "Vienna" book.

As an example, Fix points out that Bass Ale is 10 Lovibond and Michelob Dark is 17 Lovibond. Thus, these two beers serve as benchmarks for evaluating the color range from amber to dark copper, say.

Suppose we look at a Vienna grain bill for a 5-gallon batch and its expected color:

9 pounds pilsner malt (1.78 L)	3.29
6 ounces crystal 10L	0.75
6 ounces crystal 60L	4.5
6 ounces crystal 120L	9

Total = 17.54L as the expected color. Now, as a matter of fact, the above grain bill will produce a beer close to Bass Ale in color. The linear color math is wrong, and overstates the expected color of the beer.

For light beers, linear color math is a useful approximation; for dark beers, it's more or less irrelevant; and for amber beers, it's wrong enough to matter.

As for the grain bill of brown ales, surely crystal malt should be featured for its color and flavor contributions. Some chocolate malt, up to a level of a few ounces, would probably be okay.

Subject: Kegging systems

For anyone who might be interested, I recently put together a kegging system for a very reasonable amount. First I orders three soda kegs from DeFalco's in Texas for 35.00 plus shipping. I believe they sell both pin and ball locks. You can also buy them individually for 15.00 each. I also ordered a set of O-rings for each keg. Then, I called up BCI Industries and ordered a used, steel, co2 cylinder for 35.00 plus shipping. I sorta know this guy who cleaned beer taps at a local bar I frequent and he was kind enough to give me a ton of assorted clamps, fittings, bar faucet, sankey tap and a cleaning brush. He also gave me some 5/16 gas tubing and 3/16 product line with it. In that box was also some special tools to crush the clamps and a special wrench to tighten fittings on the bar tap. All this and two 8 gallon wine kegs for 30 bucks... not bad. I bought a picnic faucet at the local brewstore for about 5 bucks and wala... now I have a kegging system. In the process, I also aquired two SS half barrels. The half barrels, I know what I can do with :-) but anyone know what I could use the 8 gallon SS wine kegs for??? Be NICE !!!! They have a single sanke fitting on top just like the half barrels do.

Below are the names and numbers of those who helped me:

DeFalco's Of Houston
713-523-8154 (Conrad)

BCI
1-800-284-9410 (Chuck)

Both numbers as well as others I called were gleened off the HBD, many thanks to those who posted them. I have no affiliation with either of these companys other than being a satisfied customer. After kegging and force carbonating two brews - believe you me -- I'm satisfied. Bottling is a drag!! Does anyone know where to get a good counter pressure bottle filler??? :-)

good luck!

Subject: Re:Rager Number Error

In response to Mark Garetz on Rager's Number Error;

In looking at the conversion between metric and english units, there does appear to be an error with the conversion factor of 7462. To my best calculation, this factor should be 7490. In reality, the difference between these numbers means nothing in any practical sense to the homebrewer, as they are so slight. The error probably occurred in the rounding of either Grams to OZ or liters to gallons.

Subject: beer soup

Awhile back, someone was asking about cardamom, so when I saw this recipe in the "Old Depot Mail Car" (the newsletter of the Old Depot pub/restaurant & Dallas County Brewing Company in Adel, Iowa), I couldn't resist posting it.

SWEDISH BEER SOUP

12 oz Old Depot Ale
2 qts. milk
1/2 cup flour
1/2 cup molasses
1/4 tsp ginger
10-12 whole cardamom seeds

Rinse kettle in cold water to prevent milk from scorching. Pour 6 cups of milk into kettle and bring to a boil, stirring frequently. Blend the rest of the milk with the flour to make a smooth, thin paste - add to the boiling milk stirring briskly to avoid lumps. Reduce heat and let the soup simmer ten minutes. In another pan, bring the Ale, molasses and condiments to a boil. Combine the two mixtures while beating vigorously with an eggbeater. Taste for additional sweetness [but it doesn't say what to do about this].
Serve frothing in soup plates with gingersnaps as a complement. Serves eight.

Note: This is a pungent, sweet soup which is served in Sweden as a dessert. According to old-country custom, it is frequently the Good Friday dessert. It is one of those dishes you either like very much or not at all. The woody covering of cardamom seeds have a peculiarly pleasing aroma in this combination.

* * * * *

For the record, the Old Depot Ale is light in color and fairly bland (i.e., it's purportedly dry-hopped, but it must be at an extremely low rate as it's not even noticeable, especially by left-coast standards, and it's not very estery either... to my admittedly undereducated palate it could pass for a well-made but not very interesting lager -- now the Old Depot Porter, on the other hand, is quite flavorful, by I don't imagine it would be very good in this soup).

Another note on cardamom is that there is some lore floating around that

holds cardamom to be one of the "secret" ingredients in Anchor Christmas Ale, although since it's a different recipe every year, I don't know how reliable that rumor may be. Personally, I would try it in beer but haven't yet.

Subject: underpitching

The recent thread on pitching rates is of interest to me. I have been plagued for the last few batches not so much by long lag times, but by awfully "gentle" (i.e., not anything remotely deserving the description "explosive") and sometimes rather l o n g fermentations, often with slightly high terminal gravities (mid-teens on O.G.'s in the low 40's).

Could this be a function of underpitching? It has occurred to me that it could be under-aerating as well, or perhaps both.

For better aeration, I plan to make a "carburetor" out of a plastic tube as has been described here many times. I have thought I might also try boosting my starters a little more. This would make some sense for me as I have lately taken to splitting my Wyeast package into several bottled cultures which are held in the fridge until I re-start them with fresh wort prior to pitching.

My typical procedure is to boil up one cup of D.M.E. in a solution which, after some evaporation, turns out around 750-800 ml. Should I use more D.M.E. in the first place? Or should I step-up the first starter into a second? If I do that, do I make a stronger solution the second time (as in more extract per volume of water)? I'd love to hear from anyone who wishes to share their experience and expertise on this subject as a fellow-chronically-underpitching-homebrewer.

Subject: Mash out

I would be very curious to see Chris Campanelli attempt to brew, let's say, a wheat beer with 70%+ wheat malt without a mash out (was his post tongue in cheek or not?). I know from experience attempting to sparge after forgetting to mashout, or attempting to remove a lauter decoction through a false bottom, that any mash with a significant protein content will cause a stuck sparge without a mash out. The point of a mash out is to denature all proteins, not just enzymes. The viscosity really decreases as well, and I suspect that extract efficiency improves due to the greater solubility at higher temperatures.

I am sure that it may be possible to sparge a 100% barley malt mash without a mashout but I would suspect that the extra time the sparge would take would be greater than the time saved by omitting the mash-out, and perhaps efficiency would be less.

Subject: Hop Utilization

Mark Garetz writes (in HBD #1240):

| To summarize, then, it appears that low boil volume (regardless
| of the SG) gives less utilization, but *boil* gravity has no effect.

Al Korzonas replies (in HBD #1241):

| WRONG! PERIOD!

| I have a two brewing logbooks (with my respective tasting notes) and a
file
| folder full of BJCP judges' comments that contradict Mark's contention.

Mark Garetz replies (in HBD #1242):

| Finally, I'll deal with Al's comments off-line.

Please, don't take it off-line! I am very interested in getting to the truth on the subject of bitterness utilization. There are a few contradictions between Mark's research and other brewers' experience, not to mention "conventional wisdom". I don't know who to beleive.

Rager's article is clearly in question. Does anyone know where he got his utilization numbers? Where did all those formulae dome from?

Back in June, Glenn Tinseth reported that he was working on a research project to settle some of these issues scientifically. He was doing experiments in a reputable Oregon hop lab. Whatever came of that? Is Glenn still around?

Please, let's get to the bottom of this.

Subject: hopfest '94

This is an item that is mostly a concern to central New Yorkers but here it is anyway:

The Madison County Historical Society is planning a Hopfest for 1994.

There will a planning meeting on:
Thursday Oct. 14, 1993 at 7:00 PM ET at:
Madison County Historical Society
Cottage Lawn
435 Main St.
Oneida, NY 13421
Phone Barb Evans at 315-363-4136, Tues-Fri 1:00-5:00 pm for further details.

Oneida and Madison Counties (Central New York state) were once a major hop growing region. There is some question as to the hop varieties that were grown here. The Historical Society maintains some hop vines and is harvesting a crop this year. Some of these hops may be available to brew with. There may be a homebrew contest associated with the hopfest (maybe Nov. 1994).

I expect people from all over the country to attend this colossal event so get your plane tickets right away. :-)Thanks.

Subject: funny fermentation

Okay, I am having a problem with my fermentation. I am brewing an Old Ale. I did my primary in a 6 gallon glass carboy. At about 2 days after fermentation started, (it took a little long to start) I racked to my 5 gallon glass secondary. It was chugging along at about 1 bubble every 10 seconds or so. I did not have time to bottle right away so it sat in the secondary 2-3 weeks. Last night, when I decide to bottle, I opened up my closet and POW! it was fermenting again at a pretty rigorous level. I had to replace the airlock with a blowoff tube.

So my question is: Is this somewhat common? It sounds like it could be an infection to me, but I am not sure. There are no off aromas pouring out. At this point, I guess I can only let it continue to ferment and hopefully it will stop in the next week or so.

Please e-mail me with a reply (if you have one). I am not sure how to proceed.

Thanks

Alex

Subject: Mashout & Algebra

Well, with all the controversy on mash-out and algebra that's been flying around I decided to put in my \$.02. I think we should try to remember that most of us got into home brewing because we wanted a better beer and wanted to have some getting it. I don't use a mash out, I figure it'll be hot real soon anyway. Then again, (as most of my cohorts in BFD will tell you) I'm a tech-no weeny and have an overkill gravity fed, multi-burner, IC controlled re-circ mashing pico-brewery in my garage. I built it from scratch, not because it was required to produce better brew, but because it was fun, for me at least. Beer making has been going on for centuries, without algebra and statistically designed experiments. But if you enjoy making your beer and having fun with numbers or you feel mash-out is the Way, so be it. Just enjoy your art.

From: AGENT COOPER <CENSWM@vaxa.hw.ac.uk>
Subject: Brewing Equipment suppliers (UK)

Hi,

First time on this list, but a BIG question (to me anyway)

I've been making my own beer for a few years in 5 gallon batches, using a burco type boiler etc.

I want to move up in scale a bit and have often wondered about starting my own micro brewery. But where to start? Does anyone know of some good reference material/ books on starting a brewing business (small scale, brew pub etc) Where would I find out about suppliers of hardware etc, I just cant find much info in the home brew magazines I've been looking at, but I may be looking at the wrong ones.

What sort of capacity do the brew pubs in the 'States have like, how many gallons a week etc?

Any general advice welcome.

Stuart

From: drose@husc.harvard.edu
Subject: SLOW counterflow

Greetings:

Well, after 7+ years of cooling my wort in the bathtub, I finally decided to make a wort chiller. I decided on a counterflow design because it is supposed to be more efficient and because I cant imagine it is really as hard to sterilize as some maintain. I had a design for one from one of the zymurgy special issues (all grain brewing?) and it looked straightforward. One question I had was what is the optimal length for the thing? Zymurgy says 20 ft in their article. Dave Miller in his book says it must be at least 40 ft. I looked into prices for copper tubing, etc, and determined that, economies of scale being what they are, it was worth it to build a longer one. I bought 50ft of garden hose (a lot cheaper than tygon tubing), 50 ft of 1/4" copper tubing, and built a 40 ft chiller (10 feet of the hose going to the connecting lines).

Well, I used the contraption a few days later. It certainly did a fine job of cooling the wort, but it is SLOOOOOW. It took about 50 minutes for 5 gallons of wort to pass through this baby! This is not much faster than my bathtub method (although I recognize that each little bit of wort cools down very fast indeed, contributing to a good cold break). All the while the water is running and I am feeling guilty about wasting so much, and besides I hoped that building this thing would save me some time.

One possibility that I am considering is that the thing is a lot longer than it has to be; could i cut it in half and make two chillers, each of which would run considerably faster? Or is this slow speed pretty much the norm for these things? If so I am seriously considering "downgrading" to an immersion chiller.

Another general question that I have is how do people direct the wort into their counterflow chillers. In the past I always imagined that i would just hook it up in series with my hopback, but recent talk about the evils of hot-side aeration have spooked me on this idea. The alternative is to siphon directly from the brew kettle, but this has its own problems (the old mouth-on-the-siphon-hose conundrum, and the problem of hops clogging the chiller (yes, I know about the chore boy solution but

it seems to me that that is going to leave a lot of hard-earned wort in the kettle)). So, what do people do about that?

Any and all information would be appreciated. So far, I am looking back longingly on my inefficient but simple bathtub...

Dave.

From: mferts@taec.com (Mike Fertsch)
Subject: Schmidling Rebuttal (was JUDGING)

arf@genesis.mcs.com (Jack Schmidling) talks about Subject: JUDGING

>Last weekend, my wife and I had the pleasure of serving as apprentice
>judges in a local competition... First of all, it demands a great deal
of
>time, is a lot of work, most of which is very boring and unenlightening.

I find that judging helps me learn a lot about brewing and tasting. I
learn
what makes a good example of a style and what makes a bad example. By
critically evaluating lots of beers (good and bad), I learn how to make
my beer better. I owe a lot of my brewing success on judging at
competitions.
It is neither boring nor unenlightening.

> The only way one should be qualified to act as a judge of other
> people's beers is if he or she is truly an expert in the style. The
> only way one can become an expert in a style is to live with it for a
> significant period of time. Brew it, taste a wide range of commercial
and
> homebrew versions and essentially do nothing else for months.

Ideally, judges ARE experts in the styles they are judging. This is
particularly important in BIG competitions where the judge needs to split
the finer hairs, determining which of several remarkable, in-style beers
match a) the published style descriptions, and/or b) the commercial
beers of particular geographical regions.

In most smaller competitions, most entries are not remarkable
reproductions of the world-class beers. Experts with months of
intensive training are not needed to judge these. Every judge in the
program knows broadly what pilsners are supposed to taste like. If a
sour, amber, flat, fruity beer is served to the judge, he/she can
comment on it without living and drinking in Pilsen for months. Judges
need to know what certain defects taste like, and they need to broadly
know what each style can and can not have in its flavor/appearance
profiles.

> At that point, the candidate should be evaluated by another qualified
> expert in that style and this should include the ability to identify a
> recognized sample of that style in a blind tasting of mixed/similar
> styles.

Many homebrew judges can do this exact thing. In our club, we often
get together to judge homebrews in a particular style. We always throw
commercial ringers in the flight. Served blind, we have several judges
who can a) pick the ringers (usually not too difficult), and b)
identify which specific commercial beers the ringers are. We had a
specialty beer contest yesterday, and we included an old bottle of
Anchor Christmas beer. One judged identified it as an Anchor Christmas
Ale, and when asked for the year, said "Tastes like a 1986". Bingo.
Not bad for a judge that admittedly does not like Anchor Christmas
Ales.

My point here is that certain judges are EXPERTS, and can pick beers out
of a lineup. These judges are those who have high levels in the BJCP
program, and are often called to judge big competitions and best-of-show

competitions. Other judges have broad knowledge of the styles, are familiar with good and bad tastes, and know what the words on the style descriptions mean. A broad knowledge of styles, a good palate, and a good understanding of what can go wrong in beers is more than adequate for judging almost all competitions. This is what the BJCP fosters.

> Like I said earlier, it's not the people or the results that bother
> me. Our light lager came in 2nd place and 4th best of show. The
> problem is I don't know what it means. Last year we came in first, in
> the same category with a much inferior beer.

What did the judges say on their evaluation sheets? Every year, the quality of homebrews improves markedly. Winners of competitions a few years ago would not get a second thought if judged today. If you want to keep winning, you have to keep improving.

How was this competition run? How many entries? Most competitions have one entry from each style in the best-of-show round. A second place light lager is normally not judged in the best-of-show, and would never be "4th best of show".

From: andrewb6@aol.com
Subject: Regulators, Beer mix, and enamel pots.

Recently I acquired (read: given by good friend) a two guage oxygen regulator that had previously been used for welding purposes. One guage reads from 0 to 90lbs, while the other reads from 0 to about 3000lbs as I recall (actually, the high pressure side has a dual scale and reads gas flow and/or pressure). I realize that the part that fits onto the tank may have the incorrect thread, however this piece is removeable and I'm sure I can find a new fitting to match the tank. Would this regulator be suitable for kegging purposes? Can I expect any noticeable off flavors, or contamination problems due to the fact that this has been used for welding?

I believe the beer mix is a nitrogen and CO2 mix, and will reduce the problems with over carbonation of beer, if the keg is kept on tap for a prolonged period. This sounds great, as I prefer my beers with little carbonation anyway, (I am a native Briton after all). However, are there any disadvantages to using a Nitrogen/CO2 mix.

Has anyone tried mounting a "Slotted T drain" in an enamel-on-steel pot? Obviously welding is out of the question, and I imagine that chipping/splintering of the enamel would be a problem too, but are there any fittings (perhaps an o-ring or a compression type) that will be strong, seal well, and still hold up to the rigors of boiling wort?

Thanks in Advance:

Andrew Baird

Subject: Booby vs Bogy

mailx -s "Boogy vs Bogy homebrew@hpfcmi.fc.hp.com

>From: korz@iepubj.att.com

>I think you mean boogyman, but in any event.....

Funny you should mention that because I researched the word which I am using in the title of an article I am writing. "Boogy" is a musical term and refers to a type of jazz and a "boogyman" would be someone who plays or dances to it although no such word is described in my dictionary.

"Bogy" is a type of gremlin, hobgoblin or other bad actor who keeps throwing wrenches into gear boxes. It is also the term adopted by fighter pilots to identify an enemy plane. It is pronounced with a long "o" but I find no reference to a "bogyman" in my dictionary either. It seems to be redundant corruption and although I try to change people's brewing habits, I don't have time to change the American language.

Unless someone comes up with something convincing, I will stick with bogyman.

>If you have a very fine lautering screen (like the [Ee]asy[Mm]asher), a finer grist is better, whereas if you have a coarse lautering screen (like the Zapap) you need something more like the "textbook" crush.

This is a common misconception of the filtering process as regards lautering of mash.

ALL of the filtering is done by the husk material and the only purpose for the screen or false bottom is to keep the big chunks from clogging up the spigot while the filter bed is establishing itself. Once the bed is established and the wort runs clear, it serves no purpose whatever.

If one were to rely on the screen to do the filtering, it would have to be huge (about the size [volume] of the grain bed) to avoid getting hopelessly clogged in a very short time. This would be particularly true if it were fine enough to provide clear wort by itself.

>There's one piece of information that is missing, namely that Jack uses a very thin mash. This is important because a stiff (thick) mash would just sit there and not make it through the lautering screen.

I can't speak for other methods but the one I champion happens to incorporate kettle mashing on the stove top. This allows a mashout step that greatly facilitates thick mashes and minimizes the viscosity by assuring that it is at the maximum temperature consistent with good brewing practice. There is no mash consistency that will not properly flow through the em if at a reasonable temperature.

>You can carry porridge in a sieve, right?

I think we are debating an issue here, the resolution of which is as near as your store room. Why don't you brew up a batch in the EM I gave you and report back on what you find instead of guessing or creating bogymen?

Subject: re: Calculating Beer Color

The discussion regarding beer color has now passed through a number of different fora, and I'd like to get my reply spread back. Perhaps we ought to try to keep the predictive and measurement discussion in HBD, and the elements that affect judging in the Judge Net.

In HBD #1244, Tony makes a number of salient points.

tony@spss.com (Tony Babinec 312 329-3570) writes:
> linear math that we use to calculate the "expected" color of
> beer is wrong. This point is made by George Fix in George
> and Laurie Fix's "Vienna" book.

The original article that the Vienna book quotes is Zymurgy Fall 1988 (v11, #3), if you'd like to read the whole thing.

And his conclusion is right on:

> For light beers, linear color math is a useful approximation;
> for dark beers, it's more or less irrelevant; and for amber
> beers, it's wrong enough to matter.

To go a step further, I have a (complicated) algorithm for predicting beer color that I feel is ball park accurate for darker beers. I wrote about this in the Judge Net (#637, 10/9/93), and which I will restate below. However, this algorithm only accounts for malt colors and whatever additional coloring went on in the brewing processes that George Fix carried out in writing his article, which I assume (without any basis in fact) are purely "normal".

DSR> In my commercially available computer program, The Brewer's Planner
DSR> (shameless plug), I use a different technique based upon the curve
DSR> presented in Fix's article. The basic idea of this algorithm is to
DSR> determine how big a batch would be required to make a proposed grist
DSR> produce a 2-4 SRM beer (where the lb. * lov. / gal. formula is
DSR> expected
DSR> to work) and then move backwards along Fix's dilution curve to
DSR> determine the antidilution represented by the actual batch size. It
DSR> gives much better approximations of color, up to the 17 SRM limit of
DSR> that curve.

I will add to this that the published descriptive words I've seen applied, both from Fix's article and in Eckhardt's "The Essentials of Beer Style", do not match as the color numbers go up. I would really like to know absolutely what 20 and 30 SRM looks like in a beer.

Subject: Judges & Competence

In respect to Jack Schmidling's comments on homebrew judging, certification, etc.: Well, yeah, that's probably true.

But, on the other hand...

People involved with the Beer Judge Certification Program, the national competition, etc. are conscious of problems with the program and with the whole concept of "qualification." Ideally, as Jack suggests, a judge would be competent to evaluate a certain style because he/she had "lived" it. Ideally, all weizenbier judges should be visiting Bavarians and all lambic judges should come from Payottenland. But, the idea of the certification program is to help competitions provide judges with a good, broad understanding of beerstyles -- there are necessarily going to be some holes.

In an attempt to patch over those holes, there is a movement afoot to develop a specific style certification in addition to the BJCP certification. In other words, not only would judge A be a BJCP judge, but he/she would also have demonstrated specific, enhanced understanding of, say, barleywines. The trick, of course, is to develop a program that assures that such a specific certification would be justified, that the judges *really* knows what a barleywine is, or can be, or might be, not simply what one author somewhere said it was. Not an easy assignment.

But at least it's being worked on.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)
Subject: Questions: Sparging/H2S/milk stout

A few unrelated questions:

1) Is a continuous sparge really necessary? Has anyone tried just draining all of the mash liquor out of the tun, refilling with the sparge water all at once, letting it sit, and then draining it? Since I use a easymasher of the Schmidling design, re-establishing the filter bed would not really be a problem. This seems to me to be much easier than monitoring the flow from my sparge vessel into the mash for half an hour.

2) What is it that causes yeast to produce a rotten egg smell during fermentation? I recently had a fermentation using Wyeast Chico Ale which generated a lot of this smell in the primary. I tasted the beer when I transferred to the secondary, and it tasted OK, actually very good, so I am not too worried, just curious. This is the first time in maybe 8 batches using this yeast that I ever had this bad smell. FYI, I used 8 lbs pale malt, and fermented at 65 F.

3) Stupid question: If one really wants lactose in their stout, why not add skim milk to the boil? Seems to me the protein will precipitate out in the boil, leaving lactose behind.

Thanks for your help.

Subject: Wyeast Munich Lager Yeast

Greetings from the Twin Cities:

I am about to attempt my first true lager... using a ferm-fridge and liquid lager yeast (Wyeast Munich Lager - I don't have the number with me right now). Can anybody help me...?

I took the yeast out of the fridge without realizing that you have to wait for a couple of days before the packet swells up so you can make a starter. I broke the inner vessel, mixed it all up and let it sit for about an hour before I realized that it was going to take a few days. I had to leave for a business trip in two days so I decided to delay the brew session. So I put the yeast packet back in the fridge.

It is now 2 weeks later. The yeast packet has really swollen up. I put it in an extra bag in case it explodes. The question:

Can I still use this yeast? (by just letting it warm up and then making a starter with it?)

Or should I bite the bullet - truck all the way over to the homebrew store and buy some new yeast?

Any suggestions....? Please reply to mwestra@stpaul.msr.hp.com

Cheers,
Mike Westra

Subject: GABF Summary

Here's my short? summary of the GABF for those of you interested in going in the coming years:

Highlights: The winners were announced during Saturday afternoon's special AHA tasting. Most of the people who care about this are there in the afternoon. And this year, we could actually hear them! I saw the Celis crew when one of them brought up the Gold Medal and they took pictures. It was a fun moment.

Lowlights: Two frat boys doing their best imitation of wine snobs: "It has a wonderful bouquet, not presumptuous". Gag. Most of the crowd was great.

Interesting (to me) medal winners:

American Pale/Amber Ale:

Gold - Sierra Nevada Pale Ale, Sierra Nevada Brewing Co., Chico CA (the "blinde" part of the judging must be lost when a beer this indentifyable is served)

Traditional Bitter:

Gold - None

(I disagree with this practice)

Silver - Boulder Amber, Rockies Brewing Co., Boulder, CO

Barley Wine:

Gold - Old Crustacean, Rogue Ales, Newport, OR

Silver - Old Bawdy Barley Wine, Pike Place Brewery, Seattle, WA

Bronze - Old Woolly, Big Time Brewing Co., Seattle, WA

Hon. Mention - Barley Wine, HOPS! Bistro & Brewery, Scottsdale AZ

- Sierra Nevada Bigfoot Barleywine, Sierra Nevada Brewing Co., Chico CA

- Hercules Strong Ale, Slesar Bros. Brewing Co., d/b/a Boston Beer Works, Boston, MA

(Lots of great barley wines...)

Herb, Spice:

Gold - Celis White, Celis Brewery, Austin, TX

(Any doubt?)

Specialty:

Gold - Abbey Trappist Style Ale, New Belgium Brewing Company, Fort Collins, CO

Silver - Winterfest, Coors Brewing Company, Golden, CO

(interesting category to have these two together)

Bock:

Gold - None

(!)

Silver - Bock, Stoudt Brewing Co., Adamstown, PA

Bronze - Samuel Adams Double Bock, Boston Beer Company, Boston, MA

(I can't wait to see the commercials: "The third best bock in America, just two steps below nothing!". Maybe not)

For those of you keeping count (like the Olympics!):

Other US - 39 medals

CA - 26

CO - 13

WI - 7

OR - 6

The big boys did not fair well, even in the "American Lager", "American Light Lager", and "American Dry Lager" categories. Sell your stock. BBC (tm) won a silver and a bronze; maybe they'll quiet down a little about the GABF. I doubt it. I suppose I ought to mention a brewing related topic: There was a vendor there selling a RIMS system built from reconditioned kegs. It was pretty interesting, with a uP controlled gas burner to heat the recirculating wort. It consisted of the mash/lauter tun, a sparge water tank and a boiler on a steel frame with interconnecting pipes and pumps. He claimed the mash efficiency was 30% higher than with a normal infusion mash. Hmmm \$3000 dollars (really!) to save \$4 per batch (this is a 5 gallon system, BTW). That would mean I'd break even in 2056, assuming I could get 0% interest if I left the money in the bank. I put my credit card in my underwear for safe keeping.

Cheers,
norm

Oh yeah, apologies for the bandwidth. That seems to be a new rule around here.

From: John Brooks <jbrooks@u.washington.edu>
Subject: More on Pyramid Yeast

Last week, I posted a request for information about the ale yeast used by Hart Brewing (Kalama, Washington) for its Pyramid Ales. Nobody responded, so I called their microbiologist. I asked whether their proprietary strain was closer to Wyeast's London (1028) or American (1056). He said that theirs was "very attenuative" and implied that it was more like a Young's.

After reviewing the recent yeast FAQ (which IMHO is a great resource), I note that Wyeast London, American and British (1098) are all listed with 73-77% apparent attenuation. My questions for today are:

- is 73-77% considered highly attenuative?
- between the 1028 and 1098, which is (a) more attenuative? (b) more like Young's.
- since my goal is to clone Pyramid's Wheaten Bock Ale (O.G. 1.061), any educated opinions out there as to which yeast strain would be best for this style?

Posts or private e-mail replies both OK; TIA!

From: rcd@raven.eklektix.com (Dick Dunn)
Subject: carboy handles (summary of [mostly non]responses)

A while back, I asked for first-hand negative experiences with "carboy handles" (the plastic-cushioned wire-loop handles that attach to the necks of carboys). Put simply, "Has anyone ever seen one of these suckers snap the neck off a carboy?"

The answer seems to be "no". I'm sure a lot of us have heard some anecdotal, urban-legend, FoaF horror stories, but I've heard no direct accounts of failures.

I have to qualify that slightly: I did hear from one person who had put a carboy handle on a 25-liter (6.5 gallon) carboy, and had seen some (my interpretation) crazing around the neck. It didn't actually break off, but he was (justifiably) scared away from using it. The reason I discount this one data point is that the carboy handles are not designed to fit that size of carboy. Obviously they weigh more, but the main issue is that the neck diameter is different.

5-gallon (and 3-gallon) carboys, the ones I've been able to check, are 2" diameter (50-51 mm if you will) within about a mm. The carboy handles are designed to fit this; the point is that they need to fit snugly, but not tightly, so that they hold a circle around the neck without generating any local points of high stress. (It's like picking up the carboy by the neck with your thumb and index finger forming a circle.) This requires that they match the neck. A 25 liter carboy has a neck diameter more like 59-60 mm, which is way more than a standard carboy handle can accommodate; if you try to force it on, you'll probably end up overtightening it and cracking the neck.

Summary:

- This is reality. I'm reporting results, not telling you what to do. If lawyers must be uncaged, they should be on a short leash. All I'm saying is that nobody who responded had any failures with the handles on 3 and 5 gallon carboys.
- A full carboy weighs a bunch; *any* sharp shock--regardless of whether a handle is involved--can break it. They are sturdy but not indestructible, so be careful but not paranoid.
- Remember, Mother Nature bats last.

If anyone has any useful evidence to add to this, I'll be glad to accumulate it and report back. ("It works for me" is not useful at this point...because basically, they work for everyone so far.)

Subject: re: Maple syrup/sap

> ...I have been brewing extracts for a few years and now want to try
> something different. I also make my own Maple syrup...

Hmmm...I think I'd be willing to trade either mead or barleywine for
maple
syrup, even (1:1 vol)!

>...I have heard of people
> using this in beer and also using the uncooked sap instead of water...

I have had a maple-syrup mead that was nothing short of remarkable. It
was
one of those things where the mead-maker offered it tentatively, as "you
may find this a bit unusual but I think it's interesting"...I liked it
enough that the next time there was a general mead-tasting among friends,
I said "Be SURE you invite <Z> and tell him to bring a bottle of the
maple!!!"

It does seem to be one of those things that you either like or don't, no
middle ground. If you don't like real maple syrup, you probably won't
like
it. (If you've grown up with imitation maple, you may well not like it.
)
My wife is a Brit; she doesn't care for this mead at all. But she looks
askance at various other new-world foods.

There's the usual mead-maker's dilemma, applying equally to beer here:
"What will this incredibly-sweet raw substance taste like after there's
NO
sugar left in it?"

I'd think the raw sap wouldn't do much. Isn't the ratio for boiling-
down
substantial, like more than >>5 (that is, 2^5)? This mead I'm talking
about used syrup at a rate somewhere between >>3 and >>4, so you wouldn't
get that sort of taste level using sap even if you used sap to replace
ALL
of the brew water. (I'm not sure how the difference between mead and
beer
affects the situation here...some factors say you'd want more maple
flavor
in beer, some say less.)

Maple in beer is obviously an idea with merit, worth exploring, but also
one that will require experimentation to figure out what works. It seems
you'd want a relatively light (*not* lite!) beer, probably with more malt
and less hops than average, to let the tang of the maple come through
with-
out getting swamped by the hops, and let the maple-sugar be accented by
the malt sweetness. Add a fair bit of crystal? Probably no really dark
grains. This is intuition speaking--not direct experience, just back-
ground.

Dave (drose@husc.harvard.edu) wrote:

>the thing? Zymurgy says 20 ft in their article. Dave Miller in his
book
>says it must be at least 40 ft. I looked into prices for copper tubing,

40 feet is excessive, 20 is minimal. If you go with my suggestion here,
that is, use 3/8 " tubing NOT 1/4, I have had good success with 30 feet.
Length isn't the only important variable, you also have to consider the
diameters of your inner and outer tubing, flow-rates, cold water
temperature,
and so on. Point is, you could probably get by with 10' if you really
cranked up your cold water flow. If you start going with too long of a
tube,
though, some of the crud from the cold break can "gel" in your tubing and
really slow down the rate (recent potato and rye brews demonstrated this
to me).

>worth it to build a longer one. I bought 50ft of garden hose (a lot
>cheaper than tygon tubing), 50 ft of 1/4" copper tubing, and built a 40
ft
>chiller (10 feet of the hose going to the connecting lines).

I did the exact same thing on my FIRST try, without reading anything
about
how to build one, etc... It was a miserable failure, so I upped the
diameter
of tubing from 1/4 to 3/8, and it works greaat.

As Usual:

- 1) Make sure the inside of your tubing is free of machine oils
(mine was not)
- 2) I will supply free my online plans for building a wort chiller to
anyone who asks.

From: "Robert K. Toutkoushian" <TOUTKOUS@vx.cis.umn.edu>
Subject: Boiling wort question

Hello:

I have a question concerning how to properly boil wort. I have noticed that often my O.G.'s are considerably lower than what are listed in similar recipes, even though I have been using the same quantity of fermentibles, and was wondering if I could be "overcooking" the wort.

When I first started out, I would combine my extracts & water, bring to a boil, and leave on low heat for 1 hour. Lately, I have been bringing the water to a boil first, then adding my extracts, returning to boil, and then continue boiling on high for 1 hour. What leads me to think that I could be overboiling the wort is that (1) I tend to get a lot of gunk (i.e. extracts and malts) sticking to the bottom of the boiling pot, even with frequent stirring, and (2) after 1 hour, the level of the wort seems a bit lower than the starting level, and I tend to get about 44 bottles out of a supposedly five gallon batch.

My question to the wise homebrewers out there is this: once you bring the wort to a boil, do you reduce the heat to keep it at a low boil, or do you continue to go full blast on high heat? Also, does it help to bring the water to a boil before adding the extracts, etc.? As I noted above, the O.G. for my last batch were about 0.020 below what I thought it should have been, and while fermentation took place and all, the gravity fell from 1.030 to 1.010, which means that the alcohol content is also a bit lower than I had expected for this particular batch.

Thanks in advance for any help. The books that I have seen usually say something along the lines of "continue boiling for 1 hour," but I guess there could be degrees of boiling (no pun intended).

From: toddj@readmore.com (Todd Jennings)

I have heard of a brew by the name of WILLIAM YOUNGER #3; read about it in a soccer magazine, actually. In the mag article, the brew is described as "the ruin of a good many young men". The article goes on to refer to the beer as the preferred brew of LAGER LOUTS, the British football hooligans we hear so much about.

Is there anyone who can tell me what the story is with this apparently British beer, i.e. what is the style, and where can one get it here in the States(if anywhere)? I assume it's a bitter ale, but perhaps I am off the track here. Can't wait to find out!!

Subject: GABF results

Thanks to Norm for the interesting post on the GABF...one thing, is this sort of the AHA nationals for breweries? Is there an AHA nationals for brewers? Could someone please take the time and post info on winners in all categories or e-mail me or perhaps just regular mail me a list of winners? I'd like to know these things so I could have a good reference list of just what is a good old amber, barleywine, specialty etc. so I can better develop my palate. Any other palate development techniques other than birth and drinking lots of different beers? Thanks again, email address below. Actually there's a fax # here so if anyone doesn't want to write or already has the info on paper....

Thanks - Chris

Subject: UK hops

J.S. Hough ("Biotechnology of Malting and Brewing") lists a few hops used in the UK. I don't have access to them and haven't used them.

alpha

Target 11.5
Northdown 11.2 (seedless)
Yeoman 11.0
Challenger 9.8 (seedless)
Zenith 9.0

These hops are all modern hybrids developed at Wye College in Kent. Fuller's ESB uses a blend of a number of them. One reason for the blend might be that these hops vary in their resistance to diseases such as wilt, downy mildew, and powdery mildew.

Subject: Beer Mix, Smoked Porter

Andrew Baird says:

>

> I believe the beer mix is a nitrogen and CO2 mix, and will reduce the
> problems with over carbonation of beer, if the keg is kept on tap for a
> prolonged period. This sounds great, as I prefer my beers with little
> carbonation anyway, (I am a native Briton after all). However, are
there any
> disadvantages to using a Nitrogen/CO2 mix.

>

You are correct about the gas mixture of the "beer mix" sold at
refill stores. It definitely cures the well known problem of eventual
overcarbonation when kegs are kept online for extended periods. I also
prefer the English ales and don't like the amount of carbonation that
is so common for American beers. The only drawback to the "beer mix"
is that you can't force carbonate your kegs. I have found that I
prefer to let my ales naturally carbonate, usually takes about 3
weeks, the gas bubbles in solution are very tiny and give a great
long lasting creamy head. I have found over the years that the
addition of 4oz of wheat malt to all my brews gives great head
retention. I'm never in need of having to wait for carbonation
to complete because I always have two kegs on tap with at least
2 kegs waiting to go on tap so my ales are always nicely aged by the
time they finally go on tap.

Smoked Ales:

I recently made a Pecan smoked porter that has turned out wonderful!
I have a real smoker - where the fire pit sits off to the side of the
smoke chamber- and I smoked 2 pounds of Belgian Bisquit malt for one
hour. The temperature remained 110-120 F. I started 8 charcoal
briquets and when they formed a white ash layer I arranged them in a
double row and placed a one foot piece of pecan wood on top (be sure
that when you smoke anything that the wood does not have ANY remaining
bark attached as this will impart a very bitter flavor). I adjusted
my flues to maintain the temperature for one hour. The grain was then
removed and put into a bowl and covered until the next day when I
ground all the grain. The smoked flavor is not too subtle and not too
overpowering and blends very well with the recipe of my favorite
porter. I just kegged it so it will be awhile before it gets rotated
in line to the taps, there are two kegs ahead of it - one is a
raspberry ale using the extract from Hoptech.

Subject: SLOW counterflow

Dave says about his new counterflow wort chiller:

> Well, after 7+ years of cooling my wort in the bathtub, I finally
>decided to make a wort chiller. I decided on a counterflow design
because
>it is supposed to be more efficient and because I cant imagine it is
>really as hard to sterilize as some maintain. I had a design for one
from
>one of the zymurgy special issues (all grain brewing?) and it looked
>straightforward. One question I had was what is the optimal length for
>the thing? Zymurgy says 20 ft in their article. Dave Miller in his
book
>says it must be at least 40 ft. I looked into prices for copper tubing,
>etc, and determined that, economies of scale being what they are, it was
>worth it to build a longer one. I bought 50ft of garden hose (a lot
>cheaper than tygon tubing), 50 ft of 1/4" copper tubing, and built a 40
ft
>chiller (10 feet of the hose going to the connecting lines).
> Well, I used the contraption a few days later. It certainly did a
>fine job of cooling the wort, but it is SLOOOOOW. It took about 50
>minutes for 5 gallons of wort to pass through this baby! This is not
much
>faster than my bathtub method (although I recognize that each little bit
>of wort cools down very fast indeed, contributing to a good cold break)
. .
>All the while the water is running and I am feeling guilty about wasting
>so much, and besides I hoped that building this thing would save me some
time.

Well Dave my counterflow chiller (about a month old) is only slow when my
choreboy (in the kettle) gets clogged with hops (I'm going to shy away
from
pellets whenever I can in the future). The normal, unclogged rate is
about 5
gallons in 25 minutes, if memory serves. The difference is that mine is
made
with 3/8" copper tubing, not 1/4". This is considerable. When mine
slows
down (choreboy clogage), I turn the cooling water down to a trickle. The
last time this happened ittook less than 10 gallons of water to cool 5
gallons of wort to pitching temperature (but it took over an hour). Oh,
mine
is only 30 feet long and it does a wonderful job. I suspect I could get
away
with a shorter one. I suggest one of three routes: 1) take it apart and
replace the 1/4" tubing with 3/8" tubing, 2) cut it in half to make two
chillers in parallel, or 3) change it to an immersion chiller (these work
very
nicely). The problem with 2) is that the plumbing is guaranteed to get
real
interesting.

Dave goes on talk about other chiller hurdles:

> Another general question that I have is how do people direct the
>wort into their counterflow chillers. In the past I always imagined
that

>i would just hook it up in series with my hopback, but recent talk about
>the evils of hot-side aeration have spooked me on this idea. The
>alternative is to siphon directly from the brew kettle, but this has its
>own problems (the old mouth-on-the-siphon-hose conundrum, and the
problem
>of hops clogging the chiller (yes, I know about the chore boy solution
but
>it seems to me that that is going to leave a lot of hard-earned wort in
>the kettle)). So, what do people do about that?

I don't have a hop-back but my kettle has a ball valve mounted at the
bottom.
I have copper tubing compression fittings to attach my chiller directly
out
of the bottom of the kettle. Since my kettle tap is not exactly at the
bottom
of the kettle I use a small brass elbow on the inside of the kettle and
it
takes wort almost directly off the bottom of the kettle (very little
losses).
Anyway, it is all gravity fed and works like a charm. I don't know about
hop-backs and such, I'm a low tech (in this respect) dry-hopper.

Joel asks about draining the first runnings, adding sparge water, and
draining
again to simplify his sparge. This works fine, Joel. If it is easy for
you,
do it. You might even try 3 of these "batch sparges" for more
efficiency. The
only drawback I can think of is that you are losing the original runnings
right
away, which help buffer the goods. It is possible your pH will drop more
quickly during the subsequent sparges, requiring acidification of the
sparge
water to avoid tannin extraction. I've never really had a problem with
it
(i.e. no astringent beers) but I don't take my sparges too far. I
usually get
25-27 points which indicates there is a fair amount of sugar and other
stuff
left in the grist, which I presume maintains the pH (not a lot of
measuring
going on).

good luck,
norm

From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>
Subject: Batch Sparging

Joel Birkeland in 1245 asks about batch sparging. It is my understanding that this is the old fashioned way of doing it. In past times the first runnings would make a big beer, the second runnings (after resuspending the mash) a normal beer, and the third runnings - a mediaeval version of Bud Light.

The reason for continuous sparging is that it is more efficient, and doesn't have the problem of resetting the bed, but for homebrew purposes I am sure there would be little problem. Or alternately get a big picnic cooler that you can fill with all of your sparge water.

Re Hydrogen sulfide - this is a normal breakdown product when protein amino acids containing sulphur are decayed - and well, fermentation is really controlled food decay.

From: arf@mcs.com (Jack Schmidling)
Subject: Judging

From: mferts@taec.com (Mike Fertsch)

>It is neither boring nor unenlightening.

I simply stated my opinion about much of the drudgery that necessarily goes along with a competition. You are entitled to yours.

>Ideally, judges ARE experts in the styles they are judging.

That's nice but the real world is NOT ideal.

> Every judge in the program knows broadly what pilsners are supposed to taste like.

"Every" and "broadly" are the key words here and I won't argue with them but my point was that I would rather have my beer judged by an expert in that category.

>My point here is that certain judges are EXPERTS, and can pick beers out of a lineup.

I already acknowledged that presumption. The problem arises from the fact that many can not.

> A broad knowledge of styles, a good palate, and a good understanding of what can go wrong in beers is more than adequate for judging almost all competitors. This is what the BJCP fosters.

Fostering doth not equate to create. The key here is palate. The other aspects can be memorized in a few hours but palate takes years to develop and

my guess is that very few judges have it to a confident degree of certainty.

This is obvious from the "negotiating" that goes on AFTER they have arrived at their own opinion.

>How was this competition run? How many entries?.....

You seemed to have missed the whole point of my posting. It was run competently, professionally and in a friendly manner that made it a memorable experience.

I simply proposed a system of judge qualification that would be more satisfying to me both as a competitor and as a judge.

>From: gummitch@techbook.com (Jeff Frane)

>In an attempt to patch over those holes, there is a movement afoot to develop a specific style certification in addition to the BJCP

certification.

Sounds like I hit a nerve. That's certainly a step in the right direction but it seems like putting the cart before the horse. It would be just as rational to qualify experts up front of the overall certification and it would fill the ranks of experts much faster.

>From: andrewb6@aol.com
>Subject: Regulators, Beer mix, and enamel pots.

>Has anyone tried mounting a "Slotted T drain" in an enamel-on-steel pot?
Obviously welding is out of the question, and I imagine that chipping/splintering of the enamel would be a problem too, but are there any fittings (perhaps an o-ring or a compression type) that will be strong, seal well, and still hold up to the rigors of boiling wort?

Not sure what a "Slotted T drain" is but if you use a spigot with a male thread and a female connector on the inside, you can make a leakproof compression fit. The only hooker is you have to rethread them with straight threads as they are normally supplied with tapered pipe threads.

Drilling holes without chipping is not a problem as long as a small pilot hole is drilled first.

>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)

>1) Is a continuous sparge really necessary? Has anyone tried just draining all of the mash liquor out of the tun, refilling with the sparge water all at once, letting it sit, and then draining it? Since I use a easymasher of the Schmidling design, re-establishing the filter bed would not really be a problem. This seems to me to be much easier than monitoring the flow from my sparge vessel into the mash for half an hour.

What seems intuitive is not always so. Someone posted an article a year or so ago that explained it in terms so simple, that even I could understand, why this is not so.

It has to do with the gradual dilution effect and that the grain is always meeting up with a differential between it's remaining sugar and the dissolved sugar in the sparge water. The greater this differential is, the more sugar will be removed.

It is also easy to see that in the last batch, after stirring the water and mash, the whole liquid will arrive at some gravity. When the liquid is drained, the liquid held by the grain will be that gravity and that sugar is lost. By continually sparging, the gravity of the liquid left in the grain will be that of the last running and of no interest.

js

From: polstra!larryba@uunet.UU.NET
Subject: Re: Wort Processors Mill Evaluation

In HBD #1241, Jack writes about mill issue:

>
> Sounds like a fun time was had by all and the context and tone of the report
> indicate that it does not require much serious debate. However, there are a

Actually, it sounds like all the mills, with the exception of the original corona were more than acceptable. Price, availability and the volume of grain to be crushed seemed like the decision points - not crush quality.
> ...
> First of all, the MM used in the evaluation does not represent current design
> which will indeed crush one lb of malt in under 14 seconds with a hand crank
> and 5 lbs per minute with a motor is like falling off a log.

I can vouch for the speed and quality of the current MM design, having purchased one of the first with the knurled roller. I am sure one can crush 1lb in 14 seconds with the hand crank, but my arm falls off when doing 20lb crushes and I take much longer, say 30 sec/lb.
>...
> Finally, a note on crush quality....
>
> The most misunderstood aspect of the grist resulting from milling of malt for brewing is the boggyman known variously as flour, dust, fine particles, powder etc. I would rank the need for unscathed husks as number two. The emphasis on both of these results from the problems created by crude grain grinders combined with poorly designed and/or operated mash/lauter tuns.

I agree that grit size and uniformity is more important than husk damage. this is most true about modern 2-row grains. I have personally used two lauter designs: a perforated false bottom and a slotted copper manifold.

In both cases too fine a grind is a disaster regardless of the quality of the husks. The problems are two fold. First the flour tends to ball up and make a dough that is dry inside. This occurs during mash in and is a royal pain to get rid off. I have seen folks try to avoid this by mashing in a little grain at a time, stirring vigorously between additions. Still when fully mashed in, those pesky balls of dough continue to float to the surface. Second problem is the stuck sparge. I had never seen one until I used a roller mill that was set way too close (.025") and the sparge locked up after a couple quarts. No dribble, nothing. Just like the valve had been closed.

The malt mill I have produces a course crush (e.g. looks like cornmeal) with pretty much intact husks. I have lautered a 15.5 lb mash and recovered 11.5 gallons of 1.046 wort in 20 minutes. That is .034pt/lb/gal for you guys interested in the efficiency game. Since it was a pils, using only pils malt, the number wasn't too unexpected.

I guess my point is that with modern, fully modified malts (Please, can anyone point me to a commercially available malt that isn't?) fine crushes DON'T GAIN YOU ANYTHING but problems. Look at malt specifications: they describe the difference between course and fine crush extract yeilds. typically the difference is 2% or less. Smaller numbers are indicators of higher quality (and degree of modification).

So, to summarize: any of the mills mentioned in the Crush off should work fine. I have used homemade roller mills, coronas, corona knockoffs the malt mill and converted coffee grinders. The only one that was consistently bad was the coffee grinder. All others could be adjusted to produce great crushes fast lauters and excellent extracts.

>
> The perfect grist for mashing would be molecule sized particles of malt from
> which all the husk has been removed. It would wet perfectly, dissolve
> instantly and produce 100% yield of crystal clear wort.

This is a gross simplification. Malt contains more than husk, starch and enzymes. All the gums, protein, cellulose, etc. are best left in matrix rather than trying to filter them out.

Subject: Yeast Growth/ Starter Size

>Jonathan Knight
>Grinnell, Iowa

*Jonathan asked about slow starts and long ferments...
>My typical procedure is to boil up one cup of D.M.E. in a solution
which,
>after some evaporation, turns out around 750-800 ml. Should I use more
>D.M.E. in the first place? Or should I step-up the first starter into a
>second? If I do that, do I make a stronger solution the second time (as
in
>more extract per volume of water)? I'd love to hear from anyone who
wishes
>to share their experience and expertise on this subject as a fellow-
>chronically-underpitching-homebrewer.>>
>

Just a little primer on yeast growth and metabolism:

Growth vs. Time (low and high starting populations)

This is only a cartoon. Had this been a real graph there might be data to support it. Take it as you will- can you speak "hypothetical?"

With a low starting population the lag time before exponential growth is lengthened. It is during this period that the greatest danger of infection exists. A high starting population will result in a narrower growth curve, whereas the smaller pop. will grow slower, for a longer time. It is reasonable to believe that the small init. pop will never achieve the maximum population of the high start.

There are definite benefits to a high starting population, and definite disadvantages to a slow start. I can't imagine you could "overpitch" a wort- unless you collected the yeast from ten brews and added inadequate fermentables to make them live. If the yeast run out of nutrients they may turn to unfavorable metabolic pathways. But I'd be inclined to think that if you supply a full bodied wort and sufficient aeration to the number of yeast collected from as much as a 1 gallon starter will do no harm.

A good process for growing up a starter- I use a 200 ml starter of about 020 sp gr. for a colony from a plate. For a liquid yeast- say a 500ml initial starter. Same sp. gr. Grow this for a day or two. Let settle- Collect yeast sediment, add to a fresh wort of a slightly higher sp. gr. say 030 in a larger volume-

500 ml (culture), 800 ml (liquid). Grow up 1 day. Till active ferment.
Brew Day: Take some of the wort from the sparge and boil quickly. Cool
and combine starter with equal volume of fresh wort. By the time the
boil
and cool are done this will be active. Cool wort and pitch. You should
get a good start.
Stepping up the volume and strength of the starters will allow the yeast
to both increase in number and acclimatize to the brew gravity.

G'luck. Hope this helps. John (The Coyote) Wyllie SLK6P@cc.usu.

>but crystal clear beer!

Crystal clear maybe, but probably quite oxidized. Does your beer have a sherry-like aroma? I think you may want to try to find the source of your haze (perhaps you are just not waiting for the yeast to settle -- some strains take quite a while -- maybe just try a different strain). As the fermented-out beer falls from the funnel into the 2nd carboy, you are going to introduce a lot of oxygen (unless you purge the carboy with CO2, perhaps) and this will give your resulting beer sherry-like or wet-cardboard aromas.

>

A very good point. The recipes that I have been referring to have little or no wheat malt. A clarification is needed in this robust discussion. We should limit the playing field to mashes which have little or no wheat malt.

For the record, I am a zealous believer in temperature steps for mashes that contain a high-percentage of wheat for reasons explained in Eric Warner's book.

Having narrowed the breadth of definition, I continue to maintain that a mashout is unnecessary and await rebuttal.

>FYI to all attending future Great American Beer Festivals.

>The members only tasting on Saturday afternoon at the GABF was definitely
>the place to be. Uncrowded conditions allowed relaxed tasting and
>conversation with the brewers.

It was an extremely relaxed session (as compared to the 2 night sessions, but it also had an annoying aspect as well. The majority of the brewers were out accepting their awards and only volunteers were manning the taps.

I received an "I don't know." to the majority of questions I asked during the AHA-only tasting. At night, while it was more crowded, at least I could speak with the brewers.

FWIW, I'm not a member of AHA, so I had to "sneak" into the elitist society function. I had so much fun that I might even join next year. Nahh! That would take all the fun out of it.

>By comparison, Saturday night was a zoo.
>Did anyone go on Friday night? What was it like then?

Friday night was quite crowded, but no where near as crowded as Saturday.

To all the AHA duly-appointed royalty. Why not have more food stands? With all that beer and so little food available, I found it to be more expedient to leave Currigan Hall and go to the local Burger King as opposed to waiting in that one horrific food line.

Cheers,
Andy A

You don't mention the diameter of the copper tubing that you used. I
made a counterflow chiller out of garden hose and 20 feet of 3/8 inch
copper tubing (I think that was the size, it was the largest I could find
that was still flexible enough to work with.) This cooler works well and
works fast. The way my brewing is set up, it is about a 15 foot drop
from
the boiler to the fermenter. This cooler takes in from boiling to tap
water
cold. Total siphon time is about 5 minutes for 5 gallons.

> Another general question that I have is how do people direct the

I've not settled on a method for this. I've used the chore boy method,
but I've had problems getting a decent flow. I usually just try to
work around the hops. Fortunately, I haven't had many problems with
clogging.

>
You would have a regulator that is rated for "non-corrosive gases".
These gases would include: oxygen, hydrogen, methane, ethylene, ethane,
carbon monoxide, nitrous oxide, and carbon dioxide. The difference, as
Andrew suspected, is in the connector between the regulator and the tank.
The oxygen would use a CGA 540 connector and the carbon dioxide would use
an CGA 320 connector. I would also recommend swapping the 0 - 90 psi
guage
for a 0 - 40 psi guage, because for beer, one rarely needs more than 25
psi for the carbonation.

You should be able to get the proper connector from a welding supply
shop. Most welding suppliers also sell regulators and the associated
connectors. If they don't have it, try a compressed gas vendor.

> I believe the beer mix is a nitrogen and CO2 mix, and will reduce the

> prolonged period. This sounds great, as I prefer my beers with little
> carbonation anyway, (I am a native Briton after all). However, are
there any
> disadvantages to using a Nitrogen/CO2 mix.

>
I don't know about this mixture. I have not seen it in the compressed
gas
catalog of our local gas vendor (I work part time in the chemistry stock
room), but any gas vendor will mix it up for you, for a price. Stick to
pure CO2 and use a pressure that provides 1 - 1.5 volumes of dissolved
CO2. (Most beers contain 2 - 2.5 volumes of CO2) I have seen a
dissolved gas vs. pressure/temp. table on the HBD, but I don't know when
it was.

startup brewing
I'm about to take to plunge and start brewing. I have read the NCJHB, the latest Zymurgy, and been reading this digest for some time now.

I'd like to know the following things:

what equipment should I start out with?
plastic vs glass fermenters.
extract 'kits': good ones, bad ones
about how much \$\$\$ for equipment?
how much \$\$\$ for a 5 gallon batch?
can I brew 1/2 a recipe by cutting the ingredients?

Thanks...looking forward to your kind replies.

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>
Subject: Metric to Avoirdupois Conv.

Talk about deja vu. I had just sent the revised Rager Constant to Mark Garetz

yesterday. For everyone's benefit, I will include the derivation for it here.

What Regent said about the accuracy not being terribly significant to the results is true, but I'm perspicacious. (yeah, that's it)

$$\begin{array}{rcl} 28.3495 \text{ grams/oz} & \text{gram gal} & \\ 1000 \times \text{-----} & = 7489.1689 \text{ -----} & \\ 3.7854 \text{ liter/gal} & \text{liter oz} & \end{array}$$

The numbers are correct to four significant digits. Round all you want. The factor of 1000 is from the fact that SI units are based on Kilograms.

John Palmer

PS. I have received favorable response regarding the DOE posting, so I will post specifics for the next two experiments in the near future.

A few thoughts on the GABF

I went there Saturday evening. HUGE line to get in, but it moved reasonably fast. The size of the hall was nice in that I wasn't jostled as often. Interesting toys, like the hi-tech, computer controlled home brew workstation ;'[]], and the party pigs (a 2 1/4 gallon fermenter/server). The popcorn was TERRIBLE and had this mutant yellow color. I ended up buying the soft pretzils to clear the different beer tastes. A couple more wash stations would of been nice too.

Given the larger area, greater number of people and displayers, I would of appreciated more time to browse the beers. I guess that's a good reason to join AHA, so I could of got in that afternoon. I was on a "rare" bear style hunt (smoked, alt, oatmeal stouts, fruits). Liked most of what I had, but some people seem to think that stout=burnt. The Cherry Rail was my favorite fruit beer. Blue Tail Ale from a Ca. micro was one of my favorites, but it's not bottled (waaaa!) Sierra Nevada's Summerfest was a good one too.

I've rambled enough

Subject: Beer Drinks

Greetings,

I was roaming around an old bookstore the other day and I came across a book on cooking with beer (can't remember the title, and didn't buy the book). In the back, there was a section on beer drinks. I also don't remember many specific recipes, but most them looked like they treated beer as a regular liquor.

Anyways, I wondered if other people had heard about making drinks with beer? Now, I've heard of adding some woodruff or raspberry liqueur to a Berliner Weiss, a lemon to hefeweizen, and even mixing fermented apple cider to ale, but I've never heard of beer being used as merely an additive in some drink concoction. Has anybody else?

Quite frankly, I thought beer was a finished beverage, whereas hard liquor needed "diluted" by mixing with something else.

On a similar note, Is something considered part of the beer if it is added post fermentation? Or is it more or less a "beer drink"?

Just wondering,
Sean Taylor

Subject: Carboy Source/John Pavao

Hello Readers,

Upon receiving 1) many queries for a 7 gal carboy supplier and 2) getting my PC finally reconnected to the Internet, here's the address for a brew supply supplier.

James Page Brewery & Beermaking Supplies
1300 Quincy ST. NE
Minneapolis MN, 55413-1541
1-800-347-4042

You can use this 1-800 # to place orders or request a catalog. They ship UPS so

I assume Cal. money is as good as WI money.

I'm but a lowly graduate student and profit not from this, much less any other, professional relationship (disclaimer). Speaking of disclaimers, how come we list disclaimers when we post supplier info and not when we expouse the virtues of a commercially micro-brewed beer?

Page sold a 7 gal. in lieu of 6.5 which had sold out. As posted in an earlier HBList, the openings of the 7 gal are too narrow to use a carboy cap in starting a siphon.

In reply to John Pavao's request...

The 7 gal and perhaps (help me out here people) 6.5 gal carboys have enough head space to use as a primary fermenter w/o a blowtube. I use an airlock. The above supplier also carries long racking canes which will fit 7 gal carboys.

Sorry to take up the extra bandwidth...couldn't get my message directly to John.

Subject: Idophor question

I just recieved this message from a friend of mine in Los Angeles:

> I just finished a batch of spiced ale. Actually it started as a Belgian Brown

> ale, but I used Idophor(sp?) to clean with and found that I can not tolerate

> Idophor. This stuff is the stuff that gave the flavor to the keg beers at the

> Maltose Falcons meetings that you and I could not stand. So I added lots of

> spices and dry hopped to save the batch (it seems to have worked except that

> the dry hops increased the profile of the allspice and it is taking a while

> to mellow out.

Since I'm in Michigan now, I couldn't taste the original beer, but I remember

very well the oftaste that he's referring to. I have always disliked the idea

of using Cornelius kegs because every kegged beer I tasted seemed to have a

similar background unpleasentness (which I assumed was due to metal leaching or

"unnatural" CO2 impregnation).

Could someone comment on the use of Idophor (flavor characteristics, threshold

of dection, poison rating, personal experiences, etc.)? I know he rinses

thouroughly, so it's not sloppy technique. In the past we have always sanitized

with bleach with resonable results.

Subject: Brewpub review

The following reviews represent my opinions only. You can judge for yourself what they are worth.

The rise in popularity of microbrewing and specifically brewpubs is beginning to develope and ugly side, and I have recently seen this side in the form of the Belmont Brewing Company of Belmont Shores, California.

I guess it should come as no suprise that as brewpubs are becoming more and more trendy, there will be some designed especially to appeal to the yuppy set. This is not to say that there is anything at wrong with the growing popularity of brewpubs. Being a very frequent patron of any brewpub within reach, I find the growing numbers to be very reasuring. However, my experience with Belmont Brewing Company indicates that pubs that cater specifically to trend followers can lack a certain amount of quality.

While the pub is in an outstanding location and the interior seems well-designed, with plenty of seating (actually, quite a lot of seating) and the staff (well some of the staff) is friendly and attentive, the food lacks the care and quality one expects in a brewpub. This is especially irritating when you consider the high prices.

But on to the most important part, the beer. The best way to sum up my impression is this: If you enjoy the over-powering taste and smell of yeast, combined with an almost total lack of any hoppy taste, aroma or bitterness, this is the beer for you. The following beers were sampled:

Beer Name:	Official Description:
Marathon	"Light bodied ale. Low bitterness. Hint of Aroma"
Strawberry Blond	"Just a hint of fruit. Light in body. Low bitterness.
Long Beach Crude	"For beer lovers who enjoy full flavor. A hint of bitterness and chocolate"

The description of the Marathon Ale is pretty accurate, except that it is wildely understated. The strawberry flavor in the Strawberry Blond was about as subtle as a strawberrypie in the face. Not unpleasant, but very overpowering. Mixed with the heavy taste of yeast makes for a bad combination.

The L.B. Crude was the best of those sampled. Really a light stout. Good flavor with a lighter body. Very tasty chilled. Could be a very good warm weather stout if it wasn't for the ever-present yeast taste and smell. Unfortunately, the taste and smell get worse as you continue to drink.

I can't really describe the brewing setup as I didn't have opportunity to check it out, but from across the resturant it looked nice.

Another review of yet another L.A. area brewpub will follow shortly.

I used to be disgusted, now I try to be amused.

Subject: Boogymen and bogymen

korz and arf have been debating the spelling and pronunciation of bo(o)gyman. The American Heritage Dictionary has an entry for "boogieman" (pronounced either with the vowel of "book" or with the vowel of "boot")

,
under which they say "Also boogyman, boogeyman, bogyman, bogeyman" (the last two pronounced with the vowel of "boat"). All of these refer to a hobgoblin, as does the word "bogy" (also bogey, bogie). (The spelling they prefer for the golf and military terms is "bogey".)

In addition to all the above forms, I have heard "boogerman" (with the vowel of "book" again). Note also that "booger" and "boogie" are both attested as count nouns corresponding to the mass noun "snot".

Other related words are "bogle", "bugaboo", and "bugbear". All of these words were borrowed from some Celtic language, either Scottish, Welsh, or Cornish.

To sum up, there's a lot of dialect variation here and there's no one "correct" form.

Now excuse me, I need a homebrew.

Subject: GABF Denver

I attended the GABF on Friday evening, the members-only tasting on Saturday, and an "Evening with Michael Jackson" at the Wynkoop Brewing Co. on Sunday.

Friday Night:

What a zoo, but that's what I expected. Actually I believe it to be a little better than last year simply because Currigan Hall is larger.

Personal Favorites:

Santa Rosa Brewing Companies Cascades IPA.

Excellent hop nose and taste. The perfect amount of bittering hops. The best IPA I tried at the fest.

Dixie Brewing Companies White Moose.

A white chocolate beer with an incredible chocolate aroma and light chocolate taste that's not overpowering.

Alaskan Brewing Companies Smoked Porter.

Has always been one of my favorites. Although last year's batch was better this is still the best smoked beer at the fest.

Vermont Pub and Breweries Smoked Porter.

A very close second to Alaskan's.

Spring Street Brewing Companies WIT.

A Belgium white with orange and coriander, very interesting.

Saturday Afternoon:

I went in prepared with a list of various styles I wished to try. I was interesting in the many pumpkin and certain fruit beers, IPA's and Imperial Stouts.

Personal Favorites:

Adler Brau's Great Pumpkin Spice.

This is by far the best pumpkin beer I've ever tried. It had a very nice pumpkin taste with the perfect spices. The only thing it lacked was the whipped cream.

Hubcap Breweries Killer Bee Honey Ale.

More of a light mead than an ale. Not as overpowering as most meads but a very light, honey taste.

Marin Brewing Companies Blueberry Ale.

A very nice blueberry nose and taste. I was enjoying this one when it took the gold and everyone raised their glasses in salute!

Pacific Coast Breweries Imperial Stout

A slightly sweet but full bodied Imperial Stout.

Vermont Pub and Breweries Avid Tartan Wee Heavy.

A nice sweet and strong Scottish Ale.

Sunday Evening:

Michael Jackson presented a tasting of "For The Love Of Good Beer:
Denver

Against The World." Michael gave an one hour biography and history of
beer followed by a tasting of 4 "World" beers and 4 "Denver" beers:

Pilsener Urquell(Czech Republic)

Bass Ale (England)

Paulaner Oktoberfest (Germany)

Guinness Stout (Ireland)

Home Run Ale (Champion Brewing Company)

Altman Amber Ale(Rockbottom Brewery)

India Pale Ale (Breckenridge Brewery)

Churchyard Ale (Wynkoop Brewing Company)

From: Ken Miller <KCMILLER%SJSUVM1.BITNET@cmsa.Berkeley.EDU>
Subject: Bogymen/Boogymen/Lactic Acid/Low-Alcohol Beer

Many and multifarious are the ways of the English language. Webster's Ninth New Collegiate lists all of the following: bogeyman (preferred), bogyman, boogymen, and buggerman (all with the same meaning); also bogey, bogy, and bogie (without the -man suffix). So everyone was right (until they started dissing each other) and we can move on to another topic...unless maybe someone wants to pronounce it with an umlaut? :^)

Phil Brushaber solicits non-basic information:

> A brewing friend suggested using Lactic Acid. Got a bottle
>of Kent brand 88% Lactic Acid. I could use a suggestion from you
>Brewing Chemist types....

I'm not a Brewing Chemist...but I play one on TV (not!)

> Any guess on how much of this 88% Lactic Acid I might use
>to adjust the PH in 5 gallons? You know something like: "1 tsp of
>88% Lactic acid should lower 5 gallons of liquid by .4 PH degrees".
>I could use trial and error but I've got a hunch that someone
>out there may have the answer or be familiar with this stuff.

Sorry, it isn't that simple. pH is a logarithmic scale, and the degree of lowering will depend on both the volume and pH of both the liquid and the acid. If you know the exact pH of your water, it is possible to calculate the amount of lactic acid needed to lower 5 gallons of it to a specified pH. (When I get my hands on a Merck Index, I'll post the equation.)

In practice, it's probably easier to use trial and error, since tap water pH can vary from brewing to brewing (mine varies from 7.2-7.9, according to the water report) and the amount of lactic acid needed is usually quite small (on the order of < 2 tablespoons). Dave Miller (in TCHOHB) recommends diluting the lactic acid first, using a ratio of 3 cups water to 2 tsp lactic acid; this is not strictly necessary but makes over-acidifying by accident less likely. I usually wind up using about 2 cups of diluted acid (i.e. about 1+ tsp of 88% concentrated acid) to lower about six gallons of water to a pH of 5.7 (your mileage will vary).

Bill Kitch speculates:

>Does anyone have a procedure for producing low or no alcohol
>carbonated malt beverages?

>
>My intial thought is to:
> 1) brew in the normal fashion
> 2) heat to evaporate the alcohol
> 3) cool
> 4) add priming sugar and fresh yeast
> 5) bottle
>

>Is this reasonable? Has anyone tried this? Did it work?

Gee, I hate to be so negative today, but I don't think you'd be very happy with the brew so produced. The problem is with step 2. The heat that drives off the alcohol will also drive off

other volatile flavor components, leaving your brew poorer for the experience. Also--and this is pure speculation on my part--since heat increases the speed of most chemical reactions, certain reactions (e.g. oxidation reactions) which don't occur at fermentation/storage temperature might occur rather quickly at alcohol evaporation temperature. Whatever this does to your beer, it's not likely to have a positive effect....

As I recall, one of the methods commercial breweries use to produce no-alcohol beer is a variation on this technique in which the evaporation is done in a partial vacuum, which allows the evaporation to occur at lower temperatures. Perhaps one of the numerous engineer-types on this forum can send you plans for a vacuum distillation device....

BTW, if you do try this method, be sure not to condense or in any other way keep the evaporated alcohol...producing distilled alcohol without the proper paperwork is literally a Federal offense. :^(

Subject: Maple Brews

Read the post about maple beers.
I have a friend who makes maple syrup
up in Maine. Recently, he attended a
maple festival and returned with a
cookbook of maple recipes from the
1800's. In the book are two recipes
for maple brews. The recipes include
such ingredients as checkerberries,
pah-sis-o-wah (both members
of the wintergreen family which are
native to New England) and, believe
it or not, hemlock tips (I'm going to
substitute spruce, I think it'll be safer).
Since I missed the checkerberry season
this year, I'll try it next year.

Subject: Compare Contrast Kits vs Scratch

I have made beer both by kit, and by scratch, and I have had mixed results. I have used the "Malt Extracts" in the orange cans and I have used the Coopers Ale Malt Extracts (\$15.00 a can, Expensive!). I have made ok beer with the Orange cans and made a pretty acceptable Oz lager with the other. I tried a batch from scratch (Imperial stout) and It came out bitter, not to mention I now have beer all up inside my stove after it over boiled... I followed the directions provided in my Beer Bible but, I guess things went south somewhere. What I really would like to do is brew a beer that is similar to the great beers of Austria (St Augustiner Brau - brewed by Trappist monks in Salzburg not that crap you get in the bottle imported from Germany). I have also been contemplating a Heife Wiezen. My problem is this, what would be better:

Brew using a kit? If so:
which one is best(brewform,Orange, etc)?
Is it better to buy kits from mail order (cheaper,better quality) ?
If so who, in your experience has been the best to deal with?
Any recipes?

Brew from scratch?
to boil or not to boil?
Strain vs grain bag
Note worthy recipes?
Brew kits are much more expensive, but for their ease are they worth it?
Is their quality better than what most can create?

I would really appreciate everyone's input on this, as I would like(as well as many others out there) a little wisdom from some of you who have been brewing for a while.

Carboy Dieum

From: Matthew Evans <matt@cadif.cornell.edu>
Subject: Re:Carboy handles: A Better Solution?

I haven't actually tried the carboy handles that were described, but I think I lucked out and found a better way to move carboys. The carboy that I conveniently "found" was an old glass spring water bottle. But what made this carboy even better was that it had its own wooden crate that provides a great way to lift the carboy when full. The way the thing is built it also protects it from being banged around when moving (this carboy has moved over 1000 miles without any special padding).

You still wind up lifting the carboy from the sides, but you still are a lot better off than hugging your beer (although I guess there is something to be said for that too!) to move a full carboy. If you would like more info, or dimensions send me a message. Good luck.

Subject: smokin' grains

Reading the past couple of articles regarding smoked porters has peaked my interest. I'm considering trying a batch of this stuff.

The one brewer mentioned he had a real pit smoker (smoke area off to the side of the pit fire). I, on the other hand, have one of the tower type smokers. Has anyone smoked grains in one of these things? What are any special tricks to getting the most out of the smoking? I'm wondering if the temp gets too hot in these that one ends up burning the grains before achieving smoke flavor in the grain.

You may email me directly and I'll be glad to post a summary of responses (if I get any :)). Thanks...

Subject: younger's no. 3

In Scotland, McEwan's has an ale known as 80 Shilling or IPA, with a gravity of 1042. In England -- spotted in London in The Sun -- you'll find Younger No. 3, a cask-conditioned ale of SG 1043. Think of this as an example of AHA Scottish Export. In the US, you'll find the bottled counterparts to these two beers. The IPA goes by the same name, and I don't remember the name of the other beer, but it might be McEwan's Export. In some parts of the U.S. you might find McEwan's Scotch Ale, but at SG 1088, this is a much stronger beer. If anyone has access to the Scotch Ale, send me one :-).

Subject: new at all grain - how 2 make tuns?

In the last week or so I've been reading this, it's like I've stumbled on a treasure trove of brewing knowledge here. You guys are some serious brewers -- just the type of forum I need to learn the finer points of making excellent brew.

I've been brewing with concentrated worts from extracts using some grain supplements for a few months and I'm ready to make the leap to all-grain brewing. I'd rather make my own equipment whenever possible as much of the ready-made stuff is much more pricey than the sum of its parts. I am wondering about the best way to go about making a mash tun and a lauter tun. I have only seen them vaguely described, and never seen a detailed diagram of how they are built. I would prefer to avoid the food bucket route as it seems they are a bit on the small side. I understand you can make a mash tun out of a big picnic cooler. Is that right? If so, how does the heating system work without burning the cooler? Also, how do you keep the heating element from burning the grain?

Thanks for your feedback - it sure is nice to be able to ask real experts about this!

Regards,
Eric

Subject: Milling and Mashing

>From: polstra!larryba@uunet.UU.NET
>Subject: Re: Wort Processors Mill Evaluation

>I agree that grit size and uniformity is more important than husk damage.
this is most true about modern 2-row grains. I have personally used two lauter designs: a perforated false bottom and a slotted copper manifold.
In both cases too fine a grind is a disaster regardless of the quality of the husks.

My recently posted tests results with flour made from a Corona indicate that a third lauter design is worth looking into.

> The problems are two fold. First the flour tends to ball up and make a dough that is dry inside. This occurs during mash in and is a royal pain to get rid off.

That is most absurdly so and the only problem I had with the Corona flour.
I can imagine what a real pain it would have been in a full sized batch.

>Second problem is the stuck sparge. I had never seen one until I used a roller mill that was set way too close (.025") and the sparge locked up after a couple quarts. No dribble, nothing. Just like the valve had been closed.

Not so with the easymasher. The flow with the flour was no different than with a "normal" crush.

>The malt mill I have produces a course crush (e.g. looks like cornmeal) with pretty much intact husks. I have lautered a 15.5 lb mash and recovered 11.5 pretty much intact husks. I have lautered a 15.5 lb mash and recovered 11.5 gallons of 1.046 wort in 20 minutes. That is .034pt/lb/gal for you guys interested in the efficiency game. Since it was a pils, using only pils malt, the number wasn't too unexpected.

Just for the record, Larry's mill is a fixed spacing model and makes a good case for my contention that adjustability of spacing, on a well designed roller mill, is of no real value to the home brewer. It is offered as an option because people think they need it and the customer is always right.

From: Domenick Venezia <venezia@zgi.com>
Subject: Over boiling

Rob Toutkoushian asks in #1246 if his low S.G.s could be caused by "over boiling" his extract based wort. He further explains that he gets a lot of "gunk" on the bottom of the brew kettle.

Given that you are indeed following the recipe, and I assume you are doing a high gravity boil, then perhaps you are burning the wort. As you vigorously stir you simply allow fresh wort in contact with the too hot kettle bottom and burn more of the fermentables to the bottom of the pot. I don't know your boiling set up but if it's an electric stove you may be forced to use the highest setting (cherry red) just to get a boil. Since you are not boiling to reduce your wort volume perhaps you could cover or partially cover the kettle (WATCH FOR BOIL OVER) and this might allow you to turn down the heat. Also thin bottom pots tend to get hot spots, so switching to a thicker bottomed kettle may help, though this may not be financially possible.

Also 44 12 oz bottles, with head space accounted for, is exactly 4 gallons, and in my experience an uncovered good rolling boil evaporates just about 1 gal/hour.

Good luck, keep us informed.

From: polstra!larryba@uunet.UU.NET
Subject: Fast, Cool Sparges and Malt Charactor

Folks following my postings (sparse as they are) will note that I am a proponent of fast sparges. I always let my sparges run as fast as they can and I typically get very good extract yields from my mashes. My second to last batch was 20 min for 11 gal at ~34 pt/lb/gal. I also typically skip mash out maybe heating the mash to 158-162 just to maintain a mash bed temp of 140-150 and to force conversion if the iodine test is not negative after 20-30 minutes.

Once, a year or two ago, I asked the forums if there were any negative issues w/regard to fast sparges. I got no responses. Well, at the last Seattle Brews Brothers meeting I was talking with a brewer about malt character and mashing techniques. Many brew brothers do decoction and modified decoction mashing claiming improved malt character. This guy's claim was that fast, cool sparges produce low malt character. He said that he always runs a very hot sparge (180 or higher) because that husky graininess makes for more malt character.

This guy also suggested an experiment for me to do to test out his ideas: next time I begin to lauter a 10 gal batch, to set aside 2 gallons of mash and bring it to a rolling boil before adding it back into the lauter tun. I guess this a way of simulating a decoction mash and the caramelization that occurs during the boils. He claimed that the change in malt and physical characteristics of the mash would be obvious as I brought the 2 gallons to a boil.

The question: What do folks think of this theory and the experiment? Am I likely to just end up with a bad starch haze and a puckery beer? Will I be safe from a starch haze due to the low temps of my lauter and the fact that I rarely mash for more than 40-50 minutes (two/three step infusion mash) there should be plenty of enzyme activity in the mash?

- Larry Barelo

Subject: rotten egg smell in fermentation

This is approaching Frequently Asked Question status on HBD, so here's a brief explanation.

The rotten egg smell is hydrogen sulfide -- H₂S. Just-fermented green beer contains detectable levels of hydrogen sulfide, and the threshold value for this compound in beer is in the 5 - 10 ppb range. Hydrogen sulfide is present in wort, but is driven off during the kettle boil. Sulfur-containing volatiles, including hydrogen sulfide, are formed by some strains of yeast during primary fermentation. The level of hydrogen sulfide is reduced during beer maturation, and is presumed to take place as a result of the scrubbing action of carbon dioxide bubbles when produced in a beer fermentation. In conclusion, reduction of H₂S occurs during secondary fermentation, and is therefore one reason among many to consider doing a secondary fermentation.

Subject: GABF Size

Chris asks whether the GABF equates to the AHA nationals for the pros. I don't know that much about the AHA, but I think the GABF is open to all professional brewers, regardless of affiliations. Many brewers there are Institute for Brewing Studies members, but not anywhere near all of them. This thing has gotten so big, though that it is difficult to get any idea of what's available.

I would like to see several regional ABF's and have the GABF an invitation-only affair. The invites would go to the regional winners in each category. That way the regionals would be of a more reasonable size and so would the GABF (used as a national run-off competition). I went to the Saturday afternoon tasting and back again Saturday night, and I don't think I made a dent in the total number of beers there (nor would I try). Does anyone else think this thing is a leviathan? Dr. Fix, I believe you had one of the judging jobs, which should give you some insight into the organization. Is my idea feasible, possible, or a pipe dream?

From: andrewb6@aol.com
Subject: Re: William Younger's No. 3

Ah, that brew of brews, that nectar of nectars, that heavenly concoction worthy of any man's affection. No. 3 is the beer for which I yearn. You're right it is an British brew, made by William Younger which is part of the Scottish and Newcastle group. I believe it is still made in Edinburgh, Scotland, and is typically consumed only in Scotland and the North of England.

I must admit in my younger days (not too long ago) I consumed a cask or two of this beer, but as is typical of so many Britons, we spent many hours enjoying the brew and little time analyzing and pondering it's complexity. In other words I can't give you too much in the way of a description.

Commonly thought of as a bitter, it's somewhere between a bitter and a brown ale. At first glance it looks black, and when served properly it's topped by a thin layer of dense creamy head. However when held up to the light (even in it's customary pint glass) it reveals a beautiful rich, ruby red color.

It is certainly malty, but not sweet, and is balanced well by bitterness. As I recall it has an OG of about 1058. Michael Jackson gave it a poor review in his last book, and mentioned that it had a cult following. This last fact I can certainly attest to. Even the casual mention of it's name would cause a seasoned beer drinker to salivate and become glassy eyed (much as I am now). IMHO it's a fine beer and compliments William Younger's Scotch Ale and IPA. As far as alcohol content goes, maybe Jackson's book will tell you, but I can't put a number to it (but from experience, nine pints of No. 3 and you're really under the table).

I'm not so sure about your comments on "Lager Louts". This beer is as far from being a lager as budlite is from being full-bodied. But if a football hooligan did take to drinking this beer, I would have to consider it his one redeeming feature.

As far as finding it on this side of the pond--good luck. Unless things have changed in the last couple of years, No. 3 is only produced in cask form, and they don't ship it very far (in fact I've never seen it in the south of England). If you find out otherwise, let me know at

all-speed.
If you need to know more I'll gladly research it for you :-)
going --I'm

From: tony@spss.com (Tony Babinec 312 329-3570)
Subject: beware of glycogen depletion

Intermittent posts to hbd have called attention to yeast pitching rate and the consequences of underpitching. A perhaps more serious concern is yeast vitality as measured by yeast glycogen content.

Glycogen depletion is a consequence of long storage times, warm storage temperatures, and number of other causes. Pitching glycogen-depleted yeast can result in problems with the primary fermentation and the finished beer:

- sluggish fermentation
- slow attenuation
- higher terminal gravity
- poor flocculation
- poor alcohol production
- high diacetyl
- high SO₂
- high acetaldehyde
- less flavor stability and shelf life.

All the more reason to build up yeast in some starter wort before pitching into your beer.

It doesn't seem very likely that "Lager Louts" would drink Youngers No. 3
(no # sign, since this meaning does not extend to the UK), it being a
dark ale. Football hooligans in general would be hard pressed to find it
outside of certain areas. It's made in Edinburgh by Scottish &
Newcastle,
one of the large national brewers, but isn't commonly available in their
pubs. S&N are the brewers of McEwans Export, widely available in the US,
but I doubt that they export a keg version of No. 3 (especially as I've
only seen it in cask-conditioned form).

No. 3 is fairly rich, a little stronger than ordinary ales at OG 1043,
and
if served with a head keeps it pretty well. In good condition it can be
quite delicious. I'm not sure what style I would attribute to it - it's
too strong for a dark mild and not as strongly flavored as a porter.

Bass have a range of strong canned Scottish beers popular with certain
types of soccer fan. They include Tennants Super (such beers are often
named like grades of gasoline), also known colloquially as "Doom". Since
this is also favored by drunks and winos as a quick and cheap way to get
blitzed, I wouldn't really recommend it as a fashionable new trend with
which to associate oneself. :^)

Subject: Alcohol Percentages

Hello out there,

I've got a question not really about homebrew, but about beer in general. This originally started with my desire to get more exciting microbrewed beers here in the beer wasteland of Alabama. About the most exotic thing we can currently buy is the Samuel Adams Boston Lager. Figuring this was a (good) starting point, I called the local distributor and asked if they were planning to bring in any of the other Sam Adams beers. The distributor said they were working on getting another, the Octoberfest, but that there were some that they could never get (the Double Bock).

According to the distributor, all beers in the state of Alabama must be less than 4 percent alcohol (I'm not sure if this was buy weight or volume). We have Guinness, Bass, Hofbrau, etc. I thought that Guinness and some of the others would be higher than 4 percent.

This leads me to wonder if brewers brew different versions of beer for different states. Does anyone out there in HBD-land have any knowledge on this subject?

Subject: carboy disasters

Dick Dunn's summary of carboy handle experiences prompted me to send a warning/bit of painful advice to all of you brewers:

> - A full carboy weighs a bunch; *any* sharp shock--regardless of whether

> a handle is involved--can break it. They are sturdy but not indestruc-

> tible, so be careful but not paranoid.

ABSOLUTELY!!

When a carboy breaks, it tends to form some pretty large shards of glass that are capable of slashing through skin to the underlying bone quickly and

quite painlessly. Unfortunately, the repair (Read: Numerous stitches and probing for glass slivers) involves quite a bit of pain and downtime of the

limb. I never used a carboy handle or anything similar until after my accident a few weeks ago. Luckily, no beer was lost - just a 5 gal carboy.

Since then, I have kept my carboys in plastic milk crates - great for transporting the full ones around (especially when wet), and they fit nicely

in my wetbulb container and chest freezer.

Be careful, don't regress to plastic if you break one, and above all - NEVER

SHOW FEAR TOWARDS THE BEER.

Subject: Re: low O.G. readings and boiling wort question

Hello again:

Thanks to everyone for the great suggestions concerning how to properly add extracts to water when boiling, and reasons why the O.G. readings I have been getting might be lower than expected. Let me pass along what I have learned:

I had a problem with adding extracts to my boil, in that I have been getting some of the extracts sticking to the bottom, despite stirring. Several people have suggested that one should (1) bring the water to a boil, (2) remove from heat, (3) add extracts, and (4) put back on high heat and bring to a boil once the extracts have dissolved. It is important to then keep on a high boil in order to bring out the proper flavors of the hops, etc. Previously, I had been bringing the water to a boil, and adding the extracts directly to the boiling water while the pot was still on the stove, hence the scorching and the "gunk".

Concerning the low O.G. readings, someone pointed out that if I was doing a partial boil, where I add the wort (extracts + 1.5 gallons water) to 3.5 gallons of water, then it is probable that the specific gravity of the wort at the top of the fermenter will be lower than the specific gravity at the bottom if the extracts settle to the bottom. (er, that word was supposed to be "specific").

Anyway, thanks to all again...I really appreciate the continued great advice of the subscribers here!

Subject: Re: counter pressure filler (was Kegging systems)

Don asked about counter pressure fillers:

I got a counter pressure filler from Benjamine Machine Products that seems to work well. I posted the same question to the net, also asking for comments on the Foxx CPF. The general consensus was that the Foxx product was not well made, and that the BMP CPF was a good buy. I got one, used it, and had a problem with it leaking when the liquid valve was closed. Made for quite a mess until I got the process down. I called

BMP and asked about it, and the guy said it was unusual, but not unheard of, to have a problem with the valve seat. He said to take it off, send it back, and if there was a problem with it he would replace it. When I went to take it off I found that it was loose to start with. I'm thinking

that this may have caused the problem, but I won't have a chance to check it out until next week. BTW, the BMP CPF was supposedly designed by Micah Millspaw who, if you are a long time reader of the HBD, you recognize

his name. If you don't, he was the source of some very good information and

is now the head brewer at some place in California (I think).

BMP has ads in most (including the latest) issues of Zymurgy. If you don't have access to it, let me know and I'll dig it up for you. Price was about \$55 with shipping.

BTW Don, I tried to email directly to you, but my mailer daemon doesn't recognize all those !'s in your address. If you have an address that is in internet format you might add it to your signature.

Subject: Hard Cider Recipe?

Hello All,

Does anyone out there have a good recipe for Hard Cider? A bunch of my homebrewing cohorts and I are going to make some (40 or so gallons between us) next weekend, if we live through the New England Brewer's Fall Festival that is. We plan on making the cider ourselves, as I have access to a cider press, so we don't have to worry about watered-down commercial cider. Any suggestions would be welcome.

Oh, BTW for all of you involved in the bogeyman/boogie man controversy, look up piss-ant in the dictionary. (hint: it has something to do with splitting hairs!)

Cheers!

From: Kevin O'Connor <kocon@ctp.com>
Subject: Chris Seiders' article

This was Chris Seiders' article. It was base-64 encoded (a MIME encoding format). As he says, please bear with him.

Chris, try to tell your mail package to send mail to the digest in clear form.

The message:

Since this is my first post to this list, please bear with me. I am new at brewing, and have recently started my second batch of brew. I have encountered some things which I haven't encountered before (not surprising on only the second batch) and am looking for some words of advice/encouragement. I started an all-extract Brown Nut Ale on Sat. After boiling the extract for 1 hr I added it to my 5 gallon glass carboy and brought it up to 5 gallons with water. I then cooled the carboy in a water/ice bath until it cooled to 76xF at which point I hydrated the wort by rolling the carboy along the kitchen floor along with some manual shaking. I then rehydrated my yeast (14g) in 1/2 cup of 90xF water for 15 min before adding to the wort. Fermentation began quickly (within 3 hours) and alot of crap blew out of my 1" blowoff tube (approx 2 quarts blowoff).

Now the problem:

I noticed that the blowoff stage had pretty much stopped as of last night (Mon.). I replaced the blowoff tube with a fermentation lock, but it now appears as if fermentation has stopped completely, ie I don't see bubbles coming through the lock. My previous batch was a stout kit and fermentation seemed to continue through the lock for at least a good week after removing the blowoff. My carboy is located in a closet which keeps it at about 74xF. Is this normal? Should I wait before bottling or go ahead if the fermentation has stopped? After only 3 days? Please, oh veterans of homebrew, pass down any wisdom you may have on this subject. I am becoming quite confused/frustrated since I feel like I am still shooting in the dark with each step. Thanks!

Chris Seiders (SEIDERS@HANDI.MED.UTAH.EDU)

I have had an experience like this myself with an unbelievably fast (seeming) fermentation. Actually mine may have even been faster, 2 days if memory serves

me. Check your specific gravity. If you are down around 1010 or so for a brown ale, I would go ahead and bottle. It won't hurt to let it sit a bit too as long as there is still CO2 in the head space between the top of the carboy and the top of the fermenting beer.

The batch that fermented fast on me was good drinking, so hopefully yours will be too. Good luck!

Subject: COPS and AHA

For you AHA people out there: Did your organization ever contact the producers of COPS, Fox channel 25, or the police department "featured" in that infamous homebrewing issue of the COPS show? Seems to me that the defense of the hobby of homebrewing, and the education of the general public about the hobby, should be among the highest of the AHA's priorities. Certainly the fact that the AHA's president's book (Complete Joy of Homebrewing) was shown in an extremely negative light on national television should warrant(!) some sort of response. Perhaps you could ask your membership for donations to be used for a 30 second TV ad:

"Hi, I'm Charlie Papazian, president of AHA and author of TCJOH. Perhaps you've seen my book featured in the back seat of a police car on the show COPS. While the AHA in no way condones any illegal activity, making beer and wine for personal consumption is legal in all 50 states. (ed. true yet?)

As in all hobbies, the advanced homebrewer requires specific equipment, much of which looks similar to that used in the illegal process of distillation. The AHA does not condone the production of distilled liquors. It is illegal and dangerous. But once again, the homebrewing of \*beer and wine\* \*is\* legal.

Homebrewing is an enjoyable and creative hobby...founding fathers brewed.. helps the economy....personal freedoms...for more info call..."

You get the idea.

Subject: Brewpub review

<The rise in popularity of microbrewing and specifically brewpubs is beginning to develope and ugly side, and I have recently seen this side in the form of the Belmont Brewing Company of Belmont Shores, California.

<I guess it should come as no suprise that as brewpubs are becoming more and more trendy, there will be some designed especially to appeal to the yuppy set.

While I can be critical of many breweries and dont object to Mark being critical of the beers at this brewery, I do feel Mark is being a bit naive in his critisim of any establishment targeting certain individuals/groups of consumers. This is after all a buisness. This buisness requires a hefty capital investment. People expect a reasonable return on investment, in a reasonable timeframe. Is it really suprising that a brewpub in southern California is targeting the yuppy audience? Whats wrong with this? Dont these people have the liquid assets to pay off the breweries debt? How many other towns have brewpubs oriented to this segment of society? Gorden Biersch is one of the most successful brewpubs ever and the Palo Alto location has consistently been bashed for this "yuppy thing". As Dan prepares to open his fourth brewery, he's laughing all the way to the bank.

Good brewing,

Subject: More on the GABF

Message Creation Date was at 14-OCT-1993 10:10:00

I just got back from my first trip to Denver and my first GABF. First, let me say it was a great experience. I went to all three sessions, and despite the crowds on Friday and Saturday nights, I got to taste any beer I wanted with minimal difficulty. Concur completely with the Alaskan Brewing Company's Smoked Porter and the Vermont Pub and Brewery's Tartan Wee Heavy. Both deserved their gold medals. Also, any visitor to Denver must spend adequate time at The Wynkoop (adequate means as much time as possible). Great beer, great brewpub.

That said, I was wondering if anybody out there who doesn't live in eastern Colorado is happy about the GABF always being held in Denver? This includes brewers and potential attendees. Why not move the thing around the country so more people have the chance to go to and participate in the event? I'm sure Denver is convenient to the guys who run the festival, but there are beer lovers across the country who deserve a chance to try the beers. It is, after all, the Great AMERICAN Beer Festival, so let's send it all over America. I'm sure Charlie P. will appreciate any input.

Subject: Mashout revisited and pH

After reading all the accounts of mash out free sparges, and in need of doing a quick lager batch so I'd have krausen for 2 batches that had been hanging around for a while I tried a quickie brew - not my usual decoction effort. I mashed in at 124 (still nervous about omitting the protein rest) by adding the grain (9lb 2 row, 1/2 Cara, 1/2 crystal) to 136F water in my cooler with copper manifold false bottom. After 1/2 hour infused boiling water to 146, and after another 1/2 hour infused water to 155. After an hour total I attempted a runoff with no mashout and ran into difficulites. Part of the problem was stuff coming through somehow - maybe due to mashing in the lauter tun, but it wasn't long before the runoff died a death. Naturally I cursed all those on hbd who said mashout weren't necessary, and cursed my bad judgement against going against a procedure that worked well for me. Eventually I started to sparge after recirculating much cloudy reheated runoff, and managed to free up the sparge with a knife quite well so that the total time was only slightly longer than it would have been if I'd mashed out and sparged. It would be fair to note that the problem may have been a very thin mash (after all the infusions) which compacted the bed. I may try again sometime, but in meantime will stick to tried and trusted procedures.

Ken Miller incorrectly states that the amount of acid to be added is dependent on the pH. It is dependent on the buffering capacity of the water - basically the amount of carbonates. A water with a very high pH >9 may be so because it is so soft, and may require no acid for a mash to reach the right range. If the water is fairly hard acid is needed except for the blackest stouts and porters. I suggest the original questioner get pH papers and add conservatively the first time till the right range is reached. Thereafter it is much easier.

I am sure it would be possible to do it without indication by getting a water analysis and working out stoichiometrically how much acid is needed to neutralize most of the carbonate and then carefully measuring out that correct amount of acid - carefully noting the concentration and density of the acid when doing so. A micropipetter would be needed unless the acid was diluted, and in the absense of an accurate guage conversion factors to tablespoons would be needed. It probably wouldn't be too gruesome, and I may even do it as an excercise some time - for 100 ppm carbonate per 5 gallon add 2 tablespoons of lactic acid diluted 1-10, unless there is chocolate malt in the grist, add 2.3 that amount and when the moon is full...

From: Shawn Nunley@Novell.COM (Shawn Nunley)  
Subject: Re: Beer Drinks

Sean Taylor asked about Beer Drinks, so here is one that can be fun...

Flaming Dr. Pepper from Hell

This drink requires a shot glass and a tumbler style glass. Fill the shot glass with Amerretto (sp?) and the tumbler half full with beer. The idea is to have just enough beer to cover the shot glass when you drop it in the tumbler. Now, light the Ameretto (2nd try at spelling) and let it get pretty warm, not too hot. When the time is right, drop the shot glass in the tumbler. That's right, drop the whole shot glass in the tumbler so that it is standing up on the bottom of the glass. Now drink the whole thing as fast as you can. The Ameretto will pour out with the beer yet will remain kind of seperated. The resulting taste is remarkably close to a Dr. Pepper. This is a fast drunk, BTW. Hangover City too.

Shawn

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: mashout

Tallying the responses from both HBD and email, it appears that there are quite a few homebrewers out there who do not perform a mash-out. More so than I imagined. And of course, there were the traditionalists who tried to defend the mash-out ceremony. Homebrewing makes for strange bedfellows.

> Chris mentioned one of the benefits of mashout (the debated  
> one), but failed to mention the one on which most of us agree,  
> namely mashing out raises the temperature of the mash much  
> quicker than simply pouring sparge water and therefore more  
> quickly decreases the viscosity of the runnings. Runnier  
> runnings mean faster sparging (without a loss of extract  
> efficiency), less chance of a set mash (stuck runoff) and more  
> efficient extraction of sugars. Remember, warm honey pours  
> easier than cold honey.

>  
> Al

Ok I'll bite. Where's the dividing line between "warm honey" and "cold honey" i.e. at what point do wort sugars flow and not flow? I skip the mash-out and sparge with 170-180 F water. I usually sparge 5 gallons of water in 30-45 minutes. My mashing efficiencies are consistently over 80%. Given these facts I think it's safe to assume that wort sugars flow without a mash-out.

> I agree that the reasons you quoted are not very rational  
> reasons for doing a mashout but there is one reason that I think  
> is a good one. By raising the whole mash 20 degrees or so, you  
> stand a far better chance of keeping it in the optimum range

> who kettle mash but it is probably not worth the trouble for the  
> bucket infusers.

>  
> js

Ouch. An idol's dagger plunges the deepest. You assume that we all agree there is an optimum range and that thus there is a need to be within that range. I do not support such assumptions. I skip the mash-out and consistently get good yields. It should also be noted that I use a picnic cooler and never perform a protein rest (Belgian malts). I won't tell you how I grind my malt because I'll be forced to use the "C" word.

Looks like Godzilla and Mothra have teamed-up to combat the onslaught from BOQAT. So far BOQAT remains unscathed. Can Tokyo withstand another melee? Tune in tomorrow. Egg rolls served during the matinee.

Subject: re: William Younger's No.3 (again)

In 1247 re: Younger's No. 3, Tony Babinec writes:

>In Scotland, McEwan's has an ale known as 80 Shilling or IPA, with a gravity of 1042. In England -- spotted in London in The Sun -- you'll find Younger No. 3, a cask-conditioned ale of SG 1043. Think of this as an example of AHA Scottish Export. In the US, you'll find the bottled counterparts to these two beers. The IPA goes by the same name, and I don't remember the name of the other beer, but it might be McEwan's Export. In some parts of the U.S. you might find McEwan's Scotch Ale, but at SG 1088, this is a much stronger beer. If anyone has access to the Scotch Ale, send me one :-).

Perhaps I misinterpreted, but it seems that you're implying that McEwan's 80 shilling and/or IPA are the Scottish version of Younger's No.

3. Not True!

Both t

he 80 shilling (written 80/-, and often referred to as 80 bob) and Younger's

are available in the north of England. While it is true that No.3 is a cask

conditioned ale and 80/ is served from a keg with a higher level of carbonation, these are two separate beers (not the same beer dispensed differently). No. 3 is darker and to my recollection much more malty. In my earlier post (which will probably appear in

this issue) I suggested that No.3 has a gravity in the 50's. I think perhaps my thirst was impairing my memory--1043 sounds right.

Incidentally, S&N make scotch ales under the names of McEwan and Wm. Younger. Here again, Younger's is cask conditioned and McEwan's is

not. As to wheth

er they are the same beer masquerading in different containers, I can't really say, but I suspect not. I have not seen the IPA over here, but you

are right that the 80/- is sold as McEwans Export. Incidentally, the canned

version is sold under the name of McEwans Export in Britain, too -- but of

course they're bigger cans : - )

Not a flame, just a clarification (I hope).

From: David Atkins <ATKINS@macc.wisc.edu>  
Subject: hemlock and cranberries

Hello readers.

I recall someone not wanting to use hemlock in a brew recipe. The hemlock mentioned in the recipe is not the weed that took Socrates out of circulation. The non-toxic hemlock is a coniferous tree and harmful only if it falls on you (confermation for an authority knowledgeable person would be appreciated).

Of course, since I'm not a toxicologist or forestry prof. or Ewel Gibbons I don't condone or encourage the consumption of this or any other sylvia. I had some spring water once that poured over the fallen trunk of a hemlock...if beer could ever taste that good.

Also, I'm going to skin the cat's meow in search of extract recipes utilizing cranberries...'tis the cranberry season. If anyone has any other experiences/favorites, I would eagerly read them.

Thanks,  
David Atkins

From: GANDE@slims.attmail.com  
Subject: Last Year's Hops

It's past harvest time for most hop growers and the '93 crop is available for purchase at most locations. It seems that one can still get '92 hops at a really good price since most vendors want to unload them.

Would anyone know what percent of Alpha Acid has been lost in the 1992 crop, assuming they were stored under optimum conditions? I just purchased about a pound and would like to adjust my recipes.

TIA....Glenn Anderson

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re:Maple syrup/sap

I believe it's the Niagara Brewing Co. of Niagara Falls, Ontario that brews a 'Maple Wheat' beer. It's around 8 percent alcohol by volume (if memory serves). This may be to ensure some residual sweetness. The maple flavour is definitely subdued, and mostly detected in the finish. A nice enough beer, but not something I'd go out of my way for (it's fairly pricey too), but then I've never been big on strong beers. Perhaps I should get a bottle to refresh my memory re: specifics of its flavour, etc.  
Cheers, Rick C.

I've had good luck using a mix of bleach and TSP to clean real grungy  
bottles. Make some with real hot water and soak overnight. By morning  
most of the labels usually fall off. Some bottles are real tough though  
namely, Legacy lager. They get real slimy.

Pardon? Unless the AHA styles are even more bizarre than I recall,  
Younger's No. 3 is nowhere close to a Scottish Export. It's more like  
a strongish dark mild or a mildish/sweetish porter.

> In the US, you'll find the

> bottled counterparts to these two beers. The IPA goes by the same  
> name, and I don't remember the name of the other beer, but it might

McEwan's Export definitely isn't the same beer as Younger's No. 3.  
Although they're both brewed by Scottish & Newcastle in Edinburgh,  
the former has OG 1046 and is a dark amber color, and the latter is  
OG 1043 and dark brown. Roasted barley vs. crystal malt, I'd say.

I don't know if the IPA is the same or not. I'm not very impressed  
by any of S&N's pasteurized products, so if I have seen the IPA  
around I probably just ignored it... :^)

From: "DEV::SJK" <SJK%DEV.decnet@mdcgwy.mdc.com>  
Subject: Belmont Brewing Co.

I have to respond to Mark's comments about the Belmont Brewing Company. Let me first admit that while the BBC is one of my favorite brew pubs, it's mostly because of the location (which is ON the beach with a fabulous view) and the fact that it is only a 20 minute walk from my house ;-). In this light, I'd mostly just like to take the edge off of some of Mark's comments.

As far as the food is concerned, it's unfortunately very variable. The pizzas are all good as is the tortellini with sausage. The chicken and mushroom pasta is very bland. This regrettably leaves very few choices. The food, in my opinion, is the BBC's weakest link.

Now to the beer. Mark is essentially correct and the beer varies a little more in quality than it probably should. The Marathon is to be avoided. It is VERY light, and doesn't have enough body or taste to cover the minor errors which are obviously made with this beer. The Strawberry Blond is a Marathon with much too much strawberry flavor. Cut the berries back a little and you'd have a fine specialty beer, with the berries covering up some of the problems with the Marathon. Then again, they may just be making what people want. They sell a lot of it. Order a glass rather than a pint.

The Sail Ale (not mentioned by Mark) is excellent and is my favorite. It is described as a pale ale, but it's really more in the Blue Heron tradition (as opposed to Bass) and is almost, but not quite, an IPA. (BTW, I hear Bridgeport is thinking about maybe considering the possibility of sending some of their production from their new facilities to CA. Oh please, God, I'll do ANYTHING... Any real info on this out there?). The Crude is also very good, but could be a little more distinctive.

Also, I disagree with Mark in that I have always found the BBC's beer to be a little over-hopped. Haven't been in a month or so; maybe they're trying to widen their market by dropping their hop rate. I also haven't noticed excessive yeastiness, except maybe in the Marathon which is always cloudy.

Concerning prices, I think they are comparable to other restaurants in the area. After all, this is L.A. (more or less) and they are on the beach. I've always found the service to be better than average.

There are other points in the BBC's favor, but I think I'll just say that they've been very consistent, and gotten consistently better, since they opened. Two of their four beers are very good and the view is worth the trip. Don't write them off completely.

Mark made one comment that really didn't sit right with me, and that was his description of the BBC as trendy. I won't say that it isn't, because I'm not exactly sure what he means, but don't ALL brewpubs "cater specifically to trend followers"? At still less than 1% of the national beer market, I'd have to say that ALL brewpubs and micros could be said to fall into the "trend" category. And if fruit beers are a trend, then I'm all for being trendy. If the decor is what Mark meant by "trendy" (oak, brass, a few plants, fish tank), remember they have an ocean view and want to show it off. They necessarily have a lot of glass. A traditional English pub would be better off somewhere else.

Besides, who would begrudge a yuppie (do they still exist?) a good beer once and awhile? They're misguided maybe, but not evil. (Buttweiper is the ugly side of brewing, if you ask me.) I have a feeling I know what Mark's next L.A. area brewpub review is going to be like. No slam intended, I just don't think he's going to find what he's looking for.

Mark is really on pretty firm ground as I know others who don't care too much for the BBC. On the other hand, I know a lot more people that do. So, is the BBC worth the trip? I think so. Is it worth a repeat visit? That depends on how far you live from Hopland.

Scott Kaczorowski  
sjk%cl7fcs.decnet@mdcgwy.mdc.com

P.S. While I'm here, I'd like to make a request: No more b\*g\*yman, please. If we're going to split hairs, we should at least keep it in the area of brewing (trub, anyone?).

**Subject: Maple in beer and wort chiller length**

For what it's worth, Sam Adams Cranberry Lambic claims to use maple syrup to balance the tartness of the cranberries.

Please, let's not start again with the Koch bashing. I'm simply passing on some info about the use of maple syrup in a commercial beer.

Someone asked about appropriate length for a wort chiller. When this was asked awhile ago, I dug out my copy of the Chemical Engineers' Handbook and posted some equations. You can probably find it in the HBD archives. You need to make some assumptions and decide on the maximum amount of time you want to spend in cooling the wort to come up with a length.

>Al.

OK, I'll be the heretic. Hey, new brewers! DON'T worry about oxidation when transferring to secondary. The beer is cool and saturated (probably supersaturated) with CO2. If it foams a little when you transfer it there is virtually no way it will oxidize, because CO2 is coming out. If it doesn't foam when you transfer it it was probably in primary too long and you might as well bottle it. I can't see any harm in what is described here. Filtering hot wort is one thing, filtering cool fermenting beer is something entirely different.

Relax, have a homebrew, and shove that nasty ol' oxidation bogeyman back in the closet where it (usually) belongs.

From: relay.hp.com!daver!nexgen!bart (Bart Thielges)  
Subject: hot priming

When I prime my fermented beer with corn sugar, I usually cool the priming solution to 70F with an ice bath before mixing with the beer. (Egads ! I've just publically admitted to both priming and use of corn sugar. There goes my chances of CamRA membership !)

I've always thought that this step is probably not necessary since the thermal mass of 1 pint of 200F sugar water is nothing compared with 5 gallons @ 70F. So what if I zap a few yeast cells on the initial contact ? They don't have very good lawyers anyway.

I've never had the guts to actually risk a batch with this hot combination experiment. Has anyone else done this successfully ? I'd like to simplify my process.

Thanks,  
Bart

>
```

Sorry Ken, it isn't that simple. Not only is pH logarithmic, the change of pH depends on the composition of the solution to be adjusted. The information you get from Merck Index, Handbook of Chem & Physics etc. will all be for distilled water. The dissolved things in tap water (metals, salts, minerals, organics, etc.) may buffer the water to some extent. Buffering means that the pH is \*more resistant\* to change, ie. more acid is needed to effect a pH drop.

```
> In practice, it's probably easier to use trial and error, since
  ^^ ^^^^^^^^^^^ ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
> tap water pH can vary from brewing to brewing .....

Both of Ken's statements make good chemical sense. Remember 88% lactic acid can cause \*serious\* burns if splashed on bare skin.

Subject: Making drinks with Beer?

In HBD #1247, sean v. taylor <sean@chemres.tn.cornell.edu>  
RE: Subject: Beer Drinks writes the following:

>Anyways, I wondered if other people had heard about making  
drinks with beer? Now, I've heard of adding some woodruff or  
raspberry liqueur to a Berliner Weiss, a lemon to hefeweizen, and even  
mixing  
fermented apple cider to ale, but I've never heard of beer  
being used as merely an additive in some drink concoction. Has  
anybody else?

In London, England they mix bitter orange soda with beer and call the  
resultant beverage "Shandy". In some parts of England this is called  
"Orange  
Shandy" and other soda beverages, Cherry, for instance, mixed with beer  
would  
be called "Cherry Shandy".

It is almost shameful to admit it but (shudder) Orange Shandy tastes  
pretty  
darn good as a "lawnmower style" malt beverage. I know that this  
probably  
offends the sensitivities of most of this audience, but, refuse to judge  
until you've tried it. Mix equal parts Schweppes Bitter Orange with  
Double  
Diamond and see what I mean!

From: npyle@n33.stortek.com  
Subject: Jim Koch won't shut up!

Having visited the 1993 GABF, and enjoyed the news that Boston Beer Company did not win any gold medals, I was dismayed to read the following in "The Brew Review" (copied without permission, so sue me. No wait, how about 30 lashes with a siphon hose?):

"GABF CONTINUES NEGOTIATIONS WITH BOSTON BEER COMPANY"

"Boston Beer Co. has changed their promotional print and point of sales printed material to comply with the new GABF post-event publicity rules. However, Boston Beer Co. intends to continue its non-complying radio advertising, promoting its late 1980's wins in the Consumer Preference polls. For the purposes of avoiding litigation, the Rules Committee has voted to allow the Boston Beer Co. to participate in the 1993 Festival, in spite of its use of radio advertising statements regarding Consumer Preference poll awards that do not meet post-event publicity rules. The decision was made based on anticipated agreements and compliance in 1994. However, the Rules Committee continues to condition all brewery's participation, including the Boston Beer Co.'s, in the GABF on compliance with the post-event publicity rules with respect to any reference to Festival medal awards."

Unfortunately, it sounds like BBC's lawyers have won this round through coercion and the threat of lawsuits. Every brewery in the country appears to be complying with GABF rules except BBC. This hits me the wrong way. I have to admit I continued buying BBC products from time to time because I like the beer, though I always disliked the business practices (I'm so ashamed). This is the last straw, though, and I join the chorus here and now:

BOYCOTT BBC!!!

norm

Opinions expressed above are mine and mine alone. They do not represent the opinion of my employer in any way. (first time for that, sucks doesn't it?)

From: npyle@n33.stortek.com  
Subject: Re: beginning questions & begging all-grain questions

George Tempel asks:

>what equipment should I start out with?

You'll need:

3 gallon pot  
racking cane  
siphon hose, 6'  
ratcheting hose crimper  
air lock  
rubber stopper to fit your...  
fermenter  
bottles  
thermometer  
1" blowoff hose, 3'

>plastic vs glass fermenters.

I prefer glass.

>extract 'kits': good ones, bad ones

Pick a recipe from Charlie's book. Don't bother with kits.

>about how much \$\$\$ for equipment?

\$50 is a good guess.

>how much \$\$\$ for a 5 gallon batch?

\$20 is another good guess.

>can I brew 1/2 a recipe by cutting the ingredients?

Yes. Remember, George these are my own opinions and you could get a dozen answers to some of these questions. The equipment list I gave is a minimum. Things like a larger pot, a hydrometer, bottle washer, hop bags, etc. could be considered up front as well. If you get as hooked as the rest of us, you'll soon be buying more "stuff", which has been defined as anything you can use in homebrewing. "Junk" is defined as anything you thought could be used in homebrewing but can't. At least that's how I heard it.

\*\*\*

Matthew Bohne asks about using kits or not. I recommend you disregard brewing kits in general because there are so many good beginning recipes out there. They are easily done, and make better beer. TNCJHB and other books are loaded

with them. Boil or not? ALWAYS boil, just watch the boilovers. Don't boil grains, though, strain them out. BTW, Imperial Stouts are a fairly bitter product, with the alcohol bite, the dark grains, etc. (actually, I don't know if "bitter" is an accurate descriptor) Maybe you don't like Imperial Stouts.

\*\*\*

Kelly Jones forgot to mention:

```
bmN(*&^(-- asdfDA;JFDV--9238VIJNCZ[CVZCXVHnIG9uDQpvbmx5IHRoZSBz
ZWNvbmQgYmF0Y2gpIGFuZCBh2-34798ADFVCV ;FD=GF9GUG SDFKJzIG9mIGFk
```

but otherwise his reply to Chris Seider was right on the money. (you can't remember everything, Kelly, especially after several homebrews!).

\*\*\*

Eric Feris asks about tun construction (but makes the mistake that he's talking to "experts" here). Eric, this is another place that you could get about 1735 different answers, depending on people's experiences, investments \$\$\$'s, time, etc. I use a 48 quart rectangular cooler as a mash / lauter tun. It has a copper manifold in the bottom which looks like this (bottom view):

There are numerous small slots cut into the pipe (1/2") with a hacksaw. The slots are on the bottom, away from the grain bed. The pipe drains out the hole in the cooler and makes a perfect fit with the gasket sold with the cooler.

Another way to do it is Jack's method, which is a single pipe with a piece of SS screen over the end to keep grain out of the pipe. In both cases the grain does the filtering, the "manifolds" only serve to pick up the liquid. One thing that needs clarification: if you build a mash/lauter tun from a cooler (an inexpensive option) you cannot add heat to it easily. Nobody I know has a heating element in their cooler tun, although its not impossible. Jack and some others mash in a kettle on the stove, which is handy for adding heat. A

large SS pot is way more expensive than a cooler, but a cheap canning pot could be used. For simple infusion mashes (one temperature) I don't need that capability. I add 1 quart of 170F water for each pound of grain in the cooler and it settles out around my mash temperature 152-154F. Here it is being used as a mash tun. After conversion, I start sparging and it is being used as a lauter tun. I see no need for separate tuns. Good luck in your tun construction; for me, it is almost as fun as brewing.

Cheers,

Hmmm. This sounds like a good recipe. Maybe you should substitute 2 oz of ThoE RTOHosehqKJOHlke instead of 1 1/2 oz of YmVmb3JlIGJvdHRsaW5n as you mention above. Otherwise, I am really not sure what your problem is.

Good Luck! I look forward to more of your posts! ;-)

What I use is an old milk crate. This works nicely for handling full  
carboys  
and usually one get get milk crates for nuthin' if you look hard enough  
(or  
at Kmart for \$4).

Yes, just tried it this past Tuesday night. Not bad stuff, IMO. To me,  
it  
tasted quite similar to Miller's answer to the Microbreweries (what was  
the  
name of that brew?). It hardly, IMO, qualifies as a Bock though!

Subject: Transporting Homebrew

I have recently bottled my first two batches of homebrew - one a light pilsner and the other a bitter ale. I would like to transport about a case of these bottles to Thanksgiving dinner (about a 7 1/2 hour car ride). Is there any danger in terms of exploding bottles during a long trip such as this? Also, assuming the sediment becomes disturbed during the ride, how long should I wait for settlement before opening?

Any tips for protection during transportation would be appreciated.

Thanks,

Robert Urwiler

I have filtered a little bit of beer. I still dont filter most of my beer. Yeast cells are around 5-10 microns, so a 5 micron filter will remove most if not all of the yeast. I would avoid the filters sold in HW stores, they will be poor in efficiency, and basically become a \$4 one shot deal. I have used one as a one shot deal for a real coarse filtering to remove hop pellets. Invest in a reuseable 5 micron polypro filter from the filter store, 1-800-828-1494. Costs about \$25, good for at least 200 gallons. Filter flat beer, then force carbonate. Filtering has no effect on carbonation provided you use forced CO2.

If you want to remove protein haze, and reduce head retention, you can buy a sterile filter of .5microns, but it will cost ~\$32.

Good brewing,

From: Paul deArmond <paulf@henson.cc.wvu.edu>  
Subject: Mashout

As I recall, the Great Mashout debate started with a question about the necessity of killing off enzymes at the end of mashing. It has now taken a turn into sparging technique.

I would most humbly and obsequiously submit that stuck sparges and denaturing enzymes are different critters.

How one handles their sparging is dependent on a large number of variables: types of grain, crush, mechanical details of the mash/lauter tun, even (yes) temperature. Of all of these, the mechanical details of the mash/lauter tun are probably going to be the most influential for beers made from mostly barley malt. High proportions of gooey, floury, pasty sticky grains will make the details of the sparging setup even more important.

At the risk of becoming highly technical, allow me to submit the following High-Tech (tm) illustration:

There are a great number of different sizes and shapes of containers to hold the cooked grass seed: garbage cans, Alaskan (and the smaller Texas-size) construction helmets, kitchen sinks, nail kegs, buckets, foot basins, Rhode Island swimming pools, water beds, etc. Likewise a great number of perforated thingies are also used: soil pipe, panty-hose (both used and new), buckets that have been used for target practice, hair-nets, old socks, venetian blinds, storm grates and clever specially designed appliances that are made in Mexican sweat-shops and then marketed here with cheesy little "Made in USA" stickers on them.

Most people use some kind of hose where the watery stuff falls out, though in very backward areas (such as Chicago and San Francisco), it is just allowed to fall on the floor. This "drop and mop" technique is claimed to yeild incredibly high extract rates.

Given the large range of equipment in use, it seems only reasonable to this author that there will be some variation in practice, including adjusting the temperature of the cooked grass seed before trying to get the watery stuff to fall out the hole in the bottom. What this has to do with killing off the enzymes (which look like little people in tights with Pac-Man heads according to one widely published work) continues to elude me. I personally don't like to do it, because their pitiful little screams upset me. Others with harder hearts may choose to do differently.

>cap in starting a siphon.

Although the orange carboy caps are too large for the 7 gallon  
carboy they can be made air-tight, to start a siphon, by wrapping duct  
tape tightly around them.

>airlock. The above supplier also carries long racking canes which will  
fit 7  
>gal carboys.

Another option here is to use the 3/8" coper tubing. It can be  
shaped, is nearly indestructable,  
sterilized by heat by baking in the oven, and is exactly the  
same size as the plastic ones sold in homebrew stores.

For those asking about DME effects on specific gravity, 1 pound of  
DME in 1 gallon of water yealds an SG of about 1.042. Therefore,  
for example 1 pound added to 6 gallons of water will increase the  
SG by  $.042 / 6 = .007$  points.

Subject: bad COPS & bananas

Hello,

I missed the COPS episode ala Elliot Ness cracking down on the hapless homebrewer. I agree with Russell Gelinis that homebrewers should take an active role in educating whenever the opportunity arises, I question the practicality of a nationwide PR campaign. Perhaps, thinking globally and acting locally would serve the purpose better. Local brewclubs can advertise events in local media & maybe get some newspaper/tv exposé to boot. Clubs could draft letters or complaint to deliver to both the local station airing COPS and the shows producers. The AHA could do some PR work, having pr/information experts and spokespersons ready to field reporter queries or to provide talking head bites to local or national tv crews. But to publicize outside of addressing the producers of COPS and the local stations that televised the program could be misguided. How many people saw the show? How many people even remember seeing the show? Unless there is a groundswell of prohibitionist fervor threatening your home brewer or local supply store, any negative publicity or perputuated misunderstandings is probably over-rated.

Well, off my soap box and into the kitchen...Banana esters. I have a brown ale with slight banana esters (used Yeast Labs British Ale). Are these esters a regular characteritic of the yeast, a result fermentation at 69-73 F ambient, or both?

While I'm in the kitchen, is there any chance at all I could brew an extract dopplebock & lager it in a cool basement on a concrete floor? I want to make a dopplebock for a graduation party "The Matriculator" but I don't have a spare 'fridge to lager the bottled products. Has anyone tried this? Any minimum temps. I should pray for? The current temp. ranges from 59-62F and I it should get cooler as the sun wanes.

Thanks for any comments and advice concerning homebrew pr and bananas and dopplebock.

Subject: formula request

Greetings,

I would like to second Jonathan Knight's request (HBD 1247) for a way to calculate the O.G. with malt extracts. As an avid user of equations and a terrible deriver of equations, I'd like to be able to solve for any one of the three factors, quantity of malt extract, volume of water, and O.G.

By the way, is there any NET consensus on the result of one pound of DME and LME in a gallon of water? I've seen a range of 1.035 to 1.045 for DMS and a range of 1.032 to 1.040 for LME. What's up?

Cheers,  
Joe

Subject: rotten egg smell in fermentation

Tony wrote:

>This is approaching Frequently Asked Question status on HBD, so  
>here's a brief explanation.

(brief explanation deleted)

Thanks for the explanation, Tony. I appreciate your response, but I guess I mis-stated my question.

What I was interested in was why this particular batch should smell like H<sub>2</sub>S. I used Wyeast 1056, which is what I have used quite a bit in the past, without any H<sub>2</sub>S smell. The only thing I changed was the malt, which was DeWolf-Cosyns Pale malt. The yeast starter did not smell like H<sub>2</sub>S, but the primary fermentation did. This leads me to speculate that it is not the yeast, but rather something to do with the formulation of the wort.

Any takers?

Joel

> problem? What did I do wrong? Thanks, Tom Sauret

>

Without checking TJOHB for the reference, it sounds as though your  
problem was adding "flaked maize to my wort". Did you really add it to  
your wort? and when did you do an iodine test?

If you're adding flaked maize to an extract-based beer, try doing a  
little infusion before adding the syrup. Take your flaked maize, et al,  
put it in a cheesecloth bag and soak at about 150F for 1/2 hour or.  
Then rinse it with hot water, save the resulting liquor, and add your  
extract to that. Flaked maize shouldn't cause *\*any\** problems with  
starch; in fact, George Fix recommends adding it late during the mashing  
cycle in an all-grain beer.

How does Charlie phrase it? "Chill out and suck some brew"?

Subject: alcohol percentages, too

I have a question that is a tangent to Brian Moore's posting regarding varying alcohol percentages in beers distributed to different states.

If the maximum percentage of alcohol allowed in a beer distributed to my state is 3.5, for instance, what about the beer that might be produced in a brewpub in my state? Must they conform to the same percentages as the distributors or are there exceptions for an "on premises only" beer?

Just curious...

From: COYOTE <SLK6P@cc.usu.edu>  
Subject: Mash & Lauter Tuns/ Yeast Starter Media

There seems to have been a number of questions recently regarding mash tuns/lauder tuns. I thought I'd chime in with a basic rundown on the varieties- and describe my modification to the copper tubing version. There are commercial versions out there- but I'll deal with the home-made varieties.

The most basic equipment needed for mashing is a LAUTER TUN. A vessel used to filter the grains out of the wort (sparging). I generally start my grain in my boiling pot (my grinder sits on top and grinds into the pot. The bottom is flat so I can use my paddle to mix in the hot tap water and thoroughly mix the grains with the water. I then add hot water to bring the temp up to mash-conversion and transfer the slop into my lauter tun. Some people will adjust their temps in the lauter tun. I know I risk HSA- but haven't observed problems with my approach. The temps are still WELL below boiling. One guy was concerned about how to apply heat to the mash tun- bring temps up with hot water. Unless you use a bru-heat type mash/lauder tun you don't need a heat source IN the tun. I used to apply direct heat- but it's SO easy to overshoot, or apply uneven heat.

The concept is to establish a FILTER BED out of the grain husks. Big pieces at the bottom, small toward the top. This rests on some sort of filter mechanism-allowing the sweet wort to flow out, leaving the grain behind. Ideally the system will HOLD a fairly constant temperature for the duration of the conversion.

The common lauter tun approaches are:

1. Grain bag in a bucket with a spigot near the bottom of the bucket. Grain bag is held in place with elastic (bungee). Bag is mesh material. I used one of these for several years. Worked fine. Disadvantage: Size limitation, not insulated, unless you stick it in a box. Bag would slip sometimes.
2. Zapap: Bucket w/in a bucket. Upper has MANY holes in bottom. Drill zillions of 1/8 " holes. Spigot in bottom bucket. (3/8" MPT= male pipe thread, rubber gasket- into 1/2" OD hole CP) Sorta tried one of these once, but not really. Sould work fine. Insulation is again a problem. You can fashion a styrofoam lined "box" to contain it.
3. False bottom. Bucket or metal pot. Stainless steel plate full of holes like the zapap- is placed an inch off the bottom of a pot or bucket. For a pot this requires welding a spigot onto it. I never wanted to do this to my pot. I'd probably manage to break it off! (clutz) With a metal pot this would have the advantage of enabling direct heat application.
4. Copper tubing manifold. Can be holes, or slits drilled or cut into a network of copper tubing- which collects the wort and allows it to flow out into the boiling pot. Often set up in a cooler, either round, or rectangular will work (debate rages!), allowing temp. maintenance.

Ok now to attempt some ASCII diagrams- I know they've been done before...but

Top View: Side View:

I think we need a verbal description here too. I have a 48qt rectangular cooler. I removed the drain valve. Drilled a hole at the opposite top. Collected suitable hardware for threaded connections inside and outside the drain- attached a standard garden hose faucet outside the cooler. The manifold is made from 4 lengths of 3/8" tubing sawed through halfway (hack). Connected with T-pieces and small pieces as needed. The middle end pieces are T's. Drain side goes out, the opposite attaches to the Down tube. A T at the tops of the down tube exits the cooler through the hole drilled there, and also attaches to the Sparge Tube. This tube extends across the top of the cooler, and has holes drilled on both sides. The advantages of this tube and T are that I can place a bucket w/spigot above the cooler containing hot sparge water, and let it trickle onto the mash bed. I can control the in-flow rate to match the out-flow rate. Constant bed height. I can also remove the sparge tube, close that off and underlet water into the bed-or if necessary blow air into the downtube allowing me to RESET the grain bed. The original idea was to allow me to run water through the manifold to clear it. I also fashioned a metal screen to fit over the manifold- kinda like a false bottom to make a flatter surface for the grain bed (can you say "overkill"?). It keeps big grain bits away from the tubing- aiding the grain bed establishment, and makes it easier to lift the grain out of the cooler into my healthy compost pile. I don't know how clear this will be to everyone- but if you have questions drop me a line and I can elaborate- or snail mail you a hand drawing. As has been discussed- be sure to use LEAD-FREE solder for the tubing. I used a propane torch for heating the tubing, then sweated in the silver solder.

I fashioned mine such that the manifold is removable. A nice benefit for cleaning. I love the simplicity, and consistency I get. I have more than adequate space for as much as a 30# grain mash. The flow control is very nice. I don't cause any disturbance of the grain bed once set. and I don't have to stand over it once the flow rates are set. I don't lose temp over a 1-2 hour mash. It is very beneficial to add hot water to the tun first before adding the grains- preheats, and allows the grain bed to set better. Boy...makes me wanna go use it NOW!

Costs: I got the cooler for \$5 at a yard sale. Copper tubing was about the same. I bought a straight piece, 10' I think. Fittings connectors: maybe \$10-\$15 for solder and all. I could spend almost that much for a grain bag! I much prefer my newer system.

\*\*\*\*\*  
Another Note: Yeast Culturing: Someday (after I write my thesis) I plan to write a pamphlet on culturing for homebrewers (Al!). I have R. Leistad's, but find it lacking. No offense to Rog, it's a useful booklet, but he's not a microbiologist. That is clear. And the organization is a bit strange to me.

As for how much malt/sugar for specific specific gravity readings... I will do an empirical study and publish a table...BUT in the meantime ...Rog's recipe for a starter solution is 1 Tbsp malt (dry), 1/16 tsp yeast nutrient into 1 cup H2O. This translates to 1/4 cup

malt, 1/4 tsp YN per quart, or 1 cup malt, 1 tspYN/gallon. He does not state what sp.gr. that makes. I haven't checked. Paul Farnsworth suggests 8 tbsp dry malt or 10 tbsp syrup in 2 1/2 cups water. This is from the Zymurgy special issue on yeast. There are some good ideas in there, but they are rather scattered. FYI 1 quart ~= 1 liter. I'll publish conversion tables too!

Bandwidth- what bandwidth. I don't need no stinking bandwidth!

Brew On! John (The Coyote) Wyllie SLK6P@cc.usu.edu

From: LeRoy S. Strohl <lstrohl@s850.mwc.edu>  
Subject: Re: Catching up on mail

Sean Taylor asked about beer drinks in a recent HBD. Two which I have encountered are the Shandy and its cousin the Shandy Gaff: the Shandy is a mix of beer and lemonade (my favorite version of this was the Tiger-Tops that I had in HongKong in the early 1960's - Tiger is a pretty good lager made if memory serves in Singapore, and Tops was a lemon soda that was very popular with the British sailors I'd met) the Shandy Gaff is much the same except it is made with ginger ale. The best ratio for me was just a splash (how do you like that for accuracy) of either the lemonade or ginger ale. I guess if I were going to recommend these it would be that they be considered a summertime drink.

JM Montgomery asked about smoking grains - JM I have smoked grains using just a regular covered/kettle grill. Whatever grains you want to smoke can be placed in a pouch of aluminum foil, puncture it all over with a fork to make lots of little holes. Outside of the grill get two or three charcoal briquets to the point that they are covered with gray ash, place them on the coals rack and cover the briquets with a couple of handfuls of previously moistened peat moss. I usually leave them in the grill for at least 30 minutes. For my own purposes I think it adds a nice touch to a couple of my Scotch ale recipes. Hope this works.

Mark Nelson talked about the yuppification of the brewpub business. OK it seems that you would be wise to think of the business part of it first - the guy that is running this brewpub is in it for the money. Yuppies have disposable assets and the guy is glad to take it to pay his rent, grocery store, wait staff and grain bill. Second if his beer is not good one of two things will start to happen - people like yourself will tell him his beer leaves much to be desired and if he doesn't change you'll stop going to the restaurant and maybe others will too, and hey who knows, he may go out of business. However, there is a funny alternate scenario. Lets say he doesn't change his recipes, but the yuppies keep on coming, and they posture around with talk about hop bouquets, malt texture, mouth feel and yeast flavors. You probably don't want to hang out with this kind of crowd, and you'll have the satisfaction of knowing that a bunch of effete posers are drinking bad beer. Keep on making your own, it's probably better anyway.

From: Steve Seaney <seaney@ie.engr.wisc.edu>  
Subject: Amalyse Enzyme

I am a bit confused over the use of Amalyse Enzyme (I hope this is spelled correctly) when brewing all grain beer. My understanding is that it contains Alpha Amalyse.

My understanding is that Alpha Amalyse is denatured around 130 degF. If this is correct what good is the enzyme at mash temps above 140 degF?

I don't have my copy of Papazian or Miller at the moment. Can someone help out?

When should Alpha Amalyse be used?

Thanks,  
Steve

From: smennitt@oasys.dt.navy.mil (Stuart Mennitt)  
Subject: Wit and Brewing with Liquors (???)

I've just started a batch of Wit based loosely on Miller's recipe. I'm using 3.3 lbs M&F wheat syrup extract, 2 lbs M&F pale dry extract, 1.5 oz of 2.9% Hallertau hops, and 1 oz ground coriander seed. The yeast is Wyeast European Ale.

I'd like to add a slight orange flavor, and I was considering adding some triple sec liquor to the ferment. I've got some Bols brand that uses curacao and seville oranges for its flavor. Should this work?

Any idea how much triple sec to add?

I've also considered using a more "Belgian" yeast for this. Any suggestions here? Would it help to culture a Chimay or Duvel and repitch with some honey or corn sugar? Any other "Wit" style extract recipes out there? Am I asking too many questions? Thanks.

> Watch those line lengths...

Please accept my sincerest apologies. The message appeared clean when I sent it. The digest software rejects postings with lines longer than 80 characters, so I didn't expect any problems.

Here's a summary of responses that I have recieved:

> Iodophor has a sort of metallic-chlorine-like taste ... It's less objectionable to me than chlorine itself, though. I think the key has to be to drain thoroughly after sanitizing with the stuff, and to use pretty low levels to start with. ... 12ppm is easily detectable. We could do an experiment...

> The advantage [of iodophor] over bleach is that chlorine in very dilute concentration combined with polyphenols in beer will easily generate chlorophenol compounds that have a taste perception threshold in the few parts per billion magnitude. If you're finding a harsh medicinal character in the beer, that's chlorophenolic. This can be cause by rinsing with city water with high amounts of chlorine, or can be present from the start if you brew with water out of the tap....

[This shouldn't be the problem. Our technique has avoided this in the past.]

> Iodophor is routinely used in restaurants as the final sanitizing rinse for dishes & glassware, which may be used immediately for food service. FDA considers 10ppm iodine safe for consumption, though iodophor solution also contains phosphoric acid and isn't very tasty by itself.

> You might want to verify that your friend rinsed out the iodophor. I frequently see one of its benefits listed as "no rinse required." They certainly tout this in its use in the food industry (from what I have seen in Superior Products' catalog and on the bottle I have). George Fix, in his book "Vienna," says that although no rinse is required he still recommends rinsing with cheap commercial beer ("Way waste our own.") - 12 oz. is good for rinsing a 5 gal container. Dr. Fix commented that amber and dark beers in particular are more apt to react to residual sanitizer giving it a flavor that can easily be mistaken as an infection. I guess all this is to say that it is probably no surprise that iodophor causes off-flavors and should indeed be rinsed...

[The original beer was a "Belgian" brown... I would describe the flavor as smoothly medicinal rather than infected]

From: Gary S. Kuyat <gsk@sagan.bellcore.com>
Subject: 5/2/.5 micron filters
Full-Name: Gary S. Kuyat

After playing around with a couple of filtering systems, and counter-pressure filling bottles with force carbonated, filtered beer, I have these notes on different filter elements.

5 micron:

Takes out big chunks, like hop particles. No effect in flavor, no effect in body, no effect in chill haze. Other than as a pre-filter 5 mic. seems pretty useless.

2 micron:

This seems to be the best all around. Removes yeast. Some very slight loss of body. Clears and "crispens" beer taste. Almost have to say "why wouldn't you run all your beer through this?" (that is if you're kegging!) Don't try in-the-bottle carbonation with this, 'cause most all the yeast will be removed!

.5 micron

Removes yeast, some body and if your beer is very cold when you filter, this removes chill haze! Kinda leaves your beer with a "thin" mouth feel. If you are making lite beer (and I have) then this is the filter for you! Half micron filters are not cheap! Beer that is cold-filtered through a half micron really should be put in clear bottles (IMHO) to let your friends hold it up to the light and see. If you follow "better to look good than to..." this might just do the trick.

.1 micron

Removes beer...

I think you will increase your chances of a starch haze. Depending on
your
crush, you will have some amount of unconverted starch hiding among the
husks. Bringing this to a rolling boil will gelatinize this hidden
starch
and give your beer a starch haze. Avoiding this problem is one of the
reasons that Noonan recommends taking only the thin portion of the mash
(just the liquid) for the final decoction (the one leading to mash-out).

Personally, I don't like a husky character in my beer. Malty is one
thing,
but husky is another. Consider the flavor of wort and the flavor of
spent
grains. Wort tastes malty, spent grain tastes husky. I prefer only the
former.

Al.

Subject: Fast Spargeand Godzilla

>From: polstra!larryba@uunet.UU.NET

>My second to last batch was 20 min for 11 gal at ~34 pt/lb/gal
I also typically skip mash out maybe heating the mash to 158-162 just
to maintain a mash bed temp of 140-150 and to force conversion if the
iodine test is not negative after 20-30 minutes....Once, a year or two
ago, I
asked the forums if there were any negative issues w/regard to fast
sparges.
I got no responses.

I was so impressed and humbled by both postings that I had nothing to
say for
a change. When someone claims he can make a silk purse out of a sow's
ear
and backs it up with the numbers, it's tough to say something clever.

>This guy also suggested an experiment for me to do to test out his
ideas:
next time I begin to lauter a 10 gal batch, to set aside 2 gallons of
mash and bring it to a rolling boil before adding it back into the
lauter
tun.....

>The question: What do folks think of this theory and the experiment? Am
I
likely to just end up with a bad starch haze and a puckery beer?

Not sure the experiment makes any sense but mashout and hot sparges have
become a ritual with me. All you have to do is bring your mash to
mashout
temperature to realize that lots of stuff is going on here. The change
in
color, iodine reaction, viscosity and taste would indicate that the end
beer
ought to be effected. Whether this is good or bad is your call or the
competition judges.

I would suggest that a far more meaningful experiment is the obvious
one.
Brew up a batch using a simple decoction, i.e. boil a couple of gallons
after
the main mash reaches such temp and dump it in. Continue the mash as
usual
and mash out at the end. Sparge slowly with hot water and finish the
beer.
Then report back to us with the difference in your beer from previous
batches.

BTW, you "mash out" at 162F might be enough to get you over the hum. It
is
not exactly a cool mash and most infusions would be far cooler by the
time
sparging is begun.

>From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)

>Tallying the responses from both HBD and email, it appears that there are quite a few homebrewers out there who do not perform a mash-out. More so than I imagined.

As the vast majority of all grain brewers mash in plastic buckets of one sort or another by adding hot water to the grain, it is not surprising that the vast majority do not mash out.

> I agree that the reasons you quoted are not very rational reasons for doing a mashout but there is one reason that I think is a good one. By raising the whole mash 20 degrees or so, you stand a far better chance of keeping it in the optimum range during the lautering process. It's easy enough to do for those who kettle mash but it is probably not worth the trouble for the bucket infusers.
>
> js

<Ouch. An idol's dagger plunges the deepest. You assume that we all agree there is an optimum range and that thus there is a need to be within that range.

No! I assume that everything I say is taken as gospel and no further discussion is necessary.

> I do not support such assumptions. I skip the mash-out and consistently get good yields. It should also be noted that I use a picnic cooler and never perform a protein rest (Belgian malts).

Right! And there are those out there who claim they make REAL beer with extract. We AGS's just raise our collective noses higher at such nonsense.

> I won't tell you how I grind my malt because I'll be forced to use the "C" word.

I understand you once had a MM but traded it for a Corona because the grain kept coming out of the hopper when you turned the crank. The Corona has an arrow telling you how to turn the crank and I can understand how No-Mashout-Types (NMT's) feel more comfortable with it.

>Looks like Godzilla and Mothra have teamed-up to combat the onslaught from BOQAT.

Keep in mind that Godzilla is for real but the others are just just fictional characters.

I sometimes wonder why anyone else even bothers posting to this forum, anything other than questions. Unless it comes from me, one can never be certain that it is the truth.

Subject: help on yeast

I'm a novice brewer (second batch) who has now learned, don't throw away the labels to your mixes or yeasts! My question is about yeast. I brewed two days ago a hopped extract for a strong ale. Before adding the yeast to the (pre-)wort mix, I put it in water and warmed it. The wort was at 70 degrees when I added the yeast. Forty-eight hours later, there's been nary a bubble through my fermentation lock. Would overwarming have killed the yeast, or was it more likely something else? Has anyone ever added a second dose of yeast or does that do funky things to the batch? Any help anyone can offer would be much appreciated.

Thanks,

David

From: RADAMSON@delphi.com
Subject: 5 Liter Kegs

I've now read a couple new posts re: 5 liter kegs and being a 5 liter expert now, I thought I'd update a post I made from around then end O'March 93:

"I have received several inquiries regarding the 5 liter metal keg setups. Here are my datapoints:

The problem with getting Dink, Dab, et.al. cans from the stores is that the tap you get is a gravity tap that you insert in bung, flop the keg upside down and 'can-open' a hole in what was the bottom (and now on top). Certainly makes the vessel un reusable.

The solution is these bottom-feed CO2 cartridge taps made by Beer*King in Germany. I originally got my tap(s) from Hoster Brewery (brewpub) in Columbus, OH - but they no longer 'keg' into 5 liter cans (and, therefore, don't sell the taps anymore). Dock Street Brewery in Philly kegs into 5 liter cans, but I'm not sure about the type of tap they sell. Likewise with Stoudt's in Adamstown, PA.

A source that I do know of (and have no affiliation with) for both taps and new empty kegs is:

Randy Martin, Proprieter
Brew Ha Ha, Ltd.
209 High St
Pottstown, PA 19464
800-243-2620 (orders)
215-326-2620 (Dr. Brew)

Randy picked up a bunch of kegs from the now defunct Happy Valley Brewery (Penn State) and could probably set you up. [10/93 Note: These things went fast and I don't know about current stock.]

The tap has a central stem the height of the can which feeds brew from the bottom. There may be a small yeast burst in the first couple ounces of brew/foam when first tapping, but none whatsoever afterwards. The tap has an adjustable CO2 valve that I "tweak-up" a little at a time to introduce more gas - you can hear it enter and build up a bit, then back it off to zero. I put more gas on for overnight storage, haven't had any leaking. Also available are Whippets or N20 cartridges to power your creamy stouts! (I do notice "sweeter" ales when dispensed with nitrous). I guess you could also "try" force carbonating, but stock up well on CO2 carts.

As far as kegging these skippers, I usually fill 3 kegs and a dozen bottles per 5 gal batch. And to keep it simple, I still bulk prime as if doing bottles with either DME or Corn Sugar (.75 cup) and just fill the cans as I go along. I use a bottle filling wand that does not contain a spring - just gravity & pressure control. I just drop the wand in the keg and do a take-5 for a bit.

Use your own standard priming rate, mine are low-to-fair carbonation level (British Ales, mostly). Since the volume is larger than that of a bottle, the maturation time is increased (takes longer to reach carbonation), but is well worth it. I leave about 1" headspace on the kegs and have had no overcarbs. Handling and storage is the same as if they were bottles. The 5 liter is equivalent to about 14 12oz bottles - but it goes in the fridge better.

For Sanitizing, I just drop a few tbls of Bbrite in, fill and soak for a couple hours prior to kegging. So far the hardest part about these is forcing the bung in after I fill the keg."

[current post again]

About the only problem (sic) I've had is possible inappropriateness of 5 liters of some beers (at a time). Like, I made a great Raspberry Patch Brown Ale, but kegged it all. Its great to take or have for an event, but I do get my fill of raspberry fairly early. The beer is a perfect match for 22 oz brown or 25 oz champagne bottles. I will probably only fill 1 keg with my Pumpkin Patch Ale, the rest in bottles.

From: Domenick Venezia <venezia@zgi.com>
Subject: Yeast nutrients

What are the opinions on using yeast nutrients when preparing starters?

Chris Raymond, here at ZGI, has an experimental brew going in which he split the starter wort into 2 portions and added "Yeast Nitrogen Base" to one of them and did the other as normal. YNB is a commercial preparation of Ammonium nitrate, trace elements, and amino acids. It is added in the amount of about 7g/liter. Chris grew the starters under the same conditions then assayed them for total cell counts. The YNB starter had a cell density 10 times (!) of the other. The numbers worked out to 10×10^{10} cells/liter. I seem to remember an optimal pitch for 5 gallons is 4×10^{10} cells so using YNB you could pitch with a pint and get an optimal cell count.

Of course something could be wrong with this. Maybe happy yeast changes its flavor profile. Maybe it loses attenuative ability. Who knows? And that of course is the question. Who knows? If you do know or even have an opinion, let's hear it.

Chris is brewing a batch with both starters, so we should be able to do a side by side comparison of the results.

>
> Al
>

Ok, I'll bite. Where's the dividing line between "warm honey" and "cold honey" i.e. at what point do wort sugars flow and not flow? I skip the mash-out and sparge with 170-180 F water. I usually sparge 5 gallons of water in 30-45 minutes. My mashing efficiencies are consistently over 80%. Given these facts is it safe to assume that wort sugars flow without a mash-out?

>
> I agree that the reasons you quoted are not very rational

>In London, England they mix bitter orange soda with beer and call the resultant beverage "Shandy". In some parts of England this is called "Orange Shandy" and other soda beverages, Cherry, for instance, mixed with beer would be called "Cherry Shandy".

>It is almost shameful to admit it but (shudder) Orange Shandy tastes pretty darn good as a "lawnmower style" malt beverage. I know that this probably offends the sensitivities of most of this audience, but, refuse to judge until you've tried it. Mix equal parts Schweppes Bitter Orange with Double Diamond and see what I mean!

I think it should definitely be referred to as "Orange Shandy". Traditionally, shandy is an even mix of beer and lemonade--where lemonade is something akin to 7-Up, not the type you find at a lemonade stand here in the US. I agree, shandy is not to be dismissed until you've tried it, and it's a great compromise if you've got to take it easy 'cos you're driving. I would avoid the premixed shandy though -- it's bad, very bad.

x
If you're in Britain and you've got an obliging landlord have him mix it with beer from the hand pump. You will probably have more luck with this in the south of England than in the north because (generally speaking) recirculating handpumps are more common in the north. The next customer wouldn't appreciate your lemonade in his best bitter.

Perhaps you may even want to try a "lager and lime" -- generally Rose's Lime Cordial. Or even lager and black (black currant cordial), or then again how about a Guinness and black.

BTW, shandy is indeed a traditional English mix. Invented by a famous big-game hunter (whose name eludes me for the moment, but I'll look it up), traveling in Africa. He found that the traditional English beer (presumably an IPA) was not as thirst quenching as it was in a more moderate climate, and started mixing it with other beverages. Like the man said, "lawnmower style."

In Germany, people will mix a light-colored beer (insert Pilzen or Weiss
here) and mix it with the equivalent of Sprite (tm) and call it a
"Radler."

I believe it is done in a 50/50 ratio. It is quite tasty on those hot,
summer days and every now and then I will consider doing the same with
some
of the swill I see in my parent's 'fridge. Good stuff! I recommend it!
Be daring! Give it a try!

Subject: Beer hunting in Belgium: Introduction

Beer Hunting in Belgium

Introduction
(by Phil Seitz)

With this post I would like to introduce a seven-part series on beer and brewing in Belgium, based primarily on research conducted by Jim Bush and myself during a visit this past summer.

Our goal is to share as much of the beer and brewing information we collected as possible, and the final post will contain information on cafes, stores and other resources for future visitors. A few of the posts will go beyond brewing to offer a broader narrative, particularly in cases like our tour of the trappist brewery at Rochfort, where we were privileged to do something that others probably won't be able to. In these cases we'll try to offer a vicarious tour, but hopefully without tiresome comments about what a good time we had, etc.

To avoid HBD bloat I will send out one "chapter" each day, although the actual time of appearance will be subject to the whims of HBD. The topics covered will be as follows:

Part 1:Rochfort (Trappist brewing)
Part 2:Brasserie de Silenrieux (Brewing with spelt and buckwheat)
Part 3:Liefmans and oud bruins (Sour brown beers)
Part 4:Brasserie la Caracole (Running a very small brewery)
Part 5:Oud Beersel (Lambics)
Part 6:Aged beer tasting (25-year-old Orval and more)
Part 7:General information (Where to drink and shop)

This was my seventh trip to Belgium in six years. At this point my French is pretty functional, and I have a large number of friends and connections--many of them beer related. While I've been brewing for about 2 years, Jim has been doing so for much longer and has a much deeper understanding of the processes, equipment, and problems involved. So we teamed up, traveling the Belgian countryside, listening to Jim's substantial collection of Radiators tapes, and searching for good beer.

While I can therefore say that Jim and I brought a certain amount of experience to this task, we are painfully aware of all the questions we forgot to ask, or couldn't. You are welcome to write to either of us with inquiries about the material you'll be seeing over the next few days, and we'll try to answer as many as we can. Please try to be understanding if we fail you.

I plan to continue visiting Belgium on a regular basis and welcome suggestions for addition information that needs to be collected.

Apologies are also offered for all the typos, misspellings, and other editorial incongruities you'll undoubtedly find in the posts that follow. I've worked them over a bit, but decided that people would rather have the information now than wait until we could produce a more elegant piece of writing.

Above all, we hope the following posts will be informative and enjoyable to read.

Beer Hunting in Belgium

Introduction
(by Phil Seitz)

With this post I would like to introduce a seven-part series on beer and brewing in Belgium, based primarily on research conducted by Jim Bush and myself during a visit this past summer.

Our goal is to share as much of the beer and brewing information we collected as possible, and the final post will contain information on cafes, stores and other resources for future visitors. A few of the posts will go beyond brewing to offer a broader narrative, particularly in cases like our tour of the trappist brewery at Rochfort, where we were privileged to do something that others probably won't be able to. In these cases we'll try to offer a vicarious tour, but hopefully without tiresome comments about what a good time we had, etc.

To avoid HBD bloat I will send out one "chapter" each day, although the actual time of appearance will be subject to the whims of HBD. The topics covered will be as follows:

Part 1:Rochfort (Trappist brewing)
Part 2:Brasserie de Silenrieux (Brewing with spelt and buckwheat)
Part 3:Liefmans and oud bruins (Sour brown beers)
Part 4:Brasserie la Caracole (Running a very small brewery)
Part 5:Oud Beersel (Lambics)
Part 6:Aged beer tasting (25-year-old Orval and more)
Part 7:General information (Where to drink and shop)

This was my seventh trip to Belgium in six years. At this point my French is pretty functional, and I have a large number of friends and connections--many of them beer related. While I've been brewing for about 2 years, Jim has been doing so for much longer and has a much deeper understanding of the processes, equipment, and problems involved. So we teamed up, traveling the Belgian countryside, listening to Jim's substantial collection of Radiators tapes, and searching for good beer.

While I can therefore say that Jim and I brought a certain amount of experience to this task, we are painfully aware of all the questions we forgot to ask, or couldn't. You are welcome to write to either of us with inquiries about the material you'll be seeing over the next few days, and we'll try to answer as many as we can. Please try to be understanding if we fail you.

I plan to continue visiting Belgium on a regular basis and welcome suggestions for addition information that needs to be collected.

Apologies are also offered for all the typos, misspellings, and other editorial incongruities you'll undoubtedly find in the posts that follow. I've worked them over a bit, but decided that people would rather have the information now than wait until we could produce a more elegant piece of writing.

Above all, we hope the following posts will be informative and enjoyable to read.

Wow, supersaturated beer out of the primary?? How do you accomplish
this,
with a pressure tank, and bunging with 3+ Palto of residual extract? Wont
this cause the carboy to explode :-) Seriously, fermented beer when
young
will have around 1 atmosphere of CO2 in solution. While this will rise
out of solution as the beer is racked, the original posters experience
with a filter is certainly going to introduce some degree of oxidation.
A small degree of splashing into the secondary is OK, putting it through
a filter/funnel is sure disaster. Its just not worth it, or necessary.

Subject: Brass in the Boil

Ooops, I forgot to add this to my last post.

Are there any negative effects from using brass fittings in boiling wort?
I'm
thinking in particular of a brass Swagelok (sp?) bulkhead fitting.
(Thanks
Joel for the bulkhead tip)

Also, is it safe to assume that a ball valve attached directly to the
kettle
would be effectively sanitized by heat conducted from the kettle. I'm
thinking
of using an immersion chiller, so hopefully all I have to do to avoid
worrying
(heaven forbid) about infection is to attach a sanitized hose to the end
of
the ball valve and drain merrily into the fermenter.

Any comments?

Thanks in advance.

Subject: Liquid Yeast: Friend or Fiend?

Greetings,

Long time listener, first time caller. I'm afraid that this will have to do with deep philosophical questions, and therefore I may later regret having brought it up at all. But here goes...

I usually ferment my wort with dry yeast, usually with good and reliable results. Periodically, I will use WYeast, particularly when I intend to make several consecutive batches of similar beers, as reusing the yeast slurry becomes economical. Such was the case over the weekend. I was to make a basic pale ale on Saturday morning. I had gotten a WYeast American Ale packet, and burst the inner packet on Thursday evening. Sure enough, by noon on Saturday it was nice and puffy. My 1043 wort was at 70F, and all was well with the world. So, I sanitize the yeast package in bleach water, rinse it off, cut it open, drop liquid into the wort, cap it and swirl it up. I then wait for fermentation to begin, but lo! nothing happens and keeps on not happening until Monday morning.

So far, a dull story. But the reason for the post is that this the third time in four instances of liquid yeast use that this happened to me. The questions I have are:

Why does this happen? Up until the instant that I introduce the yeast to the wort, it behaves as advertised. After pitching, it appears to literally die. I will note that all of the worts that have been victim to this behavior have been revived with dry yeast, and all were completely acceptable, at least to me.

Why does liquid yeast seem so my less robust than dry? This is the thing that I wonder most, since as noted above all of my liquid yeast failings have had dry yeast added and gone on to ferment properly. Also, I have never had a wort not ferment after I pitched dry yeast.

Should this happen when I use the liquid yeast as directed on the package? It's not as if I'm just dumping yeast straight from the fridge to the wort. I know the perceived wisdom hereabouts is to make a starter of some sort, but WYeast's package says that I should be able to do what I did and get fermentation.

Should I just admit abject failure and use dry yeasts exclusively? By extension, will I make a beer with "666" tattooed on its forehead if I reuse the slurry from a batch fermented with dry yeast?

Any suggestion is appreciated.

Subject: re:Hard Cider Recipes

Since there have been a few inquiries about hard cider lately, here are some
cider making ideas from the northeast:

A friend of mine usually puts up a couple of 55 gallon wooden kegs each
fall with 40 lbs of brown sugar in each. I believe the sugar is dissolved
in a pan of warm cider then added to the keg. A rubber bung/ air lock is
inserted and he waits for spring. The slower it works off, the better. A
temp
of 55 to 40 is ideal.

Other traditional recipes use pears or raisins, or both. Basically you
can add
anything which will give the wild apple yeasties more to eat and impart a
flavor to the cider. You may opt to not add anything, which will render a
very
dry cider.

My method involves using green 1 gal wine/vinegar jugs. With these small
1 gal
amounts you can experiment and not worry about ruining a whole batch.
They also
work off quicker than larger batches. Check with local restaurants about
saving
you some. Sterilize, use a rubber stopper/air lock and keep out of
sunlight.

My favorite recipe uses 1 gal of cider with 1 rounded cup of brown sugar.
Place
in cool basement and wait 8-12 weeks. We've also used canned tropical
fruit,
molasses, raisins, white sugar, corn sugar, DME, frozen cranberry juice.
..
experiment!

Cider can be bottled in champagne bottles, Grolsh style bottles or plain
beer
bottles. If you bottle early, you can get a sparkling cider. We've used
cork
and regular bottle caps successfully. Dont disturb the sediment when
siphoning.

Then there's always the possibility of making apple-jack, which is
freezing
hard cider. The water solidifies around a core of alcohol, very potent
indeed.

One last note to those who may not know, its important to purchase cider
without any preservatives (pot sorb), or better yet go to a cider mill.
They
will usually charge less if you have you own container, and even less if
you
bring you own apples. Our local mill is cira 1905 and makes fine cider.

good luck, and watch out for those cida-ffects - mike

Subject: Poly Hose

I just bought a thick-wall polyethylene hose to run from my lauter tun to my boiler. The hose I use now is a thin-wall vinyl hose which has a tendency to collapse when the hot liquor is flowing through it. Any experience with this PE hose? It is quite stiff, compared to the vinyl, translucent (similar to the vinyl after coming in contact with boiling wort), and has almost a waxy feel to it. Also, it is rated for a fair amount of pressure, but says nothing about temperature. Use it or lose it?

Thanks,
Norm

Subject: re: Gravity Calculations

jclayton@TACOM-EMH1.Army.Mil (CLAYTON Joseph A Jr) asks about gravity equations:

>As an avid user of equations and a terrible deriver of equations, I'd
>like to be able to solve for any one of the three factors, quantity of
>malt extract, volume of water, and O.G.

My equation is $OG = 1 + \text{\#pounds of stuff} / \text{\#gallons of wort} * .042$ for dry extract, and

$OG = 1 + \text{\#pounds of stuff} / \text{\#gallons of wort} * .036$

for liquid extract.

The 0.42 and the 0.36 is the "extraction rate" of dry and liquid extracts.

This works backwards to get: $(OG-1)/.042 * \text{\#gallons} = \text{pounds of DME needed}$

For more complicated recipes, we can add the result of several factors:

$OG = 1 + (\text{\#pounds of material "a" * extraction rate of material "a" + \#pounds of material "b" * extraction rate of material "b" + \#pounds of material "c" * extraction rate of material "c" + ...}) / \text{\# of gallons}$

Thus, a recipe with 3.3# of syrup, 3# of dry extract, and 1# of corn sugar gives

$OG = 1 + (3.3*.036 + 3.0*.042 + 1.0*.044)/5 = 1.058$

>By the way, is there any NET consensus on the result of one pound of
>DME and LME in a gallon of water? I've seen a range of 1.035 to 1.045
>for DMS and a range of 1.032 to 1.040 for LME. What's up?

I use 0.42 for DME, 0.36 for syrups, .044 for sugar. Mashed grains work the same way except the extraction rates are lower (.028-.031). I rarely use DMS in my beer, and when I do, I keep them in the parts per million range. This does not effect wort gravity significantly! :-)

available.

This is absolutely correct. The only exceptions are breweries which
misuse
competition results in ad campaigns. Norm touched on this point in
HBD#1249,
and I am in complete agreement with him.

>I would like to see several regional ABF's and have the GABF an
invitation-only
>affair. The invites would go to the regional winners in each category.
That
>way the regionals would be of a more reasonable size and so would the

this
>thing is a leviathan? Dr. Fix, I believe you had one of the judging
jobs,
>which should give you some insight into the organization. Is my idea
feasible,
>possible, or a pipe dream?

This is an excellent point. Both Laurie and I were on the professional
panel,
and it was our view that there were too many beers per judge, and not
enough
categories. In particular, there were over 900 beers entered which were
evaluated by ~40 judges in a 48 hour period. The panel itself had a good
mix of large industrial brewers, microbrewers, consultants, and misc.
academic
types. Many of the major brewing countries were represented including the
UK,
Germany, and Scandinavia, to cite but three examples. Nevertheless, the
work
load was higher than desirable. Of the 900 or so beers entered, only ~
150-200
were in serious contention for awards. This is why Norm's point is of
great
relevance. Had there been local screening a la AHA nationals, then a
better
and more complete evaluation could have been done at Denver. I felt

particularly frustrated by the time constraints, and the effect it had on the quality of feedback the brewers will be getting from the score sheets.

I usually like to write a couple of paragraphs, particularly with problem beers. Unfortunately, at the GABF time permitted only "one liners", something

I see as highly unsatisfactory.

To implement Norm's ideas one would need cooperation at the local level.

This, however, IMHO is exactly what the MBAA and the various small brewers associations should be doing.

I was also uneasy about the number of categories. In particular, there were no categories for Belgian styles. This forced Pierre Celis to enter both his white beer (which won) and Grand Cru in the same category, in spite of the fact that these two beers are dramatically different. In fact, the category in question, i.e., spices, vegetables, et al, seems to me to be ill defined, and as a result needs to be reorganized.

Both Laurie and I were upset about the merger of the Vienna and the Festbier categories. There were ~ 40 enties, 6 of which were world class (three of each of each type). The Viennas had OGs in the high 40s, while The Fest versions were all in the high 60s. I have found that when one is evaluating beer based on 1 oz. samples, there is a skew toward high gravity versions. This is indeed what happened, for the gold and silver metals went to Festbiers. At the private AHA tasting we rounded up as many homebrewers as we could find and tasted the six beers in question, this time with 8 oz. samples. There was general agreement that the two versions were sufficiently different to warrant separate categories, and that each of the 6 samples was worthy of an award. BTW the Viennas won the Gallo test in this informal evaluation, i.e., they were the beers which the evaluators drank the most of. This is not to say the Viennas were superior, but rather it underscores the importance in (amateur or commercial) competitions of not forcing judges to evaluate apples and oranges in the same category.

These comments are not to reflect negatively on the awards that were actually given. The silver went to the Festbier that Pittsburgh brewed for Jim Koch. Those who have read Laurie and my book on this style will know it has been a long favorite of ours, and this version was a good sample. The gold went to one of the best Festbiers I have ever tasted. Still we felt terrible about the 4th place entry (a Vienna brewed in Georgia) for it too was world class, yet it did not get an award.

George Fix

P.S. The judging was blind, and the entries were known to the judges by numbers. Brewers on the panel did not evaluate categories where they had entries. After the awards were announced, members of the panel were permitted to match up the numbers with breweries, to see how various operations came out. There were several samples where I thought I knew who brewed beer being evaluated, and even considered disqualifying myself from their evaluation. It turned out that I was right some of the time, but not in all cases. The biggest shock came from the American Light category, where some small operations blew versions from AB, Coors, and Miller out of the water. I judged this category, and at the end would have sworn that the winners were all from large industrial brewers. What a pleasant surprise!

contact ?
>They don't have very good lawyers anyway.
>
>I've never had the guts to actually risk a batch with this hot
combination
>experiment. Has anyone else done this successfully ? I'd like to

The only reason I cooled my boiled priming solution was I didn't want to dump boiling liquid into my carboy (I add the priming solution first then rack the beer into it). Priming in a keg, however, I have no qualms about dumping the hot priming solution staright into the keg (after flushing it with CO2 first...)

David Atkins writes:

>Well, off my soap box and into the kitchen...Banana esters. I have a brown ale
>with slight banana esters (used Yeast Labs British Ale). Are these esters a
esters a
>regular characteritic of the yeast, a result fermentation at 69-73 F ambient,
>or both?

A hint of banana creeping in under the hop nose is an acceptable part of british ale. The isoamyl acetate (banana ester) can be strong if the temperature is too high (73^F should be OK, but don't let it get higher), if there is insufficient oxygen in the wort, and if the yeast is underpitched. So, aerate that cool wort, pitch lots of yeast, and a whiff of banana (should not come through in the flavour) is acceptable, some might say desirable, from a british ale.

Subject: Re: O.G. Formula

Joe writes:

>I would like to second Jonathan Knight's request (HBD 1247) for a way
>to calculate the O.G. with malt extracts. As an avid user of
>equations and a terrible deriver of equations, I'd like to be able to
>solve for any one of the three factors, quantity of malt extract,
>volume of water, and O.G.

I've used the formula

$$\text{O.G.} = 1.000 + \frac{[\#DME + 0.8\#LME + 0.7\#GRAINS]*0.042}{\text{gallons}}$$

where # means pounds. This formula uses 1.042 for a pound of DME (dry malt extract) in a gallon of water, about 1.034 for LME (liquid malt extract), and about 1.029 for speciality grains.

>By the way, is there any NET consensus on the result of one pound of
>DME and LME in a gallon of water? I've seen a range of 1.035 to 1.045
>for DMS and a range of 1.032 to 1.040 for LME. What's up?

I'm not sure where I've seen the 1.042 figure (probably Charlie P.'s book) and maybe a Zymurgy issue. The 0.8 factor represents an approximate average, and you'll find a variation probably between 0.75 and 0.85 depending on the manufacturer of the LME. The 0.7 factor is dependent on the grains, their crush, and your sparging (straining) technique. On the other hand, I've compared the above formula to measured O.G. values for over a dozen extract batches and have had an average error of about 1 point (0.1%), and a maximum of 4 points, on O.G.'s ranging from 1.026 to 1.057.

Subject: RE:Oxidtn/Shandy/Raspberry&Peach/Spruce/Legalities!

I think we all like to encourage the continuation of the art. Bad first attempts have put off more than one newbrewer! No harm in taking the trouble to drop a hose to the bottom of a secondary (or stuff one into the "out" end of a funnel) so we aren't SPLASHING brew from the top of a carboy. Fermented beer is a reactive shlew of chemicals. Alcohol being one of them! Not to mention that the yeast are quite comfortable in a relatively aerobic environment.

I would vote the claim that oxidation can and will happen upon sloppy transfers- it IS worth taking efforts to avoid it. Buy a longer hose if needed! The stuff's cheap. Cheap beer ain't...well...it is... but

Some IS GOING TO HAPPEN- in almost ANY system, but just keep it down to a managable amount. Unless you like chewing cardboard!!! :),

-blazo talks about how...

In London, England they mix bitter orange soda with beer and call the resultant beverage "Shandy". In some parts of England this is called "Orange Shandy" and other soda beverages, Cherry, for instance, mixed with beer would be called "Cherry Shandy".

*I was familiar with "shandy" being made with bitter lemon soda. A similar mix can be made with 7-up or the like. (the brittish soda has less sugar than our sodas). You could have flavor variants, but a lemon or lemon/lime was the basic.

It is almost shameful to admit it but (shudder) Orange Shandy tastes pretty darn good as a "lawnmower style" malt beverage. I know that this probably offends the sensitivities of most of this audience, but, refuse to judge until you've tried it. Mix equal parts Schweppes Bitter Orange with Double Diamond and see what I mean!

* It is a common afternoon drink, served frequently to kids (it is half as strong as a beer!). Squatters brewpub in Salt Lake serves one. It's ok. Good for the yuppies at luncheon business meetings! I've made 'em. Even with my own homebrew. I had to do something with that 5 gallons of slice I had in the keg I purchased! Too sugary though!!!!
Lemon or Lime in a light beer makes a nice summer ferment. But now's not the time. Dark lager season is on the way!

Norm says he:

(copied without permission, so sue me. No wait, how about 30 lashes with a siphon hose?):

Tsk, Tsk, Tsk.

What length of tubing? With or w/o bottling cane attached?

Do I hear a call for copper tubing?

Subject: Raspberry or Peach beer...

I would like to try using raspberry or peach to flavor my next batch of beer, but I don't know what quantities to use. How should I vary the hopping levels when using these fruit adjuncts? Has anybody got a good recipe for an extract based peach or raspberry beer?
steve tollefsrud

*I've done raspberries in stouts/ pales, primary and secondary. I now have my first peach on the way. I can tell you that a flat of raspberries (4 #) at the end of the boil makes a nice red berry flavor and pink head in a malty pale ale. I'm about to keg up my raspberry brown with berries in the secondary. It's a yummy one! I think I'll drop in some molasses to balance the tartness of the berry. I used about a half bushel of peaches- pitted, frozen, smushed into carboy- and secondary beer dropped on top. I feel that a lighter beer is more fitting for peach.

I'm inclined to keep the hopping rate down on a fruit beer to let the fruit come through. Something semi floral. but not too overpowering. Say Williamete rather than Cascade. Raspberries are commonly found paired with stouts. I like seeing the color all that fruit lends to a brew. Maybe a light porter if you want dark flavor in there.

Freezing fruit- and pectic enzyme can help get the most out of fruit, and aid in clearing of the brew.

Subject: SPRUCE beer

I am thinking about making an extract-based batch of spruce beer. I would be interested in comments about whether it's worth it, and if so, how much spruce should be used for a five gallon batch. Thanks in advance.

John
pavao@ptsws1.npt.nuwc.navy.mil

* I will never try this again (I don't think...???) I tried extract (6 oz) for a 10 gallon batch (was supposed to be good for up to 6 gallons....) and it tasted like PLASTIC. SO...when in Oregon in the spring I tried picking spruce and the "spruce" hemlock tree- fresh green sprigs. I had a gallon bagful. Added them like hops, and had a beer that tasted like sucking sap or something...a chemical flavor that was not "enjoyable". I rarely EVER dump a batch..but...

Maybe a very small sprig of spruce... waved above the pot during the boil, then tossed in the fireplace... I'll stick with fruit for now!

**

OK OK Enough of that "dpdGggc29tZSBtY-ing" on Chris's blip.

So not everyone is a computer guru. I don't think we need any more bw used quoting gobbledy goop, or discussing men who boogy.

BTW Thanks for the ACTUAL translation that was posted.

THAT HELPED!

JC ferguson mentioned a brew which...

tasted quite similar to Miller's answer to the Microbreweries (what was the name.....

* Miller Reserve (especially the amber), 100% Barley Draft...

>making beer and wine for personal consumption is legal in all 50 states.
>(ed. true yet?)

No, not true yet. In Missouri we are still dangerous criminals producing powerful, mood-altering drugs. Let's do keep our facts straight.

* Utah too suffers from Prohibition laws in our "modern" age. At least Georgia got out from under. Write your congressman today!

*also note: Brewking sack ad in Sharper Image quotes:
"federal govert allows you to make up to 25 gallons of homemade beer each year. NFS in AL,Georgia. Resident of UT,Alabama, Oklahoma please consult local authorities before ordering"

Yeah right. Like I'm gonna ask first! Like I'm gonna order a brewbag anyway! All grain or bust! (well...occassionall extract... but only on a weeknight!) It's \$39.95 plus 6 S&H for 25 pints. They have a "traditional export ale" and "premium lager". Oh yum.

Damn at 25 gal/yr I could be done brewing in 2 weeks!
Too bad The Sharper Image doesn't have a Sharper grasp of the legality.

It is nice the know that the authorities here are not interested in enforcing this law. I have good reason to believe that.

Unless someone were to get stupid and try to sell it...like at a deadshow or something... but hey...that might work....hmmmmmm!

If the maximum percentage of alcohol allowed in a beer distributed to my state is 3.5, for instance, what about the beer that might be produced in a brewpub in my state? Must they conform to the same percentages as the distributors or are there exceptions for an "on premises only" beer?

Just curious...

*Unfortunately YES. At least in my "great" state. I would hate the burden and restriction of producing "legal" beer. The only "illegal" beer you can purchase (imports and the like) are obtained ONLY thru a STATE LISCENCED and OPERATED STORE. But the micros do manage to make some tasty brews once in while. I'm glad that my personal "brewery" is not required to conform to such strick regulations! But then it ain't open to the general public either.

End of blabber for now. John (The Coyote) Wyllie SLK6P@cc.usu.edu

From: John DeCarlo<jdecarlo@homebrew.mitre.org>
Subject: Beer Drinks

Check any bartender's guide or list of recipes. Some that I have tasted in the past and enjoyed include:

Black Velvet--stout and champagne
Red Eye--beer and tomato juice
Shandy--British lemonade (more like US Sprite than US lemonade) and ale

Unfortunately, most of the beer recipes just call for "beer", since they have been formulated by people who have only been exposed to one kind of beer--Worldwide megabrew tasteless pilsener.

Now if we could just get some interesting combinations with good styles. Anyone know if a Red Eye is better with an IPA, for instance?

"Orange Shandy"? "Cherry Shandy"? I count myself as a Londoner and I've never come across either of these. "Shandy", a half and half mixture of British lemonade (lemon soda) and beer is quite popular throughout Britain,

especially as a thirst quenching drink on a hot summer day. Some people drink "bitter top" - bitter with a splash of lemonade - but they are usually occasional drinkers who need something to sweeten their beer.

If I remember my beer-lore correctly, I thought Big Jimmy O'Carter made
homebrewing technically legal in this country (correcting an earlier
oversight). Being but a simple software engineer, my legal credentials
are a good approximation of nil, but I thought federal law superceded
state/local law. That is, if the Feds say it's OK for me to manufacture
certain kinds of drugs in my kitchen, then it doesn't matter one whit
what Missouri or any other state has to say about it. Yes?

This reminds of the request (by ?) recently for a recipe/ procedures for
making an eisbock. Isn't this a form of distillation (intentionally
concentrating the beer by freezing some of the water and drawing whats
left off) and isn't that illegal? Just wondering...

Subject: Beer Drinks

I have a short shandy saga: once in London I had dragged my luggage to Victoria Station and was absolutely exhausted. I noticed a vending machine with shandy available (it's my impression that just saying "shandy" gets you beer & lemonade). Perishing with thirst, I raised can to lips, and instantly recovered my full vigor - nothing like sugared beer to really get you moving.

Other beer drinks -

Dog's Nose - beer and gin; a favorite of seamen in the age of Nelson, and curiously enough, amongst present-day Japanese. Keep the gin in the freezer,

use any old lager, great at the beach.

Snake Bite - beer and cider - excellent, but incredibly intoxicating - especially when you hit the open air.

Black Velvet - Stout and cider - my favorite - it's like a stout milkshake. I

know that BV also refers to Guinness & champagne, but if you ask for BV in a pub

you'll get it with cider.

And of course Red-eye; beer and tomato juice; thanks anyway.

Well Bart this has been my standard practice for the start. I just put
the hot
sugar solution in the bottling carboy and rack the beer for the secondary
right
on top of it. I have had no problems with it as of yet. As you said
before the
thermal mass of 1 pint of 200F sugar water is nothing compared with 5
gallons @
70F.

Mark

P.S.

I heard that the yeast cells are consulting with a new legal firm.

Subject:

Anyone have any good ideas on how to blowoff those kraeusen chunkies from a 5 gal carboy without compromising sanitation? I've heard ghost stories about little critters creeping up unsealed blowoff tubes, so I've tried attaching a fermentation lock at the end of a really long blowoff tube. A clumsy solution: the foam still manages to percolate through the lock, sometimes clogging and blowing off the lid. It's rather comical. The only other makeshift idea I have is to simply submerge the end of the blowoff tube in a bucket of chlorox solution. Sure, you'd have to change the solution every once in a while once it got polluted, but at least none of those critters would crawl up the tube. Or is this much ado about nothing?

Is the kraeusen itself protection enough from critters?

Subject: Re: hot priming

Bart asks if anyone has added near-boiling priming syrup to beer.

Yep. I *usually* cool my syrup down before it comes in contact with the beer, but there have been times when I was just too darn impatient.

Result: screams of about 10,000 yeast dying, then . . . silence.

As far as I can tell, there was no detrimental effect. The beer carbonated quite nicely, no funny tastes, no law-suits from disgruntled yeast-relatives.

From: "Mark S. Nelson" <mnelson@eis.calstate.edu>
Subject: Brewpub Review

The opinions expressed below are mine only. Others can decide what they are worth.

On a recent visit to the Los Angeles area I had the opportunity to visit two brewpubs (both fairly new). This is a review of the Huntington Beach Brewing Company.

Being that it had been over two years since my last visit to Huntington Beach, I was very upset by the recent changes to the area around the intersection of Pacific Coast Highway and Main St. What used to be a charming area with strong local atmosphere has now been converted into a stale, sterile tourist scene much like many others in southern Calif. Most of the old buildings have been torn down and replaced by stuccoed, pinkish things that are horrible to behold.

However, there are still some hold-outs and the Huntington Beach Brewing Co. is located in one. Although the pub is a bit difficult to locate on the first try, it is worth the search. HBBC can be found upstairs in one of the older buildings still standing. I was immediately impressed by the old brick, stylish wood furnishings and high, beamed ceilings. There is outside, patio seating and plenty of indoor seating as well.

The brewery is located directly behind the bar. The hot liquor tank, mash tun and kettle are in front, with the fermenting tanks behind. It seemed a bit cramped, but very functional. The crushed grain comes down from the storeroom in the attic and the holding tanks are in a cooling room adjacent. They also brew pilsners and lagers.

The beers they had on hand were:

Main Street Wheat: This is a light, slightly dry wheat. Very tasty and refreshing for hot, summer days. My only complaints with this beer would be that it was filtered and that it was a little light on the wheat taste. However, these complaints are minor and would not stop me from happily drinking it.

Huntington Beach Blond: This is a light pilsner. In all honesty, this is the first pils. I've ever had in a brewpub. It was a very tasty, American style pilsner. Sort of like what the major breweries could do if only they cared... Light in the mouth with a pleasant ending.

Bolsa Chica Bitter: A mild bitter. Nice red color and crisp taste and feel. My favorite of those on hand.

Pacific Porter: I honestly can't say too much about this one, as it was the last I sampled. I do know that I liked it, and happily finished off a pint before going back to the bitter.

Overall, the beer was very good, as well as the food. The atmosphere was friendly and comfortable, although it was during the day. I'm sure it

gets very crowded at night though. My only consistant complaint would be that all the beers I sampled seemed heavily filtered. Considering their clientelle, though, this is not suprising. Again, this complaint is not a serious problem and I look forward to my next visit.

Subject: rock bock/sam adams (tm) radio spots/mixed beer drinks

RE: Rolling Rock Bock

I tried this about a month ago when I saw it at the store. I was drawn to the neat bottle. I thought it was nice (the label is a clear plastic type with the printing on the plastic, sort of like what some of the bottle waters are using). I guess I liked the bottle better than the beer. I certainly wouldn't call it a bock. But it was very drinkable. The packaging got me to bite on a 6-pack. I doubt I would get any more though.

RE: Sam Adams radio spots

Thanks Norm for the update on what GABF was doing in conjunction with Jim's advertising. I thought it strange that IMMEDIATELY after the GABF, I started to hear more of his commercials, something to the effect of "best beer 4 years running". Made it sound like he won again. Then I saw the winners list (I didn't get to go to the fest). I can't recall the station I heard it on, but it had to have been a Denver or Colo Springs station. It was on the following Monday though.

Guess this goes to show what \$\$\$ can buy in the way of lawyers and creative marketing types.

RE: Making drinks w/ Beer.

Here's an old set of recipes from my early college days. I'd like to think that I'm a bit wiser these days. The source is an old roommate from Kansas (nothing seemed to affect this boy!).

Kansas Whirlwind:

1 can Coors Light, drink 1/4 of the can, top off can with Everclear.

Kansas Twister:

1 can Coors Light, drink 1/2 of the can, top off can with Everclear.

Kansas Tornado:

1 can Coors Light, drink 3/4 of the can, top off can with Everclear.

I REALLY don't recommend these, but I thought it could provide some interesting reference point for someone. BTW, my roommate typically used the tall cans (16 ounces)! I never could keep up with that one.

Also, when I was over in England (1991), I saw a number of people order up mixers of a bitter and lemonade. I can't recall what they were called though. Seemed like the name varied depending on whether it was a bitter, Special Bitter or ESB. Looked strange, but then so did all of the Bud longnecks! I never did try one though (or a Bud - does the Bud in England differ from the Bud found in the States? I'm sure what I saw was not an import from the USA. I never thought about until I returned from my trip.).

From: "Bob Jones" <bjones@novax.llnl.gov>
Subject: My UK trip

Well I'm back from 3 weeks of pub hoppin in England, Wales and Scotland. I got to tour 4 brewerys, Young's, Sam Smith's, Calandonion and Traquir House (it was under reconstruction). The brewerys were all very nice and seemed to bend the rules more than a bit when I mentioned I was a brewer from the states. I came back with 4 yeast samples and am looking forward to brewing some real ales. A few thoughts on things I was surprised about in the UK.

* I expected cellar temp beer and low carbonation. The real ales are cellar temp (55 deg f) and DEAD flat. The ales may have a head if pulled via a sparkler on the beer engines.

* All the beers were extremely small gravity compared to our beers here in the states.

* Your average pub goer will consume 8-10 or more pints a night. They expect to drink to a glow and keep the glow, not pass out from alcohol.

* All the beers seemed much more subtle than I expected. There was malt and hops, but with the zero gas levels, they seemed much smaller than our ales here in the states.

* An Imperial pint was about \$2.25.

* The Brits are very fussy about both clarity and a good pour. The fill damn well better be to the top and they don't want any haze. All the beers were extremely clear. I expected some floaters, I say NONE.

* I really got use to the no gas, small gravity, cellar temp beers. I could drink 3-4 pints and was ready for more. We all make such a big deal out of carbonation in our finished product and would probably throw out a batch that had a gravity of 1038. Well relax! I'm looking forward to brewing a real ale (I won't however vent to the atmosphere). I will keep the gravity very low, the flavor up and serve it cool.

* On a negative note, smoking is not declining in the pub scene. It was a real challenge to find a corner where I could smell something other than cigarette smoke.

* I attended a beer festival in Bedford that had 53 real ales on. The beers were in the center of the room on a scaffolding made of steel pipes and wood planks. The kegs had a piece of muslin cloth that was damp over them and a

fan was blowing across them. How's that for room temp? The kegs all just gravity drained into the tasters mug. Quit a difference from our tasting, eh?

Just a few thoughts, hope you enjoyed them. I sure did enjoy experiencing them.

Be bold, fry the little buggers!

I don't bottle much anymore (kegs are great), but I got tired of
waiting for the priming solutions to cool back when I did bottle. I
tried an experiment where the priming solution was well over 100F and
it worked fine. Next batch it went in nearly boiling and guess what,
no carbonation whatsoever. Fooled you! It worked fine, as you have
guessed, the thermal mass of 1 cup of boiling sugar solution has very
little effect on the thermal mass of 5 gallons of beer. Your mileage
may vary, but if I ever have a need to bottle an entire batch, I
certainly wouldn't worry about killing the first few 100 million yeast
cells.

Beer Hunting in Belgium: Part 1 of 7

Rochefort (Abbaye de Notre Dame de St. Remy)
(by Jim Busch: BUSCH@DAACDEV1.STX.COM)

Through an amazing stroke of luck and Phil Seitz's wealth of connections in Belgium circles, we were able to arrange a tour of this monastery. It turns out that one of Phil's friends is the son of the man who assesses brewing taxes for the Rochfort region, and as a special favor to his father--who is retiring--the monks allowed our friend to bring several guests for a very rare look inside the monastery.

Rochefort is located a modest drive south from Namur. The sign next to the door of the abbey reads "No Visitors." We knocked and were greeted by a classic brother of the order, dressed in the traditional robes, sandals and cane, and hunched over with the burden of his years. We were led to a spartan reception/waiting area where the silence of the monastery began to hang on us. A short while later, head brewer Brother Antoine greeted us and we followed him to the brewery.

The brewery occupies a corner of the monastery, in a tall room roughly 20 meters long. Two sparkling traditional copper "onion dome" kettles were situated on the lower area, while another traditional copper lauter tun was situated on the far end of the room on a platform 2 meters above the main floor. The area was illuminated by tall stained glass windows, some of which sported hanging ivy plants. A large cross was on one wall. The traditional copper grant was embedded into the tiled platform wall, and the brewer still manually operates the grant handles to equalize the runoff rate from the lauter tun.

Inside the vessels were a slew of mechanical devices; the normal rakes and sparge arms in the lauter tun, but lots of probes and gadgets in the kettle. The second kettle was originally used to produce a table beer--a very normal practice at breweries that make high gravity beers, but a practice that is becoming less common. It is no longer used except to heat water (talk about wasted equipment!). When lautering, all the original mash water is allowed to drain from the mash, then additional water is added. The table beer, when it was made, came from later runnings off the mash.

Three beers are produced at the monastery, and are named for their strength in Belgian degrees: 6 (7.5% ABV); 8 (9.2% ABV); and 10 (11.3% ABV). We were also told that all three beers originate from identical mash bills (that is, the exact same mix and amount of malt), the difference being in the quantity of candi sugar added to the kettle. The mash bill consists of CaraVienna and Pils malts, with maize being added as an adjunct. Ground coriander is added to the kettle in addition to pulverized whole hops, Styrian Goldings for kettle hops, Hersbrucker Hallertau for finish. This is the first brewery I have ever been to that goes to the trouble of using whole noble hops and then pulverizes them prior to addition to the kettle. This is done to ease the centrifuging of the cast out wort. The original gravities of the three beers are: 17P, 20P and 25P.

The cast out wort is passed through the SS centrifuge, then a plate heat exchanger, and then is dosed with a two-strain yeast from a small cylindro-conical yeast tank. The fermentation is

done in what appears to be a tiled open fermenter that was modified by the addition of a closed SS top. The top looked to be quite involved, with piping and controls everywhere. The two fermenters occupied a relatively small room.

After primary fermentation, the beer is filtered using a Diatomatous Earth filter (DE or Kieselgur filter) and then racked into maturation tanks. A brief conditioning period is followed by the addition of priming sugar and three days later bottling is done. The bottles are steam cleaned and sterilized before being filled in a very large Kronen bottling line. Every piece of equipment in this brewery was of high quality, well engineered and of greater capacity than what appeared to be required. These monks certainly built it right.

Rocheport beers are some of the harder-to-find Trappist beers even in Belgium, and the monastery purposefully perpetuates this. The brewing schedule is always the same. They only brew 3 days a week. The brewing schedule varies little; 2 weeks of Rocheport 8 (6 days), and 1 week of Rocheport 10 (3 days). A week of Rocheport 6 (3 days) is thrown in from time to time. It is no wonder that the '8' is the most prevalent beer of the three. It was the '8' that Brother Antoine opened for us in his study. As Michael Jackson has noted, the study is a special place, adorned by literally hundreds of beer steins from brewmasters that have visited, many from great breweries in Germany. Brother Antoine himself is a bit special in that he seemed genuinely amicable to us and did not typify the Trappist stereotype monk. He dressed quite plain and normal, not in the robes of his other monks. There was even a plastic Jesus with flickering light on a shelf.

The beer was fantastic. The really remarkable thing about all of the Rocheport beers is the art of creating a significant amount of alcohol but keeping the flavor perceptions several percent lower than the actual alcohol. This is not an easy feat.

Brother Antoine is one of 24 monks that live in the spacious monastery. Economically, sales of the beer support the monastery and its projects. Even at three days a week of brewing, the monastery is making boatloads of money. Brother Antoine proudly told us of the newly renovated Chapel and we stopped there after our Rocheport 8's were consumed. The high cathedral ceiling and walls are made from the stone blocks of old farmhouses in the Loire Valley, and the high narrow windows are filled not with glass but with thin slabs of alabaster. The pews were being hand made and carved by local craftsmen as we were there, and the column capitals had also been elaborately carved. The floor of the entrance area is adorned with a very large circular marble inlay. The marble was cut into arcs and inlaid and polished. All of this was being paid for by the brewery.

Since it was the end of a work day, the workers were relaxing with a case of Rocheport 8! It was quite a sight.

According to Brother Antoine, the other Trappist breweries have broader financial responsibilities. In addition to supporting itself, Chimay also pays the expenses for four other monasteries or convents, and Brother Antoine believes Chimay began brewing years ago to provide jobs and economic development to the people in its region. This puts their high production into context.

What kind of filters are you using, what is thier efficiency rating and
what
are they manufactured from? All of these factors will effect filtering.
Also,
how fast (psi) so you push the beer from keg to keg, and do you condition
it
prior to filtering?

> optimal cell count.

Usually, cell counts are expressed in cells/ml, so the above numbers look
more
impressive than they actually are. 4 million cells/ml is underpitching,
even
for ales, although not by much (many UK ale brewers pitch between 5-10
million
cells/ml). For lagers, it is 1 million cells/ml/degree plato. So for a
12P
lager, pitch 12 million cells/ml. For a 17P lager, use at least 17
million

cells/ml, and as it goes even higher, up the density. The 10 million/ml is a good pitching rate for most regular beers. If you have access to thick slurry, pitch 1 lb per BBL of wort.

In Germany, they were making "radler"s before Sprite(tm) was available.
Every radler I ever had was beer and lemonade. I believe that was the
original drink, which literally refers to bicyclists. Perhaps
in need of a lighter drink than straight beer, they were among the first
to drink lots of them (what German would dilute their beer without
pressing need). radler is probably now used to mean any beer/soft drink
combination.

OK, now here's a real beer drink for you. I've heard this referred to
as a Slip, Strip and Go Naked:

1 12 oz can frozen lemonade emptied into a pitcher
12oz gin (measure using the now empty lemonade can)
3 12 oz beers

Mix it all together and you'll experience the name.
This is a summer drink and it's the only gin drink I ever remember
(barely)
liking.

I do it every time. My technique is to boil 1 cup of water, then add between 1/2 and 2/3 cup corn sugar, turn off the heat, and let it sit until cool.

Except, I never allow enough time to let it cool.

What the heck, I just pour it through a sanitized (or at least rinsed) kitchen funnel onto the beer while racking into the priming carboy.

It works for me.

Subject: Distillation and the home-brewer

Actually, as I remember way back a couple of years ago, there is a classic beer style (eis-bock?) that *requires* distillation. There was quite a brew-ha-ha (sic!) as to whether it was legal to make this style or not, as it uses freeze-distillation (you freeze the fermented-out wort and remove the ice cake, which leaves the final product awaiting carbonation). Freeze distillation is technically probably illegal, but, in the spirit of this thread, probably not dangerous...

From: davep@cirrus.com (David Pike)
Subject: Carbonation and Filtration

While reading the Fix'es Vienna book last night, I came across the sections on filtration and carbonation, and I suddenly got confused as to which order they should occur in.

1. carbonate then filter
2. or filter then carbonate

It seems some of the big boys filter and then pump into a conditioning tank to carbonate, so this would be #2. Other breweries, Anchor for one, end secondary fermentation with the beer naturally carbonated, and filter afterwards.

At home, it can be either method. Secondary ferment, then filter, then carbonate in a keg, then bottle(or drink). Or it can be the other way around, ie. from the secondary, to the keg for carbonation, then filtration, then bottling.

Whats the HBD consensus, which method is used, and why?

Cheers!

Dave

Subject: lemon beer/yeast nutrient

Subject: lemon beer/yeast nutrient

Hi All:

>In Germany, people will mix a light-colored beer (insert Pilzen or Weiss here) and mix it with the equivalent of Sprite (tm) and call it a "Radler."

I believe it is done in a 50/50 ratio. It is quite tasty on those hot, summer days and every now and then I will consider doing the same with some of the swill I see in my parent's 'fridge. Good stuff! I recommend it! Be daring! Give it a try!

I first became aware of such strange things when I was in Germany too, I tried it and hated it. Later back home it occured to me that this might be a perfect thirst quencher after triathalons.....It was! Don't waste good beer on this. The combination of lemon and beer is far better than other *replacement* crap like Gatoraid or Exceed (tm,tm). Regular beer doesn't cut it-too much carbonation. Besides, you can have a quart or so, experience the tremendous muscle relaxing effects and rehydrate without falling down.

While I'm here, I'll bite on the yeast starter question....

from Domenick Venezia

>.....[edit].....Chris grew the starters under the same conditions then assayed them for total cell counts. The YNB starter had a cell density 10 times (!) of the other. The numbers worked out to 10×10^{10} cells/liter. I seem to remember an optimal pitch for 5 gallons is 4×10^{10} cells so using YNB you could pitch with a pint and get an optimal cell count.

FWIW 10×10^{10} cells/L isn't really that high. These values are usually expressed in cells/mL and this translates to 10×10^7 /mL or 100 million cells/mL. A typical normal fermentation may produce cell counts of 50 million cells/mL which is dependant on strain, O2 levels etc. As far as pitching of 4×10^{10} cells, you don't give a volume of pitching culture, so lets assume that you mean 1 L. 4×10^{10} cells into 19 L (5 gal) will provide about 2×10^9 cells/L or 2×10^6 cells/mL. Optimal pitch rates are debatable, but I think it is agreed that this rate is low for ales (should be 5-10 $\times 10^6$ /mL) and extremely low for lagers (should be 10-15 $\times 10^6$ /mL), especially lagers STARTED at fermentation temperatures near 50F, (not pseudo-steam-start-'em-at-70-and-cool-'em-to-50-lagers). Noonan recommends even higher rates for Scotch Ales and other strong beer in his new book.

What kind of lag time did he get? I'll bet it was on the order of 10-12 hours, not bad, but greater than optimum.

Subject: mashout

> I understand you once had a MM but traded it for a Corona
> because the grain kept coming out of the hopper when you turned
> the crank. The Corona has an arrow telling you how to turn the
> crank and I can understand how No-Mashout-Types (NMT's) feel
> more comfortable with it.
>
> js

Well, that's partly true. I did own a Maltmill but returned to my old Corona. Yes, I admit that I couldn't figure out which way the crank turned. That and the fact that once I figured out how to operate the Maltmill, it really didn't do a good job of ringing-out my wet laundry like I thought it would.

But we seem to be digressing from the original proposal that mashouts are unnecessary. What is called for in this debate are cold, hard facts. After all, this is HBD not late night cable tv.

In that vein I have summarized my last two year's worth of brewing records. What I found was that all grists were composed of Belgian malts. Small amounts of wheat were used but never more than 5%. For background: Corona grind, simple infusion mash, mash & sparge ala picnic cooler, never a protein rest, never a mashout and rarely a ph adjustment.

The bottom line remained unchanged: no stuck sparges and mashing efficiencies over 80%. Given the simplicity of the efficiency measurement I think it's safe to say the numbers can be trusted.

Assuming that one is using a grist that does not have a high percentage of wheat or rye, I remain confident that mashouts are a waste of time. But why take my word for it? Why not give it a try next time?

Over time, we incorporate new techniques into our brewing methodology when convinced of the new technique's merit. I'm proposing the same action only in the opposite direction in that techniques can be eliminated when deemed unnecessary. Such is the case with mashouts.

Subject: lauter tun designs/amylase/Belgian yeasts

Wyllie Coyote posted a very good summary of lauter tuns. I'd like to add just a few comments:

> 1. Grain bag in a bucket with a spigot near the bottom of the
> bucket. Grain bag is held in place with elastic (bungee). Bag is
> mesh material. I used one of these for several years. Worked fine.
> Disadvantage: Size limitation, not insulated, unless you stick it
> in a box. Bag would slip sometimes.

Please note that due to a fluid mechanics phenomenon called "channeling" it is recommended that the grain bag you use for the above system should have relatively "waterproof" sides and only the bottom should be made of mesh.

>to allow me to run water through the manifold to clear it. I also
>fashioned a metal screen to fit over the manifold- kinda like a
>false bottom to make a flatter surface for the grain bed (can you
>say "overkill"?). It keeps big grain bits away from the tubing-
>aiding the grain bed establishment, and makes it easier to lift
>the grain out of the cooler into my healthy compost pile. I don't

Perhaps it makes it easier to remove the grains, but if indeed it keeps the large particles of grain away from the manifold, then you don't need the manifold. As you said yourself, it's the grain bed that does the filtering and it requires that the large pieces be at the bottom, smaller on top of those, etc. If the mesh is holding up the large husk pieces, you should be establishing your bed on the screen and omitting the manifold.

In all fairness, the commercial devices should have been mentioned. The ones that I know of are the Phil's Phalse Bottom, which is similar in function to the Zapap design, but works a bit differently. The only comment I have about this design is that it has been mentioned on the HBD that the hose has a tendency to kink where it comes out of the Phalse Bottom. Replacing this with an elbow seems to fix the problem.

Another design I know of is available commercially and you can make it yourself: the EasyMasher(tm) or easymasher. This design uses a piece of screen (like stainless window screen) formed into a tube and then hoseclamped to a brass tube that makes its way through the wall of the kettle. I would imagine you could mount it in a cooler too. My concern about this design is that the runoff is drawn from a very small area of the mash and would (again, due to channeling) theoretically give lower extraction rates than a lautering system which takes the runoff from a wider range of the cross-section of the grain bed. I must stress *theoretically* since a number of users have reported very good extraction rates.

There are a number of very expensive commercial systems (made from straight-sided kegs), which are actually scaled-down versions of full-size commercial lauter tuns. I have no experience nor have heard much about them so it's too soon to tell. Cost is a big disadvantage.

Finally, the RIMS system should be mentioned. RIMS stands for Recirculating Infusion Mash System (I believe) and recent improvements have apparently increased the capacity of this system. I know that George Fix was very impressed with the new design of this system. It's biggest disadvantage is cost.

Disclaimer -- I don't sell ANY lauter tuns or commercial devices for the building of lauter tuns, so I'd say I'm pretty impartial on this.

Steve writes:

>I am a bit confused over the use of Amylase Enzyme when brewing all >grain beer. My understanding is that it contains Alpha Amalyse.

>

>My understanding is that Alpha Amylase is denatured around 130 degF.

>If this is correct what good is the enzyme at mash temps above 140 >degF?

I assume you are talking about a commercial version of Amylase Enzyme. I've never used any commercial versions, but you really shouldn't need any unless you are using a lot of adjuncts like boiled rice, oats, wheat flour, oat flour, cornstarch, unmalted grains, etc. Malted barley and malted wheat have more than enough amylase on their own to convert their starches as well as a reasonable amount of adjuncts.

There's alpha amylase and beta amylase. Alpha amylase is less temperature sensitive than beta. Alpha slowly begins to denature above 140F, I believe, but will last a couple of hours even at 158F. Beta amylase also begins to denature at about 140F also, but denatures quite quickly above 150F. Alpha amylase converts starches and dextrans into glucose until it reaches a branch that it can't "eat" leaving a limit dextrin. Beta amylase works by cutting large chains of glucose into smaller chains. If you mash at the lower end of the 148F to 158F range, the two enzymes will work together to make a highly fermentable, thin (low body) beer. If you mash at the higher end of the range, you will get a less fermentable, heavier (higher body), slightly sweeter beer. Something in-between, will get you something in-between.

The enzymes that denature around 130F would probably be one of the proteolytic (protein degrading) enzymes. There are two there also: Peptidase and Protease, but I forget which does what. The two of them work together like the amylase enzymes to break large proteins into small proteins and amino acids. At lower protein rest temps, you get more amino acids, less body and less head-retaining small proteins. At higher protein rest temps, you get less amino acids and more small proteins (better head retention and more body).

Stu writes:

>suggestions here? Would it help to culture a Chimay or Duvel and repitch

Chimay is bottled with the fermenting yeast, Duvel (I've been told) is not.

I don't know about the taste, but I've been told by the manufacturer,
that Iodophor is non-toxic WHEN DRY. All the instructions regarding
its use around brewing have included the mention of DRYING the sanitized
article.

>immediately for food service. FDA considers 10ppm iodine

Around here 12.5ppm is what the Health Dept. requires.

>safe for consumption, though iodophor solution also contains
>phosphoric acid and isn't very tasty by itself.

Not all iodophors contain phosphoric acid -- the "phor" has nothing
to do with phosphoric acid -- this is what a chemist told me.
I found a really interesting article in an ASBC publication from
the 50's. I'll see if I can get around to posting some of the
more interesting parts.

>[The original beer was a "Belgian" brown... I would describe the flavor
as
>smoothly medicinal rather than infected]

Smoothly medicinal sounds to me like stale grain. Some grains are more
suceptable to developing a phenolic smell/flavor -- I've found that
DeWolf-Cosyns CaraPils is the most likely to develop this problem of all
the grains that I've tried. I was talking to Tim Norris about this
recently
and he suggested that perhaps it's the moisture content, since the CP has
a high moisture content compared to the other DWC grains. The phenolic
flavor I'm talking about is similar to BandAids(tm). Is that what you
smelled/tasted? A little wheat malt can give you this flavor/aroma too.
Any wheat in the recipe?

>overwarming have killed the yeast, or was it more likely something else?

How warm did you warm it? You should rehydrate yeast at between 90 and 110F and then let that slowly cool to your wort temperature before pitching.

I suspect that either you A) didn't aerate your wort enough, in which case you should aerate the wort and add more yeast, B) shocked the yeast by rehydrating in too COOL a water, in which case you should wait some more, C) killed it by heating it over 130F, in which case you should add more yeast, or D) it has already fermented out the whole batch while you were not

looking (is there a brown ring of crud on the walls of the fermenter, about

an inch wide, just above the level of the wort? if yes, then it's probably

D). If the lag time ends up being more than three or four days, then I would taste the beer before bottling and dump it if it got infected.

Subject: Hot priming and peach beer

Bart Thielges asked about adding hot priming sugar solution to wort for priming. I do that all the time and haven't seen a problem yet. I pour the boiling corn sugar/water solution into my bottling bucket and then start siphoning the beer into it.

Steven Tollefsrud asked about a peach beer. I made one a couple of months ago when my peach tree started producing. I used a recipe from Dave Miller's "Brewing the World's Great Beers". It's basically a lightly hopped, lightly colored, wheat & barley beer. Ferment to near completion in primary and siphon onto 10 lbs. of crushed peaches in the secondary and let ferment another couple of weeks. It has a great peach aroma and a very light and refreshing taste. The biggest problem I had with it was separating the beer from the peaches. I ended up leaving almost a gallon of beer behind because of clogging siphons. This caused a bit of a complication since I primed for 5 gals -- the beer has to be well chilled to avoid gushers.

Subject: Beer hunting in Belgium: Part 2 (Brasserie de Silenrieux)

Beer Hunting in Belgium: Part 2 of 7

Brasserie de Silenrieux
(by Jim Busch: BUSCH@DAACDEV1.STX.COM)

This brewery opened in December 1992, and is still largely unknown. A friend of one of our Belgium hosts had just visited the brewery the month before our we arrived in Belgium, and reported that they were brewing with unusual grains. So when a visit was suggested, we jumped on it.

It turns out that the government of Belgium had the notion of developing brewing processes using non-traditional grains, primarily as a way to stimulate agricultural production and open markets for local agricultural products. Early research and small scale brewing experiments were performed in Canada and at the university of Louvain-la-Neuve. Successful beers were produced using buckwheat and spelt (a wheat relative) as principal ingredients. These experiments were underwritten by subsidies from the Belgian agriculture ministry, starting with 3-liter lab batches and working up to 6 hl batches using the brewing studies facilities at Louvain-la-Neuve.

Monetary assistance may also have been provided to the organizers of the brewery, who have built a truly beautiful modern facility in the south of Belgium near Chimay and a vacation lake/camping area. The brewery consists of three dedicated production vessels; a mash tun, a special lauter tun, and the kettle. The mash tun and kettle are normal enough stainless steel vessels while the lauter tun (if one can call it a that--a separator might be more accurate) consists of a large SS vessel containing a removable circular basket, or strainer, and the strainer/basket is attached to a crane attached to overhead support structures. The strainer has slots in the bottom and up the sides about 1/2 a meter from the bottom. The entire saccrified mash is pumped from the mash tun into the basket, which is then slowly raised via the crane out of the lauter tun. In effect, the basket is used like a giant tea bag, with the liquid runoff flowing through the slots into the vessel, leaving the grains in the basket. The liquid is then pumped over to the kettle. There is no sparging performed. The brewers admitted to less than ideal extraction of sugars and a generally difficult separation stage.

Three SS unitank fermenters are used as primary vessels while a fourth is used only for mixing the priming sugar prior to the hand filling of champagne-type bottles. A typical Belgium top fermenting "abbey" strain of yeast is used, most likely quite similar to that employed in numerous Belgium strong ale breweries, including La Chouffe, La Binchoise and possibly La Caracole. Kegs are also used, and are sanitized using forced steam; a steam hose is just pushed into the kegs and allowed to vent, resulting in about 120 decibels of noise pollution. Definitely not my idea of a nice working environment. The brewers were a bit frustrated in terms of keg sales since it is near impossible to break the stranglehold that the giant Belgium brewing consortium, Interbrew, has on tap handles in the country.

One of the nice things about the design of this brewery is that there is a steel catwalk running the entire length of the brewing vessels, including the unitanks. This allows the brewer

to do most of his work up top and close to the action. The brewery is generally well designed and constructed, although the brewers noted the difficulty involved in packaging the products. While the rest of the brewery is quite modern, there is no bottling line. A set of manual bottle fillers are used for the champagne bottles, and labels were applied to the bottles we bought the old-fashioned homebrew way--with milk.

The brewhaus is separated from the tasting room by large plate glass windows. The ceiling of the tasting room is brick!

We were able to sample the brewery's two products, Joseph and Sara. Joseph is a blonde beer of 6% ABV. It consists of 55-60% spelt and the balance pale malt. The bottle describes the product as "Bier d'Epeautre" (epautre=spelt). It is blond with a big creamy head, typical "abbey" aroma and some citrus notes. Despite being produced from a large percentage of cereal grains, the beer retains a high degree of malt/hop/yeast balance. It is a broad cross between abbey beers and the ever popular Wits. The beer is named after the person in the agriculture ministry who lobbied for the revival of spelt as a brewing and food grain and who, not coincidentally, provided the subsidies for the early brewing experiments.

Sara is a brune (brown beer), called "Biere de Sarrasin" (sarrasin=buckwheat). It is produced from equal parts of buckwheat and malt and features a caramel aroma intermixed with the abbey esters with a fairly light caramel finish. This is a good beer, but did not approach the quality of the Joseph. It is also 6% ABV.

Not true. (You can decide for yourself whether this is good or bad).
I don't want to rant too much on this, but the U.S. Constitution attempts
to give states the ability to make their own laws, while giving the
federal
government jurisdiction over inter-state issues (interstate commerce,
dealing with foreign countries, etc.) and enforcing rights guaranteed by
the constitution. When the feds want to enact a law which appears
outside
their jurisdiction, they generally do it in one of these ways:

- * Pass a constitutional amendment (prohibition, for example).
- * Argue that the issue crosses state boundaries and therefore is
already
within their jurisdiction (FCC, for example).
- * Impose taxes/licensing on some products or services (brewing).
- * Threaten to withhold federal revenue from states unless the states
pass their own laws for which the feds otherwise have no jurisdiction
(many highway laws).

In the case of beer brewing, the feds collect taxes on alcoholic
beverages.
The change that Carter signed simply said that if you make less than a
certain amount of beer for your own use, the feds won't tax you on it,
and
won't require any special licensing. There is no guarantee that any
particular state won't further restrict home brewing.

I think there is little chance of a U.S. Constitutional amendment being
passed to guarantee the right to brew beer. Are there active movements
in the
more restrictive states to have their state laws changed?

Subject: Liquid Yeast: Friend or Fiend

In HBD 1251 Jerome asks if liquid yeast is Friend or Fiend. FRIEND!!

Liquid yeast is a friend. My beer got much better when I switched to liquid yeasts. Although the Wyeast package says you can just pitch directly from the package, my experience is that this is not a good idea and a starter is absolutely necessary. Why? The number of yeast cells in the Wyeast package is very low and results in an incredible under pitch which can lead to very long lag times raising the risk of infection.

> I had gotten a WYeast American Ale packet, and burst the inner packet
> on Thursday evening. Sure enough, by noon on Saturday it was nice and
> puffy. My 1043 wort was at 70F, and all was well with the

...snip

> ...wait for fermentation to begin, but lo! nothing happens and keeps on
not
> happening until Monday morning.

It has been my experience that Wyeast is ready to pitch after about 24 hrs, sometimes less. By the time the package is really puffed the yeast has gone way past high kraesen (sic?), and flocculated. It's had a good meal and dozed off. Pitching this means not only are you under pitching, but you are under pitching sleeping yeast that will need some time to wake up. By using a starter you can pitch more cells and perhaps better time your pitch to occur just before high kraesen. So I think that a 48 hr lag time (Sat-Mon) is not unexpected.

Another thing to watch out for is that dry yeast is often contaminated with bacteria. Reusing slurry from a dry yeast fermentation may allow the bacterial population to build up to infection levels.

Let me suggest that you download the yeast FAQ from sierra.stanford.edu to get some guidance in propagating a yeast starter.

Liquid yeast is your friend. You just have to treat 'em right.

From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>
Subject: Relax, Don't worry, ...

In 1251 jmp@shoe.wustl.edu related difficulties with Wyeast used straight. I remeber using Wyeast straight and having 2 day lags, but so what? If the system is clean there won't be any contamination. The last thing I would do is worry and contaminate a \$4 culture with a 30cent sachet of microflora assortment. And you'll develop plenty of slurry for a quick fermentation. If using a Wyeast one should make a starter, and if it's a lager the starter should be around a gallon.

Onanother note that I will refer to as Chicago time warp. How come a response from js appeared before the posting from Chris C to which it responded (in 1250)?

as directed on the package?
> Should I just admit abject failure and use dry yeasts exclusively?
>

Jerome, this happens because you are (a) underpitching and (b) probably under-aerating. There is a fairly small quantity of yeast in the package, which is why the general wisdom is that you need a starter. A starter (which is really very simple to put together and use) will get the cell counts up to something approximating the correct number. You will never get counts like that simply pitching from the package. Dry yeasts generally have much higher counts, although the percentage of viable cells in the packages isn't very high. It is possible to get a decent fermentation from the packet, but it's asking a lot, and it requires a very fresh package and extremely thorough aeration of the wort prior to pitching.

You should: follow the instructions on making a starter wort, and begining the process of building up your yeast several days before brewing; and you should shake the bejabbers out of your cooled wort (or follow some more advanced instructions about using an aquarium pump to aerate -- see Dave Miller's articles in Brewing Techniques). You *will* see a difference in the quality of your beer. Really.

No. State law supercedes federal law in this instance. This is why each state has been able to set guidelines for alcohol content, drinking age, etc. (for example, in Oregon and Washington you can only buy distilled beverages from state-operated liquor stores, while in nearby California you can buy the stuff virtually anywhere). On the other hand, while the federal government prohibited homebrewing, the state could *not* allow it. Clear? No? Well, it doesn't make any sense to me either.

From: COYOTE <SLK6P@cc.usu.edu>
Subject: Amylase

> >When should Alpha Amalyse be used?

>Thanks, Steve

* Amylase (sp!) is a combination of alpha and beta amylase. Two starchdegrading enzymes- diastatic enzymes. Most commercial "amylase" is actually diastase- a mix of alpha and beta amylase. The alpha cuts the middle of enzymes (endo-) while beta chops off the ends (exo-). Alphas are most active at 65-67 deg C, or 149-153 deg F. Beta works at 52-62 deg C, 126-144 deg F. Alpha inactivates at 67 deg C (153), while beta ceases at 65 deg C(149). These temps are not exact cutoffs and inactivation takes a period of time (40 min-2hrs) to completely eliminate activity. Both enzymes will be active simultaneously. A higher temp mash will result in more unfermentables (more complex sugars) by favoring the alpha activity, whereas a lower temp will favor the beta and smaller more "digestable" sugars for the yeast.

Amylases and other enzymes are present in pale malts (grains) and some other grains (munich, vienna...etc). If you are mashing they are there and required for the process. If you are using extracts you don't need to worry about them. If you do a partial mash, or add something like flaked corn (NOT Kellogs!) or rice you need to have enzymes convert the starches to fermentable sugars. For this you can use pale malt, or some purified amylase. You can add amylase to a mash if you are not getting good yields- but probably better to work out a system that works more effectively! Someone mentioned using flaked corn in an extract beer and making tea with it. What is the point of that? You are adding starch. Corn can lighten a beers body while adding fermentables w/o much color or substance, but where is the advantage in an extract brew? Has anyone done this? Does anyone have a REASON behind doing this?

Hope some of this helps a bit. John (The Coyote) Wyllie
SLK6P@cc.usu.edu

Kevin asks:

>Why do you consider distilling to be dangerous? There is an element of risk

> involved with making anything. (including fried chicken) Distillers simply

> take a fermented product and evaporate and condense the alcohol.

>

> >Illegal? Yes. Dangerous? Hardly.

>

*Can you say DEATH & BLINDNESS! Ethyl alcohol goes to a vapor within a specific temperature range (I ain't gonna quote it!) while OTHER alcohols vaporize at different temps. While ethanol won't do us any harm...well...maybe a little nausea in excess...a bit of a headache... some other alcohols, or components of a ferment could do some harm. If it's done right- sure you can get a fine distilled product. I even tried one once- could've dropped it in a NA beer too, but I wanted to try it straight. Tasty it was! (peeeka boo!)

I don't have all the chemistry here to explain it...but there are

dangers in distilling. That is WHY there are real laws about it, and why those WILL be enforced, as depicted by such "fine" TV programs. Look it up in a library. Most universities will have something on it.

From: greg.demkowicz@circellar.com
Subject: WORT CHILLERS

There's been a lot of posts about what type and size of wort chillers to use, be it cold water bath, immersion, or counter-flow. Most counter-flow designs are based on a length of 3/8" copper tubing passing through the center of a garden hose. This is quite effective, but awkward to use.

So, here's a question for all you Thermodynamic type people: how effective would a 30 foot length of 3/8" diameter, coiled copper tubing, be in a 2 foot long, 4" inside diameter, PVC pipe? Essentially, I want to place the coil inside the PVC, with the ends of the coil entering and exiting the capped ends of the PVC. The cooling water would enter the capped ends as well, but counter-flow. The "coil" diameter would be about 3.5", resulting in a circumference of about 11". With each "coil" spaced about 1/4" apart, the length would be about 2 feet. Of course the length and size of the copper tubing can be altered, (the PVC diameter is the max. I can get) but, is the idea feasible? Any comments appreciated.

Subject: Hose vs copper tubing

Norm writes:

> I just bought a thick-wall polyethylene hose to run from my lauter
> tun to my boiler. The hose I use now is a thin-wall vinyl hose
> which has a tendency to collapse when the hot liquor is flowing
> through it.

I was also concerned over the use of a plastic hose in the kettle
and the fact that the hose was close to the open flame of the
propane burner near the side of the kettle. Also, The hose flattened
out where it looped up before going into the kettle.

My solution was to use a length of 3/8 copper tubing inside the
kettle and attach the hose to that.

The top of the tubing has an S curve so that I can hang it on
the kettle itself. It's a tight fit, so it doesn't fall out
if you accidentally yank the hose.

The bottom of the tube is 1/4 inch off the bottom of the kettle.
This minimizes (eliminates) splashing of the hot wort as it flows
into the kettle. The outside end curves back up so that the hose
coming in meets it straight on and doesn't droop and flatten out.

Federal law supercedes state law except when it doesn't. What they often do, and did in this case, was leave further regulation of brewing to the states. ie: "Its OK for you to manufacture up to 200 gallons of certain drug-containing beverages in your kitchen unless your local government objects, in which case you're stuck with the more restrictive regulations." Funny how they can write whatever laws they want...

Subject: re: HB law questions

Scott Kaczorowski speculates on the Federal statute allowing homebrewing, and questions Federal law superseding local laws.

>If I remember my beer-lore correctly, I thought Carter made
>homebrewing technically legal in this country (correcting an earlier
>oversight). I thought federal law superceded state/local law.

My guess is that the law removed the Federal restriction on brewing. This is not the same as saying the law grants permission to brew. Without a Federal restriction, states and localities are allowed to make their own regulations. This is why dry towns and dry counties are allowed to exist.

Subject: Spruce Beer

You guys are giving Spruce Beer a bad rap! I've been making it for four years and have to keep it quiet that I have a new batch in the fermenter. My friends hound me for a taste of the elixer. I use Papazian's recipe with 4 oz of spruce tips picked from a Spruce tree (not hemlock) in the spring added like hops (in the hops bag). I have NEVER had a bad batch nor a sappy or any other off flavor. I have never used essence. Being a purist, I think it poor style but I would suggest just a hint of Spruce essence and then add more in future batches.

Subject: Hops FAQ nearly ready

The Hops FAQ is nearing completion but I have one sticking point. I've used IBU's so long that I can't recall the definition of HBU. I looked up AAU in Miller's and Line's books, and I have that. Rager says the two are the same, i.e. AAU=HBU but Al Korzonas mentioned that he thought one of them was batch size dependent, based on a 5 gallon batch (and that rang a bell with me) .
According to Miller and Line, AAU is just the alpha acid percentage multiplied by the weight in ounces. This leaves HBU as being the batch size dependent one if they are not the same. This should be simple but I figured the quickest way to get the answer to this would be here on the HBD. Thanks for your input.
Expect to see this thing in the next few days.

Old Lucifer (the barley wine from hell that just won't quit!) update: OG= 1.039 after 4 weeks. At this rate I may bottle it before Christmas after all!

From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)
Subject: Liquid Yeast: Friend or Fiend?

Jerome Pierick asks in HDB #1251 (essentially) about yeast pitching rates, and the instructions on the Wyeast packages which say essentially that sufficient yeast cells for a five gallon batch are grown in 50 ml of wort. He goes on to say he has experienced lag times exceeding 48 hours, and wants to know why this is versus the dry yeast he's been using. Finally, he asks about repitching yeast grown from a dry yeast culture.

Well, I've used Wyeast as directed on the package and I experience lag times just like Jermome. IMNSHO, the directions on the Wyeast package do a great disservice to homebrewers as well as the company. Yes, it *will work* but its far from ideal. According to various sources summarized by Patrick Weix in the famous HBD Yeast FAQ (what would we do without those TLAs?) says that you need 1 volume of yeast solids per 250 volumes of wort for lager yeasts, and 2/3 that rate for ale yeasts. This translates roughly to 2 cups of yeast slurry in a five gallon batch of ale, or three cups in a batch of lager. Compare this with the teaspoon or so you dump out of a Wyeast package. When the term "yeast slurry" is used I thake this to mean the tan stuff that'll settle out of a wort after fermentation. The Wyeast package contains about ten teaspoons of wort, but no where near that much yeast slurry.

Well, I rarely pitch at ideal rates. Usually I step Wyeast up twice, using a pint of sterile wort each time. This yields maybe 1/2 cup of slurry. Still a far cry from ideal, but much better than the package directions produce. Usually the beer is fermenting away the next morning. When the planets are properly aligned, I sometimes pour a new wort on top of the yeast cake in my secondary fermenter to make a second beer. This is much closer to the ideal pitching rate, and I get amazing fermentations when I do this. Very short lag times -- just a couple hours.

So, what's a brewer to do? If you don't want to take the time to step your Wyeast up, and I can perfectly well understand why you wouldn't, you can follow the directions on the package, and thoroughly aerate your wort. This works, and makes very tasty beer. Just count on longer-than-ideal lag times. This means you'll want to be scrupulous about sanitation. Wear rubber gloves, use plenty o' bleach, and all that. If you do these things I think any pure Wyeast or YeastLabs culture will produce a better beer than any dry yeast I know of. I keep a package of dry yeast around in case a wort isn't fermenting after 72 hours. I used one once, and the beer was OK. This is I think what Jerome is doing after 36 - 48 hours.

If you DO continue to use dry yeast, repitching is not recommended. ALL dry yeast is contaminated with wild yeast and bacteria. But there's a lot more good yeast than contaminants, so the yeast effectively out-competes the other beasts for the goodies in your wort. But the contamination is still there, and will increase in concentration with subsequent reuse of the culture. The reason you see such short lag times is that there's lots more yeast in the dry package than in the Wyeast package.

Hope some of this helps...

Subject: Re: Applejack/distilling

Hello All,

Because freezing hard cider to make apple jack concentrates the alcohol in the solution, a physical separation if you will, technically it's not a distillation. Distillation is used mainly to purify, as well as separate;concentrating the solution is a beneficial side effect. Applejack is one of those things you can play dumb over, "jeeze I had no idea it would do that officer! I just wanted to keep it from going bad.". Any of you who have ever seen a "still" know that it obviously can't be passed off for anything else. However, I'm just a lowly research tech., not a lawyer (thank god!) so I can't quote laws, but as far as I'm concerned making apple jack wouldn't be illegal because you aren't doing any distillation. BTW, distilling hard cider would result in apple brandy, not that I wish to plant ideas into anyone's head.

While I'm at it, I can see why cops & the law (especially the ones who haven't got a clue) would confuse homebrew apparatus with distillation apparatus. Those of you who cool your wort with copper coils beware, they're the give-away as far identifying moonshiners!

Cheers!

Pam

Subject: Homebrew and the law

COYOTE <SLK6P@cc.usu.edu> writes:

>*also note: Brewking sack ad in Sharper Image quotes:
> "federal govert allows you to make up to 25 gallons of
>homemad beer each year.

<snip>

>Damn at 25 gal/yr I could be done brewing in 2 weeks!
>Too bad The Sharper Image doesn't have a Sharper grasp of the
>legality.

Correct. Federal law allows for the production of 200 gallons per year per household if there are 2 or more adults in the household or 100 gallons/year if there is only one adult.

Scott writes:

>If I remember my beer-lore correctly, I thought Big Jimmy O'Carter made
>homebrewing technically legal in this country (correcting an earlier
>oversight). Being but a simple software engineer, my legal credentials
>are a good approximation of nil, but I thought federal law superceded
>state/local law. That is, if the Feds say it's OK for me to manufacture
>certain kinds of drugs in my kitchen, then it doesn't matter one whit
>what Missouri or any other state has to say about it. Yes?

As a simple law librarian I can't program my way out of a paper bag (well I might get that far, but maybe not) but I think I can clarify this misunderstanding a bit. The law that Carter signed exempted homebrew (within limits, e.g. 200 gallons/household) from excise taxes. The oversight Scott refers to is that an earlier law that exempted home winemaking from the excise tax did not do the same for beer.

Now, exempting homebrew from excise taxes ain't quite the same as providing a constitutional right to brew. I guess that since many of our founding fathers were brewers and nobody had threatened this right, they didn't seem fit to include it in the Constitution. This being the case, I believe state goverments can pretty much do as they please. On the other hand, if the feds said homebrewing is illegal, the states couldn't say otherwise.

From: gjsparks@aol.com

Subject: Alabama Laws

Some comments and questions in the HBD concerning whether xhomebrewing is legal in all 50 states prompted me to investigate the situation here (to borrow a phrase) in the beer wastelands of Alabama. According to Mr. Charles Ball of the Alabama Beverage Control Board Enforcement Office in Montgomery: 1) Homebrewing is strictly illegal in the state of Alabama. 2) Transporting any alcoholic beverage into AL (as a personal citizen, not a distributor, obviously) is strictly illegal; distributors must comply with all of AL's labelling and tax requirements. 3) Distributors are prevented by law from importing any beer with greater than 4% alcohol by weight (5% by volume). 4) Commercial breweries (microbreweries, brewpubs, et al.) must be built in an historic building or historic district in which draft beer was sold prior to Prohibition (??).

My personal impression is that they don't really care about enforcing the homebrew laws (unless one were to try and sell it or some other obvious violation). This was the extent of the information I got in the short conversation I had with Mr. Ball; I am also interested in what the federal regulations are, and how they interact with the state laws. If anyone can provide me with or direct me to this information, please e-mail me, or if it's sufficiently interesting, post it here. Maybe a compilation of basic regulations for all 50 states could be created? Thanks.

Subject: name?/forced decoction

Subject: Time:1:26 AM
OFFICE MEMOname?/forced decoction Date:10/21/93

Greetings:

The last batch of beer that I brewed I had intended to be lazy but I was FORCED to do a decoction-this isn't a bad thing, but plans are plans, anyway more on that later. As I brought the mash up to saccharification temp (67C in this case) I could TELL when I was almost there just by looking at the mash. Suddenly it became very foamy and just looked right. I have noticed this in the past, but this time it hit me....THERE MUST BE A NAME FOR THIS. Surely the Germans had (have) a name for it. Any guesses? Like maybe Saccharification with an umlaut or two?

The reason that I did a decoction is less clear. I used Durst malt, a high quality German Pilsner malt. I had planned to mash in at protein rest temp and then recirculate and bring the mash up to 67C by heating the tun. I mashed in at 50C and as I started to recirculate, nothing but a trickle. VERY milky looking. Stirring helped, thinning helped, but it would always slow and then stop. OK, OK, OK, I'll decoct. The beautiful malt aroma that was produced during that step made me wonder why I was tempted to do without. As soon as the main mash came up to 67C, recirculation commenced and things went as expected, although an hour later than desired. Sparged wonderfully, no problems here. This is the second time I have used this malt and the second time I had this problem which was solved the same way in both cases. Since the first was a Triple and the second was a deviant variation-on-a-Pilsner maybe this is Gambrinis forcing me to do the right thing-decoct with continental malt. Comments? Don't tell me to switch malts, I still have most (65 lbs) of a 100 lb sack to go.

This COULD be a Motor-Corona problem although I have never had this difficulty with Breiss malt. I'll use a Malt Mill in the next go to eliminate that variable. Perhaps adding a small percentage of Breiss to establish a better filter bed or assist in conversion/protein breakdown may help. Anyone else seen a stuck RIMS only at protein rest temp that went away at saccharification temp?

Subject: Beerhunting in Belgium: Part 3 (Liefmans and Oud Bruins)

[NOTE: My apologies for the long time it has taken for these posts to materialize; the problem is the long line of posts waiting for Digest publication. Having had too many Rocheforts myself, I'm not even sure which chapters have been posted and which haven't, and apologise if any of them appear twice. We'll make sure they all get out. I only hope it will have been worth the wait.]

Beer Hunting in Belgium: Part 3 of 7

Liefmans Brewery and Oud Bruins
(by Phil Seitz)

Oudenaard is known for its brown beers, particularly its oud bruins, which have a characteristic tartness. Local brown beer breweries include Liefmans, Roman, Claryisse and Cnudde. The first three are featured in an annual brown beer festival held in late June.

The Liefmans Brewery is located just outside Oudenaarde in a group of aged brick industrial buildings. Liefmans was purchased several years ago by the Riva brewing company, and has seven on-site employees.

A substantial part of the brewery is now being converted into a beer museum and reception center. The brewery is no longer mashing or boiling wort; instead, wort is prepared at the Riva Brewery in Dentergem and delivered, sterile, for fermentation at Liefmans. Liefmans' antiquated mash tuns and kettles are being retained as part of the museum.

Our initial expectation of lessening quality with industrial ownership appeared to be unfounded. Our guide, one of the brewers, said that during the 1980s Liefmans had substantial quality control problems, and that production had fallen from 30,000 hectoliters in 1980 to 8,000 hectoliters in 1990, which is approximately when the change of ownership took place. Production is now picking up (11,000 hectoliters annually) and quality appears to have stabilized. The tales we'd heard of Madame Rose, who lovingly looked after the brewery, sounded like myths as we heard stories of about what appeared to be a lack of proper attention to operations.

Other published information also appears to have been a bit mythologized. For instance, Liefmans boiled in room-size square kettles for an overnight simmer. These days the beer receives the standard 1.5-2 hour boil. This sounded like a concession to modern times until we saw the kettles, which contained heating elements so obviously inadequate that it quite likely took all night just to get the wort to the boiling point.

The one aspect where there has been a substantial change is in the cooling. Prior to Riva Liefmans used two large cool ships for initial cooling, and during cooling diluted its high-gravity wort with approximately 1 part water to three parts wort. From these cool ships the beer was then pumped over open-air cooling columns (beudelots?) and into the open fermenters. Nowadays the sterile wort goes straight to the fermenters. We thought that exposure to beneficial micro-organisms might be sacrificed by skipping these steps--affecting the trademark sourness of the beers--but our guide felt the Liefmans' yeast strain was sufficient to produced the desired flavor. Tasting was believing in this case and it appears that the new regime has not resulted

in any major sacrifices.

The brewery makes two basic beers, one at 5% ABV and one at 6%, from which a variety of blended products are produced. Both worts are made entirely from pilsner and caramel malts, and each is fermented with the same yeast in swimming-pool-sized open fermenters. We were there during the first day of fermentation, and the quantities of foam and yeast running off were truly impressive. On day 3 yeast is skimmed and collected for reuse.

The basic beers then go into steel secondary tanks. The 5% beer is run into fermenters loaded by hand with cherries or raspberries--typically about 1 lb per gallon. The beer sits on the cherries for a year or more before being filtered, blended with about 40% of the 6% beer, pasteurized, sweetened and force carbonated for bottling.

The 6% beer itself becomes Goudenband, which receives much the same treatment but is not blended. Another beer, Odnar, is produced by diluting the 6% beer to about 4.5%. This is sold locally as a table beer, and presumably is sweetened also.

We had a chance to taste the unblended beers directly from the fermenters, and found the product at this stage to be rather lambic-like in its tartness, though much cleaner overall. Obviously there is a bacterial component to the yeast being used.

Another change in recent years is that the Goudenband is no longer aged before sale. This is unfortunate, as the brewer noted that at least six months of down time improves the product substantially. We asked why this would be, given that the beers contain no residual yeast. He said oxidation from exposure to air in the head space adds an essential element to the mature product. He also said local consumers were aware of the change, and laid their bottles down prior to consumption. A taste of fresh, on-tap Goudenband later on did seem to indicate that a certain bite was missing. The cellars shown on page 105 of Jackson's NEW WORLD GUIDE still have bottle in them, but it is a bad batch from 1987 that is being retained for purposes of the beer museum.

Throughout most of Europe Liefmans products are sold wrapped in tissue paper. We happened to be there on the day that a large number of bottles were being wrapped--by hand. The workers' speed was impressive--between 2,000 and 3,000 bottles a day--but frankly, between the wrapping work and the need to load and evacuate the fruit from the fermenters by hand, this did not seem to be a particularly attractive place to work.

Because the brewery is small it does cater to special orders and requests. Liefmans sells beer in bottles up to magnum-sized, but area residents can bring larger bottles and leave them to be custom filled. We saw a storage area with a fair number of jereboams and larger bottles, each one tagged with the name of the owner, awaiting pickup.

Liefmans has an indoor taproom and outdoor terrace fronting on a canal. A glass of Goudenband and each of the fruit beers is included in the tour price. Their fruit products, always formidable in my opinion, are truly divine when fresh on tap. This is particularly true of the framboise (raspberry).

Tours of the brewery are available by appointment, and cost 100 francs. We were the only people on the tour. Our guide spoke English, and was obviously intimately familiar with the brewing process, having worked at Liefmans as a brewer for several years and also having received a degree in brewing studies in Gent. The telephone number is 055/31.13.91.

Other local brown beers include Felix (produced by the Clarysse brewery), which is similar to Goudenband, and brown ale from Roman, which is similar in color and body to its neighbors' products but is hoppier and not at all tart--rather a rich version of a standard brown ale.

Several of the people I know who make barleywine use 2 yeasts, including the one whose recipe I started from for my first one (thanks Glenn). I start the fermentation with ale yeast and after it's started to slow a little, I pitch champagne yeast. I don't recall off the top of my head which particular yeasts I used.

I believe the last I heard the price of the CP filler was \$55. Yep Micah is the designer of this CP filler, I use one and highly recommend it! I spoke with Micah earlier this week and ask him how things were going at the brewery? He said they are selling all the beer they make and are in the process of expansion. He is a one man show at Murphy's Creek brewery. I personally haven't had much chance to taste any of their beers, they are not widely distributed here in the bay area. They seem to find a market in the gold country large enough to sell most all their beer they make. I plan on going up and brewing with Micah one of these days and will report back. I told him I would not clean out any mash tuns!

Subject: Re: Beer Nuts (Matthew Rowley)

Paul asks about brewing with nuts (not bold brewing-proper nuts). You've read my mind, brother. That same question was why I logged on this morning.

I had an idead to throw some roasted almonds in a batch, but refrained because I've seen all kinds of wierd business go into beers, but never nuts; I've never seen any recipes for it, either.

I suspect that the oils in nuts would absolutely kill any head, though (comparable to doing the nose grease trick to your entire run). If'n anyone can offer advice otherwise, I'd love to be shown wrong.

Matthew

Subject: infected brew and head

A couple weekends ago I brewed up 2 batches, a red bitter and an octoberfest. Last weekend, I racked both into secondaries. Well, I was a little lax in my sanitation, and I think the octoberfest is infected. A day after racking, the red bitter developed a nice "mini" krausen, while the octoberfest had none, although it was bubbling frequently. I let both go for a couple days, and yesterday I decided to try I revive the octoberfest. I gave the carboy several good shakes, and while it developed some "froth", it quickly dissipated. Aerating the same batch in the primary produced a dense head that lingered. By the way, I used Wyeast European Ale yeast (in 2 sixteen oz starters) for both batches.

I decided to taste the octoberfest to see if it was sour, and it was (a little) but didn't really taste too bad. So I think I have learned two important lessons here:

1. Sanitize everything carefully (dah)
2. The problems that a lot of people have with carbonation and head retention (including myself) may be related to infections that don't completely foul the beer, but just add off flavors. In fact, if I didn't think that this beer was infected, I might not have even noticed (if it was bottled and chilled), although I would have noticed the poor head retention.

But why does an infection kill head? And what can I do with this 5 gallon batch of infected brew?

Thanks,
Tom

Subject: Holiday Ale anyone?

Salutations!

My homebrew club, the famous Snowy Range Foamentors, is going to have a local homebrewing contest. The beer of the month for December, the month of the contest, is Holiday Ale. I'm wondering if anyone out on the Net has any really good extract ale recipes they think might be good? I'm always preaching the values of a well read HomeBrew Digest to them,

but most of them think they can live with out the wealth of information available here. Well, I'm going to tap this source and try to win the contest. Any suggestions?

From: Dave Lame <dlame99@prog.c4.gmeds.com>  
Subject: Brewing with nuts

Paul Selkirk asks -

"The other day, while roasting some hickory nuts from my neighbor's tree, I got to wondering if anyone ever brewed with nuts."

I will answer - sort of.

I make mead, and I'm also a member of the Society for Creative Anachronism, a medieval recreation group. I was reading a book called "The Sacred Bee", all about the history and folklore of bees, mead and honey. It had a quote from an eighth century Irish manuscript in which there was a reference to mead made from "honey of the bee and milk of the hazel". There were also references in other places to "hazel milk". The author went on to explain that immature hazel nuts had a thin white liquid in them, and that these eighth century lads would gather the immature hazel nuts and use this little liquid to add to their mead.

They would do this because the hazel was a sacred plant which, like honey, would give eloquence and insight to the imbiber. So, mead and hazel together was sure to be a magical drink.

I couldn't picture people running around finding unripe hazel nuts and getting a few drops of liquid from each one. Their old magic was a bit more practical than that. Being strongly inclined to recreate something from eighth century Ireland, which was only 100 years or so later than my own adopted time period for recreation, I decided to experiment. Instead of using "hazel milk" from immature hazel nuts, which would be rather difficult to find and process, I just decided to throw in some nuts.

I crushed up the nuts, and I always boil some honey and water together to put into the primary. I boiled the honey and water, and poured it over crushed hazel nuts. Lo and behold, the boiling water pouring over the nuts released a lot of oil in them, and it formed a suspension in the top of the primary. The result was a milky-white liquid. This, I realized, was the real "hazel milk" to which the Irish were referring.

I have no doubt that this hazel milk made the Irish mead better, and I'm sure that they attributed this to the magical property of the hazel. I suspect that another factor may have been at work. Their quality control wasn't the

best, and I'm sure that they made many a bad batch, polluted by lots of the sulfur compounds that produce awful smells. These sulfur compounds are soluble in oil much more so than in water. By adding the "magical" nuts, and skimming off the oil, they got rid of the sulfur compounds, making the mead taste better.

Enough history, you might be wondering how well it worked. I've had mixed reviews. There are a couple of problems with using nuts. First, there is the flavor of the nuts themselves. It is very strong and somewhat "woody" in the final mead. Not very many people associate this with wines, and a lot of people just plain don't like it. Some do like it, but many don't. I suspect that it might be somewhat more popular in a beer, especially a darker, heavier, beer. Second, there is the oil. Most beer and wine is made with water and sugar, adding a fair quantity of fat in there requires special caution. I've made two batches so far. In the first batch, although the mead looked clear, I actually ended up with floating patches of oil in the glass. The residual oil had gotten together and floated to the top after a few months in the bottles. In the second batch, I used finings, twice. I racked it an extra time, being very sure not to mix it up in transport, so that all the oil would be on top. I made sure the siphon was well below the top so that the oil would not come with the mead. It worked fairly well. There was no oil left in my second batch, although it was not as clear as some of my other efforts. One thing you should definitely do, in my opinion, is to use the "hazel milk", or milk of whatever nut you use, rather than using the whole nut. I did that with my second batch, and it was much easier to handle, with no noticeable change in the nut flavor. Grind up the nuts and pour boiling water over them, and use the liquid that forms. I don't know what is a good amount. I used two pounds of nuts for a gallon of mead, but that was just a guess. I wouldn't use any more, and next batch I'll probably use less.

I submitted it for judging. The judges recommended using oak chips in the next batch, and they also recommended a long aging period, to let the flavor mellow somewhat. The mead was also dry, and they recommended making it sweeter. Some experiments mixing sugar into it confirmed this was probably a very good idea, as the bouquet and flavor were both improved.

All things considered, mead and nuts were an ok idea, and I intend to do it some more, but it is definitely a specialty drink. You will find a few people who really like it, and a lot of people who would really rather have a nice

amber ale.

Since I intend to try this some more, I would like to know if anyone else has used nuts, and how well it worked. I haven't seen any other references to nuts in brewing in books written since the eighth century.

From: todd@ted.hac.com (Todd Thompson)  
Subject: Aerating wort

I'm a new brewer and have been reading homebrew digest for a couple of months. My question has to do with aeration of the freshly pitched wort. I've made two batches over the last few weeks while reading Papazian and Miller's books on the subject of homebrewing. Only then did I realize that I had done no where near the amount of shaking/stirring and bubbling they suggest. By this time my fermentations had stopped (after only 3 days).

I took off the airlock and replaced it with a stopper and proceeded to shake and swish the wort (now beer?) around for a few minutes. Immediately the beer started fermenting again and fermented very slowly for the next couple of days. Now the questions:

- 1) Was it a mistake to aerate once fermentation had stopped? (I would rather not drink wet cardboard flavored beer!) Have I oxygenated too late in the process?
- 2) How much aeration is necessary? Shaking a five-gallon fermenter even for a few minutes can be hard on the back. Besides, some wort always spills from around the edges of the lid while shaking. Is it really necessary to shake the fermenter for 5 minutes every hour or two for the first day? (Sorry I don't have the exact recommendations with me. It seemed like alot of shaking to me, though.)
- 3) Is there a better way to aerate than shaking or the aquarium pump/air stone method? It seems like an air stone for aquariums would be difficult to sanitize.

Great discussion group! This is my only source of info other than books. Thanks for your responses in advance :-)!

Subject: Polyethylene Mashout

>From: npyle@n33.stortek.com

>I just bought a thick-wall polyethylene hose to run from my lauter tun  
to my  
boiler. The hose I use now is a thin-wall vinyl hose which has a  
tendency to  
collapse when the hot liquor is flowing through it. Any experience with  
this  
PE hose? It is quite stiff, compared to the vinyl, translucent (similar  
to  
the vinyl after coming in contact with boiling wort), and has almost a  
waxy  
feel to it. Also, it is rated for a fair amount of pressure, but says  
nothing  
about temperature. Use it or lose it?

I am using Low Density Polyethylene tubing for transferring wort. It is  
FDA  
approved and has a temp range of -70 to 120F and it handles sweet wort  
temp  
just fine. It softens up just enough to feel good. I have a short  
piece of  
copper tubing on the kettle end that goes to the bottom of the kettle to  
avoid HSA for what ever that is worth. I also have a ball valve above  
the  
kettle so I can control the flow rate down there.

I started out with 1/8" i.d. but the flow rate was too slow so I now use  
1/4". Not sure what you mean by thick-wall but this is 3/8" o.d. on the  
1/4"  
i.d. tubing.

>From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)

>Over time, we incorporate new techniques into our brewing  
methodology when convinced of the new technique's merit. I'm  
proposing the same action only in the opposite direction in that  
techniques can be eliminated when deemed unnecessary. Such is the  
case with mashouts.

Finally had to get serious and spoil the fun, didn't you?

That's tough to argue with, Chris and in the spirit of pioneering, I  
will  
(might) give it a whirl on my next batch. The only excuse I have left  
is  
that the mash cools off very rapidly in a steel kettle compared to an  
insulated cooler and you might want to offer me a special dispensation.

From: COOK@CDHF2.GSFC.NASA.GOV (Chris Cook)  
Subject: Beer Drinks, Fruit Beers and Spruce Beers

#### Beer drinks

- - - - -

A couple of years ago my wife and I went out Polka dancing with another couple that had recently returned from Germany. In between dances we were dringing from pitchers of Dortmunder Union and Coke. Without prior provocation, the husband mixed the two in his glass, calling it a 'Diesel'.

A what? we asked.

Diesel, he said, shrugging, that's what they call it in Germany.

Anything with a name that bad has to be tried. It wasn't bad.

#### Fruit Beers

- - - - -

I was making wines for years before starting beers, and fruit wines are easier and quicker than grape wines. It was simple extract stuff - dump in a can or two of concentrate with corn sugar, sterilize using camden tablets, balance the acid and, a day later, pitch dry yeast.

My first attempt to combine canned fruit must ['must' is the wine version of wort] with beer was a cherry stout. It was based loosely on Papazian's recipe, with one 48 oz can of cherry wine concentrate added during the boil. Unfortunately, I think I was having a bad sanitation day - the beer had metallic overtones that spoiled the flavor. Or maybe boiling the cherry concentrate was the mistake?

My second attempt was a light raspberry mead, which was fabulous. It was a lower-gravity sparkling mead, with one 48 oz can of raspberry must concentrate and 7.5 pounds of honey for 5 gallons. Everything was added at the start of fermentation and I used camden tablets to sanitize, rather than boiling. I drank the last bottle years ago, but I remember it being sparkingly clear, dry with a very pleasant raspberry nose, a subtle flavor and a very nice reddish color.

Anyone else try using canned fruit must?

#### Spruce Beer

- - - - -

In HBD1251, John (The Coyote) Wyllie <SLK6P@cc.usu.edu> talks about spruce beer disasters. I've mentioned by love for a good spruce beer before in the Digest, and with a recent batch I have another datapoint.

I've made variations of Papazian's Goat Scrotum Ale every year, including spruce most of the time. While they've all been different, they were all

generally rich, very full-bodied and dark beers, and the spruce just worked well for me. Until last year.

My procedure before that was to add a bottle (2 oz?) of spruce essence with the extracts at the start of the boil. The kitchen would smell strongly (and nicely, I thought) all during the boil, and the resulting spruce flavor was nice without being overpowering.

John mentioned using 6 oz of essence. I don't know the brand, but that sounds like a whole lot of essence.

Since I went all-grain, I started getting fancy ideas, and I thought that maybe I shouldn't be boiling off all those aromatics in the spruce essence.

So for the next batch I added about the bottle at the end of the boil.

All

I can say is that it looked good on paper; the beer was undrinkable, with strong, raw, somewhat chemical flavors.

I tried again this year with a dark spruce beer that I just got around to kegging. This time I made a light-bodied, dry stout with spruce added at the beginning of the boil. The spruce flavor is back where I wanted it, without the harsh overtones. Unfortunately, I find I don't care for the flavor in a dry, light-bodied beer, or at least *that* dry, light-bodied beer. This fall I'm back to old crankcase 'n spruce.

Subject: uk pubbing

>Well I'm back from 3 weeks of pub hoppin in England, Wales and Scotland.  
I  
>got to tour 4 brewerys, Young's, Sam Smith's, Calandonion and Traquir  
House  
>(it was under reconstruction). The brewerys were all very nice and  
seemed to  
>bend the rules more than a bit when I mentioned I was a brewer from the  
>states. I came back with 4 yeast samples and am looking forward to  
brewing  
>some real ales. A few thoughts on things I was surprised about in the  
UK.

You are a dog! :) I practically begged to tour Young's but to no  
avail. I got to see (from the outside anyway) quite a few  
breweries. It's almost hard not to there are so many around.

>\* I expected cellar temp beer and low carbonation. The real ales are  
cellar  
>temp (55 deg f) and DEAD flat. The ales may have a head if pulled via a  
>sparkler on the beer engines.

This is true. Almost every beer was cool enough to condensate the  
glass a bit. No head or very little each time.

>\* All the beers were extremely small gravity compared to our beers here  
in  
>the states.

I wouldn't say that this is true of my experience. Although, most  
were of low gravity. I remember one though from Gibbs Mew called  
Bishop's Tipple, that was definitely strong. I had a couple of  
pints and felt just fine.

>\* An Imperial pint was about \$2.25.

I was paying about 1.80lb (~\$3.25 then) so you got a bargain.

>\* The Brits are very fussy about both clarity and a good pour. The fill  
>damn well better be to the top and they don't want any haze. All the  
beers  
>were extremely clear. I expected some floaters, I say NONE.

They were very fussy about their cask served stuff as well. I  
visited one pub and got a cask served Young's Winter Warmer and it  
tasted awful. I had one 2 days prior at the same pub that was  
wonderful. So, I mentioned this to the barkeep, and he quickly  
apologized, covered the cask (mentioning to the others that "it  
was off"), and poured another pint of Young's Porter for me. I was  
more than a little suprised that he just took my word for it.

All in all, I had a great trip (back in March) and hope to return  
as soon as I save enough money. I would recommend that experience  
to anybody.

From: Jeremy Ballard Bergsman <jeremybb@leland.Stanford.EDU>  
Subject: amylase confusion

I believe that the confusion over the denaturation temperatures of amylase enzyme results from the fact that barley alpha amylase and the purified amylase sold by homebrew shop is a different enzyme, the latter coming from a fungus (aspergillus?), and originally for use in brewing (?) sake. There are many sources of enzymes that break down starch (can you say salivary amylase?), the fungal one is probably the cheapest. All of these enzymes will have different optimal conditions and denaturations temps. The enzyme I use for experimental mini-mashes is called Koji and the manufacturer gives 122F as the optimal temp., consistent with 130 or so as the denaturation temp.

Subject: Hot Priming/Keg Request

>>>> On Tue, 19 Oct 93 09:18:43 PDT,  
DJM1%CRPTech%D CPP@cts27.comp.pge.com said:

Dan> Does anyone out there on the HBD know where to obtain old (or  
Dan> new, for that matter) 15 gal kegs....Searches of local Recycling  
Dan> places are a no-go (yeah, I could actually buy some of that  
Dan> massed-produced swill and keep the keg for the deposit).  
Dan> TIA-----You can E-Mail me direct.

Well, it is possible to call around to beer suppliers (retail) and see if they will be willing to let you pay the deposit and walk out with an empty keg. I did this with 4 kegs. No problem. Before I did, I called the wholesale distributor and asked "If I do this, will the retailer get in trouble?" The reply was, "No, but someone up the line will eventually have to pay the \$150 value of the keg. You know that even though you pay \$12 deposit, the kegs are not that cheap and someone will eventually have to replace them."

I mailed off for some information on a RIMS system from SABCO Save-a-Barrel and got literature about the kegs which they have available. They take commercial used kegs which have been proven unfit to hold pressure, recondition them, cut out the top and install a nipple and valve. They sell from \$65 to \$150 depending on what options you get done (\$150 gets you the keg, a stainless ball valve and a stainless thermometer well). They also have lauter tun screens available for the kegs. (I am making the assumption that you want this for a kettle, not for kegging).

They included a page describing that paying a deposit on a keg and then taking it away forever is a crime and that some breweries are taking individuals to court and winning suits (civil) against them for doing this. No mention was made of how often compared to the number of people who actually do this. Of course, their tactic is to scare you into buying their product.

If anyone wants to contact them, I can look up the number, or they advertise in Zymurgy and Brewing Techniques, the ad for the RIMS system which is microprocessor controlled ( and BTW runs \$3000 for the complete system ).

**Subject: Low-temp Bottle Conditioning Query**

A friend without access to the net asked me to pass on the following question. He doing a real lager for the first time, has fermented at low temp, bottled, and is now letting the beer condition at around 45F. At this temperature, how long can he expect it to take before the beer is carbonated? He opened one after 1-2 weeks (yes, that is very early) and it was flat. Another problem he encountered: when fermenting at low temp, how does one reliably determine that fermentation is over (i. e. when fermentation is so slow, how do you decide that it has stopped?). He didn't like my answers to these questions: Get kegs so you don't have to bottle condition, and brew ales so you don't have to wait so long.

Thanks.

Dave Rose.

Date: 21 Oct 93 10:37 CST  
From: Wolfe@act-12-po.act.org  
Subject: Going all-grain

I'm ready to start all-grain brewing, and I would like some advice.

First, I am considering mashing on a burner rather than using a cooler for a mash tun. Is the primary reason for using the cooler rather than a burner the reduced investment in time and money? I guess I want to know how much of a hassle is it to mash on the stove as opposed to mashing in a cooler and if there are any differences in the quality of the brew.

Second, because I want to mash on the stove I need to invest in a larger brew kettle. So far, I've only done high density extract & partial mash brewing so I've gotten by with only a 2.5 gallon kettle. I've found a medium-duty 7.5 gallon SS kettle with a lid and a spigot for about \$100. I am toying with the idea of moving on to 10 gallon batches in the future. Is the kettle described here a worthwhile investment, and could I still use it to mash grains for a 10 gallon batch of brew?

Third, I read a comment a while back about trying to get a 5 gallon batch of all-grain brew into a 5 gallon carboy. I have three five gallon carboys (They were cheap! \$7 at a local used stuff store.). Will I have a problem using these for my all-grain batches? When I started doing partial mashes I got a lot more blowoff in the primary. Will the blowoff in a 5 gallon carboy be unmanagable with an all-grain batch. I've been using a stopper and a racking can as my blowoff valve, but have heard a number of people report using a 1" pipe attached to the top of the carboy. Any insights?

Finally, I have Miller's and Papazian's books. Can anyone suggest a good next book for someone who brews mostly ales that is getting into serious all-grain brewing (e.g., Foster's Pale Ale)?

\*\*\*\*\*

Date: Thu, 21 Oct 93 13:29:18 MDT  
From: npyle@n33.stortek.com  
Subject: Late Kettle Hop Additions

I've been thinking recently about hop additions (all this Hops FAQ stuff has forced me to think about some of this stuff). I just realized that there is an inherent advantage to immersion chillers (my old method) over counter-flow chillers (my current method). Yes, the immersion chiller leaves the cold break in the kettle but it does something else that I have not seen discussed in this forum.

The immersion chiller cools the wort and hops fairly quickly from 100C to around 50C (maybe 10 minutes). The late kettle additions are boiled for a short time (1-10 minutes) and then within 10 more minutes they are at a relatively low temperature (50C). Granted, getting the wort down the final 20C to pitching temperature is pretty slow but the volatile hop compounds which you are trying to retain with late additions are less reactive between 20C and 50C than they are at 100C.

With the counter-flow chiller the wort and hops remain near 100C the entire time the wort is being chilled. From experience I know the kettle is still extremely hot 20 minutes after turning off the flame. I would bet that finishing hops act more like flavoring hops and that flavoring hops act more like bittering hops with a counter-flow. Can anyone verify these assumptions? Do you know of any commercial brewers who use immersion chillers (they clearly have some advantages)? Probably not since immersion chillers are less efficient and I know of few commercial brewers (even micros) who care a lot about hop aroma.

I may alter my procedure a little bit to compensate for this. I haven't yet decided how. Suggestions?

Cheers,  
Norm

From: Domenick Venezia <venezia@zgi.com>  
Subject: Yeast nutrients/pitching

Thanks to Jim \*Busch\* and Daniel F. McConnell on giving some definitive and consistent numbers concerning optimal pitching rates, ales at 5-10x10\*\*6 cells/ml, and lagers at 10-15x10\*\*6 cells/ml or more. One thing that confused me at first and perhaps others was the fact that pitching rate is defined by the resultant cell density in the batch after pitching. So what at first may seem to be wildly different numbers between Jim and Dan's posts are actually the same numbers.

My goal in starting this enquiry was to somehow get my pitching rate into an acceptable range while NOT being forced to pitch a half gallon or more of some other wort into a carefully designed recipe. Remember a half gallon is 10% of a 5 gallon batch and such a volume will affect your results. I would like to do an adequate pitch in about a pint of starter. Also, I wanted to avoid having to save and pitch yeast slurry from previous batches (Hey, I want it all).

Generally, I pitch a pint starter (very seriously underpitching) and if I can get 10 times the pitching rate by using a little YNB (provided the yeast characteristics remain stable) I figure it's worth it.

If one is not reusing slurry but using a starter what's involved in getting an adequate lager pitch of 10-15x10\*\*6 cells/ml in a 5 gallon batch?

>Dan asked:  
>  
> What kind of lag time did he get? I'll bet it was on the order of 10-12  
> hours, not bad, but greater than optimum.

With Wyeast Chico Ale strain he got just what Dan expected, 10-12 hrs. However, with Wyeast London Ale strain he got a 3 hour lag.

Speaking of lag time, how exactly are we determining the end of lag time? For my own purposes I have defined the EOLT as 2 bubbles/minute from my airlock, but this may be misleading in either direction. Jim? Dan? fg

Many dry yeast users have reported problems like this when switching to  
liquid yeasts. There are two factors, both which affect lag time, that  
are significantly different between dry and liquid yeasts: 1) aeration  
and

2) cell count. 1. Before drying, the yeast destined for the drier are  
given

lots and lots of oxygen, so that after rehydration, even if there is a  
shortage of oxygen in your wort, the dry yeast cope with this dilemma  
better.

2. There are many orders of magnitude more yeast in 7gms of dry yeast  
than  
in 1.75 floz of liquid yeast. You can get by without a starter, but your  
luck diminishes as the yeast package gets older since the %viable goes  
down.

A starter is recommended, but not manditory, for liquid yeast. I've had  
good success with pitching right from the Wyeast package, but I was  
prepared  
for a 48- to 72-hour lag time. It's a real test of your sanitation! More  
recently (in the last 2-3 years), I've been using starters and get lag  
times  
as short as 12 hours, but sometimes it still takes 24 hours even with a  
starter.

>Should I just admit abject failure and use dry yeasts exclusively? By  
>extension, will I make a beer with "666" tatoood on its forehead if I  
reuse  
>the slurry from a batch fermented with dry yeast?

Recent data suggests that the bacterial and wild yeast counts of dry  
yeasts  
have gone down considerably from 5 years ago. Dry yeasts that I've had  
success with are Nottingham and Coopers and have heard other brewer's  
(who's  
opinions I highly respect) have success with the new strain of Red Star  
Ale,  
Windsor and Pasteur Champagne. I don't think you should fear repitching  
from dry yeast slurry, but as always, be careful.

>>purchased about a pound and would like to adjust my recipes.

There are a great many factors that affect AA loss: temperature, oxygen,  
packaging material, hop variety and type (pellets, plugs, whole).

Assuming optimum conditions (freezer temperatures, N2- or CO2-purged  
packaging, oxygen-barrier packaging), I would say that perhaps 95% or  
more AA would be retained. However, optimal conditions are rarely  
kept and retailers have only recently started to use oxygen-barrier  
packaging, but virtually no one purges their packages with inert gasses.  
Note that HDPE, the most common plastic used for packaging, is not  
oxygen-barrier. A good rule of thumb is "if you can smell the hops,  
it's not oxygen-barrier packaging."

Regarding hop variety variations, here's a bit of data (thanks to Ralph^  
2  
at Hopunion, USA):

variety storagabilty  
(% of AA remaining  
after 6 months storage  
at 20 degrees C)

|                          |             |

| LIBERTY                  | 35-55       |
| MOUNT HOOD               | 50-60       |
| NORTHERN BREWER (DOMSTC) | 70-85       |
| NORTHERN BREWER (HALLRT) | 70-80       |
| NUGGET                   | 70-80       |
| PERLE                    | 80-85       |
| SAAZ (CZECH)             | 45-55       |
| SPALT (US)               | 45-55       |
| SPALT (GERMAN)           | 50-60       |
| STRISSELSPALT            | 60-70       |
| TETTNANGER (US)          | 55-60       |
| TETTNANGER (GERMAN)      | 55-60       |
| WILLAMETTE               | 60-65       |

Note that 20C is about 68F, so we're talking about room temperature.  
Don't forget that this is just a measure of Alpha Acid retention and  
not the essential oils. The highly volatile aromatics of hops are much  
more fragile. My experience with the CO2-purged, 3mil Oxygen-harrier  
packaging I use, has shown that this method of storage (even at 40F)  
tends to retain the wonderful hop aromatics, whereas my old method  
of storage, Saran Wrap (tm) and foil in the freezer doesn't work as  
well. Also, regarding the type, pellets tend to retain more of  
everything  
(AA and aromatics) than plugs, which retain more of everything than  
whole.  
It's all a matter of exposed surface area.

>If I understand things right, essentially zero. No adjustments should be  
>necessary. Mark Garetz (our local Hop Expert) may wish to comment.

I would really rather that people not reinforce Mark's self-proclaimed expertise -- what I posted before is really true: Mark Garetz only started brewing about two years ago. I've been brewing for over 8 years and reading about brewing even longer and continue to discourage people from calling me an "expert." Perhaps in 30 more years. I've experienced a lot over the years and read a lot too and have found tons of inconsistency in brewing literature. No one can become a brewing expert from a book -- there's too much conflicting data out there!

\*\*\*\*\*

>for liquid extract.

I've found that various brands of DME are more consistently in the 42 points range, but that syrups vary from 35 points to almost 40 (for Northwestern). Also, crystal malts give me extracts in the mid to high 20's, but note that the Belgian and English crystal malts are 2-row, whereas domestic are 6-row and give quite a bit less extract. I have some limited data on roasted malts but have yet to extract (no pun intended) useful data out of them. Perhaps I can get a copy of the Karamarkar algorithm ;^).

**Subject: Bulk vs. bottle lagering**

With the onset of cooler weather I'm beginning to contemplate brewing lager for the first time. My guides to this point have been books by Byron Burch and Dave Miller. Burch seems to favor lagering in bulk, Miller seems to think it's alright to do it after priming and bottling. Is there a consensus on the advantages and disadvantages of the two methods?

From: paul@ftp.com (Paul Selkirk)  
Subject: beer nuts?

The other day, while roasting some hickory nuts from my neighbor's tree, I got to wondering if anyone ever brewed with nuts.

Would you mash the nuts (lots of starch in there), or "dry-nut" a more conventional beer?

What kind of nuts would be good? The walnut/pecan/hickory family all taste like they've got a lot of tannins, so they might not be appropriate. Maybe almonds, filberts, brazil nuts... (I can see it now - Rainforest Crunch Beer!)

I've been reading the HBD since the beginning of the year, plus most of last year's back issues, and I've seen some...unusual...ideas, but I don't recall anything of this sort. What say ye?

paul

Well I have tried using nuts before in a homebrew, and in my case the results weren'r worth it. In the first place, I was using black walnuts, which are probably one of the hardest nuts to shell. I mashed them in (approx 4-6 ounces) with some DMS (diastatic malt syrup) and proceeded to incorporate the mixture into a sweet stout, which I think is OK, but the walnut aroma/flavor comes across more as a fault than a useful addition. I think that this area deserves more research.

From: Kevin Schutz <kschutz@atmel.com>  
Subject: More beer drinks

Assuming that any type of beer "drink" qualifies, I almost completely forgot about some beer shake recipes. I just remembered them after reading about the Belgian beer drinks.

The first place I ran across beer shakes was at the Wildnerness Pub in Boulder, CO. They serve a Porter (Boulder) shake. Pretty tasty. Since that time, I've experimented with several varieties of porter shakes (using Boulder Porter, Black Hook, or homebrew), several Linderman's (sp?) for fruit flavors and even an Anchor Steam shake. Not bad!

The basic recipe for home use is to get some vanilla ice cream, beer (I'd recommend some beer that has a strong character so that the flavor will come through), milk (optional), and a blender. Blend to taste.

I'd recommend beer shakes to anyone unless they have a problem with lactic acid or alcohol.

From: Philip Proefrock <PSPROEFR@MIAMIU.ACS.MUOHIO.EDU>  
Subject: Growing Hops

I am interested in growing my own hops for use in my homebrew. (I don't plan to use this exclusively, but it would be nice to have hops I had grown in the beer that I brew. I expect I would only use the homegrown hops for one part of the process, say boiling, and will continue to buy other varieties for flavor/aroma.) Does anyone else do this? Can you provide some pointers, suggestions as to where I can find seedlings or seeds, etc.? What varieties will grow best in the midwest?o I hope to get starters going indoors this fall, so that I can get them growing this coming spring.

Subject: Slow CF chiller

drose@husc.harvard.edu writes about slow CF wort chillers:

HO>I bought 50ft of garden hose (a lot  
HO>cheaper than tygon tubing), 50 ft of 1/4" copper tubing, and built  
HO>a 40 ft chiller (10 feet of the hose going to the connecting lines).

1/4" tube is very thin. Try larger diameter tube. The gain:

- \* the cross section area of the tube is the square of the diameter
- \* the flow is the cross section area times the speed of wort in the tube
- \* the resistance to flow is reduced by increasing diameters => faster flow

Increase the diameter by a factor of 2 and you get about 6 to 8 times faster volume flow. Maintain the length of the chiller.

The other possibility is to increase the driving force: increase the height difference.

Yes, they do have lots of starch, but also lots of oil. You risk the  
possibility of having a "headless" beer. Hey, Euell Gibbons used to make  
biscuits from acorn flour, why not give it a try?

From: "Phillip Seitz" <p00644@psilink.com>  
Subject: Beer hunting in Belgium: Part 4 (Brasserie la Caracole)

Beer Hunting in Belgium: Part 4 of 7

Brasserie La Caracole, Namur  
(by Phil Seitz)

In Belgium it is possible to run very small scale commercial brewing operations, and there are breweries that only sell a few hundred bottles a year. Obviously the brewers in this situation don't make their living this way, but in some cases they gain valuable experience toward opening larger operations.

One very small operation is the Brasserie La Caracole, which is owned by three partners--the minimum allowable when forming a partnership in Belgium. One of the partners owns a well-known local specialty beer store, La Cave de Wallonie, which serves as the primary outlet for the brewery's products.

Since I have previously reported on this 4 hl garage brewery in HBD I will not review the entirety of their operations. However, my return visit did give us a chance to cover some new ground, some of which will be of particular interest to small-scale commercial brewers:

**Equipment:** The brewery uses a converted steam-jacketed Army-surplus soup kettle. The jacket and inner kettle were separated, with the interior becoming their mash tun and kettle, and the exterior jacket becoming their lauter tun. Water is heated using a European-type flash hot water heater, and is added to the lauter tun just the way we do it--one dipper at a time. The fermenters are located in individual closets, which are heated when necessary and protected by UV lamps.

**Yeast:** Yeast is obtained fresh from a yeast bank at Louvain-La-Neuve, and the same yeast is used for their white, amber, and dark beers. The yeast comes in a 30 liter sealed container, with a yeast count of 5 million cells per centiliter.

Like most breweries this one has a device for cooling and oxygenating its wort. However, they've been having a problem with generation of too many yeast cells during fermentation, making it difficult to get a clear beer. They have therefore decided to temporarily do without oxygenation to see if this will reduce the respiration phase and the resultant increased cell count from reproduction.

**Malt:** The brewers here have lots of good things to say about the DeWolf-Cosyns malts, which are also available here in the U.S. Not only do they feel these are the best available in Belgium, but they also have fewer business problems with this maltings. When dealing with other sources they report constant problems receiving the wrong thing. In addition, they report that while different maltings produce the same lines of malts, if you order the same thing (say, caravienne) from each source you're going to get somewhat different products. Apparently there are no strict definitions regarding what a malt should be if its called by a particular name. Of course, this would also discourage brewers from switching malt suppliers once they've gotten used to something.

The malts from the Deskamps also got a favorable mention. They have at least one maltings, in Gembloux.

Spices: The brewery uses two different types of orange peel. Bitter orange is used for their white beer, and sweet orange for their strong ales. The former is a greenish-gray color, quite bitter in flavor, and provides very little orange flavor in the beer--only a mellow form of bitterness is imparted. Bitter orange is used at a rate of 0.5 grams per liter of finished beer. The sweet orange provides a more conventional orange flavor, and is used in quantities ranging from 0.5 grams/liter to double that or even more. Both types of peel are purchased in 50 kg sacks.

Training: The brewer (one of the three partners) received a 6 year brewing degree from Louvain-La-Neuve. The first four years focus on chemistry and biology, and the last two specifically in brewing. Presumably this is roughly equivalent to a B.S. and an M.A. I can't recall now what his day-job was (the brewery operates only on weekends), but I believe it dealt with commercial production of yeast for food products.

Economics: The brewery hopes to move to larger quarters, preferably a 20 hl facility, and is slowly collecting equipment and experience. At the moment it is loosing 60,000 Belgian francs a month, or about \$1,800. They appear to see this as a cost to be paid during their education, which is fine as long as they can afford it.

Use of fresh yeast for each batch adds 8 francs (about \$0.25) to the price of each 75 cl bottle, but at present the brewery has no yeast-propagation facilities. They must also use new bottles (as opposed to returnables, which are cheaper) because they don't have space for bottle cleaning. For that matter, they don't have electricity or plumbing either, and run a tube down the street to a sewer when they're brewing.

While the brewery sells at least 50% of its beer through La Cave de Wallonie, it also sells a substantial portion through what might be called subscription. In Belgium there are many fraternal and business organizations holding meetings throughout the year, and it is a common practice to have a brewery prepare a batch of beer with special labels for the occasion. (Some American wineries also provide this service.) It can be surprising how much beer can be sold this way, and for a small brewery the arrangement is ideal--they know how much beer they need to brew, and they don't have to worry about distribution. Someone shows up with a truck, takes several dozen cases, hands over a check, and the thing is done. In a business where cultivating and supplying retail outlets can be a major chore, the savings in effort is substantial. In addition, many of these organizations see it as a matter of pride to present unusual or high quality beers, and actually seek out smaller breweries to work with. Regional pride plays a strong role as well.

>While reading the Fix'es Vienna book last night, I came across the sections  
>on filtration and carbonation, and I suddenly got confused as to which  
>order they should occur in.

> 1. carbonate then filter  
> 2. or filter then carbonate

>It seems some of the big boys filter and then pump into a conditioning tank  
>to carbonate, so this would be #2. Other breweries, Anchor for one, end  
>secondary fermentation with the beer naturally carbonated, and filter  
>afterwards.

It is difficult to properly filter fully carbonated beer. Thus option #2 typically gives the best results. I use 5 gal. kegs for storage, and try to adjust the pressure so that the CO2 content of the beer is 1.6-1.8 vols. (i.e., liters per liter). This will not filter as well as totally flat beer, but the differences are not great. After filtration, the CO2 level is increased to the desired level (2.2-2.4 vols. for ale and 2.5-2.6 vols. for lager) by direct CO2 injection.

I always use to use a mashoff at 168F for each of my brews. Last year when visiting Anchor I noticed that they did not mash off. I asked Mark Carpenter about this and he resonded "Who needs it". Since then I have been working with a final temperature of 158F, and have seen no negative effects. There has been no major change in yields, and I still get a fast run off (which I prefer). I am using propane burners, and with this set up I find I can get a tighter control of wort color by not mashing off. In short, I think Chris has got this one right.

This is exactly what I do. Take a bucket and fill it  
1/4 - 1/2 full and submerge the end of the 1" tube in  
the water. Give it a shot of bleach to prevent any stuff  
from growing in there. Actually a tsp would be more than  
enough. I've yet to ever get an infection from using this

method. I've never had to change the solution... well maybe  
once or twice when I've used dry yeast.

From: goetze@cats.ucsc.edu (Tom Goetze)  
Subject: Scraping hops from the side of my kettle

As I was brewing my Holiday Happiness (extract/speciality/spices) last night, a question about my procedure came to me. Sometimes after adding the hops to the boil, a big head of foam forms on top of the boil which pushes much of the hop pellets up and against the side of my kettle. So when the foam subsides (which it actually doesn't always do) it appears most of hop pellet gunk is stuck to the side of my kettle. So here is my question: Should I bother scaping the hops off the side of my kettle or have all the bittering oils already made their way into the boil?

It has been my practice to scape them off in the past, but I was just curious if I actually needed to put down my homebrew to scape the hops off. It sure could save me a couple of minutes drinking time.

Thanks in advance,

tom

Date: 22 Oct 93 12:37:00 EST  
From: "Anderso\_A" <Anderso\_A@hq.navy.mil>  
Subject: Yeast

Message Creation Date was at 22-OCT-1993 12:37:00

Greetings,

I've a couple of questions dealing with the propagation of yeast as well as yeast washing after fermenting a batch. I've had generally good success in these areas in the past, but now I'm beginning to wonder about the basic processes and inherent assumptions. If anyone can shed some light on the following issues, I'd greatly appreciate it.

1. Mutations while propagating yeast: If I'm attempting to propagate the yeast for a Scotch Ale (or other high OG beer) from a slant, it will require many cycles of propagation to get the required volume of yeast slurry. I read how commercial breweries can re-use a given batch of yeast from 5-10 times before replacing. Well, I'm doing at least 5 cycles of yeast propagation for my high-gravity beers. Am I running a risk of introducing a mutant strain into my yeast? Am I running the the risk that, even though I have a lot of yeast, it may have reached the point of "being tired"? Aside from ingratiating myself with a commercial brewer who will give me quarts of yeast on demand, how do I assure that I have enough volume of a "healthy" yeast?

2. Washing yeast: In an attempt to solve Question #1, I have been experimenting with washing my yeast from one batch to use in a second. I have tried taking yeast from both my primary and then my secondary fermentor. The primary has more junk to remove (i.e. vegetable materials & cold break [I don't rack the beer off the boil pot into the carboy - I jsut strain the COOL wort into the carboy & then rack to a secondary after about a week.], but it also has more yeast than the secondary carboy. Because of this, I've done more testing with the primary carboy's yeast. I've been using a process I read about on HBD a year ago which uses sterile water and (3) 1-quart mason jars. What I want to know is, after I have agitated my sterile water, yeast, trub mixture in a mason jar, how long will the yeast remain in suspension before precipitating out of solution? As I understand it, the trub should fall out first before the yeast does. However, the longer you wait, the more clearly a separation between liquid and solids exists. Is there a general rule of thumb for the optimum time at which to decant the yeast off the trub?

My apologies for rambling so long. Any help in shedding light on these issues would be appreciated.

Cheers,  
Andy A

From: ROBERT.URWILER@sprint.sprint.com  
Subject: You can't judge a beer by the bottle, but...

I am relatively new to home brewing but have noticed that a majority of the equipment commercially marketed for the brewer is focused on the brewing process itself. Although I agree that the beer is absolutely the most important aspect of this craft, I find it strange that the final product (a superior brew) is often presented in a sub-standard package (in my case, scuffed up old Miller Lite bottles with a caps that say "real beer"). I have seen the labels offered by my local supplier and by a few of the mail order catalogs... pretty sad...

It seems to me that there would be an excellent market for custom packaging supplies for the home brewer such as high quality, custom screen labeled bottles, caps, and quality wooden cases. The same organizations who make custom screen printed coffee cups could produce these items at a reasonable cost. I know that I personally would order a couple gross of high quality bottles with my label(s) in wooden cases given the opportunity. Any thoughts or suggestions?

Subject: BEER COCKTAILS, FAQ Part I

Subject: BEER DRINKS, FAQ (Part I)

Q0001: When I make a beer cocktail should I use the lightest beer possible, like a Coors light?

A0001: Of course not. If you want to add as little flavor as possible to your drink, you should use water. Light American lagers are best reserved for rinsing out carboys or for playing BeerHunter.

Q0002: What style of beer is best used then?

A0002: Something dark, with a full aromatic palate and plenty of alcohol. Several months of intensive research and taste testing by some of Beantown's more adventurous beer cognoscenti have determined that the best beers to use in cocktails are those in which mastication of the grains by virgins is a key step in the brewing process.

Q0003: Do beers made that process really, uh, exist?

A0003: What, have you been hiding under a rock? Do I have to spell it out for you? X-I-N-G-U!

Q0004: Can you give me an example of a Xingu cocktail?

A0004: Here's one for beginners:

XING-UP (Xingu shandy)

Pour equal amounts of Xingu and 7-up over cracked ice. Shake well, pour into a tall frosted glass, add a twist of citrus (lemon, lime, or orange), and insert aswizzle stick.

Q0005: That's a nice enough recipe, but don't you have anything a little, uh, more exotic?

A0005: Certainly. Here's one that not only goes great with nachoes, but also looks great:

BLACK BANANA (Xingu Daiquiri)

Pour 6 oz. of Xingu into a blender.

Add:

1 oz rum

1 ripe, peeled banana (for those authentic tropical esters)

3 oz lime juice

10 ice cubes

Blend until very smooth

Serve in a cocktail glass (paper umbrella optional).

Q0006: Can I eat meals with beer cocktails?

A0006: Don't be a twit. Anybody who knows anything about food will tell you

that only wine is drunk with meals; cocktails are reserved for finger food like stuffed mushrooms and cocktail weiners. Here is a recipe for a beer drink that goes great with caviar:

XINGU PIRANHA (Wandamatic)

Pour 16oz of Xingu into a blender.

Add:

6 oz orange juice (fresh squeezed if possible)

dash of tabasco

6-8 ice cubes

Blend on medium speed to crack the ice.

Drop in one small tropical fish (your choice of species)

Blend until smooth. Pour into a chilled glass, insert a straw, and garnish

with a cherry and an orange slice (paper umbrella mandatory).

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)  
Subject: Yeast in Suspense

I have the following question about yeast in suspension in my beer:

At a given time during fermentation, what proportion of yeast cells are in suspension compared to those which are resting on the bottom of the fermenter? Further, are the cells that have settled out dormant and the ones in suspension active, in some sense?

This is important when pitching starter cultures and when bottling. When pitching my starter, should I swirl it around to kick up the yeast cells that have settled out? When bottling beer that has been in the secondary for a long time, should I rouse the yeast also, or will the individuals remaining in suspension be enough to take care of bottle conditioning?

TIA for any responses.

From: U-E68316-Scott Wisler <wisler\_scott@ae.ge.com>  
Subject: Wort Chillers reply

In HBD 1253, Greg asks about a wort chiller design:

>how effective would a 30 foot length of 3/8" diameter, coiled copper  
>tubing, be in a 2 foot long, 4" inside diameter, PVC pipe?

Very interesting question and design idea. It is also a very difficult question to answer quantitatively, because the heat transfer coefficient,  $h$ , is difficult to estimate without empirical data.  $h$  depends on the geometry, material properties, and fluid dynamics of the system.

I would say that the PVC chiller would be less effective than the in-garden-hose variety for two reasons: First the flow may predominately go up the center of the PVC instead of over the copper coils. You can get around this by fitting another PVC tube of say 2" dia, sealed with end caps, inside the copper coil as a center plug (as we say in the aircraft engine business). The second reason is that the cooling flow would be across the copper pipe, rather than along it with the garden-hose variety. In the cross-flow case, the cooling water will flow (relatively) smoothly over the front half of the copper pipe cross-section. On the back side, there is a region of separated flow, or recirculation. The heat transfer coefficient drops off in this recirculation region on the back side of the copper tubing. Therefore less of the copper tubing area is useful for heat transfer.

But this probably doesn't answer the really important question: Will it work for me? At the .2 gallon-per-min (gpm) flow rate many CF chillers have, I don't think you'll have a problem. (I think 25 min per 5 gal is about what I've read here for no pump-assist) I know of a pump-assisted 1.0 gpm 30' 3/8 copper-in-garden-hose CF chiller that works fine. So if 30' of 3/8" CF has at least 5x in extra cooling capability, and you don't pump out, I don't see any problem with your idea.

In fact, I think its a pretty darn good one if you are brewing outside and pipe your wort into the basement. Mount that on the basement wall and you don't have to worry about hauling it around, setting it set up or it being in the way. I'd encourage you to make it at tell us how it works...

Keep up the designing !

scott

Re: The discussion of long lag times with liquid yeast.

My first batch of homebrew was from a Brewtek Kit from Brewers Resource (highly recommended, BTW, for those starting out) and it came with Wyeast liquid. I followed all of the instructions, pitched the yeast packet directly (no starter, of course -- I didn't know what one was), waited a day AND NOTHING HAPPENED! I was heartbroken. "I've killed my beer", I sobbed on my girlfriends shoulder. Here I was, all fired up to make beer and I couldn't even follow a receipe right. Of course, the next morning, when I woke up, things were fermenting along merrily and the beer turned out great. I must of sat and watched the airlock bubble for an hour. Anybody who came by was forced to watch as well.

From: WESTEMEIER@delphi.com  
Subject: Steam injection

I recently watched a fellow homebrewer use what I consider an extremely clever gadget. He had an ordinary household pressure cooker that he modified to run a steam line out through a ball valve. By simply injecting live, low pressure steam into the bottom of his picnic cooler mash tun while stirring the mash, he was able to raise the temperature to the desired point very quickly. He also used the steam to heat his sparge water in the same way. It all seemed so simple and logical that I wondered why I hadn't seen it mentioned before.

Has anyone experimented with this type of setup? What were the pros and cons?

Wow! Somebody actually agrees with that stupid COPS show! I thought I would never see the day. I don't know what he expects us to look up.

Somebody doesn't realize that methyl alcohol was intentionally added to "bathtub gin" during prohibition to increase its intoxicating ability. Poisonous, but it will get you drunk.

The government arrests people who operate a still because they want their alcohol taxes. If they tell you that they do it for your protection, just remember that they told Indians the same thing when they took their land.

From: bliss@pixel.convex.com (Brian Bliss)  
Subject: wyeast/spruce/distillation temps/and more...

In response to the responses to the  
"why doesnt wyeast take off quick enough" post(s):

I assume that it is accepted as fast that you need to make  
a starter to get the yeast population up to adequate pitching  
amounts.

- 1) the wyeast package misadvertizes that you do not need to.
- 2) there package should be large enough that you don't need to.  
if the entire idea behind the "pop the inner-pouch, let it  
swell" design was to eliminate the need for a starter, it has  
failed.
- 3) why can't wyeast make a package that does the aforementioned?  
Industrial yeast propogation is certainly expensive, but more  
from the overhead point of view that the per-unit standpoint.  
It would not cost that much more to put more yeast in the  
package. perhaps the size of the package is a factor, and  
and more nutrient in a larger pouch would be substantially  
more expensive. perhaps a cheap plastic pressure relief valve?
- 4) I find that hopping my starters substantially cuts down on  
the numer of infected ones. I still throw out 1/2 of my wyeast  
starters because they do not smell/taste questionable.  
I have NEVER had an infected batch from dry whitbread ale yeast.
- 5) I am not satisfied with the performance of wyeast as a whole.  
The last pouch I bought took 5 days to swell, then I made a starter  
and it went sour. I do not lead a life that can adjust my brewing  
schedule around when the damn package swells. I'm sure 95% of the  
human population have jobs which are even less flexible than mine.
- 6) I still buy wyeast and try to use it for those batches which require  
a special flavor from the yeast. I wish there were an alternative...  
It would not take that much more work to provide us with a packaging  
that has a larger yeast population developed before you open it.
- 7) I do not dipuste the quality of the yeast when it actually works.

- - - - -

> >When should Alpha Amalyse be used?  
>Thanks, Steve

I think the original poster also asked "how much should be used?".  
How many oz of amanlyze enzyme that you buy in a bottle is the  
equivalent of that in 1 lb of lager malt at 100 Lintner?

- - - - -

>Kevin asks:

>size of the copper tubing can be altered, (the PVC diameter is the max.  
I  
>can get) but, is the idea feasible? Any comments appreciated.

try wrapping the copper tubing around a 2.5" PVC pipe, and place the  
entire  
thing inside the 4" pipe. seal off the inside of the inner pipe. the  
design  
could ceratnly be adequate, but in your proposed design, there would be  
a large amount of water that would flow near the center of the tube that  
would never come near the copper pipe. It would work, but require more  
water.

Subject: PH Malt, Beer Drinks

Greetings,

I have a question about the use of PH malt and hope that someone out there has an answer. After receiving back comments on several of my brews, and after purchasing a PH meter, I come to the realization that my mash PH's are WAY TO HIGH!! They are in the range of 6.6 - 7.0 for a pale ale. Unless I am mistaken, they should be more in the range of 5.0 - 5.5.

I have tried adding several teaspoons of gypsum to the mash but am yet to see any change.

It was suggested to me that I try some PH malt. For those of you who have not seen (or tasted) this stuff, it is barley malt that has been allowed to partially "rot" for lack of a better term. This creates a very acidic malt that allows brewers to lower their mash PH and still meet the German Purity Laws.

My question is, how much should I use in a 5 gallon batch with 9 - 10 lbs. of other grains? Has anyone else had problems like this with mash PH? What do you do?

Beer Drink: My favorite starts out with a 32 oz glass with two commercial beers in it (I wouldn't treat my beer like this). Then you add one or two (depending on your mood) shots of Canadian Mist and then the trully unique ingrediant. One raw egg is cracked into the glass and allowed to sit unbroken on the bottom of the glass. The idea of the drink is to "slam" the whole thing in one drink and believe me, when you see that raw egg start to slide down the side of the glass it gives you the incentive to keep all that liquid moving quickly. :) We call this drink "The Chicken Maker" and it is a New Years tradition. Enjoy!!

Subject: Cider Reply

Martin W. - I cant get back to you cause of the ccm! in your address so I'll answer you here... From what I understand, there is naturally occurring apple type yeast in the cider which makes it "go bad". When I make a batch, I usually dissolve the sugar, either white or brown, in a little warm cider first then added it back to rest. It seems the yeast have a harder time with the white sugar and this seems to leave a sweeter result. They eat almost all the brown. The batch I made this weekend used 1/2 cup frozen sliced strawberries, 1/2 cup white sugar, 1 gallon cider.... I'll let you know how it turns out around new years.

Good luck - mike

Beer Hunting in Belgium: Part 5 of 7

Oud Beersel - Lambic Day  
(by Jim Busch: BUSCH@DAACDEV1.STX.COM)

Located just a short drive south of Brussels is the town of Beersel, where the Vandervelden family has been brewing lambics since 1882. We had called these people early in the day. They had informed us that the brewery only has tours at set times, but that we would be welcome if we wanted to come a week later and join a group of 30 people. We accepted this, but were a bit disappointed.

Not being able to visit this brewery, we decided to venture elsewhere in search of lambic-type beers. Our first stop was an accidental discovery in the small town of St. Genesius-Rode, located south of Brussels and east of Beersel. There we found beer hunting heaven, Drinks Wets (209 Steenweg op Halle), a Belgian version of Liquor Barn. In this beer store one can find a entire wall full of lambics, some with the "old style" white-washed bottles, some with big names like Cantillion and Frank Boon, and some actually oozing lambic out of the wet cork (Hannsens). Our shopping carts quickly filled with lambics, Belgian specials and Abbey beers and of course, Belgian glassware. Fortunately for us, they accepted VISA! We each departed with a hefty load of some really diverse beers. The day was young and we were already quite pleased with the results.

We ventured on to Beersel, in search of the cafe that Michael Jackson notes in his book on Belgium beers (The Three Fountains). When we arrived we realized the cafe was closed on Tuesdays, the day of our visit. We got a bite to eat next door and inquired about good beers of the area. We were informed that Oud Beersel was the best lambic around and the brewery, being right on the other side of the town, and a must visit.

Off we went, and following the Oud Beersel signs we had little difficulty finding the brewery. The outside features red and white tiles with the words: Kriek/Gueuze. Upon entering, an older man began a discussion in French with Phil, that I was not in tune to. Much back and forth ensued, with the occasional apology offered from Phil. Soon I was informed that the discussion centered on the fact that we had called earlier and were told NO, only to arrive later anyway. Phil successfully explained that we had no idea that Oud Beersel Brewery and the Vandervelden were the same thing. It helped at this point to inquire about purchasing their lambics, and sure enough we were informed that beer was available for sale, as long as we were willing to buy it by the case. No problem. We got six 750 ml bottles each of Kriek and Gueuze.

The beer was stored in the traditional manner, on the side with a swath of white or pink paint to indicate "up". After some discussion, it was decided that labels might help, since we already were transporting a ton of beer around the country. The brewer glued the labels on one by one.

While Phil was busy taking care of this important activity, I ran back to the car for my camera, and started shooting pictures of the place. Eventually we asked enough questions that we were given an unofficial tour. A typical lambic brewery, the mash tun and boil kettle are weathered insulated cylinders, the

insulation being held on with duct tape. A vertical system was in use, where a masonry-built painted grain shoot feeds the mash tun. Everything was quite dusty, with wooden planks forming a second tier walkway for the brewer to work on the top of the tanks. I was constantly concerned that I would fall through this very crude arrangement. There were two separator/cooling tanks, if one can call them a tank. They were basically a coolship in the shape of a tall bath tub, with slotted plates on the bottom. This was the traditional cool ship, where the hot and cold breaks settle out and the initial inoculation of the local microbes begins. (One note: this takes place deep in the interior of the brewery; there appears to be little direct exposure to outdoor air.) I recall a comment that the wort sits in this overnight. After exiting the coolship, the wort is transferred into one of two large primary fermentation tanks, constructed of metal. After a primary fermentation period, the beer is racked into Chestnut casks--the brewer swears by them and recoiled with horror at the possibility of using oak. The casks are marked and stored in the lambic way, noting the dates and contents on the face of the cask.

Of note in this brewery is the wall full of hand cooperage tools from the mid nineteenth century. Also of note is the old barrel cleaning device, a frame in which the cask is suspended, allowing it to be rotated with hot water and chains inside to "knock" off the gunk. This is nearly identical to the arrangement at the Cantillon brewery.

The brewer himself (presumably Mr. Vandervelden) is getting on in years, though hardly decrepit. He informed us that his young nephew was now in the business, which is likely to stay open for a good while. They're not getting rich, but the brewery makes enough money to stay open and support their families. Most sales are to serious beer connoisseurs--the popular market provides little if any support.

The beers:

In my opinion, these beers are certainly traditional lambics, dry nearly to austerity, and exhibiting a flavor and aroma profile that has some horsehair and saddle notes. This is not to say I disliked them; on the contrary, they are good, enjoyable lambics.

The Kriek had definite cherry notes and flavor, but not in the dominant way that a Frank Boon or Hannsens does. It is more of a subdued and blended flavor. It's color is almost fluorescent pink. The gueuze is a good example of a traditional lambic, but nowhere near as tart and acidic as a Cantillon, nor as sweet as the Belle Vue-like beers.

In comparison with other lambic products, the Oud Beersel beers are less rich than some others (if this is a word that can be used to describe beers as attenuated as these!). The beers are certainly less horsey than the Girardin products, less fruity than Hannsens, less extreme than Cantillon but also lacking in some of Cantillon's satisfying lactic character. Obviously, though, none of these are what the average lager drinkers are going to warm up to, and if you're into lambic beers the differences are ones that you'd enjoy exploring.

Oud Beersel products do not appear to be widely distributed, but can be purchased at the brewery, and also in some stores in Beersel (of which there are not many). We saw them for sale in the delicatessen across from the church, next door to the 3 Fountains.

Isn't Methanol(wood alcohol) the usual culprit in death and blindness cases resulting from consumption of illegally distilled adult beverages? I always thought this was not a result of the distillation process, but due to the \*bad stuff\* that the moonshiners put in their mash i.e., "fermentables" other than corn, potatoes or rice, etc. Is this true? Perhaps other alcohols (fusel alcohols) could result in death in very high concentrations?

Mark Garti writes:

> what are people using to store their grain in?  
> how long, under good conditions, will the grain be  
> fresh? besides rats, are there any problems associated

> mrgarti@xyplex.com

I have found that the food grade containers that deli's use are good for storage of grains. I think the square mayonnaise containers work best. They are the easy to clean and the lids are fairly easy to attach and remove. I recommend filling them to the top and purging with CO2 to keep the grain as dry as possible. I have tried to use containers that pickles and salad dressings are shipped in and could never get the vinegar odor out. I suggest using mayo containers or icing containers from bakeries if you go this route. Scrub them several times to make sure they are totally clean.

Question: Someone posted something regarding IODOPHOR in this or a previous HBD: what does the -phor designate in the name IODOPHOR? I have used BTF iodophor which doesn't contain phosphoric acid and I have recently obtained an iodine sanitizing solution that \*does\* contain phos. acid. What gives?

>besides rats, are there any problems associated with buying and keeping  
50  
lbs of grain?

The most serious problem I have is with cereal moths. They are  
impossible to  
get rid of once they find you so prevention is the best cure. Keep the  
containers covered at all times.

>Subject: Plans for Grain Mill

>The other day I saw one of Jack Schmedling's (sp?).....  
.....Schmidling...

> grain mills at a brew store. It doesn't appear to be that hard to  
make.

It's not if you have all the equipment and skills needed; lots of people  
have  
but don't confuse making one for your own use with making them to sell  
to the  
public.

>The cost seems extremely high.

I think you mean price as you don't seem to have a handle on the costs  
involved in making them.

Keep in mind that when one decides to retail something, the stores have  
to  
mark it up and if you sell through distributors who sell to the stores,  
they  
also take their cut. Add your own profit on to that and you will  
understand  
why the market is not flooded with inexpensive roller mills.

The two that have come out since the MM should give you a clue. One has  
only  
a single roller and both are less than half the size of the MM but are  
only  
\$20 less at the retail level.

>Has anyone out there ever made a roller mill?

Yes. I made one and it cost me \$10 and a weekend. But when strangers  
started to buy them I had to put a value on that weekend.....

> Do you have any plans handy?

What do you need plans for? Just look at a MM and copy it. Nothing  
could be

simpler :)

>Subject: Going all-grain

> First, I am considering mashing on a burner rather than using a cooler for a mash tun. Is the primary reason for using the cooler rather than a burner the reduced investment in time and money?

I won't attempt to define primary reasons but the only reason I know of for using a cooler is because they are about the right form factor and being insulated, they retain heat well. I don't see how it can be less expensive than stove top mashing because you must have a kettle in either case.

> I guess I want to know how much of a hassle is it to mash on the stove as opposed to mashing in a cooler and if there are any differences in the quality of the brew.

Both of these are subjective but as there are proponents of both, there is a good reason to ask. The cooler requires little attention but has limited flexibility while the opposite is true of kettle mashing.

> Second, because I want to mash on the stove I need to invest in a larger brew kettle. So far, I've only done high density extract & partial mash brewing so I've gotten by with only a 2.5 gallon kettle. I've found a medium-duty 7.5 gallon SS kettle with a lid and a spigot for about \$100.

It would be fine but you can do just as well with a \$40 enamel on steel 8 gal kettle for mashing and boiling. When you want to move up to larger batches, just buy a larger boiler and use the original as a mash tun.

>Third, I read a comment a while back about trying to get a 5 gallon batch of all-grain brew into a 5 gallon carboy.

My suggestion is to use the kettle as a primary fermenter and move the beer to the carboy after primary is over and you will have no problem with the carboy size. I have been fermenting in my mash tun for several years now and find it terribly convenient.

> I've been using a stopper and a racking can as my blowoff valve, but have heard a number of people report using a 1" pipe attached to the top of the carboy. Any insights?

Take a Ritilin and pack your blowoff stuff away for one batch and try my suggestion. My guess is you will never unpack it.

Subject: barleywine yeast-handling

You should be able to brew a barleywine using a suitable ale yeast. Pitching a second yeast, such as a champagne yeast, is not necessary.

The yeast you use must be alcohol-tolerant and moderately attenuative. If there is any doubt about these properties in the yeast you intend to use, then you should try it out in a test wort first. Apparent attenuation should be about 70%, as with any beer you make.

It is important to pitch an adequate amount of yeast, and this is especially true for barleywines. As a rule of thumb, for any ale, consider pitching a one-quart starter. For the typical 5-gallon batch, this represents a 1:20 volume pitch, and is easy to remember. For high-gravity beers, pitch a half-gallon starter, which represents a 1:10 volume pitch.

I feel it is important to aerate the wort. The home-made aquarium pump aerator works well.

Yeast that work include Wyeast "American" ale and Wyeast "British" ale. Regarding "American," consider that Chico Brewing uses it in all their ales including Bigfoot Ale, a high-gravity barleywine. Regarding "British," it is an amalgam of three yeasts: one is a fast starter that quits at low alcohol levels, a second is a slower-starting alcohol-tolerant fermenter, and the third is a "chainer" that causes the yeast to flocculate.

So, if you use the right yeast and help them get started, they'll produce a barleywine with no added champagne or wine yeast.

From: SCHREMPP\_MIKE/HP4200\_42@ptp.hp.com  
Subject: wort chillers

In HBD 1253, Greg Demkowicz asks about coiling a copper tube inside a 4" PVC pipe to make a counter-flow chiller. Here's my 2cents worth:

Your idea sounds like a lot less frustration than trying to slide 30 feet of copper pipe through 30 feet of garden hose. I've done it and it isn't fun. If anyone does try this, definitely use a lubricant, like soap, and plan a few hours of frustration. I'd suggest that you also put a length of 2" PVC (capped at both ends) down the inside of your cooling coil. This will keep the cooling water flowing around the copper coils and not down the center of your chiller.

That being said, I'd also advise you to think through whether it's worth the effort of brewing with the counter flow device instead of an immersion chiller. I've gone full circle with wort chillers, from immersion to counterflow, and finally (just this weekend) back to immersion. I've found that counterflow chillers are the fastest to cool the wort, but immersion chillers are the easiest to use.

My counterflow chiller was outside and was hooked to the garden hose. Using it meant sanitizing it, carrying a pot of boiling wort outside, getting the flow running, figuring out what to do with the water, and finally cleaning the thing out. What a pain in the butt!

This weekend I bought the cheapest immersible pump I could get at the hardware store (\$33.95 for 120gallons/hour) and I made a coil out of some 3/8" copper tubing. I use the pump to circulate water from an ice chest filled with ice and water (actually I ran the outflow into the kitchen sink, and added cold water to keep the ice chest topped up). With 20' of plastic tubing (10 at each end of the chiller), and the chiller (20' of copper), the actual flow rate of the pump was about 2q/min. I left the recirculating setup running while I sanitized my carboy. It took about 45 minutes to get from boiling down to 70F, not fast, but then I'm not into speed-brewing. Plus, the big advantages: no moving a pot of boiling wort, no sanitization hassles (I put the chiller into the boiling wort),

and no flowing water to put somewhere. All told, a major improvement in lowering the stress of the brew day.

Steve> Has anyone out there ever made a roller mill? Do you have any  
Steve> plans handy?

Well, I can remain silent no longer. So many people look at a commercial product and say exactly what Steve has. What they fail to recognize is the difficulty of actually tracking down all the specialized parts and \*tools\* necessary to duplicate almost any commercial product available. How long will it take you to find a supplier of just the right allen head set screw to attach the handle? Will you have to get your end mill sharpened before cutting the flat on the roller to tighten the set screw up to? How many taps will you break tapping the hole for the set screw? How many drills will you dull? Do you have the correct router bit to round over the wooden edges. How much lubricating oil will you use in milling the grooves in the rollers? How many times will you have to re-make the rollers until you get them made out of just the right kind of steel (or are you a metallurgist)? How much electricity will you use running your machines and lights while you make it? How much is your time worth? You probably will take at least 5 times longer to make a roller mill than a commercial vendor takes. Do you have a lathe and mill? How much wear and tear will you put on these expensive machine tools?

Bottom line, you may be able to make any commercial product for much less than it is sold for if you ignore everything but the cost of the materials. On top of that, you are not trying to make a living out of it. If you really figure \*everything\* in, I would doubt you could beat the retail price by much if any at all since anyone who intends to remain in business will be buying in volume and getting prices on raw materials which you could never come close to at onese prices.

If you enjoy building things, by all means, you have my whole-hearted support to go ahead. I even wish you the good fortune to improve upon Jack's mill or any other brewing product for the betterment of all of us brewers. But, please do not make light of the effort that goes into producing the great products which are being offered to us. Knowing what it takes to produce these, I am quite satisfied that we as home-brewers are getting fair value for our money from the vast majority of brewing equipment manufacturers.

Steve, I do not mean to single you out, this thread has popped up so many times, I just took the opportunity of your post to reply to a topic which has been bugging me for a long time.

Subject: Filtering / Roller Mills

Jim Sims asks:

>Okay - I give up. How \*do\* I filter out those bits of gunk, fruit,  
>etc from the primary (or secondary) fermenter when ready to bottle,  
>without oxidizing? To say nothing of trying to filter out the hops,  
>etc \*before\* going into the primary....

Letting it fall out of suspension, then quiet racking is the usual solution.  
Using a racking cane, you leave the bottom 1/2" in the vessel (this is usually the stuff you don't want). You could put a hop bag over the end of your racking cane to help it out. Using whole hops eases filtering every step of the way, BTW.

Steve Seaney writes:

>The other day I saw one of Jack Schmedling's (sp?) grain mills at a  
>brew store. It doesn't appear to be that hard to make. The cost

>  
>Has anyone out there ever made a roller mill? Do you have any plans  
>handy?

Steve, I've made two grain mills, with tons of help from my father-in-law the tinkerer. They are hard to make, if you are going to do it right. The rollers are the key, and getting a constant distance from the shaft to the surface of the roller is the hardest part. We are talking about some very small tolerances here. The mill I now use cost about \$75 in parts and many hours of labor. Jack's mill may or may not be better (I suspect it is a draw) but it is without a doubt a better "deal". IMHO, Jack's mill is worth the price. On the other hand, if you like making brewing equipment, then build it yourself. I did, and I love it! Oh, I don't have any plans handy, sorry!

Also, Messieurs Miller, Papazian, and Rager should not be overlooked. They have all contributed to this FAQ, directly and indirectly.

I thank you and the HBD thanks you. Here 'tis:

- - -

Q: What are hops?

A: Hops are cultivated flowers (*humulus lupulus*) used for preservative and flavoring characteristics in beer. The bitterness of the hop is used to balance the sweetness of the malt, and the essential oils add a flavor/aroma which cannot be achieved by any other plant. The hop plant is a perennial spiraling vine which will grow in almost any climate given enough water and sunlight. It can climb either string or poles and can reach heights of over 25 feet. The flowers (or cones as they are called sometimes) are usually dried before use.

- - -

Q: What are the compounds which provide the bittering? What about the aroma compounds?

A: Read on:

#### Bittering Compounds

One of the major contributions hops give to beer is a characteristic bitterness that provides a counterpoint to the rich sweetness provided by the malt. This bitter flavor is extracted from the hops during the boil. It is during this time that virtually insoluble Alpha Acids are isomerized (rearranged without changing their composition) into more soluble and stable iso-Alpha Acids, the main bittering substance in beer. Five different naturally occurring Alpha Acids have been isolated from hops which are:

humulone -  $\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2$   
cohumulone -  $\text{CH}(\text{CH}_3)_2$   
adhumulone -  $\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}_3$   
prehumulone -  $\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)_2$   
posthumulone -  $\text{CH}_2\text{CH}_3$

Although isomerized Alpha Acids are the biggest contributors, hops contain Beta Acids which also add bitterness to beer. The Beta Acids are similar to Alpha Acids both in structure and abundance. In contrast to Alpha Acids, it is not isomerized Beta Acids that add bitterness, is the oxidation products of the Beta Acids that make their presence felt.

Both the Alpha and Beta Acids are very susceptible to oxidation, especially at temperatures above freezing. Losses of Alpha Acids of up to 60% are not uncommon when hops are packaged and stored poorly. Once Alpha Acids have been oxidized they can no longer be isomerized into iso-Alpha Acid, thus decreasing the hop's bittering potential.

For this reason, the "storageability" of each hop variety is often provided, along with the Alpha and Beta Acid levels, by the hop broker. This parameter is usually given as a percentage of the Alpha Acids present after 6 months at 20C. Some good storage hops (usually high Alpha Acid) lose only 15-20% of their Alpha Acids: Cluster, and Galena are among the best. Most high quality aroma hops lose anywhere from 35-65% of their bitter acids unless anaerobic conditions and cold storage (<0c) are provided.

This is why it is imperative for brewers to buy the freshest hops available and store them in the freezer, properly packaged.

#### Essential Oils

Hops bring a lot more to beer than bitterness. The volatile oil, usually 0.5 - 3.0% (vol/wt) of hop cone, is an important part of many types of beer. Brewers seeking to maximize hop flavor and aroma generally make late kettle additions (0-15 min. before cooling) with high quality "aroma" hops. Dry hopping, i.e. the addition of hops to the secondary fermenter or serving tank, is another way to add hop character to a beer although the aroma components retained by this method differ from those obtained in late kettle additions. The maximum oil utilization is about 10 - 15% which decreases with increased boiling time.

The essential oils are what give hops their unique aroma; each variety has it's own distinct profile. The smell of hops freshly crushed in your hand is quite often different than that in a finished beer. This is due to the fact that the major components in hop oil, beta-pinene, myrcene, beta-caryophyllene, farnesene and alpha-humulene, are not usually found in beer. However, fermentation and the oxidation products of these compounds, especially humulene epoxides and diepoxides are considered contributors to "hoppy" flavors and aroma. The exception here is with dry-hopping, where some of the hop oil components do survive into the beer intact.

Researchers have not been able to duplicate the complexities of hoppy character by adding pure chemicals in any proportion or combination. Consensus is that there is a synergistic blend of several compounds, some of which may have not yet been discovered.

Hop researchers, using capillary gas chromatography, have detected and identified more than 250 essential oil components in hops. Twenty two of these have been pinpointed as being good indicators of hoppiness potential. They are subdivided into 3 groups, humulene and caryophyllene oxidative products, floral/estery compounds, and citrus/piney compounds, as listed below:

#### Oxidation Products:

caryolan-1-ol

caryophyllene oxide  
humulene diepoxide a  
humulene diepoxide b  
humulene diepoxide c  
humulene epoxide I  
humulene epoxide II  
humulene epoxide III  
humulenol II  
humulol

Floral/Estery Compounds:

meade@readmore.com  
asked about:  
Cider  
Sorbate/Sulphate

\* Potassium Sorbate is a "stabilizer" It will not STOP an active ferment but will inhibit initiation of growth. Both yeast and bacteria.

You Don't want cider with sorbate. Find an orchard and get the fresh pressed- unfiltered stuff. Much worth it!

\* Sulfating cider- hell why not! You DON'T want to BOIL it! I've done it. Personally I prefer CYSER to CIDER> Add honey. Makes MORE alcohol, and adds a sweeter complexity. Straight cider tends to become rather dry. Cinnamon is a nice addition too.

\*\*\*\*\*  
gartim@mrg.xyplex.com (Mark Garti)  
Subject: grain storage

>what are people using to store their grain in?  
how long, under good conditions, will the grain be fresh? besides rats, are there any problems associated with buying and keeping 50 lbs of grain?

\* I like metal cans with tight fitting lids. You can line them with a plastic bag to close down tighter as grain is used. IAMS pet food commonly has gifts of cans which will hold about 30# of grain. You may find old square metal flour cans. They fit better on shelves, and hold- 20#. Smaller cans are useful for dark and specialty grains. Check your local surplus store. Watch out for anything- wet, dirty, smelly, or which stored chemicals! Plastic buckets would work fine too.

Grain will store well under room temp and cooler UNGROUND for long periods of time. After grinding grain loses some of its potential. The big enemy- besides rats, in my case... MICE!- is MOISTURE. You want to be sure to keep it dry. Mold will do bad things to grain.

\*\*\*\*\*

>First, what kind of critters can invade a bad batch?  
What is the worst illness that you have heard of from drinking 'bad beer'?

\* Besides the normal nausea from drinking too much GOOD BEER!... there are multitudes of wild yeast and bacteria which can invade and create off FLAVORS. But as for getting sick...the only story I heard of was when toot ended up with a sour stomach after drinking the sediment from many bottles of spiced beer (clove, cinnamon...etc) and got sick from the excess spice bits reeking havoc in his tumtum.

Relax...Don't fret...Be cautious...but not 'noid! :) Then have a brew.

\*\*\*\*\*

To Norm Pyle- working on the HOPS faq:

\* Have you contacted Steiner's at all? I wrote for a catalog and price list and was sent a nice ~200pg HARDCOVER booklet on hops- varieties- growth- dristribution...etc. Kinda nice! and FREE! ok...it's actually 80 pages, with a spanish and german translation!

I believe they generally cater to BREWERIES not just brewers (like us) I don't have the address handy- but e-mail me if you want it. I've tried emailing you- but I get bounced. I hate getting bounced!

\*\*\*\*\*

About the sig. line re: Orgasms and baseball.

I guess some folks are a little sensitive. Personally I get a chuckle everytime I see it. I don't think sig.lines should be censored- just kept BRIEF! Maybe a disclaimer at the beginning- noting parental discesion and what not!

Here's to Screaming and Squirming!

Subject: re: Brewing with nuts

Dave Lame gives an interesting description of the use of hazel nuts in a mead:

One caution Dave. You have assumed that people who lived over a thousand years ago did not do something because you think it would be impractical, and then conclude that the only shred of evidence you have (of what they did) is wrong based on your one experiment, when you admit that it yielded mixed results.

Perhaps they did collect immature hazel nuts and press the juice from them (and had some use for the leftover nuts). Perhaps the juice of the immature hazel nut produces a superior mead. Perhaps the juice from immature hazel nuts is water soluble. Maybe your source on the use of hazel nuts in 8th century Irish mead making is wrong and they never used nuts at all.

Admittedly, it would not be practical for most people to try using immature hazel nuts, but you shouldn't conclude that the oil produced by pouring boiling must on mature hazel nuts is the 'real' hazel milk. If your luck is anything like mine, somewhere down the road a source for immature hazel nuts will mysteriously appear. ;)

Good for you for going out and actually trying the experiment!  
Cheers, Rick C.

From: lyons%adc3@swlvx2.msd.ray.com  
Subject: Apparent attenuation ... function of yeast & malt.

Glenn Anderson in HBD 1254 asks about apparent attenuation numbers for various yeasts. I have had widely different apparent attenuations from my all grain batches, most likely due to variations in the mash temperatures from batch-to-batch. My records show apparent attenuations ranging from 52% to 78% using the same yeast (Whitbread dry ale yeast). I have had very consistent apparent attenuations over several batches with the same DME & same yeast. However, I get completely different apparent attenuations between different brands of DME (AA of Laaglander <> AA of M&F) with the same yeast. In my latest batches I have been using Wyeast 1338 (European) liquid yeast and have gotten apparent attenuations of 75% with M&F based recipes, and 56% with Laaglander based recipes. I guess my point is that although the yeast is important in determining the apparent attenuation, the percentage of fermentable sugars in the malt also plays a significant roll in determining the final gravity.

Question: When companys give apparent attenuation numbers for there yeasts, is there a standard malt (or recipe) that they are using?

Subject: Good Head/Spruce BOIL/junk

\*\*\*\*\*

Tom said:

>The problems that a lot of people have with carbonation and head retention (including myself) may be related to infections that don't completely foul the beer, but just add off flavors.

...snip...

But why does an infection kill head? And what can I do with this 5 gallon batch of infected brew?

\* Good Beer Head (as compared to...\*slap\*) requires the presense of proteins to form stable bubbles. Proteins surround CO2 bubbles and establish a network structure stabilizing the bubble. Can you believe that researchers are funded to study this kind of thing! Maybe I should apply for a grant...Splitting the Beer Atom!

Bacteria and yeasts may choose to chew on the necessary proteins for food, or building materials and deplete the beer. Some of these same protein eaters may also produce products which result in what we consider "off flavors" or aromas. But to them...it's just what they do. Don't blame them- JUST ELIMINATE THEM! Call the TERMINATOR!

\*\*\*\*\*

Chris Cook praises boiling essence for SPRUCE BEER

>John mentioned using 6 oz of essence. I don't know the brand, but that sounds like a whole lot of essence.

\*I was thinking about that one. I think it was a 2 oz bottle. Good for up to 6 gallons??? Maybe I should have boiled it, and made a darker beer. Hmmm. Still don't think i want to try it again. Maybe I'll experiment with smoke instead! (RauchBier!)

BTW: Not to slam a style..Not me! Give it a try if it tickles your pickle. I'm DEFINITELY not Rheinheitsgebot myself! Anyone else ever tried Cajun Spice in a brew? Interesting.

\*\*\*\*\*

Jeremy Bergsman says:

>(can you say salivary amylase?), the fungal one is probably the cheapest.

\* You're not gonna start telling us to chew our grains in our mouths and then spit into our boiling kettles are you! Starts sounding like some wierd indian corn concoction! Hmmmmmmmm. So what if we add some fungus to our mashes- MushroomBrew?

\*\*\*\*\*

Oh Nuts...Yeah. Oil. Kills head. Maybe you should spit in it. That's coooool. Huh huh, heh, heh.

\*\*\*\*\*

Oh...and BTW

Norm mentioned his Barley wine was down to an OG of... Wait a minute here. OG= Original Gravity. How can it be down to...

FG= Final Gravity, SG= Specific Gravity. Let's be nittypicky! :)

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>
Subject: Fermenting Process question

Hello Group,
I have made a spiced Christmas Ale (de la Phleming), and I used Wyeast European Ale. I wanted a malty roundness to support the spices.

I would like your perceptions as to the quality of my fermentation.

I may have rushed things a bit. I squeeze the packet early Saturday, by evening it was plump and I added it to a high gravity starter (I haven't measured it, but from the remainder's color, I'd guess 1.06) Next morning It was foaming with a half inch of foam in the pint jar. I made my beer and pitched that afternoon. I had good activity afterwork the following day (monday). It had a sluggish fermentation overall judging from the meager three quarters inch krausen. Most visible churning had ceased by Thursday and the krausen is now settling back in.

Other particulars:

aeration: Liberal splashing of the bathtub cooled wort into the 7gal carboy.

And some shaking. a little.

OG: about 1.06 (measured warm and adjusted)

FG: as of sunday 1.03

Temp: Air Stat'd at 69F

Time Elapsed: 7 days as of 5pm Monday Oct.25

I am using the Brewcap system but am having a difficult time getting my sediment out of that teeny 1/4 inch hose. (hop pellet fine particles) I need to do that tonight. I am thinking of going ahead and racking it.

..

I can wait a while though, probably.

Does my fermentation seem too feeble to you? This is my first use of Liquid Yeast, the dry Red Star always had a furious krausen... The three point drop in gravity looks good, but is that the whole story? I appreciate any and all comments.

-John Palmer

>While we are on the subject of beer drinks: does anybody know how to
>get two differently colored beers (like Guinness and Bass Ale) in two
>layers in the same glass? We tried it once during a party, with no
>success.

You must use draft guinness, either from a tap or from the can.
Pour a layer of anything else on bottom, then pour the guinness
slowly & carefully over a spoon held against the wall of the glass.

Does it work if you try to put guinness on the bottom?
I'd go out and buy some, but they don't sell the cans in TX.

From: mwithers@hannibal.ATL.GE.COM (W. Mark Witherspoon)
Subject: Update on "RCA"

Ok, folks my Rusty Cream Ale came out. The verdict...

It ain't cream ale. It looks and tastes like
a Killians Red clone.

To refresh everyone's memory here is the recipe..

2 lbs of pale malt
1 lbs of flaked corn
1 lbs of crystal malt (about 50 l)
4 lbs of Alexanders Pale Malt

1 oz of Tettanger Hops (3.8%) (boil @ 45 min)
1 oz of Liberty Hops (3.2%) (half and half boil/finish)

Whitbread ale yeast

OG = 1.052

FG = 1.012

It appears that the Whitbread yeast that I used was
really atteuntuave. The % alcohol/vol is around 6.5.
The preliminary tastes puts it nice, smooth, a bit thin
(its' been ageing about 2 weeks). It should have some
character in about 1-2 months.

Thanks for the reply's about it.

Subject: Sheaf & Vine Brewing Supply

Please excuse the use of bandwidth, but due to the proliferation of my catalog via electronic means, I have no way of knowing who of you out there were planning to place a Sheaf & Vine order by mail.

It is with deep regret that I must report Sheaf & Vine Brewing Supply will be suspending mailorder operations until further notice.

As many of you know, I have been running Sheaf & Vine Brewing Supply (retail store AND mailorder) singlehandedly, evenings and weekends after putting in 40+ hours per week at AT&T Bell Laboratories. The reasons for suspending the mailorder side are:

1. health -- often I would be up till 3am packaging hops & grains and this has really taken a toll on me,
2. no time to spend with my wife -- we just celebrated our 1 year anniversary
(even on our anniversary day, I met with a potential customer)
and, most importantly,
3. decrease in quality -- the heavy load of mailorder requests has increased
turnaround time to unacceptable levels... if I cannot provide the best possible service to my customers, I would rather suspend operations rather than compromise quality.

If and when I make Sheaf & Vine a full-time business or if retail operations require the hiring of an employee, I will resume mailorder operations. Please accept my appologies.

Al.

Jim writes:

Okay - I give up. How *do* I filter out those bits of gunk, fruit, etc from the primary (or secondary) fermenter when ready to bottle, without oxidizing? To say nothing of trying to filter out the hops, etc *before* going into the primary....

Once the wort is cool you can splash all you want -- this is the time to filter out bits of hops and stuff you added during the boil. I use hop bags and thus get very little stuff to filter out. After primary fermentation, one way to filter the beer is to put a mesh over the end of the siphon hose. You can increase your filter surface area by first putting a sanitized copper scrubbie (like a Choreboy) over the end of the siphon tube and then covering that with something like a hop bag (thanks to Al Andrews and/or Kinney Baughman for this tip).

Domenick writes:

pp.87-92

Mark writes:

>what are people using to store their grain in?

I store it in white, 5-gallon, HDPE pails with gasketted lids (they are a bear to remove, even with the lid-lifter tool!) at about 60-65 degrees. You can get between 25 and 30 pounds of grain in a 5-gallon bucket. What else is nice, is that the pails stack much better than 110lb sacks!

Doug writes:

>First, what kind of critters can invade a bad batch?

Lots, but none that are dangerous. lactobacillus and pediococcus are the most common, but you can also have acetobacter, molds and sherry flor.

>What is the worst illness that you have heard of from drinking 'bad beer'?

The worst thing that can happen is you'll like it and develop 'bad taste.'

But seriously, a hangover is about the worst thing you can get.

>Second, what is a good McEwan's taste alike? I have had this beer and like it's

>style.

I assume you mean McEwan's Scotch Ale. There are very few beers that I know

of that are similar to McEwan's Scotch Ale and are imported into the US.

Note

that if you like MSA, you may also like a beer which is perhaps the lager counterpart to MSA, namely Doppelbock. Salvator Doppelbock is a bit less sweet

but in a similar vein. Celebrator by Ayinger is another good one you might

try.

Phil writes:

>Has anybody had experience with this yeast (Wyeast Munich Lager #2308)?

I don't know what they mean about the instability, but I can report a very intense "home perm solution" nose for the first 4 months of lagering.

I fermented at 50F and then later at 45F. After 4 months, the off aroma disappeared and the beer did well in a few competitions.

Jamie writes:

How does the Wyeast Belgian compare to cultured Chimay yeast? Which am

I better off using?

Judging from the flavor of two beers that I recently tasted, one brewed with

Wyeast Belgian and the other brewed with cultured Chimay dregs, I would say

that the yeasts are identical. There are trade-offs with each: going the Wyeast route is more expensive but the Chimay dreg route is a bit riskier,

since you don't know how much the bottle was abused on its way to you from

Belgium.

Tom writes:

>But why does an infection kill head?

Because part of what gives good head retention are dextrans and other more-complex carbohydrates which yeast can't eat, but some bacteria can. The bacteria cut up the large carbohydrates (and perhaps even proteins -- but this is just a guess, although small proteins are very important to head retention) into pieces that are edible by yeast (which is why infected beers often turn into gushers -- overcarbonation from the yeast eating stuff you wanted unfermented).

From: FILTER@xavier.xu.edu
Subject: Hemlock Beer

There seems to be some confusion among some people as to the difference between Eastern Hemlock (an evergreen found in the far north down to Tennessee along the mountains,) and the Hemlock(& water Hemlock) 'weedy-type' plant. The two are not at all related, and I'm not at all sure how they gained the same name.

The evergreen tree is one of our most beautiful coniferous trees. It has small perfectly shaped cones. According to 'Euell Gibbon's Wild Foods Guide,' you may take a handful of the needles brew a delicious tea. It's good, I've tried it over the camp fire. 'Peterson's Wild Food Guide' agrees and goes on to state that a highly nutritious flour can be made from the inner bark. 'Peterson's North American Tree & Shrub Guide' states that both Native Americans & early frontiersmen brewed tea from the Eastern Hemlock. Unfortunately, the future of this tree is uncertain because of some ugly, little insects we've imported into this continent.

The weedy-type plants, Hemlock & Water Hemlock, are easily distinguished from the evergreen. They've got leaves, as opposed to needles. They may only grow a yard or two tall. And most of all, they look like Wild Carrot & Queen Anne's Lace. In fact, I think they're related to the latter. Both Hemlock & Water Hemlock are highly poisonous, requiring only a handful of the leaves to do in the average person.

Rest assured, if you can tell the difference between an evergreen and a weed, you can use the Hemlock in your brewing(like the spruce.) I've never made beer from either. Good Luck, Jeep (Filter@XU.XAVIER.EDU)

From: r.mcglew3@genie.geis.com

Subject: Nut Beer

I judged specialty beers last year at the HOPS-BOPS HB contest held at the Sam Adams Brewpub. We gave a nut beer 1st place, it really was a good

beer. When we first tasted it we were not all that impressed, but after some re-calibration of our palates, we gave it a second try and voila.

I can't remember the recipe, I believe it was either walnut or pecan, and

I seem to remember that it was a brown ale. If anyone is connected with HOPS, maybe you can look back in your records.

For anyone that enters a specialty beer in a contest, be aware that the judges in that category are subjected to a lot of widely varying beers and

have a hard time picking the right one, the judges' taste preferences really are the major factor. So, if it doesn't do well, let your own taste buds determine if you should do it again.

Aged beer tasting
(by Phil Seitz)

On the last day of our trip we were able to arrange a tasting of aged beers. While we did request certain types of beer to sample, the final selection was made by our host. We cannot vouch for the actual age of the beers (the bottles were not labeled with dates), but can certify that they were certainly old, and looked it--covered with dust, well sedimented, corks all moldy, etc. As it turned out, the effects of ageing were a bit unpredictable anyway, so what follows here should probably be taken as a range of possibilities rather than a strict prediction of the effects of time on unusual beers.

Beer #1: 15 year-old gueuze from the Wets brewery (St. Genesius-Rhode); 75 cl corked bottle

This beer was completely flat, a medium caramel brown in color with a tart, rich, cherry-like aroma. It was surprisingly sweet, and at first taste we were convinced we'd been given a kriek. Our host explained to us that in some cases gueuze can get sweeter with age (!), and that, no, there were no cherries in this beer.

The initial flavor was quite full, tart, slightly caramel- and cherry-like, a bit like Rodenbach Grand Cru or Alexander but with more of the lambic funkiness, less acidity, and no oakiness.

The consensus at the table was that the beer had reached a state of maturity, or peak flavor and character.

As with older wines, exposure to oxygen produced some interesting effects. We drank our glasses over a 20-30 minute period, and different tastes and flavors would come forward and then retreat again. Most notable was a banana-like flavor that only lasted a few minutes.

The Wets brewery no longer exists. A line of gueuze products is still available under that name, but our host said these are made by the Brasserie Girardin. Later comparison showed that modern Wets and Girardin bottles are identical.

Beer #2: 10-year-old Liefman's Goudenband; 37.5 cl corked bottle

Here the effects of exposure to oxygen were very dramatic. Following the initial pour the beer was well carbonated, quite similar to the current Goudenband in body, but slightly darker and with brown tints in the head. Then there was the flavor and aroma. As beer snobs we had a hard time coming to agreement--did it taste more like a washcloth that's been laying around wet for three days, or just a really bad pair of smelly socks?

However, within ten minutes all the washcloth smell and flavor had vented off, leaving the beer with a rather convincing flavor of cabernet sauvignon. Slightly fruity, slightly tannic, very wine-like. Fortunately it stayed that way, at least until we were finished with our glasses. A remarkable performance.

Beer #3: 20-year-old gueuze from the Wets brewery; 75 cl corked bottle

Our host introduced this beer by saying it was the same style and type as the one we'd previously had, though obviously

the year of production (and therefore some of the microflora used in the brewing) were different. In fact, the two beers could hardly have been more different.

This beer was also flat, with the color of dark milk chocolate. The aroma and flavor were very pronounced, and featured bitter chocolate, coffee, and strong caramel. A lot like drinking strong coffee flavored with cocoa powder and butterscotch, rather bitter but not overpoweringly so. In fact, a lot like Mexican mole sauce.

Our surprise was evident, and we asked how two ostensibly similar beers could turn out so differently. The reply was that, well, after ten years the development gets unpredictable. I can't say I'd drink a beer like this very often, but it was not objectionable and certainly an interesting experience.

Beer #4: 25-year-old Orval; 33 cl capped bottle

Unfortunately no aged Trappist beers like Westvleteren Abt or Chimay Bleu were available, but a stock of Orval had been retained. At the time this bottle was produced Orval as 5.6% ABV; now it's 5.2%.

Despite the crown cap it had retained plenty of carbonation. In fact, it tasted a lot like Orval, particularly with regard to the "hair tonic" yeast flavors. If anything, it had just softened a little, possibly due to the decline in hop flavors. Any reasonably experienced beer drinker could have pegged this as Orval blindfolded. Was it really bottled in 1968? I had to wonder.

Subject: RE: Steam injection

Ed Westemeier proposed a method of Steam injection:

>I recently watched a fellow homebrewer use what I consider an extremely
>clever gadget. He had an ordinary household pressure cooker that he
>modified to run a steam line out through a ball valve.

Be VERY careful modifying pressure cookers. High pressure steam can be
dangerous! The last thing you need is a hose rupturing, burning
yourself.

>By simply injecting live, low pressure steam into the bottom of his
>picnic cooler mash tun while stirring the mash, he was able to raise
>the temperature to the desired point very quickly.

>Has anyone experimented with this type of setup?

I once had the privledge of brewing a batch of beer at the Vermont Pub
and Brewery. The recipe called for a step mash. The VP&B mashtun is
equipped with hot water valves feeding the top, and steam valves
feeding the bottom. A combination of hot water and steam heated the
grain for the high temperature step. They force steam into the bottom
of the kettle - this helps heat the grain to the desired temperature.
One problem was mixing the grain. As would be expected, the bottom of
the grain bed gets very hot, and needs to be stirred up. We stirred
like mad (not easy with 1000 pounds of grain!), and also injected CO2
into the kettle from the bottom. The CO2 gave the grain a little more
mechanical motion and assisted mixing the mash. (Raising the
temperature was NOT fun - imagine standing on a ladder with a big oar,
stirring the mash. As the same time, steam and CO2 are comming off the
grain. If the stirring doesn't fatigue you, the steam doesn't burn
you, or the CO2 asphixiate you, you are destined to fall off the ladder
and break a leg!). Everything worked out well - the beer was
fantastic! (no one got hurt, but don't call OSHA!)

Subject: Hops FAQ, Part 2/5

Hops FAQ, Part 2/5:
- - -

Q: Should I use pellets, or plugs, or loose hops?

A: Much has been written about what form of hops should be used. Loose hops are just that: loose cones which have been dried after picking. Plugs are loose hops which have been subsequently pressed into a bung, generally in 0.5 oz. sizes. Pellets are loose hops which have been ground to a fine powder and then pressed into rabbit-food-sized pellets.

LOOSE HOPS

Advantages: They are the most natural form of the ingredient. They float, which is good for siphoning out from under, and form a natural filter bed. When they are fresh, they beat all others in terms of aromatic hop oils.

Disadvantages: They float, so some contact with a still wort (as in dry hopping) is lost, when compared to pellets. This problem can be overcome, though by using weighted hop bags, or it can be ignored. Since they are loose, exposure to air is the greatest and they lose quality quickly when compared to the other forms of hops. When stored in vacuum-sealed or CO2 or nitrogen purged Oxygen barrier bags or jars, this problem can be avoided. They are bulkier than other forms.

PLUGS

Advantages: Are nearly the same as loose hops, in that, when hydrated, they become whole hop cones again. Like loose hops, they float. Unlike loose hops, they are better protected from air.

Disadvantages: Few hop varieties come in this form. Currently, any domestic varieties are first shipped to England where they are made into plugs and then shipped back to the U.S. This may negate any freshness advantage they have over loose hops (for U.S. varieties) It is difficult, but not impossible to separate into increments smaller than 0.5 oz.

PELLETS

Advantages: Convenient to measure and have the best protection from air. They sink, so they get maximum contact in a still wort, as when used for dry

hopping. This advantage may be mitigated though, if they are subsequently covered with dead yeast, so later additions are recommended. They reportedly contribute 10% more alpha acids to the wort because of maximized surface area, so are a more efficient use of this relatively expensive ingredient. They are generally available in more varieties and are generally a more consistent product.

Disadvantages: They sink, so it is sometimes difficult to avoid them when siphoning. The extra processing may reduce/change hop aromatics.

Given the pros and cons listed, the choice of which form of hop to use in a certain application is up to the individual brewer.

- - -

Q: What are AAU, HBU, and IBU's?

A: Alpha Acid Units (AAU) and Homebrew Bittering Units (HBU) are the same.

For the sake of discussion we will use AAU's, which are calculated as follows:

$$AAU = AA * W$$

where AA = alpha acid % provided with the hops
W = weight of the hops in ounces

The units of AAU's would be "percent-ounces". They are usually considered "unit-less". It is generally assumed that, when using AAU or HBU, the batch size is the standard homebrewing unit of 5 gallons. If a beer is said to have 10 AAU's of bitterness in it, and it is a 5 gallon batch, there would probably be no confusion. If on the other hand, it is a 10 gallon batch, there is actually half the AAU's per gallon when compared to the 5 gallon batch and the beer would be quite different. Another drawback to using AAU's is that they don't consider the utilization obtained from long, intermediate, or short boil times. Fudge factors are sometimes added but at best they offer a rough approximation.

To solve these problems, the International Bittering Unit (IBU) may be used.

With it, the brewer can get a more accurate approximation of the bitterness given up by a given quantity of a given AA hop for a given boil time. It is batch size dependent so that a 5 gallon batch with 29 IBU's has the same bitterness as a 50 barrel batch with 29 IBU's. The equations are commonly quoted from Jackie Rager's article in the Zymurgy "Hops and Beer" Special Edition published in 1990. The tables and formulae follow:

| Boiling Time (minutes) | % Utilization |
|------------------------|---------------|
| ----- | ----- |

| | |
|-------------|------|
| less than 5 | 5.0 |
| 6 - 10 | 6.0 |
| 11 - 15 | 8.0 |
| 16 - 20 | 10.1 |
| 21 - 25 | 12.1 |
| 26 - 30 | 15.3 |
| 31 - 35 | 18.8 |
| 36 - 40 | 22.8 |
| 41 - 45 | 26.9 |
| 46 - 50 | 28.1 |
| 51 - 60 | 30.0 |

Utilization can be reduced to the following smooth function, as opposed to the table, which produces many discontinuous lines. Either can be used with sufficient accuracy for the homebrewing operation.

$$\%UTILIZATION = 18.10907 + 13.86204 * \text{hyptan}[(MINUTES - 31.32275) / 18.26774]$$

(Of course, you can drop some of those significant figures.)

If the gravity of the boil exceeds 1.050:
 $ADJUSTMENT = (BOIL_GRAVITY - 1.050) / 0.2$
 otherwise,
 $ADJUSTMENT = 0$

$$IBU_PER_OZ = \%UTILIZATION * \%ALPHA * 7462 / (VOLUME * (1 + ADJUSTMENT))$$

UTILIZATION is the percent alpha acids expressed as a decimal fraction
 ALPHA is the percent alpha acids expressed as a decimal fraction
 VOLUME is the final number of gallons in the batch (usually 5).

To calculate IBU's if you know the number of ounces of hops to be used:

$$IBU = OUNCES * IBU_PER_OZ$$

To predict the number of ounces needed to hit a target IBU:

$$OUNCES = IBU / IBU_PER_OZ$$

Jackie Rager's numbers have been used successfully by hundreds of homebrewers and provide a consistent base with which to work. It is apparent that his constant 7462, derived from metric to US conversion, is actually closer to 7490. The ADJUSTMENT factor could be questioned as well, as it is intuitively obvious that a gravity of 1.049 does not affect utilization exactly the same as a gravity of 1.000 (water). It is assumed that the utilization table is corrected for this assumption and/or the difference is small enough that it has little effect on the final bitterness of the beer.

Note also that Mr. Rager's numbers are often used for pellet hops thrown loose in the boil. It is common to add 10% more hops if used in a hop bag, and 10% more than that if loose hops or plugs are used.

It has been reported that since iso-alpha acids possess a slight electrical charge, they can be lost in many ways. Among these are absorption into the yeast cell walls (and subsequent removal of the yeast), attachment to

coagulating proteins (and subsequent removal of this trub), attachment to filters, etc. It is unclear if Mr. Rager's utilization numbers have assumed these losses. A revised utilization table has been presented by Mark Garetz and can be used if desired. It is shown below for reference.

| Boiling Time (minutes)
(adjusted for
average yeast) | % Utilization |
|-----------------------------------------------------------|---------------|
| less than 5 | 0.0 |
| 6 - 10 | 0.0 |
| 11 - 15 | 1.0 |
| 16 - 20 | 4.0 |
| 21 - 25 | 6.0 |
| 26 - 30 | 11.0 |
| 31 - 35 | 13.0 |
| 36 - 40 | 19.0 |
| 41 - 45 | 23.0 |
| 46 - 50 | 24.0 |
| 51 - 60 | 25.0 |

The same IBU formulae from above can be used with this table. It represents one of the many arguable topics of hops in homebrewing.

- - -

Q: How do I store my hops?

A: At as low a temperature as possible, likely to be in your freezer. Also, attempt to remove as much air as possible from the package and use airtight, preferably oxygen-barrier packages.

>

I've been thinking recently about hop additions (all this Hops FAQ stuff has forced me to think about some of this stuff). I just realized that there is an inherent advantage to immersion chillers (my old method) over counter-flow chillers (my current method). Yes, the immersion chiller leaves the cold break in the kettle but it does something else that I have not seen discussed in this forum.

With the counter-flow chiller the wort and hops remain near 100C the entire time the wort is being chilled. From experience I know the kettle is still extremely hot 20 minutes after turning off the flame. I would bet that finishing hops act more like flavoring hops and that flavoring hops act more like bittering hops with a counter-flow. Can anyone verify these assumptions? Do you know of any commercial brewers who use immersion chillers (they clearly have some advantages)? Probably not since immersion chillers are less efficient and I know of few commercial brewers (even micros) who care a lot about hop aroma.

This is certainly true, the time/temp can be long and high. Some pro and not pro brewers add finish hops to the whirlpool in an effort to get more aromatics in the beer. I whirlpool in the kettle, so when I add late hops, it does sit at 200+F for the 15 min whirlpool, and subsequent 35 min chill. You will still end up with aromatics, but if you want more, like I do in many beers, there is no substitute for dry hopping.

Well, if dilution of the bitter wort is an issue, then decant the still beer off of the starter/yeast slurry. If you dont have enough slurry, add more fresh wort, let ferment out, and decant. Mike Sharp is a big proponent of pitching after high krausen, so the ferment and decant method makes sense. With cell densities, you are kinda forced into successive steps up to get the cell count up, or reuse yeast from a previous ferment.

This is how I do it. I have a 12 foot prechiller counterflow from the kettle to the pipeline interface. This feeds 50 feet of counterflow pipeline, second stage, underground, into basement, cross basement, to fermentation area, where it goes through 15 feet of ice bath, ball valve into fermenter. I over-engineered it for several reasons: speed, high tap water temp in summer, and hopes of lagering some day. At the end of the transfer, I hook up 175°F water from my hot liquor tank and rinse the pipeline, often diluting the cast out wort.

Subject: You can't judge a beer by the bottle, but...

Good point. If you look in any copy of Zymergy you will find a few companies that produce custom labels but I've never seen anyone who makes caps, bottles, or wooden crates.

Personally I make my own labels using a graphics editor, a ray-tracer, a good collection of gif/jpeg "clip art" of beer labels, and a color printer.

I would also like to find an outfit that produces custom beer coasters.

>how long, under good conditions, will the grain be
>fresh? besides rats, are there any problems associated
>with buying and keeping 50 lbs of grain?
>mrgarti@xyplex.com

I store all my specialty grains in a 48 quart picnic cooler (I already have a good lauter tun :-). I find this really effective for storing small (1 to 5 pound bags of crystal, roasted, and other malts. As for base malts, I still don't have a good method for storage. I usually buy 55 pound bags of Munton & Fison malts and their bags are plastic lined. As long as you close the top well, insects aren't a problem. Rats are another matter. With 3 cats in the house, rodents are not my concern :-) but they could get into that bag with no problem at all. A good solution might be a heavy duty 30 gallon trash container with a tight fitting lid.

haven't yet
> decided how. Suggestions?

I noticed a similar change in late hop character when I changed to using
a CF
chiller: I found that to obtain the same hop flavor and aroma, I had to
add
more hops *later* in the process as compared to my previous process
that
used an immersion chiller. One technique that I have found useful is to
add
hops *during* the runoff. After my boil is complete, I stir the wort
vigorously
and wait 15 min for the trub and hops to settle. During the runoff -
about
25 min for 5.5 gal - I typically add whole hops in one or two additions.
This
has improved the intensity of my late hop character. I use a slotted
pick-up
tube in the boiler to avoid clogging the chiller.

I feel the CF chiller has pros and cons: I get a much better cold break
with
my CF unit using well water. My wort exit temp is ~55-60F. Another
benefit is that, given that my chiller and settling tank are disinfected,
there
is very little risk of infection because the wort in my boiler is still
above
160F at the end of runoff. On the downside, one must deal with the cold
break
in the fermentor and the late hop character is decreased in the 30-40
min.
the wort remains in the boiler.

Subject: Miscelaneous

With HBD bunged up worse than my sink was last week, should people be lecturing about humor or criticizing the humorless in the digest rather than by email?

Re brewing. Peter Just asks about lagering in bottle vs carboy (or keg)

.  
The advantage of the latter is clarity - and very little sediment, but a disadvantage is fresh yeast should be added. The advantage of the former is timesaving and less trouble with equipment. However, I think the advantages of bulk conditioning outweigh the trouble involved (1255).

Robert Urweiler asks about labels. There was an article in the last Zymurgy, which was nearly more useful than the entire last BT (IMHO). Was anyone else disappointed with it after their first 2 excellent issues?

Scott Weisler resonds to greg with criticism of a PVC pipe design wort chiller. The problems mentioned are easily overcome with baffles, and the design can be as or more effective than the garden hose method because the flow is more turbulent. I am considering such a device. However the outer part will be metal - not PVC - possibly an old paint can or something thicker with bulhead fittings and pieces of scrap metal for baffles. Sterilize by bunging the whole thing in the oven for half an hour. Pity one can't buy a nice small shell and tube heat exchanger cheaply.

From: npyle@n33.stortek.com  
Subject: Steam injection

Ed Westemeier mentions steam injection for heating sparge water and for step mashes. It sounds fine for sparge water heating (although I can think of more efficient means of heat transfer). My first thought in using it for stepping up mash temperature is Hot Side Aeration. This may or may not be a problem, though, on second thought. Does steam contain lots of free oxygen? It is not like hot water which can contain dissolved oxygen, but it is pushing along lots of (hot) air with it.

I suspect it is not a good idea to use steam directly but it gives me an idea for putting a radiator in my cooler/mash tun. This way you could add heat to the cooler for step mashes without the complications of electricity (for some reason a direct propane flame doesn't seem like a good idea). I have lots of 3/8" copper tubing in the garage, hmmm...

From: arf@mcs.com (Jack Schmidling)  
Subject: Chillers

>From: npyle@n33.stortek.com  
>Subject: Late Kettle Hop Additions

>I've been thinking recently about hop additions (all this Hops FAQ stuff has forced me to think about some of this stuff)... The immersion chiller cools the wort and hops fairly quickly from 100C to around 50C (maybe 10 minutes). The late kettle additions are boiled for a short time (1-10 minutes) and then within 10 more minutes they are at a relatively low temperature (50C).

It is unfortunate that those who do not read rec.crafts.brewing missed the recent great debate on immersion vs counter-flow chillers. Kinney Bauman did an admirable job of defending counter-flow in light of its obvious shortcomings and naturally lost to the Lighthouse of Wisdom and Truth.

I won't re-hash the whole argument here but in summary, not a single, UNARGUABLE advantage could be brought in defense of counter-flow for home brewers and most of the good reasons are only valid in large scale brewing. The only advantage to homebrewers was the OPINION that chilling faster made for clearer beer but no one had come up with any documentation to prove the point.

Before I get into the virtues of immersion chilling, it is necessary to point out that I would no more use a poorly designed immersion chiller than a poorly designed anythingelse and most people do not have proper immersion chillers. Mine is installed in the lid of the kettle with quick disconnects to water and drain lines. Once the lid and chiller are in place, they can stay there for hours or days without risk of contamination or loss of aroma laden vapor.

Now, ponder the possibilities this allows. You have an infinite number of post boil hopping schedules that you can play with. For example, shut off the heat, put on the lid and throw in some hops. This hops is at near boil temp which kills that herbal taste but the vapor and aroma can not escape. When you chill it down, the vapor and aroma are re-absorbed by the wort. Let's say you think that some shops should be added at 163.794 degs F and

allowed to naturally cool with the wort. No problem either. Maybe you want to add some every 10 degs as it cools or how bout chilling it down right away and adding it at pitching temp but letting it sit in the kettle for 24 hours to absorb the flavor. There are no end of possibilities to toy with.

>Do you know of any commercial brewers who use immersion chillers (they clearly have some advantages)?

They have only one disadvantage.... they are ponderous and totally impractical in a large operation. They require a removable lid to get it out or an impossible cleaning headache if installed permanently in the kettle. Counterflow chillers of a modest size can chill any amount of wort given enough time.

It is another good example of what can go wrong when people simply scale down what they see in a commercial operation and assume it must be better for homebrewers. The counter-flow "snobs" are simply wrong on this one.

BTW, you mentioned that the kettle stays hot awhile with the counterflow anyway but that is not the argument. There is no magic as to how long the wort stays hot. The issue CAN be, how hot? If it falls below pasturization temp and is open to the air, there is a risk of contamination. If it stays near boiling, it is no worse than extending the boil that amount of time. And keep in mind that PU simply air cools the wort till it reaches lower temps.

The counter-flow aficionados claim that it is the instantaneous chilling of each quantum of wort as it passes through the chiller that does the magic.

While this is certainly something one can not do with immersion chilling, no one, (at least in that discussion) was able to prove that it really makes any difference. Judging from the reputation of PU, it doesn't seem to have anything to do with how long it takes to get from boiling to 150F, so it needs to be proven that fast chilling from there to pitching temp is critical.

To me, the most obvious disadvantage of the counter-flow chiller is that most of what would have stayed behind in the kettle ends up in the fermenter unless one does an additional settling step.

So, I hereby challenge the counter-flowers to start your engines....

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Show and Tell on my UK trip (Samuel Smith's)

Thought I would add a few more interesting observations about my recent UK trip. I dropped in at Samuel Smith's brewery in the afternoon and ask about a tour. They said they were all booked up. I mentioned I was a brewer from the states and the receptionist made a phone call and I was in. The tour was at 7pm that evening. My wife and I showed up in the adjoining pub with about 12 other people. Our tour began in the tack room. That's where they keep all the hardware for their horses. We heard all the details about their award winning horses before we went outside to see and feed and pet one of them. These are Shires, we're talking big horses here. I could just see over the horses back. I'm 5'8". Sam Smith's does no advertising and depends on their horses, which they show around everywhere, and public good will for their advertising. It seems to work. Afterward we entered the brew house and I got to see those famous Yorkshire slate squares I have heard so much about. I finally understand these damn things. One of them was empty and several of them were in full blown fermentation. They look like this.  
..

The unfermented wort is filled in chamber B just below the divider. As the fermentation proceeds, the foam and yeast are pushed up into chamber A. Because there is the cone shaped thing in the center, the yeast is skimmed from the beer. After a day of fermentation, they pump all the liquid from B back to A. This is just to rouse the fermentation. After this they just let the skimming action take place. Sort of neat, huh. I have no idea how they clean the B chamber. They told me they never repitch their yeast. They always grow up a fresh batch. I got to see their impressive steam generator and their gorgeous copper kettles. Then we entered the lager brewery. Yep you heard me right. They brew lagers under special contract for Ayinger. The lager brewhouse had a kettle and mash tun that was gigantic. We saw the other standard brew stuff, and made our way to the pump room. It is tucked away under the brewery. You have to almost crawl to get there. It was

easier when leaving :->. We drank their cask ales and saw a movie. After  
a  
few beers I found myself behind the bar pulling my own beers with those  
great beer engines. Lots of fun! I tasted NO diacetyl in any of their  
beers. I mentioned the skunkyness we get in their beers in the states due  
to their use of clear bottles for some beers. They seemed amazed.

Sam Smith's is located in the town of Tadcaster about 30 mins outside of  
York. There are about 4 breweries in Tadcaster, Bass, Magnet, Sam Smith's  
and John Smith's. All the breweries located there because of the water  
quality (the water is very hard). There is alot of rivalry between Sam  
Smith's and John Smith's. John was a brother and split off another  
brewery.

Sort of a family outcast. The John Smith's brewery was sucked up by  
Courage

in 1970. All of Sam Smith's beers I tasted in England were very good. I  
had

a pint of their Museum ale in London. It had a distinct woody character  
to

it. It was drawn from a wooden cask. The taste was sort of a young, green  
woody character. Maybe some of you brewers that have experimented with  
wood

chips in your IPA's would know what I mean. This was not an IPA, however.

Cheers,  
Bob Jones

From: softdesk!suez!trs@uunet.UU.NET (Tom Schwendler)  
Subject: Beer Shelf Life

Hello brewers,

I just read that sediment beers (beers with yeast sediment) have a shelf life of only 3 months. I know I have kept bottles longer than that, but does anyone know what the shelf life of homebrewed beer is? Let's say assuming you are keeping the beer in a cool dark place, how long should it store without turning sour, or acidic? Other than filtration or pasturization, are there ways the homebrewer can increase the shelf life of bottled beer?

Thanks for your help,

trs@softdesk.com

Subject: Hop Storage & Growth/Quaff & Stir

\*\*\*\*\*

Hop Forms- Stability....

> Also, regarding the type, pellets tend to retain more of everything (AA and aromatics) than plugs, which retain more of everything than whole.

It's all a matter of exposed surface area.

\* Just a comment here: One of the disadvantages (not to open a can of worms! Old debate I know!) to pellets involves the process of pelletization. This process involves physical abuse, and some temp. stress to the hops. This results in some loss of aromatic qualities from the hop as compared to fresh cones. Plugs are a good in between since the hops are not first chopped, but just pressed into pellets. So to say that " pellets tend to retain more of everything" is a bit misleading. In terms of storage...YES, in terms of qualities lost from the time of harvest thru processing, to the store, NO.

It is true that handling of flake hops (cones) does have the potential to reduce quality more than handling of pellets. I commonly find a collection of yellow crystals at the bottom of my flake hop bags. So....my solution. Grow my own! See note below....

\*\*\*\*\*

From: Philip Proefrock <PSPROEFR@MIAMIU.ACS.MUOHIO.EDU>  
Subject: Growing Hops

>I am interested in growing my own hops for use in my homebrew. (I don't plan to use this exclusively, but it would be nice to have hops I had grown in the beer that I brew. I expect I would only use the homegrown hops for one part of the process, say boiling, and will continue to buy other varieties for flavor/aroma.) Does anyone else do this? Can you provide some pointers, suggestions as to where I can find seedlings or seeds, etc.? What varieties will grow best in the midwest?o I hope to get starters going indoors this fall, so that I can get them growing this coming spring.

\* Hop Growing Experience (1 year- first season, but what a thrill!) "exclusively"- You'd need a BIG vine yard to keep up- 1 harvest to last all year. That's asking a lot. BUt maybe after a few years. "boiling"- Personally I feel I get the best advantage out of the freshness of my homegrown hops by utilizing them at finishing. BOUQUET!!!! Plus I am able to spread out there use more that way.

Planting Time: Early spring. March-May depending on location.  
Form of starts: Rhizomes- segments of roots with sprouts. No Seeds! (I actually found a seed in one of my cones. I don't know what fertilized it, but it was a rather odd find! Haven't tried growing it. )  
Female plants are propogated. Males not found- except on research plots.  
Plan on some TALL vines. Very fast growing! Beautiful sight to watch. You can actually OBSERVE growth. 3 inches per day at the peak!  
The way to plant is dig a plot- fertilize/mulch, and lay the rhizome in a hole. Protect from frost until things warm up.  
No point in starting them inside. Just count on several years till "great growth and production" is observed. Well worth it!

I planted 4 varieties:

Cascade- Good grower. Excellent production. Hardy. BIG cones!  
Chinook- not too impressive. A friend had the reverse of these 2  
Mnt Hood- 2nd best growth. Yummy cones. Also quite hardy

Perle- Not too impressive. A bit better than Chinook. I like the hop though.

NOTE: This was the first year. Subsequent years will improve dramatically

I did have quite a bit of pest problems, but the cascade was able to tough it out! I'm looking forward to next year! Can't wait till the start up again!

I got starts from FreshHops in Philomath OR. 503-929-2736. No connection. Just a happy customer. There are other sources. Write to them or call and they will inform you when the starts are ready for shipment. It's about 2-4 \$ rhizome. I used 2/hill. There is a book on Growing Hops- dont have the author at hand. It's an ok book. More of a personal account than a hard-fast guide. Some good info. He did do some research for it. That shows. There is a hop primer floating around somewhere on the net. I could try to find/post it if desired.

\*\*\*\*\*

Stuart from Edinburgh says he:

> uses a plastic brewheat thingy and I think its crap, I want to brew bigger batches and I want to use gas to heat, cos I like flames!

\* I'm sure there's a few folks around willing and able to scorch a few flames. But that would never happen on HBD...right! :/  
A note for AL...That's one reason why I didn't include the commercial mash/lauter tuns in my rundown. Not that they don't exist but just that with a little creativity one can be fashioned cheaply at home. I don't have exp w/ the commercial ones...but they are out there. Have heard good things about Phil's false butt.

\*\*\*\*\*

Tom queries:

wanted to know if....needed to put down my homebrew to scape the hops off..side of kettle. It sure could save me a couple of minutes drinking time.

\* Hold a spoon/paddle in one hand, homebrew in the other and scrape away. I don't know for sure- but I would suggest that to get FULL extraction of hop oils you want to hop material in contact with hot liquor for the full boil. I use a mesh- hop bag, so I don't have that problem. I do plunge the bag to the bottom several times during the boil. But I can do that one handed. Use a beer mug with a handle if you don't feel comfortable with your dexterity. With a little practice you can master the techniques of continuous drinking during ANY activity. If you spill a little into your wort...don't worry.

\*\*\*\*\*

Subject: Pitching large yeast starters

Domenick Venezia's concern about pitching large starters into fermentations was a concern of mine as well. What I have started doing is wait until the yeast has dropped and then decant (I have actually been removing the liquid above the yeast with a small siphon hose) and then add additional food. Then I do the same again or just pitch straight into the wort. Work G. Fix and a few others have done, has shown that there are actually ADVANTAGES to pitching yeast AFTER high kruesen. The viability issue does enter into the equation if one waits too long before pitching. I can't seem to locate any info on yeast viability with time.

From: Mark Garetz <mgaretz@hoptech.com>
Subject: Late Hops vs. Chiller, Homegrown Hops

Norm Pyle asked about immersion vs. counterflow chilling and late hop additions:

Just my 2 cents: There's no reason to go back to immersion chilling for late hop additions, unless you want to. If you like counterflow chilling, you can compensate for the effects of long "hot wort time" by either covering the wort so the volatiles aren't lost or simply adding a bit more hops. But in my opinion the difference is likely to be a small one regardless. I would think that a much more significant effect would come from those that cool their wort by immersing the pot in a sink or bathtub of ice water, which takes significantly longer than either immersion coils or counter-flow chilling. For the record, I use an immersion chiller and also cover the pot as the wort cools. A tip is that since the coils don't allow the actual lid to fit over the pot while cooling, I use about three strips of Stretch-tite (like Saran wrap) to cover the pot so that I get a good seal. Now I don't cover to keep in hop volatiles (but I suppose it does), but to keep airborne nasties out of the wort during cooling. I do not cover during the boil.

Philip Proefrock writes:

I would suggest you do just the opposite. Use the homegrown hops for aroma additions and use hops you know the alpha acid ratings on for bittering. You can at least get a sense of the aroma potential of your homegrown hops by using your nose, but there's really no practical way to know how much alpha acid is in there (without a lab analysis).

Subject: Carboy Alert!

Just a note of potential concern to you all:

Recently (about 5 mins ago) I was cleaning a carboy recruited from our stockroom that had previously held some (assumedly) harmless chemical solutions (KI in DI water and such). Anyway, after filling with approx 8 liters of water or so and dumping in about 250 g of potassium hydroxide pellets, I picked up the carboy to swirl and mix the contents. The second time I lifted the carboy, the entire bottom separated almost perfectly, dumping the contents. I am thankful that:

- 1) This occurred over my lab sink.
- 2) That the carboy contained only cheap chemicals rather than wort or (gasp!) finished beer.
- 3) That I didn't splash caustic KOH solution all over myself.

In the future, I will (and will recommend to others) to:

- 1) carefully inspect all new carboys before initial use (and used ones too.)
- 2) regularly inspect my old ones
- 3) exercise due caution when picking up or transferring my carboys.
- 4) avoid any sudden thermal shock to the glass carboys.
- 5) Avoid long-term contact with caustic soda solutions.

I am sure that most of these precautions are obvious and well-known and the others may seem like overkill, but after seeing the results of a broken carboy...

Subject: doppelbock

Around the end of August I asked for advice on priming a doppelbock, due to the concern that the yeast used to ferment would be wiped out by the high alcohol level. I received numerous responses, all of which said "pitch some more yeast when you bottle". Fortunately I had set aside a bottle of my original starter to use in a planned beer this winter, so I had yeast available. I made up a one pint starter, added this yeast and let it ferment. Then I made a primer from 3/4 cups dme added this and the yeast to the bottling bucket with 5 gallons of doppelbock and bottled. I am happy to report that a week later the beer was perfectly carbonated resulting in a very tasty brew to help me through the upcoming winter. Thanks to all who provided me advice on this.

For anyone interested, the recipe:

Baumerator
10 pounds Briesse 2 row malt
3 pounds munich malt
1/2 pound toasted malt
1/2 pound chocolate malt
1/4 pound roasted barley
1/4 pound black patent malt
1/2 crystal malt 80L
4 ounces Tettenger boiling hops
1/2 ounce Tettenger finishing hops
Yeast Labs Bavarian Lager Yeast
OG 1084, FG 1020

Protein rest 125, Mash 154, Mashout 168

Michael Hohnbaum hbaum@uts.amdahl.com
These opinions do not reflect amdahl's, but are completely mine.

Subject: More on steam injection

I got deluged with queries about my posting on steam injection, so I'll try to respond here.

First, I should mention that the originator of the technique is Dan Listermann, maker of Phil's Philler, Phil's Phalse Bottom, Phil's Sparger, the Philmill, etc. etc. Dan is an extremely creative guy, and he is constantly coming up with something new.

I'm relying solely on memory here, since I wasn't taking notes, but as best as I can reconstruct it, the setup is like this:
An ordinary pressure cooker (about 2 gallon capacity, I would guess) is modified by removing the pressure release in the center of the lid (NOT the safety pressure release, which is offset from the center on this one) and replacing it with a compression fitting. From that is run a length of flexible metal hose (the kind used for a gas line to a kitchen stove, I think) about 4 or 5 feet long.

At the end of the hose is a fitting that connects to a short (8 inches) length of 1/4 or 3/8 inch copper tubing. The other end of the tubing is pinched shut, and many holes are drilled all over the length of the tubing (to let out the steam). A rubber stopper (with a hole drilled through it) is fitted over the tubing where it connects to the hose.

If you mash in a Gott (Rubbermaid) cylindrical cooler, you have probably already removed the original valve. Stick the tubing into the hole, letting the rubber stopper seal it. Mix up your grains and mash water in the cooler as you normally would. Place the pressure cooker on your Cajun Cooker, and let the steam raise the temperature of the mash.

Several people expressed fear that the steam would melt the plastic lining of the cooler, but in fact the steam doesn't touch it. Of course, you have to stir the mash constantly while you're raising the temperature with the steam, in order to circulate it, but it only takes a few minutes. Do this as often as you like. For me that would mean once, but it's just as easy to do a step temperature infusion with several steps.

Incidentally, a single filling of the pressure cooker (oops, I mean steam generator) was much more than enough to mash the grain for a five gallon batch. I'll bet it would have handled a ten gallon batch on that same filling. It really doesn't add any measurable amount of water to the mash tun.

After conversion, Dan used his steam generator again to heat the sparge water, by simply putting the steam probe in a bucket of water and stirring to circulate the heat. Then he sparged normally.

Dan says he only put this rig together as a "proof of concept" prototype, and I don't know if he has any plans to market anything along these lines.
It's an intriguing idea though.

Subject: Channeling/Steam heat

Carl writes:

>> ...due to a fluid mechanics phenomenon called "channeling"
>
>Which is what?

As I'm sure we all know, liquid flowing through a porous substance will tend to take the route of least resistance. Channeling is one step further in the case of a substance like soil or a grain bed, in which if a much lower resistance path is found, then the liquid will tend to flow down that path, or channel. Two cases where channeling can cause a measurable loss to our extraction are:

1. when a 100% porous grain bag is used (i.e. as opposed to the type which is mesh only on the bottom), the runoff tends to go straight to the side of the bag and then run along the side of the vessel (between the bag and the vessel) down to the bottom, and
2. if you use a knife to cut a stiff mash -- the runoff will head straight for those channels you just created and tend to continue to use those channels, bypassing the other parts of the grain bed.

Ed writes:

>clever gadget. He had an ordinary household pressure cooker that he

same
>way. It all seemed so simple and logical that I wondered why I hadn't
seen
>it mentioned before.

The only "con" I can think of is the danger of scalding the brewmaster or his/her family. Live steam can really do a number on skin and worse on your eyes. I once scalded my arm just by removing the kettle lid at full boil in the wrong direction. It took a good two weeks for the 1st degree burns to stop being tender to the touch.

Subject: Beer hunting in Belgium: Part 7 (General information)

Beer Hunting in Belgium: Part 7 of 7

General Information
(by Phil Seitz)

The following information is offered for anybody considering travel to Belgium. These are the bars we like, sources we found useful, and a few additional places we went that you might not find in the guidebooks.

Cafes:

L'Eblouissant. 27, rue Armees Grouchy, Namur. 081/73.71.39.

A small cafe run by a very particular publican. Extensive beer selection, well cared for. Good meals during lunch, with food also available during dinner. Frequent concerts of Irish music. Previously called one of Belgium's best cafes by CAMRA, now relocated due to high rents but still very comfortable. Closed Sundays.

Musee de la Biere (The Beer Museum). 19, rue de la Gare B/2, Lustin, on Route #947. 081/41.11.02

A funky place in a small town. Until last year nobody I know in the area had ever been there, though everybody knew about it. The reason is that it looks a bit weird from the outside. The exterior has hand-painted signs advertising over 1,000 Belgian beer glasses on exhibit, and God knows how many bottles, some of them dating from the 19th century. Looks a little like those roadside attractions advertising plaster-of-Paris dinosaurs and two-headed cows. Admission is 35 francs, which can be applied to a purchase in the, er, gift shop. The gift shop features 11 beers on tap (including the formidable Liefmans' framboise), as well as a good 100-200 in bottles. The interior is crammed with shelves of bottles and glasses, and many of these will actually be of substantial interest to beer geeks. Overall, a very pleasant atmosphere.

If you speak French, the woman who runs the place is famous for being talkative and very well informed with regard to beer issues and developments in Belgium. The cafe is also home to a tasting club, the Guilde des Tates-Biere, whose final exam is rumored to include identification of certain beers by year of production.

Lustin is south of Namur, on the Meuse river. The museum is open weekends and student holidays only, but special openings can be arranged for larger groups.

De Stillegentier. Mechelen.

We did not visit this cafe, but it was recommended to us as stocking nearly all the lambic and gueuze products currently on the market. Hey, we had to save something for next time!

Beer stores:

La Cave de Wallonie. 6, rue de la Halle, Namur

Near the Place au marche de legumes. A specialty beer store run by one of the brewers of the Brasserie Caracole. The proprietor speaks some English, and if time permits is quite willing to discuss brewing issues and beers.

Drinks Wets. 209 Steenweg op Halle, St. Genesius-Rode.

02/380.32.27

This one's a whopper. We ran into it when we got lost on the way to Beersel, and Jim accurately described it as the Belgian liquor barn. They sell a mind-boggling variety of Belgian beers and beer glasses, as well as selected imported beers. (Good: We found Anchor Liberty. Bad: They stock Rolling Rock.) The proprietors do speak some English, and they take Visa but no other credit cards. You'll need a car to get there, but a truck might be better. The gueuze/kriek selection alone ran along an entire 35-foot wall. Perhaps the most unusual of these was the Gueuze and Kriek Girardin in polypins. Just the thing for Mike Sharp's next party!

Some notes: check expiration dates. Some of the old bottles you'll find are aged; others are just old and out of date, and taste that way. Keep an eye out for the Hanssens gueuze products; we considered these a major discovery, and their mention met with respect from our more knowledgeable Belgian beer sources. The Wets gueuze products are also available (presumably the owners of the store are the Wets of lambic blending fame, though we were told by others that the beer is now made by the still-formidable Brasserie Girardin).

Other stores

1) Spice stores sometimes sell bitter (curacao) orange peel. It's hard and white, and bitter tasting. One such store is L'Herbier in Namur, around the corner from La Cave de Wallonie.

2) Don't forget the ordinary supermarkets. Most of them sell dark and light candy sugar in 1 lb boxes, and many have formidable beer selections, including local brews and glassware. Jereboams (3-liter bottles) are widely available, and the Sarma Star hypermarket outside of Namur must stock at least 100 beers--and the glasses. Keep in mind that a charge for the deposit on each bottle will be added at the cash register. On the other hand, the larger supermarkets take credit cards, so you can spend now and pay later.

Books

We really only used two books and a map as constant reference materials. One book was Michael Jackson's Beers of Belgium, which is available from a variety of sources. The other book was Peter Crombecq's Bier Yaarboek, which is not easy to find (check better bookstores in Brussels and Flanders). The former provided us with general information in a language we could read, and proved to be reasonably comprehensive in scope, if not always providing the obsessive depth we craved. The Crombecq comes in handy here, with detailed information on the breweries (in Flemish), as well as lists of all their products and the names these are sold under. This is extremely useful information that beer hunters can draw upon to make sure they don't unwittingly buy ten bottles of the same beer.

CAMRA now has a good beer guide to Belgium and Holland, which lists much of the above information and includes reviews of cafes. As far as I know copies are only available in England, L'Eblouissant had one.

THATS ALL FOLKS!

This concludes our Belgian series. If you have any questions we hope you'll let us know; Jim [BUSCH@DAACDEV1.STX.COM] may be better for the technical brewing ones, and me for the ones on Belgium in general.

Subject: Re: PH Malt

In #1256, David Holsclaw asks:

> Has anyone else had problems like this with mash PH? What do you
> do?

WARNING! I HAVE NOT TRIED THIS. I JUST VAGUELY REMEMBER READING ABOUT THIS!

If I remember correctly, Dave Miller talks about using an acid rest in order to lower the pH of the mash. This is before the protein rest (& at lower temps of course). Using an acid rest is what allowed German brewers to brew lighter colored beers with the water they had. Check out the chapter titled "Mashing In, Acid Rest" (or something like that) in Dave's "The Complete Handbook of Home Brewing." Sorry, I don't have my copy on hand.

Subject: Post-boil wort handling question.

I've been brewing (occasionally) for about three years now. Just about every batch I've ever made has had an off taste (except for a particularly memorable batch of Bruce's Dogbolter during my "kit" days). I started out with new equipment and have good cleaning practices...I sanitize anything that touches the wort/beer.

After going through the HBD digests, I've gotten LOTS of great information on mashing techniques and plan to try some. However, I think my problems come after the mash. There's very little information on post boil handling of the wort and I'd like some suggestions on good technique.

After the boil, I let things settle for about 15 minutes. I then strain the wort through cheesecloth in a colander which is suspended over my plastic bucket primary. The straining through the cheesecloth takes a long time since I usually use pelletized hops which combined with the other solids quickly make up a semi-impermeable barrier. I then let it cool overnight and pitch a starter in the morning. I transfer into a carboy after the kreusening settles down. I usually bottle after the bubbling through my airlock stops.

I'd like some suggestions on better techniques so that I might eliminate my off-taste. Thanx in advance for any help.

PS. How does new pub/store information get submitted to the "publist" digest????

Subject: Tree parts and an occasional herb

Greetings,

Just wanted to shed some light (hopefully) on a few botanical points that have come up over the past few weeks.

First, concerning spruce beer. Spruce is in the family *Pinaceae*, genus *picea*. Pines are in the same family, but the genus *pinus*. The resins produced by individual species between these genus differ, so for the gentleman who was planning on substituting pine for spruce, take care. Remember, pine resins are used to produce turpentine and lacquer! Your best bet is to use commercially available extract.

For those brewers who think they might like to try a conifer flavored beer but are not sure they would care for the taste and don't want to risk pouring 5-gallons down the drain, let me suggest you go to a Greek restrurant and sample some retsina which is a liquor flavored with resins.

The flavor is stronger than that of some spruce beers I have tried, but essentially the same.

As far as hemlock (the tree) is concerned, genus *Tsuga*, it is not related to the famous poison cocktail of antiquity which was made from the herbaceous poison hemlock, *Centella conium*.

Concerning the posting a few days ago about Woodruff ale. I must assume that the herb added is Sweet Woodruff, a wonderfully aromatic herb of the genus *Galium*, commonly known as the 'bedstraw family'. I have had good luck growing this plant here in central Missouri and believe it is able to be grown throughout the continental US. I plan on trying a Woodruff ale myself in the near future, I'll post the results. For those who are interested, sweet woodruff is perfectly safe for consumption. The FDA has listed it as "safe for use only in alcoholic beverages."

Phillip Priefrock recently asked about growing hops in the midwest. I can assure you that few plants are easier to grow. Two years ago I purchased four rhizomes (root cuttings) from Freshhops (*insert standard disclaimer*), and harvested over five pounds of flowers this season. Freshhops advertizes in Zymurgy, but I don't have a phone number handy.

Concerning starting the plants inside during the winter, don't bother. First of all, the rhizomes are only available in the Spring, and more important, actively growing hop bines grow VERY quickly and would soon take over most light tables (mine were all over 25 feet tall this year). I have had best luckgrowing, cascade, nugget, and pearle.

Concerned about credentials? I am a research forester, currently finishing a PhD at the Univ. of Missouri.

>

I haven't gotten the impression that anyone has made light of the
effort Jack
or anyone else has put into producing effectvie roller mills designs.
I've
seen & used a MM at one of the HB shops I get supplies from. Jack did a
good
job on it. Most of the reviews I have seen have been pretty close to the
mark
regarding usability of the device. It gives a great crush but as many
people
have indicated the design could be improved upon some.

Jack's a tinkerer, of that I am sure. A large majority of HB'ers *
are*
tinkerers and would rather spend the time doing something themself than
run out
& buy something. I don't see where this thread is any different than the
ones
from people designing/making better wort chillers, lauter tuns, keggig
setups,

or lager houses.

No one said we aren't getting fair value from manufactured brewing equipment. I would agree that most of it is a good deal. However: 1) Everyone does things different and has different needs and 2) most of the time a redesign of an existing device can be improved upon. This has been shown time & time again.

As for your questions regarding tools/time & materials for the task, the same can be said for *any* serious hobby that needs such things, such as wood working, electronics, automotive mechanics... (I know, I have too many of these expensive hobbies already!-)

ObHBD: I'm working on refinishing my basement & plan to set aside an area dedicated to brewing & beer storage (with the wife's consent no less!-). I'd like to hear from anyone who has done such a thing regarding they're ideas and/or experiences in a couple of areas:

1) How do you store carboys when not in use?
I'm planning on building cabinets to store them upside down to cut down on pre-brew cleaning (such as is done for bottles). Anyone try this yet?

2) Since it will be in the basement dust could (will) be a problem. How do you keep it to a minimum on a *continual* basis, not just when brewing?

3) How many square feet does your brewery area take up?

4) What would you have done differently now that you've got it built and have been using it.

If people desire I'll summarize the responses and post it (if it's small) or put it in the archives if it's larger. (I'm also working on getting info like this out of back HBD issues but that's not exactly the quickest task I've ever taken up...)

Thanks for any & all input.

Subject: PVC wort chillery

To the brewer constructing the PVC pipe chiller.

Could filling the hollow of the copper coil with individual packets of reusable ice (that blue stuff you can freeze/refreeze) serve your needs? You could find the small ones (approx 1 X 3 X 1/2) and they may cool things down as well as help channel water around the coils.

Keep up the shadetree brewing and let us know how your new-fangled chiller works out.

From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>
Subject: Wyeast

Brian Bliss (1256) writes of disappointment with Wyeast. I am quite happy with the products. The trick is having a supplier who looks after them with TLC. My local homebrew store orders on the one day a week they package, gets the packages by 2 day air, and refrigerates them immediatly. The last pack I bought was 2 days old. I have never had any delay in getting a puff up, and generally use via a starter in 36 hours.

RE hoppy starters what I do is can all the bottom sludge, boiling with my bottled wort for priming. When I have quite a few cans I throw 'em all into my pot and dilute to 5 or 7 Balling and boil up for a while. I then bottle the clear wort, cap, and 'can' for a while. Hey presto, I have enough bottles of the hoppiest sterile wort necessary for 3-6 months of starters.

To make a starter all I do is drop a bottle into my chlorine bath to sterilize the outside and add it to the yeast in a she may bottle, shake the bejesus out of it and cap with an airlock in a 1.5 stopper. I will usually end up adding this to 2 or 3 bottles of starter juice in gallon jug for lager starters, and I always dump most of the wort off the top before pitching.

I recently purchased a Maltmill to benefit from Jacks October special. I am very happy with the crush, although there are one or two minor problems. The mill has a hard time with wheat malt (well Briess red winter wheat, anyway), and I had to dilute with barley to crush. js did tell me this was a problem with cara-pils, so for very hard grain dilution is the solution. The other problem also related to cranking is the mill's lack of rigidity and short handle. I found that I had to kneel on the mill on the bucket, while holding it with my left hand and cranking with my right hand. It was nearly as bad as the Corona (although I was crushing 17lb of grain for a Doppelbock). I will have to mount it in some way prior to its next use.

On that doppelbock, I got impatient and finished my boil too quickly. I put it in a acid carboy primary and I guess it was at least 6 gallons. I added a blowoff next morning (it was at high kraeusen after less than 8 hours at 48F - trick pitch with entire sediment from primary of previous lager) but the blowoff container was inaduate and it blew over putting a puddle of doppelbock wort all over my conditioning beer cases in the freezer. While cleaning the freezer I became very dizzy and light headed, and realized that I was asphyxiating in the CO2. I went away got my breath and allowed the air to mix a bit more. It occurred to me that ashyxiation could be a problem in larger breweries. Comments?

Subject: Who Put the phor in Iodophor?

"Robert H. Reed" <rhreed@icdc.delcoelect.com>asks about the 'phor' in Iodophor:

>Question: what does the -phor designate in the name IODOPHOR? I have
>used BTF iodophor which doesn't contain phosphoric acid and I have
>recently obtained an iodine sanitizing solution that *does* contain
>phos. acid. What gives?

We've been through this before, but the -phor has NOTHING to do with phosphoric acid. The '-phor' suffix means 'carrier of'. Iodophor means 'carrier of iodine'. Period. FWIW - 'phosphorus' means 'carrier of light' ('phos' meaning 'light', and 'phor' meaning carrier). Phosphorus tends to radiate light. Check your Webster's dictionary and look up '-phore'

The fact that SOME iodophors also contain phosphoric acid is purely coincidental. My Iodophor has no phosphoric, but I'd prefer one that does.

Subject: re:Beer hunting in Belgium: Part 5

In Jim Busch's interesting Belgian travelogue, he mentions:

>After a primary fermentation period, the beer is racked into
>Chestnut casks--the brewer swears by them and recoiled with
>horror at the possibility of using oak.

This is interesting given the fact that Chestnut is one of the few woods that contain a *really* high amount of tannin. Oak has alot lower (with oak, only the bark contains enough tannin to make extraction for leather tanning worthwhile, Chestnut wood contains enough to be useful in this application) though not insignificant amount.

I wonder if chestnut is chosen for this reason, or if the casks are so old that most of the tannin has already been removed.

Hmmmm....

Cheers, Rick C.

Subject: Hops FAQ, Part 3/5

Hops FAQ, Part 3/5:
- - -

Q: Can I grow my own hops? How?

A: Read this...

Hops for beer-making grow from the rhizomes of female hop plants. Rhizomes look like root cuttings but have buds growing from them that will become new vines. Rhizomes also contain stored nutrients to support initial growth.

Hops grow vertically as one or more vines that spiral up a twine or other support. Depending on latitude, location, and variety, they sprout from March or April and grow through the summer and early fall. A single plant can easily grow 40 feet tall when it is mature but growth in the first year is usually much less. In most instances by the second or third year the plants will exhibit full growth. Height is very closely linked to the amount of sunshine the plant gets.

Hops grow best in full sun and you should pick a spot with the best possible southern exposure. Hops grow best in loose, well drained soil. Blended peat moss and sand make a good growing environment. In cases of poor soil drainage, it can be helpful to create a mound of soil a foot or so tall which will aid drainage.

Hops need lots of water. As they grow be sure to give them a very good soaking at least once a week. There are reports that once-a-day waterings (up to 6.5 gallons per mound) give greater growth and yield. Mulch in the summer helps with weed control and also holds water. Hops also have big appetites; composted cow manure is an excellent well-balanced fertilizer for them.

Once a bed has been prepared the rhizomes are planted about 4 inches below the soil surface with any obvious buds coming from the rhizome oriented to point upward.

After several inches the new vines should be thinned so that just the most healthy and vigorous three vines are left to continue growing. This will be an ongoing process as new shoots may show up later, but the initial thinning is important. It's been reported that the young shoots that are culled may be

steamed and eaten like asparagus. On the other hand, some growers espouse cutting the new shoots at all, allowing all vines to grow to full height.

As the vines grow over a foot tall they should be trained to grow up a twine. This can be done by twisting the vine around the line. This may have to be repeated for a few days before the vine gets the idea. Hops will have a natural tendency to wrap clockwise looking down.

The most common hops trellis consists of strings running from the roof of a building down to stakes driven into the soil near the plants. Another option, often used by commercial growers, consists of a large central pole, with strings running from the top of the pole down to the foot of each plant, similar to the spokes on a wheel. Expect the string or twine to hold a lot of weight as the vines grow tall. A 25+ foot plant may weigh 20+ pounds.

Hop blossoms start out looking like large sand burrs, and then take on a characteristic cone shape as they grow in size. The size of a fully developed cone depends on the variety, varying from 1 to 2 inches long by 1/2 to 1 inch in diameter.

The hops are fully mature and ready for picking when two changes take place. First, immature hops have a damp, soft feel and when squeezed slightly tend to stay compressed. Mature hops feel more like paper, spring back when squeezed, and feel noticeably lighter. The second key test is to pick an average hop and cut it lengthwise down the center with a knife. When ready to pick, the yellow powder (the lupulin sacs containing the essential oils and bitter compounds) will be a dark shade of yellow, like the stripes on a highway, and it will be pungent. If a light shade of yellow then its likely the hops are immature.

When ready to pick it is best to snip the stems of the cones with scissors or a knife to avoid jarring the hops and knocking lupulin powder out or worse, pulling the center of the cone out with the stem, causing a great loss of lupulin. Touching hops plants can cause skin irritation in some people; gloves and long sleeves can help in this matter.

Just-picked hops are roughly 80 percent water; if left alone they spoil rapidly. For proper storage most of the water is removed by drying. A good drying method is to lie the hops on a card or screen in an attic. Just a few hours during the heat of summer or a few hours more in cooler weather is enough to dry the hops. Use a before and after weighing (and trial and error) to try to achieve about 7-10 percent residual moisture after drying.

After drying, hops keep best at low temperatures and away from oxygen. A kitchen freezer easily takes care of temperature but to get the hops away from oxygen is difficult. Tightly packing hops in canning jars will minimize the trapped air but be careful not to use too much force and break the all important lupulin sacs since this accelerates oxidation. Purging the canning jar of oxygen by blowing in carbon dioxide from a keggung system will also help prolong freshness.

It's common to get 4 or 5 harvests per year by picking the biggest, most mature hops every 2 weeks or so as the flowers ripen. Patience and judgement are important since cones left on the vine too long turn brown and begin to oxidize and spoil, while immature hops have little lupulin to give.

At the end of the growing season when the leaves have fallen or turned brown, cut the vines at the surface of the soil and if possible remove the twine. After cutting back the vines a layer of 3 or 4 inches of mulch and composted manure can be put over the exposed vines for insulation and nutrition during the winter.

Japanese beetles are the number one nuisance in many areas. A common remedy is to position a "Bag a Bug" type beetle trap about 30 feet directly up wind from the hop vines. There is some concern that the "Bag a Bug" traps may actually attract more beetles than they catch, but that probably depends on the situation. Certain plants such as rose bushes may also attract the beetles, so it's best to keep those plants away from your hops. Also, the beetles' larvae live in the ground, and in cases of extreme Japanese Beetle infestation the surrounding lawn may need to be treated accordingly. A number of other pests, such as aphids, can harm hops, and can be treated with any number of pesticides. Since you will be consuming these hops, you should use low toxicity natural pesticides, such as 1% Rotenone dust, for direct pest control on the plants. As with any consumable, you should ensure that any pesticide is well washed before using the hops.

Ladybugs are the best, most natural way to get rid of aphids and a lot of other bugs. However, it can be difficult to keep them on your hop plants once you run out of food for them. A good idea is to plant some cilantro/coriander between your hop hills. Ladybugs are attracted to this plant and it will keep their attention between feedings of aphids. You can even harvest the cilantro (the leaves) for cooking and use the coriander (the seeds) in Witbier.

One other hazard is animals. A short fence of rabbit wire will keep cats, dogs, rabbits, etc. at bay, but won't do much against deer.

Rhizomes are available from an increasing number of sources. American Brewmaster in Raleigh, NC and Freshops in Philomath, OR are two well-known suppliers. Cost is usually a few dollars each. They should be kept in plastic bags, moist and cold in your refrigerator until they are planted.

Additional information about hop growing can be found in "Homegrown Hops" by David R. Beach. Also, the 1990 special issue of "Zymurgy" is devoted to hops and contains an article about growing hops by Pierre Rajotte. The AHA also has additional hops-oriented publications.

Subject: Re: Agrees with COPS show, et al.

Whoa, now! Before everybody starts slagging John (the Coyote) Wyllie, let me say a few words on his behalf:

Mr. Wyllie holds an important position at the ACME (tm) Co, as a product tester and risk analyst. Some of you may have seen his product demonstrations on Saturday morning TV, where he gets run over by steam-rollers, hit by large spring-powered boxing gloves, zooms around on jet roller skates, rides enormous sky-rockets, has close encounters with falling anvils, explosives, catapults, giant mouse traps, etc., and falls off cliffs a lot. His expertise in risk assessment is unparalleled and gives him a unique viewpoint that is denied to many of us.

Higher alcohols are poisonous and many distilling companies adjust their fermentation processes to produce more of them, since they have considerable economic value as solvents, paint thinners, etc. They also take careful steps to make sure that it doesn't get into the potables. Some are a little less careful than others; the "cheap booze" hangover is one result.

Reading Snuffy Smith cartoons does not constitute a good education in distilling, nor does watching TV. If you let the temperature on your slobber box get too high, just be sure that you take the first drink.

As regards to regulations, think for a moment how regulations come about. The vast majority of regulations come into being because something bad has happened, and people don't want it to happen again. So they go to an enormous amount of trouble to get some pack of legislative critters to pass a regulation. Just try getting a law passed that prevents some fat-cats from ripping off the rest of us, and you will see exactly how troublesome a process regulation is.

When taxation is involved, it gets even stickier, because the regulating agencies now have an interest in the outcome. Can you say "conflict of interest?" Higher taxes frequently mean bigger budgets, larger staffs, higher salaries. This sometimes leads the regulatory process astray.

Here in Washington State, where the notorious COPS ephisode took place, we are priviledged to have some of the highest alcohol taxes in the US. We also have the Washington Liquor Control Board, which keeps us amused with continuing tales of pilferage, bribery, crime and corruption.

I remember several years ago, when one of the commissioners was caught red handed replentishing his private stocks out of a State warehouse. More recently, a Seattle TV station ran a muck-raking piece on a "training conference" that the liquor industry threw for all the State Liquor Store managers. It was held at a resort in Coer d'Alene (bad move, taking the business out of the state) and mostly consisted of getting falling down drunk while being harangued by liquor sales reps.

I'm waiting to see this on COPS. I suspect it will be a long wait.

Paul.

From: Bob_McIlvaine@keyfile.com
Subject: Make Your Own ...

What with all the comments about making your own malt mill going round, I had to chime in.

A roller mill is a pretty basic mechanical device. If your looking for ideas for designs, check out Dave Gingerys' book about building your own sheet metal roller. He shows you how to make it with hardware store stuff and hand tools. This book is part of a series he wrote about making your own metal working shop from scrap. The series includes a book for each of the following: make your own foundry, uses the foundry and hand tools to make a metal lathe, use these to make a drill press, use these to make a milling machine, and use these to make deeelux accessories for all of the above. Daves' books are available from Lindsay Publishing. By the way, I have the entire set and it can be done.

Be forwarned, as those who have noted in previous postings, making it for yourself ..IS.. different than producing a retail product. When I designed the BruTemp digital brewing thermometer, I found out first hand!

From: Drew Lynch <drew@chronologic.com>
Subject: Wyeast lag times / viability / dry yeast

Lately, there has been a bit of liquid yeast bashing going on. I, for one, use it nearly all the time. The only time I revert to dried yeast is when I decide to brew on short notice. I encourage other folks to use liquid yeast as well.

The more I thought about it, the more I realized that there are several issues not clearly defined, that may well effect brewer's success using the liquid yeast.

Wyeast advertises that the older the package, the longer it takes to swell. The age of the package is an indication of the efficiency of your retail source. I purchased a package of Wyeast American Ale last night from The Fermentation Frenzy in Los Altos Ca. It was dated Oct 20. I burst the inner pouch at about 7pm last night, and it was quite swollen by 7am this morning. I have had older packages take 3-4 days to reach the same point.

Aerate, Aerate, Aerate! I use a pump driven CF chiller. After reading a few posts on the subject (thanks!) I attached a small homemade nozzle to the outflow. I now get huge amounts of foam and (I assume) dissolved oxygen in the wort.

I have found that lag times increase drastically with increased temperature differential between pitched yeast and receiving wort. I have gotten < 8 hr lag times pitching just a swollen Wyeast package (no starter) when the temperatures are well matched. Remember that dry yeast benefits from a higher rehydration temperature, and therefore may be more tolerant of warmer wort.

I usually do use one or two steps between swollen package and pitching. I like to be certain. There is one gotcha here...each step is an opportunity for infection. Be vigilant.

I am also curious as to when people consider the package swollen. If an older package is procured, folks may see that the package has marginally increased in size, and then use it -- dont! Wait until it is difficult to compress the package between thumb and forefinger. I have been tempted to let one package go until it bursts, just to see how far I can push it.

From: "Stephen E. Hansen" <hansen@Sierra.Stanford.EDU>
Subject: YACFC, Yet Another Counter Flow Chiller.

Last week I decided to build a counterflow chiller (I had been using an immersion unit previously). I debated whether to use a garden hose or a piece of large diameter PVC pipe to enclose the copper tubing and went with the hose for simplicity's sake. I have seen one or two commercial versions of counterflow chillers that use something that looks like coiled copper in a section of PVC pipe but I couldn't find end caps that looked like they would work without more work than I wanted to put in.

What I did was buy a 50' 5/8" ID garden hose and 50' of 3/8" OD copper tubing. In addition I bought two hose end replacement connectors, one male and one female, and two of those Y hose connectors with the built in ball shutoff on each leg of the Y.

I took the hose and cut it in two with 30' left on the piece with the male connector. I slid the copper tubing through the hose from the cut-off end until about 12" stuck through past the other end. Then I cut the copper tubing leaving about 12" on both ends. The male hose repair connector went on the cut end. Getting the last ten feet or so of tubing through the hose took some elbow grease but persistence paid off.

Next I took the Y adapters and slid the copper tubing up the trunk of the Y and out through one of the legs until I could screw the Y onto the hose end. This was a bit tricky but if you counter-twist the hose before mating the ends it works pretty well. The hard part was getting the copper tubing past the ball valves in the Y. One fit perfectly but the other had to be drilled out with a 3/8" bit. The fit of the copper tubing in the Y is essentially watertight on one of the connectors but the other leaks a bit. I'll probably put some silicone sealer in that one. Once the Y connectors were on tight I just recoiled hose to about a 12" diameter and loosely tied the coils together.

As for the female replacement connector. That goes on the cut off end of the 20' piece. giving me a short hose with two female connectors on each end. You need this to connect to the inlet of the chiller.

The remaining copper got turned into a siphon cane and an aerator. The aerator was build from the description by Spencer Thomas in HBD 1081 and it works great.

The next day I made an IPAR (an IPA with Rye) and the chiller worked like a champ. Compared to my immersion chiller this is MUCH easier and faster. The wort outflow wasn't much warmer, if any, than the tap water inflow. The tap water flow rate is your temperature adjustment in this setup and I was able to use a fairly slow flow of water. Obviously, with my current water temperature I could have gotten away with a shorter chiller but the water temp will warm up a bit in the summer.

I siphoned the hot wort off the hops and hot break material in the kettle and into a plastic bucket with a tap valve at the bottom. The copper scrubber in a mesh bag tied to the end of the copper siphon wand did a good job of keeping things clear. I took the bucket full of hot wort and set it on top of the washing machine. The chiller sat just below it on a stool, a 5 gallon carboy sat on the floor. Plastic tubing went from the outlet of the tap valve to the inlet of the

chiller. More plastic tubing went from the outflow to the aerator wand stuck in the carboy.

Subject: Beer Drinks

Mark Stickler describes a Rocky Mountain Oyster Cocktail (Coors, raw oyster, etc.). I always thought Rocky Mountain Oysters were what was left over after you removed the steer from the bull. Don't know how they go with beer though.

Friends of mine who frequent Barclay's pub in Oakland, CA (28 taps of micros, regionals, and imports only) have been experimenting with topping various brews with a few ounces of Old Foghorn, e.g., Foggy Night in Dublin (Guinness & Old Foghorn), etc.

Subject: Immersion chillers / Brewkit ingredients

For those of you using immersion chillers out there, here's a way to get much higher performance. Stirring the hot wort periodically REALLY speeds the chilling. If you have enough clearance between the chiller coil and the sides of the brewpot, you can stir the wort simply by grasping the ends of the chiller and swishing the wort around. You will notice that you'll feel the outflow pipe suddenly get warmer : a sure sign that you've increased heat transfer.

If you leave the chiller sitting in the bottom of a still brewpot, the wort will tend to stratify into hot and cold layers. Since a large part if not all of the chiller rests on the bottom, convection does not aid in chilling. Conduction is the primary mechanism for transferring heat from the upper layers of wort to the lower coil, and that is sloooow.

I've found that a couple of seconds of swishing once a minute is more than enough.

Here's a question that's been bothering me for a while. I have two cans of hopped malt extract from England (Geordie and Boots). On the list of ingredients, both of them list "Barley and Malt extract" as the first two ingredients. I thought that "malt extract" was made from barley. Why are they listed as two different ingredients ? Is there some other fermentable in the can that didn't come from barley ?

Thanks for all of the advice on hot priming. I used this technique on my last batch and have yet to receive the court summons. The bottles seem to be carbonating well.

Subject: Re: #2(2) Homebrew Digest #12...

I recently converted a 15.5 gall. SS keg with a ball valve spigot. The end of the SS nipple with 90 Deg. elbow inside the keg ends about 2 inches away from the center of the keg. Will the trub that is formed by whirlpooling be likely sucked out of the drain because of it's location? What is the proper way to whirlpool? Alternately, would it be easier to remove trub by adjusting the 90 Deg. elbow so that it's is just above the settled trub layer if not whirlpooling? COMMENTS APPRECIATED.

Subject: What do 'phor' mean?

>Question: Someone posted something regarding IODOPHOR in this or a
>previous HBD: what does the -phor designate in the name IODOPHOR? I
>have used BTF iodophor which doesn't contain phosphoric acid and I have
>recently obtained an iodine sanitizing solution that *does* contain
>phos. acid. What gives?

My best guess was that it comes from the Greek root '-phoros' for
'to bear' so that iodophor is a substance that bears iodine. My
dictionary seems to confirm that.

I'm not sure what the hell they put phosphoric acid in it phor
(snicker.) Probably it's to act as a surfactant, as it is an
ingredient
in some soaps and detergents.

ObDiane'sSig: Not to pile on Mr. Lyons or anything, but I got no
problem with Diane's .sig. I mean, 'orgasm' comes from a Greek word;
it
HAS to be respectable. :-)

ObMashoutJihad: For the most part, I'm with Imam Campanelli on
this issue. My only exception (so far) is for oatmeal stout; skip the
mashout when so brewing and the Great Satan known as Set Mash (*
ptui*)
will plague you for hours.

Later...

Matt> Matt Rowley
Matt> rowley@kuhub.cc.ukans.edu

A while back I bought some Special B to "experiment" with. I took an old Anchor Steam clone recipe and replaced 1.5# 40L domestic crystal malt with 1# Special B. The resulting beer is roughly the color of a typical brown ale, and the contribution of the Special B is pretty apparent -- a sweet toffee flavor, not at all the "burnt" flavor of darker roasted malts (chocolate, black). This beer is probably more like a Scotch ale than a Steam beer, but the big load of Northern Brewer hops are pretty evident too (note that I haven't yet used the words "pleasant" or "balanced" to describe this beer :-)

I think a full pound of this stuff would be a great way to get started on a Scotch ale recipe, but for just about any other style I'd scale it way back, and I can't think of a reason to EVER use more than a pound in 5 gal. I'm planning a sweetish Brown ale next, and expect to use about 3 oz special B in that one.

While we're on the subject, I just received an order of DeWolf-Cosyns malts (hi Al!), and would like to hear what others have found with the other specialty grains -- I'm planning on "kitchen sinking" the brown ale with some of the buiscit malt, aromatic malt, and chocolate malt on top of the base pale ale malt and Special B. Any suggestions?

Subject: Spruce essence

I made a spruce beer not too long ago. It was a honey/spruce ale, going off the recipe in TNCJOH with a few modifications. I was all set to buy my bottle of spruce essence at my local homebrew shop (It was a two ounce bottle-I don't remember the brand) when my friendly homebrew guy told me that I didn't need the whole thing. He said to ignore what TNCJOH said because it just came out way too powerful.

Being a friendly homebrew guy, he put just a few drops of essence into a plastic bag and sold that to me (saving me some bucks in the process). I put the essence in my wort, adding it at the end of the boil (I think)

After brewing, I took a tour of the Celis brewery and, well, to put it frankly, imbibed a bit that evening. I was a little under the weather the next day and all I can remember smelling was that damn spruce essence. Everytime I had one of those damn beers it made my head ache.

My friends, however, seem to enjoy the beers. They didn't think there was too much spruce in them. So I guess my point is that just a few drops should do the trick. At least that's my experience.

P.S. I made a Wheat beer with the Wyeast and it came out great.
P.P.S. Our first brewpubs are opening up late this month/early next

|| quality, custom screen labeled bottles, caps, and quality||  
|| wooden cases. The same    ||
```

In the latest _Barleycorn_ (a bimonthly tabloid for brewing, micros and brewpubs in the Mid Atlantic states), there is an ad for Graphik Conspiracy for color labels.

"We will make labels to your specifications, with any design, theme or lettering...Custom-designed, full color labels start at \$90 for quantities of 150 or more."

Graphik Conspiracy, PO Box 2332, Centreville, VA 22020, 703-222-8492.

I present this for information only. Please note the price quoted is for "custom-designed," if you have your own design ready to go, it should be a lot cheaper, but then you could prolly visit any decent print shop and get good work. Color labels would generally be spot color, not four color seps work. A brewing friend had a label designed by a mutual friend who is a printmaker, and had the the labels (black and grey halftone, no color) printed at a local shop. Looks nice.

Subject: CO2-purging/HBD topics

Rob writes:

>I have found that the food grade containers that deli's use are good
>for storage of grains. I think the square mayonnaise containers work
>best. They are the easy to clean and the lids are fairly easy to
>attach and remove. I recommend filling them to the top and purging
>with CO2 to keep the grain as dry as possible.

I had thought about purging my grain buckets with CO2 also, but before I did, I filled a empty bucket with CO2, threw in a humidity meter and sealed the bucket. After 15 minutes, it read about 55% humidity.

Granted,
this was a cheap, dimestore humidity meter, but it convinced me that CO2 is not dry. Instead, I've purchased some, reusable, dessicant canisters (about \$8.00 each from a lab supply place) and put one in the bucket just after pouring in the grain. I've measured the humidity inside the bucket after a day with the dessicant and it was around 25-28%

Lately, there have been a lot of articles posted on fringe topics. I suggest that we try to restrain ourselves and try to concentrate on homebrewing, especially when the digest begins to slow down as it has recently. Fast turnaround for questions is rather important since sometimes many posters are tempted to answer a question when they notice it hasn't been answered for a while and then suddenly, two days later, there are ten responses.

Subject: Re: Going all-grain

Ed Wolfe asks about all grain equipment in HBD #1254 (sorry to take so long, I'm behind in my reading :-() :

I just recently went all-grain and have tried 2 approaches for an insulated mash/lauter tun. One was a Coleman 40 qt. rectangular cooler and the other was a 5 gal SS stockpot in an insulated box. I found that over a 90 min mash, the cooler lost ~5 F degrees. The insulated box lost 0 F degrees. I am sticking with the insulated box! The other advantage of the insulated box is that I can take the pot out to raise the temp (say to go from protein rest to sacchrification rest). Here is how I built mine:

1. Buy a Hewlett-Packard 700 series workstation. Throw out the workstation and keep the box. (Note 1)
2. Get some styrofoam sheets from your local building supply store. I got 2"x2'x8' sheets and some 1"x2'x8' sheets.
3. Cut the styrofoam to put a 7" layer of styrofoam on the bottom of the box. I found a wallboard saw worked best for cutting the styrofoam (especially the 2" stuff!).
4. The next section is for the pot. Put down enough 2" layers to cover the depth of the pot. Then cut a hole in the middle that just fits your mash tun. Cut the hole a little tight and use a propane torch to "seal" the edge so you are not plagued with little styrofoam balls every time you put the pot in/out. My hole is a little off-center but the minimum wall thickness is 3".
5. Cut the styrofoam so there is a 7" layer for the top.
6. Tape the layers that make up the top together so you don't go crazy trying to take the top off. BTW, I also taped the "pot" section together so that the layers don't come apart when I take the pot out.

Note 1: OF COURSE I have a financial interest in Hewlett-Packard! How do you think I got my box?

Second of all, I would recommend getting the stuff to allow 10 gal batches right away if you expect to go that route. If you build an insulated box as I described above, you might need to build that over as well as buying lots of new pots. I don't think that 7.5 gal will be enough for a mash tun for a 10 gal batch though. With my 5 gal stockpot, 8# of grain & 8 qts of water (which is a rather thick mash) takes up about 4 - 4.5 gal.

Subject: Maiden Voyage + gadget help

Last night I brewed a mild and used my new wort chiller for the first time. In my usual fashion, I didn't make sure of details ahead of time. I was going to hook up to the laundry faucet in the basement, but had leaks. Ended up going outside and hooking up to my garden hose. Sooo, one of those neat kitchen faucet adaptors is in order... BUT I have to say, these things are great! If you don't have one, get one! BTW, mine is called Phyllis (groan..). I am modifying a Rubbermaid/Gott 5 gallon water jug for mashing. I bought a spigot at my local homebrew shop to put on it (twist to leave open). I had to enlarge the hole to fit this spigot. The SAD thing is....the threaded part is too short and doesn't go all the way through. I need a longer one! Does anyone know where to get these? Has anyone else had this problem and come up with a good solution?

Thanks,
Sandy C.

Subject: airlines, porter, brewbup, Sheath and Vine

Just a few interesting tidbits:

Yesterday my wife tried to take 4 homebrews on American airlines out of Raleigh-Durham and was stopped at security. Although the bottles were capped, since they had no label she was not allowed to bring them into the passenger cabin. They said they could be stowed in the luggage but we declined, fearing depressurization problems.

On the DIScovery channel last night (Oct.27), they had a small piece on salvaging 1825 Flagg Porter from a sunken ship off the coast of England, saving the yeast, bringing it up to "health" for 6 months, and culturing a true porter using a Victorian era recipe.

Re: Swan V. Taylor's request for info on brewpubs in the Chapel Hill area. There are none in Chapel Hill, one in Raleigh (Greenshields)

, and one in the Winston-Salem area (Lagerhead or Loggerhead?) that I know of. the one in Durham (aka:Weeping Radish,etc.) bit the big one!

Also sorry to hear Al's mailorder is shutting down.

Subject: Beer hunting in Belgium: Part 7 (General information)

(My apologies if this gets posted twice--with a 4 day wait between posting and appearance I forget. Must be getting a cold...)

Beer Hunting in Belgium: Part 7 of 7

General Information
(by Phil Seitz)

The following information is offered for anybody considering travel to Belgium. These are the bars we like, sources we found useful, and a few additional places we went that you might not find in the guidebooks.

Cafes:

L'Eblouissant. 27, rue Armee Grouchy, Namur. 081/73.71.39.

A small cafe run by a very particular publican. Extensive beer selection, well cared for. Good meals during lunch, with food also available during dinner. Frequent concerts of Irish music. Previously called one of Belgium's best cafes by CAMRA, now relocated due to high rents but still very comfortable. Closed Sundays.

Musee de la Biere (The Beer Museum). 19, rue de la Gare B/2, Lustin, on Route #947. 081/41.11.02

A funky place in a small town. Until last year nobody I know in the area had ever been there, though everybody knew about it. The reason is that it looks a bit weird from the outside. The exterior has hand-painted signs advertising over 1,000 Belgian beer glasses on exhibit, and God knows how many bottles, some of them dating from the 19th century. Looks a little like those roadside attractions advertising plaster-of-Paris dinosaurs and two-headed cows. Admission is 35 francs, which can be applied to a purchase in the, er, gift shop. The gift shop features 11 beers on tap (including the formidable Liefmans' framboise), as well as a good 100-200 in bottles. The interior is crammed with shelves of bottles and glasses, and many of these will actually be of substantial interest to beer geeks. Overall, a very pleasant atmosphere.

If you speak French, the woman who runs the place is famous for being talkative and very well informed with regard to beer issues and developments in Belgium. The cafe is also home to a tasting club, the Guilde des Tates-Biere, whose final exam is rumored to include identification of certain beers by year of production.

Lustin is south of Namur, on the Meuse river. The museum is open weekends and student holidays only, but special openings can be arranged for larger groups.

De Stillegentier. Mechelen.

We did not visit this cafe, but it was recommended to us as stocking nearly all the lambic and gueuze products currently on the market. Hey, we had to save something for next time!

Beer stores:

La Cave de Wallonie. 6, rue de la Halle, Namur
Near the Place au marche de legumes. A specialty beer

store run by one of the brewers of the Brasserie Caracole. The proprietor speaks some English, and if time permits is quite willing to discuss brewing issues and beers.

Drinks Wets. 209 Steenweg op Halle, St. Genesius-Rode.
02/380.32.27

This one's a whopper. We ran into it when we got lost on the way to Beersel, and Jim accurately described it as the Belgian liquor barn. They sell a mind-boggling variety of Belgian beers and beer glasses, as well as selected imported beers. (Good: We found Anchor Liberty. Bad: They stock Rolling Rock.) The proprietors do speak some English, and they take Visa but no other credit cards. You'll need a car to get there, but a truck might be better. The gueuze/kriek selection alone ran along an entire 35-foot wall. Perhaps the most unusual of these was the Gueuze and Kriek Girardin in polypins. Just the thing for Mike Sharp's next party!

Some notes: check expiration dates. Some of the old bottles you'll find are aged; others are just old and out of date, and taste that way. Keep an eye out for the Hanssens gueuze products; we considered these a major discovery, and their mention met with respect from our more knowledgeable Belgian beer sources. The Wets gueuze products are also available (presumably the owners of the store are the Wets of lambic blending fame, though we were told by others that the beer is now made by the still-formidable Brasserie Girardin).

Other stores

1) Spice stores sometimes sell bitter (curacao) orange peel. It's hard and white, and bitter tasting. One such store is L'Herbier in Namur, around the corner from La Cave de Wallonie.

2) Don't forget the ordinary supermarkets. Most of them sell dark and light candy sugar in 1 lb boxes, and many have formidable beer selections, including local brews and glassware. Jereboams (3-liter bottles) are widely available, and the Sarma Star hypermarket outside of Namur must stock at least 100 beers--and the glasses. Keep in mind that a charge for the deposit on each bottle will be added at the cash register. On the other hand, the larger supermarkets take credit cards, so you can spend now and pay later.

Books

We really only used two books and a map as constant reference materials. One book was Michael Jackson's Beers of Belgium, which is available from a variety of sources. The other book was Peter Crombecq's Bier Yaarboek, which is not easy to find (check better bookstores in Brussels and Flanders). The former provided us with general information in a language we could read, and proved to be reasonably comprehensive in scope, if not always providing the obsessive depth we craved. The Crombecq comes in handy here, with detailed information on the breweries (in Flemish), as well as lists of all their products and the names these are sold under. This is extremely useful information that beer hunters can draw upon to make sure they don't unwittingly buy ten bottles of the same beer.

CAMRA now has a good beer guide to Belgium and Holland, which lists much of the above information and includes reviews of cafes. As far as I know copies are only available in England, L'Eblouissant had one.

THATS ALL FOLKS!

This concludes our Belgian series. If you have any questions we hope you'll let us know; Jim [BUSCH@DAACDEV1.STX.COM] may be better for the technical brewing ones, and me for the ones on Belgium in general.

> For anyone that enters a specialty beer in a contest, be aware that
the
> judges in that category are subjected to a lot of widely varying
beers and
> have a hard time picking the right one, the judges' taste preferences
> really are the major factor.

Speaking as one who recently judged specialty beers in a competition, I have to mildly disagree with this statement. We tried hard to evaluate each beer on its merits, according to the "style" it said it was supposed to be. Thus, a "Vanilla Ale" would be expected to have evident vanilla flavor, blending nicely with some malt, and almost certainly low hop flavor (this is where my personal taste may come in, as I can't see vanilla and hops going too well together, although I'm willing to be convinced otherwise -- send bottles!) And, of course, it should be a well-made beer.

Still, the two of us ended up having to negotiate on the top three in the category (as I recall, the first place was "obvious", but there were three beers in contention for the next two places).

And, there were beers that were really hard, because we didn't know what the specialty ingredients "should" taste like. One example was a really nice "wild ginger" beer. It didn't taste anything like ginger, but neither of us knew what "wild ginger" should taste like. In any case, it was a good, well-made, very drinkable beer, that ended up taking fourth place (out of 12).

O.K. I'll bite. What are these other problems. I find that the only way I can effectively use liquid yeast in my schedule is to pitch it into a starter in advance and then brew the moment I have the time. Sometimes it is just after Krausen but other times it is several days after the yeast has fermented out.

I am familiar with a number of homebrew clubs, each with varying degrees of formality. The least formal of these would meet in a different member's house each month, had an occasional presentation (every 3rd month or so), and mostly drank and *critiqued* beer and socialized. Other more formal clubs have a specific meeting place, follow a clear agenda for each meeting, always have presentations, and treat socializing as what you do *after* the meeting.

My own club, the Mash Tongues (Ft. Collins) is somewhere in the middle. Over the last year or so, the number of presentations has dropped off a little bit and the club has lost a lot of focus. So what did we do? Well, a number of us who wanted to see more things happen ran for office and are doing something about that. We've been fairly successful at getting the members to contribute ideas and add to our planning sessions so that the club meetings are more interesting. Here are some of the ideas that we've talked about/started:

- * presentations aimed at beginning brewers

Many of our members are just getting started, so presentations on general extract brewing techniques and ingredients are valuable.

- * presentations aimed at sophisticated brewers

Among the more experienced brewers, there is an interest in subjects like decoction mashing and yeast culturing.

- * beer judging sessions

These sessions teach members about flavor/aroma perception and the judging forms, etc.

- * club-only beer selection

We set up a panel to judge which beer should represent our club in the nationals.

- * beer tastings

Some of the beer drinking at our meetings takes place somewhat formally, where a majority of the club members can all taste the beer and offer opinions and feedback.

- * presentations by local (professional) brewers

Here in Ft. Collins, we have a great resource with the multitude of local brewers.

Other presentation ideas include brewing gadgets, cooking with beer, beer styles, a yeast experiment, etc. Until recently, we've been meeting in the back of a local bar (which isn't very good) and before that, we met at the local breweries. We've finally found space with the local homebrew shop so we can meet there regularly starting in January. I think that drinking beer and socializing are an important part of what I want from my club, but certainly not the only thing.

> keg and what kind of results/problems can I expect, particularly with
respect
> to the use of gelatin? Thanks in advance folks.

>
I used to clarify in my kegs using gelatin. It works fine but leaves a lot of sediment on the bottom that the pickup tube draws upon giving very cloudy beer for quite a while. My cornelius kegs have tapered bottoms so the yeast sediment just kept being drawn to the pickup tube. My solution was to cut one inch off the pickup tube and that cured a lot of the problem. Now I clarify in a glass carboy with gelatin and then transfer after a week to the keg just because it leaves a lot less sludge in the keg. I still cut off an inch on the pickup tubes on any new (used actually) kegs I acquire, that way any amount of sludge stays on the bottom where it belongs, not in your beer (this only wastes about a cup of beer when you've finished the keg). You'll also notice that if you keep your keg cold that any slight appearance of protein haze will settle out after a week and the beer will be sparkling clear, just another great benefit of keggering!

May your beer give you great head!!!!

Subject: Hops FAQ, Part 4/5

Hops FAQ, Part 4/5:
- - -

Q: What is dry-hopping? How do I do it? How much do I use? What type? What form of hops?

A: Dry hopping can be defined as adding hops to a cooled wort at sometime during the fermentation process. It adds a fresh hops aroma/flavor to the beer which cannot be matched with hop additions into hot wort. It is not to be confused with finish/aroma hopping, which is done on the hot wort while still in the kettle. The use of a hop-back, where hot wort is passed through the hops, is another form of finish hopping; it is not dry hopping. Dry hopping gives little or no alpha acids to the wort, so it contributes little or no bitterness to the final product.

There are several ways to dry hop, if one considers the variations of making hop teas, etc. The best time to dry hop is generally considered to be after primary fermentation has slowed and little CO2 is being driven off the wort. Dry hopping earlier than this point is inefficient as the volatile hop oils are scrubbed away by the exiting CO2. Also, if using pellets, dry hopping early in the fermentation phase may result in the hops (which will sink to the bottom) being covered with yeast and inefficient extraction of aroma.

The proper length of time for dry hopping is dependent on the temperature. At ale temperatures, 7-14 days of contact time is widely used. At lager temperatures, although little data is available, it seems obvious that longer contact times, on the order of 14-21 days, are called for. It is common to use 0.5 - 2.0 oz. or more in a 5 gallon batch, but as always it is up the individual's preferences.

Fuggles, Northern Brewer, Saaz, Cascades, all Hallertau variants, and many other hops have been used successfully. It should be noted that the aroma of the beer greatly influences the profile, and that the "correct" aroma hop should be used to match the style (i.e. English hops for English ales, German hops for German lagers, etc.). American brewers have traditionally used hops from all

over the globe so European hops, for example, can be used without much fear of an ungodly mismatch.

The first and foremost way to dry hop is to simply put the hops into the fermenter. The most common worry with this method is about infecting a beer which is nearly ready to bottle/keg. Hops are natural preservatives, and infections from this method are unheard of. If loose hops or plugs are used, they will float, and many use a sanitized hop bag and marbles to sink the hops for maximum contact. If pellets are used they will sink, but may be difficult to avoid when bottling/kegging. Also, the pellet hops can be easily covered by yeast falling out of suspension, so they should be added after virtually all fermentation activity has ceased, and a good amount of the yeast has fallen.

Another method used to dry hop is to steep the hops in a warm white alcohol (grain, vodka, etc.) and sometimes water solution for hours or days, then pour this solution into the fermenter. This is a common practice among those who want to protect against the remote possibility of infection with normal dry hopping. It should be noted that as the temperature of the alcohol/water/hops mixture is raised, the effect approaches that of finish hopping, as the most volatile hop oils are driven off.

Adding hop oil, a product recently introduced to the homebrewing market, is another way of "dry-hopping". It should be done after primary fermentation has slowed for the same reasons.

These dry hopping methods, and others, will produce different results, mainly because the desired compounds are so volatile. The variety of reactions taking place during processing and fermentation will affect the results. The "best" method is the one which gives the desired result to the individual homebrewer.

A final note about dry-hopping: the volatile hop compounds will react quickly with oxygen. For this reason, extra measures should be taken to avoid mixing with air during bottling, in order to retain the hop aroma in the bottle for extended periods of time. These extra measures may include the use of CO₂ purging the bottling vessel, very quiet siphoning, oxygen scavenging caps, and possibly delayed capping (up to one hour). This method allows any CO₂ coming out of solution during the bottling process to push the oxygen out of the

bottle before the caps are secured. This method is used by some homebrewers but the results are inconclusive. The simplest method is to use the oxygen scavenging caps, which requires no extra effort and little extra cost. For further reference, the Summer 1993 Zymurgy contains an article by Mark Garetz on this subject.

- - -

Q: What is a "hop-back"? How is it used?

A: A homebrewer's hop-back is a reservoir connected in-line between the kettle and counter-flow chiller. It is filled with fresh hops before the flow is started. The hot wort flows through the fresh hops and is quickly chilled by the counter-flow before entering the fermenter. Many of the volatile hop aroma compounds are extracted and brought into the fermenter with this process. It is generally thought to produce a flavor/aroma profile somewhere between late kettle additions and dry-hopping.

- - -

Q: Can I use fresh hops rather than dried hops? How much do I use?

A: Yes, you can but at best it is a rough guess as to how much. The rule of thumb is to use 6 times as much (by weight) as you would dry hops. A safer rule would be to do this and to only use them for finish/dry hopping. This is because the AA% is unknown, and later additions are less sensitive to AA%. It should be noted that homebrewers have had mixed results when using fresh hops (poor AA approximation for bittering, grassy aroma for finishing).

Subject: Trip Report

My wife and I just got back from 2 weeks in Belgium and The Netherlands, mostly Belgium.

Q: Is Belgium beer heaven?
A: Yes.

It wasn't a beer hunt, just vacation, but I'm guessing that I consumed 30 or 40 different beers, mostly in towns and small cities, in whatever tavern or cafe we happened to be walking past when hunger or thirst happened to strike.

High points:

- o They ALWAYS served the beer in the appropriate glass. Not just the right size and shape, but it also had to have the beer's logo on it.
- o Rochefort 8.
- o The lady at the desk in our hotel in Leuven was very proud of the fact that Pierre Celis used to brew beer in her town. She was pleased that I knew of his beer.
- o The coffee.
- o Chimay Bleue was about 2 bucks in a bar, a little over a dollar (33 cl bottle) in the grocery store (about the same as American Bud).
- o Budvar in the grocery stores.
- o We rented bikes in Oudenaarde and stopped for a breather at a tavern way out in the sticks. I was sucking on a Liefmanns Oud Bruin, and my frau was attacking a Liefmanns Kriek, both "van het vat" (on tap). She was the designated kriek taster; this one turned out to be her favorite. The beer delivery guy dropped off a couple of kegs, proceeded to sit down to the bar and down a couple, hopped back in his truck and was off to his next stop.
- o Bartenders are mostly quite knowledgeable about the beer they serve. And they drink it while serving.
- o Maastricht.
- o On schedule trains.
- o Domus, a brewpub in Leuven.
- o Brand Emperor.

Low points:

- o Belle Vue anything.

- o Most Belgians drink Jupiler (the country's industrial swill) or Stella Artois (a regional industrial swill).

- o Amsterdam.

Q: Is Heineken better in The Netherlands?

A: I'd probably have to be there at least a month before I could work my way down to a Heineken. Although I did try their Tarwebock, and it didn't suck.

I'll submit my impressions of Amsterdam in alt.sex.drugs.rock.and.roll.

Subject: Brass in the boil

A week ago, Andrew asked about brass in the boil. I have a brass fitting inside of my boiler as well, so I'm also curious to hear the answer. As far as your ball valve attached to the outside, if it gets anywhere near as hot as mine, it will be sanitized. I put a 4" nipple between my pot and valve to get it away from the heat (I also hang a wet rag over the nipple to keep it cooler). I use a CF chiller with this system, though, so mine gets piping hot wort run through it (no sanitation worries).

Old Lucifer update: 1.036 after 5.5 weeks. The yeast (started with Wyeast London Ale, pitched Wyeast British Ale later) is apparently giving up, since this beer is starting to get very clear. As much as I hate to do it, I may have to punt (i.e. pitch a frog yeast). And that's SG for the nitpicky coyote!:)

Cheers,
Norm

are
> these beers made with extremely light malt instead.

You're close. Most American mega-brewers use large percentages of corn or rice, but usually flaked or powdered grains rather than sugar. The corn or rice adjuncts are converted to sugar by the barley enzymes. This is one way of providing more fermentables without adding much color or flavor (or cost; processed sugar is comparatively expensive). Too much sugar can also produce undesirable "cidery" flavors in your beer.

Also, the mega-brewers (at least around here, Coors and Anheuser-Busch) often have specially grown varieties of barley that are specially malted. Typically, the malt is not cured, or roasted after drying, resulting in malt that is paler than you can usually find at the homebrew shop.

My advice on making a mega-brew clone: use the palest malt you can find, and use a large portion (maybe 25-30%) of flaked corn or rice extract. Most mega-beer also has less alcohol than a typical homebrew, so shoot for a lower gravity beer, maybe 1.035-40 OG. This means a higher ratio of water to grain, which will also lighten it.

Your beer may not end up quite as pale as a Bud, but I'd rather have my homebrew a few shades darker in color and a few shades higher in taste!

Subject: Carbonation

What's up?

I'm currently brewing a brown ale and would like to ask the HBD brain trust about how much I should fee my yeast before bottling. I have always used 3/4 cup of priming sugar for a 5 gallon batch. I read in the Papazian book that you could use as much as one cup, but that you have to chill the bottles and risk some gushers. Should I read "gushers" as bottle explosions, or does it refer to overcarbonation? (I have never had a bottle explode on my and I would rather keep it that way) I would like this beer to carbonate earlier than my other batches, if possible. Once ready, the beer will not stay around long because I'm brewing it for a party, so I'm not worried about it sitting too long and building up too much pressure. Would using extract rather than priming sugar make it carbonate faster? Would I be better off just using the usual 3/4 cup of sugar and making sure the bottles are at the higher end of the suggested temperature range? Should I just stick with my old tried and true method and push off the party an extra week?

Responses through the digest or directly to me would both be fine.
Thanks in advance.

>meade@readmore.com asked about:
>Sorbate/Sulphate
>
>* Potassium Sorbate is a "stabilizer" It will not STOP an
>active ferment but will inhibit initiation of growth. Both
>yeast and bacteria.

Not quite true. Although sorbate does inhibit yeast (only a small amount is needed to prevent your starter culture from working on your wort/must) it does *not* inhibit bacteria. Well, not all bacteria if it does stop some.

In particular, some strains of Lactobacillus remain unaffected. In wine/cider making, sorbate should be avoided in the initial ingredients. It can be added at (or near) the end of ferment in order to stabilise a brew containing residual fermentable sugars - you might be wanting a sweet cider. But in wine making, it should *always* be used in conjunction with campden tablets. (That might also be true for cider!). The reason: sorbate can be decomposed, by a bacterium, to create geraniol which gives a very strong smell of geraniums; the campden is needed to knock out the bacteria.

>You Don't want cider with sorbate. Find an orchard and get
>the fresh pressed- unfiltered stuff. Much worth it!

That's very good advice.

And dspalme@mke.ab.com (Diane Palme x2617) now signs off with:

"In the beginning, it was the Plan."

Now that's not funny! Not the slightest hint of the wry little smile twitched the corners of my mouth like it used to when Diane previously wrote. :-(
(snip, snip... <- that's the sound of my removing the bit about humourless moral policemen and PC speakers. It's the wrong forum. Shrug shoulders, carry on ...)

It's not true either Diane. Didn't John the Evangelist start

Subject: DRE, Wyeast, Etna lables

Hello All,

In HBD #1257 Vic asks about brewing a Bud like beer, and its recipe.
I did a batch very similer with fair results, [although more Miller
like]
and if you notice the ingredients on a Bud it says right there, Rice
Extract, I used 3 lbs DRE or Dried Rice Extract, 3 lbs DME Light Aust.
and
pitched with Wyeast #2308 Munich, useing DRE instead of sugar will
improve
crispness and will prevent the nasty cider taste of the sugar.

I have used both Wyeast #2308 Munich and #2306 Bavarian and have had
good
results, and strange fermentation rates, but still had good brew.

One comment on using Ammonia to remove lables, works great one them,
except, an Etna Lager lable, they use a rubbery glue, the ammonia
helps,
butt... let'em soak a day or two.

Subject: Mash Out (again!)

I had to add some ammo to the recent mash out wars. Note that I do not mash out; I'm looking for reasons to do it. In that vein, I found these sniglets in the Winter 1992 Zymurgy, in an article titled "Beer Stability" by Micah Millspaw (formerly of HBD-fame) and Bob Jones (currently of HBD-fame). Reproduced without permission (typos are mine):

"What is an unstable beer and why should we be concerned about not brewing one? Unstable beers are ones that tend to throw a haze and later have flavor staling and oxidation problems. Oxidation plays an important role in the formation of protein haze and melanoidins function as antioxidants to prevent the oxidation of protein. Melanoidins are compounds formed by amino acid - carbohydrate reactions induced by heat. Oxidation also plays an important part in the production of colloidal haze, hence the name "oxidation haze", first coined by Helm, a German brewing scientist, in the early part of this century. Colloids are particulate matter in a solution. Moreover, the formation of chill haze is considerably increased by oxidation."

"Unstable colloids promote chill haze and permanent haze in beer."

"Melanoidins are stable complexes formed at high (mash-out) temperatures, they are colloidal in nature and are powerful reducing agents giving an acid reaction in aqueous solutions."

"Their colloidal nature enables them to 'protect' unstable colloids present in beer and to prevent haze formation. At the same time, melanoidins are powerful reducing agents and this too can prevent beer from throwing a haze. In addition, the acid character of melanoidins helps to improve the quality of beer. Melanoidins formed at 170 degrees F (76.5 degrees C) are more stable than those formed at the lower temperatures of conventional mashing. Adding specialty malts only in the mash-out can make the mash more efficient by maximizing the formation of melandoidins, optimizing saccharifications and eliminating steeping vessels and/or grain bags."

"In 1922, Visez, a brewing scientist at Louvain, in Belgium, showed that dextrans also act as protective colloids to diminish colloidal haze. This means that beer with higher dextrin levels are much less subject to colloidal haze than beers with low dextrin levels."

"This method of using dark and crystal malts (adding them at mash-out) will increase the quantity of melanoidins in your finished beer, thereby leading to smoother and rounder flavors from the specialty grains as well as more stable and clearer beers. The use of this mash-out technique also can reduce metallic flavors that often occur in dark beers but are not actually caused by metal ions in the brewing process."

So, according to this article (color commentary in parentheses):

- 1) Oxidation plays an important role in haze and other stability problems (no surprise here),
- 2) Unstable colloids promote haze,
- 3) Melanoidins are colloidal in nature, and when stable, can protect against haze and other stability problems, (melanoidins are our friends)
- 4) Melanoidins formed at mash-out temperatures are more stable than those formed at normal mash temperatures, (mash-out helps our friends?)
- 5) Specialty grains added at mash-out help with this stable melanoidin formation, and contribute to smoother, more stable beer (I knew about the smoothness part, didn't know it would help with stability)
- 6) The higher the dextrin level, the less colloidal haze (mash-out stops dextrans from breaking down)

Interesting stuff, eh? Maybe mash-out helps? One could argue that if proper procedures are followed with respect to HSA avoidance, the mash-out may not be as critical. On the flip side, I've had haze problems in the past with very careful attention to HSA (of course, there are other factors involved in hazes). If I continue to have haze problems, I may find a way to do a proper mash-out as an experiment. I highly recommend this article as well as George Fix's HSA article in the same issue. They go into much more than what I've shown (I just wanted to provide some info on the current discussion).

Subject: Kraeusening

Next weekend I'm going to make my initial foray into all-grain brewing, but first I'd like to tap some of sage advice from this group. My current set-up for fermenting includes two 5-gallon carboys. After spending the money for most of the all-grain equipment, I decided to wait on a 7-gallon cb. Based on most recipes it looks like I can expect about 5.5 gallons of wort after the boil. that will yield about 5 gal after fermenting blowoff. I'm planning to take the initial 1/2 gallon excess, store it (via standard canning procedures for sanitation), and then use it to kraeusen the beer prior to bottling. This seems to have three immediate advantages: 1) I can continue my preferred method of primary and secondary fermentation in glass carboys, 2) I will end up with a true "all-malt" ale, and 3) the final volume will still be about 5 gallons. I have two main questions. What are people's experiences, good and bad, with kraeusening? Second, how accurate is the equation given by Papazian for determining the amount of wort (I guess now called gyle) in getting similar carbonation to 3/4 c corn sugar (Appendix 3, pp. 331-332)? Thanks in advance.

Subject: Re: Late Kettle Hop Additions

O.K. I'm a little behind on my HBD (lot of traffic on Lambic digest lately).

In Tuesday`s HBD Norm asked about extracting more bittering compounds due to the bulk of the wort sitting at a higher temp longer with a counter-flow setup. During a recent beer tasting held here in Boulder I got to talk with a brewer from one of the newer micros in the area (Lonetree, I believe) who is a homebrewer turned pro. I asked him about the transition and one of the things he mentioned was having to adjust his hop schedule because hops added late at the micro actually ended up being in contact with hot wort for quite some time while it passed through the heat exchanger etc. and therefore bittering compounds were extracted and the final beer was more bitter than he had wanted. I believe his solution was to cut back on late additions of hops.

Hope this helps,
Corby

Subject: Re: scraping hops

> Scraping hops from the sides of the kettle...

I always scrape them back in. Even if you use bags like I do, some always seem come through the bags. If you don't shove them back in you can't expect the boil to extract their bitterness.

Subject: IPA/Keg Clarity/Sigs/Distill COPS NOT!

montgomery_john had an IPA Request.

* no one answered?! Jeeez, if this ain't one of the most
common types in the Cats Meow don't know what is! Pale Ales...
A general recipe I've repeated (but never exactly) several times

5 gallon mash

8 # 2 row pale malt (preferably English malt)

1.5 # light crystal (20-40L)

BOIL: 1 oz chinook hops (~10 alpha)

1.5 oz Cascade (or centennial) 4-6 alpha

Finish 1 oz Cascade

A good pale ale yeast. English brewery maybe.

The key- keep it simple, light, and HOP THE HELL OUT OF IT!
I really like the grassy/flowery bouquet of cascade. Several
variations in hops can be used, but make it bitter, and add
lots of finishing hops. If you want extract, Williams english pale
is probably a good one.

-John Palmer's new sig.line:

>** I think sex is more fun than basketball, too.**

** Fishing can be a tossup, though. **

*** (Depends on which is biting better) *** OUCH!! " Pain Captain! "

*Makes me think of that look on Picard's face when that Cardacian (sp?)
interrogator kept pressing the red button on the remote! Sorry wrong
group!

Subject: clarifying in a keg

>Have any of you kegger types tried to add clarifiers directly into the
keg and what kind of results/problems can I expect,...

* I haven't practiced this. I live in a cloud. BUT I would
reccommend adding the clarifier to the carboy- let it sediment, then
rack OFF of the sediment. Excess goop in the bottom of a keg can
keep your beer cloudy- or worse, clog the exit valve. Bad news!
I would think part of the idea here is to keep sediment OUT of the keg.

Diane says:

>It is refreshing to know that a woman is allowed to have a sense
of humor, and even more so, <gasp!> to express it. ...snip...I'll try to
come up with an even better .sig. For the person who was offended, well,
um, pffffftt! ;-P :) :-I :-D

* Well said! Right-o! I too think a woman should have the right
to express humor, and experience orgasms as they see fit! Isn't
it in the constitution somewhere? ...pursuit of happiness and
whatnot! Looking forward to the new sig. Bound to be a winner!

NOTE: THIS coming from the guy who "agrees" with that COPS show. NOT!!!

Mike Fertsch cautions:

>Be VERY careful modifying pressure cookers. High pressure steam can be

dangerous! The last thing you need is a hose rupturing, burning yourself.

* Oh come-on Mikey. What worry? We brewers are immunized from all harm by the magical virtues imbibed with the beverages we brewed! Far would it be from me to express or agree with cautions and safeguards!

BUT REALLY: Good point. Propane burns can be bad too. Always wear shoes when transferring boiling water around. Ask my left foot!

PUBLIC NOTICE: I have been accused of agreeing with the show COPS. Now hold on just a minute there buddy. Don't put words or anything but homebrew in my mouth! I stated (w/o proper proof) that there "could" be "potential" dangers involved in distilling. Steam can KILL! for one. And I've seen some agreement that depending on what's mashed or added after the fact, harmful items can be included in moonshine. I'm SURE the government is greedy, and want taxes. OF course! BUT... sometimes there are reasons for laws and regulations. Just ask the guy who lit the Altadena fire and DAMNED NEAR burned my parents house down (neighbors on either side are GONE!) yesterday! I might never have been able to inherit all those pewter beer steins they have and quaff my way to severe brain damage!

I DO NOT AGREE WITH THE SHOW COPS. I DISAGREE WITH THE WHOLE CONCEPT OF THE SHOW. Protraying violent/graphic scenes of husbands bashing wives with baseball bats and what not (oh that's americas most wanted...)

and invading peoples homes- many of whom turn out to be innocent.... I don't think the show should be on the air. I don't think they have been fair to the art of homebrewing. I even think people should have the right to grow plants if they want to. I personally wouldn't reccommend trying distilling at home w/o proper knowledge and equipment. I do encourage homebrewing, even of wines! I wouldn't tell someone how to change a light bulb w/o first cautioning them to turn OFF the switch FIRST! Common sense. Take it as you will.

Now-- off my soapbox...Sorry for any indication of public flaming. I've seen more than enough flames in the last day to last a lifetime! Tanx CNN

FYI: My cheap dictionary defines DISTILLATION as the process of separation by vaporizing then condensing a liquid. I DON'T think that Ice beer, or any concentration of that type is considered Distilling, according to the definition. That is not to say that it is legal. I think it is less "potentially hazardous", unless you stick your tongue to the ice...oooooh that smarts! And if cops invaded your house and confiscated your latest zymurgy I don't think they'd bust you for a bucket of frozen beer they way they'll take you down for your cooling coil! So...that said. I'll shut up and crawl back in my hole now.

From: phil.brushaber@lunatic.metronet.com (Phil Brushaber)  
Subject: Dopplebock

I am currently brewing a Dopplebock and am hoping for a final flavor profile similar to Salvator. I've got a few questions related to this project and thought you could help me out.

1. How do you get that German super-malty flavor?

My recipe was based pretty much on Miller's suggestion. My grain bill (for 6.5 gallons) was something like:

4# Alexander's Pale Malt extract  
6# American 2-row  
3# German Munich  
2# American Cara-Pils  
2# 70L Crystal Malt

My hopping (7HBU in 5 gals) was exclusively German Hallertau, and no finishing hops.

Can I expect to get that malty flavor. Or should I have used some other ingredients?

2. Attenuation of yeast

I used Wyeast Bavarian as my yeast, and used a one gallon starter. I am told that you can expect about 75% attenuation. Does this refer to how much of the fermentables it will process regardless of alcohol in the environment? 75% attenuation would imply that it would take a 1.040 brew to about 1.010 (I have found this to be true, OK maybe 1.014). Can I expect this yeast to take my 1.080 start down to 1.020 (which is where I would like it.)?

3. Speed of fermentation

This dopplebock is fermenting at 50°F. In five days it has gone from 1.080 to 1.040, does this seem right? What's your best guess on how long it will take to get to 1.020? I don't want to get my expectations too high.

Thanks!

AK> the club has gone presently. It has turned into more of a  
AK> socializing and drinking club.

I'm half the newsletter editor of BURP (Brewers United for Real Potables)  
, a  
Washington DC metro area homebrew club. We have this problem as well --  
if it  
is indeed a problem; I'm not completely convinced of that (I'll get back  
to  
this). Our club is a large one, with around 300 members; we can easily  
have  
over 60 people at any given meeting. This introduces problems of its  
own; it  
can be difficult trying to do something educational with this many  
people.

We're constantly experimenting with new things to do. We've had  
educational  
programs at the meetings (for instance, identification of off flavors via  
doctored beers, and culturing yeast), and also competitions both at the  
meetings  
and offline. The meetings, BTW, are almost all held at members' homes.

There are also other events which don't occur at the meetings, and which  
may not  
be formally associated with the club. For instance, some of our members  
occasionally have private beer tastings at their homes. Another example:  
our  
Most Esteemed Minister of Education, the illustrious Rick Garvin (are you  
reading this, Rick?), is currently holding a series of classes in beer  
judging,  
which is subsidized by BURP.

Above I indicated that I wasn't sure that the bias during meetings  
towards  
drinking and socializing was such a bad thing. When viewed in  
conjunction with  
the other activities, it works out well. The large groups are best  
suited for  
exactly that; for the educational events which are held at meetings, a  
sub-group  
splits out for a while. That's good because there aren't all that many  
topics  
that would really be appropriate for \*everyone\*. Meanwhile, the drinking  
lets  
us know what everyone is brewing, which is interesting, and the  
socializing can  
lead to more offline activities.

Best club I ever joined!

From: Jim Grady <grady@hpangrt.an.hp.com>  
Subject: Re: hops & counterflow

Norm Pyle and Jim Busch have both mentioned that a lot of aromatics can be lost from hops if they are added at the end of the boil and you use a counterflow chiller.

I just bought the gadgets special issue of zymurgy. Kinney Baughman has an article about building a hop back. This is to allow the brewer to add hop aromatics and then immediately chill the wort with a counterflow chiller. In this case, the beer is not exposed to air when the oils are being added to the volatiles cannot escape. This might be a good alternative if you want to continue using a counterflow chiller and get good hop aroma. I believe Kinney said that this is what Sierra Nevada does to get the hop aroma in thier beers (I've also heard that they dry hop). I'm sorry, I do not have my copy here; Kinney, did I misquote you?

WARNING! Once again, I am offering advice from something I read and have not tried yet!

Subject: Hops FAQ, Part 5/5

- - -

Q: What type of hops are available to the homebrewer? Where are they grown? What do they taste/smell like? Who uses them in commercial beers? How much bitterness do they contribute? How do I use them? What are good substitutes?

A: The following table lists many common hops available to the homebrewer:

\*\*\*\*\*  
\*\*\*\*\*

The following hops are generally considered aroma hops although in recent years they have started to gain a following in the homebrew community for bittering as well:

\*\*\*\*\*  
\*\*\*\*\*

Name: CASCADE  
Grown: US  
Profile: spicy, floral, citrus (esp. grapefruit) aroma  
Typical use: bittering, finishing, dry hopping for American style ales  
Example: Sierra Nevada Pale Ale, Anchor Liberty Ale, Old Foghorn  
AA Range: 4.5 - 7%  
Substitute: Centennial

Name: CRYSTAL (CFJ-HALLERTAU)  
Grown: US  
Profile: mild, pleasant, slightly spicy  
Typical use: aroma/finishing/flavoring  
Example: ???  
AA Range: 2 - 5%  
Substitute: Imported Hallertau, Mount Hood, Liberty.

Name: EAST KENT GOLDINGS  
Grown: UK  
Profile: rounded, pungent aroma  
Typical use: bittering, finishing, dry hopping for British style ales  
Example: Young's Special London Ale, Samuel Smith's Pale Ale  
AA Range: ???  
Substitute: BC Goldings, English Fuggles

Name: FUGGLES  
Grown: UK, US, and other areas  
Profile: mild, soft, floral aroma  
Typical use: finishing / dry hopping for all ales, dark lagers  
Example: Samuel Smith's Pale Ale, Old Peculiar, Thomas Hardy's Ale  
AA Range: 4 - 5.5%  
Substitute: East Kent Goldings, Willamette

Name: HALLERTAU HERSBRUCKER  
Grown: Germany  
Profile: pleasant, mild aroma

Typical use: finishing / dry hopping for German style lagers  
Example: ???  
AA Range:3 - 5%  
Substitute: Hallertau Mittelfrueh, Mt. Hood, Liberty, Crystal

Name: HALLERTAU MITTELF RUEH  
Grown: Germany  
Profile: pleasant, spicy, mild herbal aroma  
Typical use: finishing / dry hopping for German style lagers  
Example: ???  
AA Range:3 - 5%  
Substitute: Hallertau Hersbrucker, Mt. Hood, Liberty, Crystal

Name: LIBERTY  
Grown: US  
Profile: fine, mild aroma  
Typical use: finishing / dry hopping for German style lagers  
Example: Pete's Wicked Lager  
AA Range:3 - 5%  
Substitute: Hallertau Mittelfrueh, Hallertau Hersbrucker, Mt. Hood, Crystal

Name: LUBLIN  
Grown: Poland  
Profile: reported to be a substitute for noble varieties.  
Typical use: aroma/finishing  
Example: ???  
AA Range:2 - 4%  
Substitute: Saaz, Hallertau, Tettnanger, Mount Hood, Liberty, Crystal.

Name: MT. HOOD  
Grown: US  
Profile: mild, clean aroma  
Typical use: finishing / dry hopping for German style lagers  
Example: ???  
AA Range:3.5 - 5.5%  
Substitute: Hallertau Mittelfrueh, Hallertau Hersbrucker, Liberty, Tettnanger

Name: NORTHERN BREWER  
Grown: UK, US, Germany (called Hallertau NB), and other areas  
(growing region affects profile greatly)  
Profile: fine, fragrant aroma; dry, clean bittering hop  
Typical use: bittering and finishing for a wide variety of beers  
Example: Old Peculiar(UK), Anchor Liberty(US), Anchor Steam(US)  
AA Range:7 - 10%  
Substitute: ???

Name: SAAZ  
Grown: Czechoslovakia  
Profile: delicate, mild, floral aroma  
Typical use: finishing / dry hopping for Bavarian style lagers  
Example: Pilsener Urquell  
AA Range:3 - 4.5%  
Substitute: None

Name: SPALT  
Grown: Germany/US  
Profile: mild, pleasant, slightly spicy  
Typical use: aroma/finishing/flavoring  
Example: ???  
AA Range:3 - 6%  
Substitute: Saaz, Tettnanger.

Name: STRISSELSPALT  
Grown: France -- Alsace area  
Profile: medium intensity, pleasant, similar to Hersbrucker  
Typical use: aroma/finishing  
Example: ???  
AA Range:3 - 5%  
Substitute: Hersbrucker, German Spalt

Name: STYRIAN GOLDINGS  
Grown: Yugoslavia (Fuggles grown in Yugoslavia), also grown in US  
Profile: similar to Fuggles  
Typical use: bittering, aroma for a wide variety of beers, popular in Europe  
Example: ???  
AA Range:5.5 - 7  
Substitute: Fuggles, Willamette

Name: TETTNANGER  
Grown: Germany, US  
Profile: fine, very spicy aroma  
Typical use: finishing / dry hopping for German style lagers  
Example: Gulpener Pilsener  
AA Range:4 - 6%  
Substitute: Saaz, Spalt

Name: WILLAMETTE  
Grown: US  
Profile: mild, spicy, floral aroma  
Typical use: finishing / dry hopping for American / British style ales  
Example: Redhook ESB  
AA Range:4 - 6%  
Substitute: Fuggles

\*\*\*\*\*  
\*\*\*\*\*  
The following hops are generally considered bittering hops:  
\*\*\*\*\*  
\*\*\*\*\*

Name: BREWER'S GOLD  
Grown: UK, US  
Profile: poor aroma  
Typical use: bittering for ales  
Example: ???  
AA Range:8 - 9%  
Substitute: Bullion

Name: BULLION  
Grown: UK, US  
Profile: poor aroma  
Typical use: bittering hop for British style ales, perhaps some finishing  
Example: ???  
AA Range:8 - 11%  
Substitute: Brewer's Gold

Name: CENTENNIAL  
Grown: US  
Profile: spicy, floral aroma, clean bittering hop (Super Cascade?)  
Typical use: general purpose bittering, aroma, some dry hopping  
Example: ???  
AA Range:9 - 11.5%  
Substitute: Cascade

Name: CHINOOK  
Grown: US  
Profile: heavy spicy aroma, strong bittering hop, astringent in large quantities  
Typical use: strong bittering  
Example: ???  
AA Range:12 - 14%  
Substitute: Galena, Eroica, Brewer's Gold, Nugget, Bullion

Name: CLUSTER  
Grown: US, Australia  
Profile: poor, sharp aroma, clean bittering hop  
Typical use: general purpose bittering (Aussie version used as finishing hop)  
Example: ???  
AA Range:5.5 - 8.5%  
Substitute: Galena, Cascade, Eroica

Name: EROICA  
Grown: US  
Profile: clean bittering hop  
Typical use: general purpose bittering  
Example: ???  
AA Range:12 - 14%  
Substitute: Northern Brewer, Galena

Name: GALENA  
Grown: US  
Profile: clean bittering hop  
Typical use: general purpose bittering  
Example: ???  
AA Range:12 - 14%  
Substitute: Northern Brewer, Eroica, Cluster

Name: NUGGET  
Grown: US  
Profile: heavy, spicy, herbal aroma, strong bittering hop  
Typical use: strong bittering, some aroma uses  
Example: ???  
AA Range:12 - 14  
Substitute: ???

Name: PERLE  
Grown: Germany, US  
Profile: pleasant aroma, almost minty bittering hop  
Typical use: general purpose bittering for all lagers except pilsener  
Example: ???  
AA Range:7 - 9.5%  
Substitute: ???

Name: PRIDE OF RINGWOOD  
Grown: Australia  
Profile: citric aroma, clean bittering hop  
Typical use: general purpose bittering  
Example: ???  
AA Range:9 - 11%  
Substitute: ???

Subject: Re: Jack & the perfect chiller

> From: arf@mcs.com (Jack Schmidling)  
> Subject: Chillers  
>

It is unfortunate that those who do not read rec.crafts.brewing missed the recent great debate on immersion vs counter-flow chillers. Kinney Bauman did an admirable job of defending counter-flow in light of its obvious shortcomings and naturally lost to the Lighthouse of Wisdom and Truth.

Not this again!!

> I won't re-hash the whole argument here but in summary, not a single, UNARGUABLE advantage could be brought in defense of counter-flow for home

MY UNARGUABLE ADVANTAGE TO A COUNTERFLOW CHILLER: IT TRANSPORTS MY CAST WORT FROM MY SUDHAUS TO MY FERMENTATION AREA, WITHOUT RISK OF INFECTION. It also uses less time and water (for my volume of brewing). By using this technique, I can run all kinds of caustics/acids/boiling water through a permanently installed pipeline, and rinse hot water through, diluting the bitter wort.

> homebrewers. The counter-flow "snobs" are simply wrong on this one.

Thats it, Jack has spoken, I must trash my equipment, send a Easycheck to the EasySalesman, get a EasyBrewery, and make easily chilled beer. Boy was I stupid to build my own brewery, when Jack had all the answers for me.

> wort stays hot. The issue CAN be, how hot? If it falls below pasturization temp and is open to the air, there is a risk of contamination. If it stays near boiling, it is no worse than extending the boil that amount of time. And keep in mind that PU simply air cools the wort till it reaches lower temps.

Probably garbage statements, certainly not a big issue if you have plenty of clean healthy yeast to pitch (like PU).

> To me, the most obvious disadvantage of the counter-flow chiller is that most of what would have stayed behind in the kettle ends up in the fermenter unless one does an additional settling step.

Where it is scrubbed away during high krausen, and prior to this, is actually beneficial to yeast metabolism.

Lets hope this thread is less tiresome than what soft drink mix's with which malt beverage.

Good Chilling,  
Jim Busch

From: Keith MacNeal 29-Oct-1993 1021 <macneal@pate.enet.dec.com>  
Subject: Wit Bier recipe

There was a recent question about a recipe for a Wit Bier. Given that and the nice articles on Belgian Brewing lately I figured I'd post this recipe. It's based on one of Dave Miller's recipes in "Brewing the World's Great Beers" and some suggestions from HBD and the Cat's Meow.

It was quite popular with my friends this summer. The only things I might do differently next time would be switch the yeast to a Belgian Ale yeast and try one of the German wheat extracts like the one that comes in a 2 kg can (actually, since I've made the switch to all grain for my last few batches I'd go all grain instead of using extract). The American Eagle Amber DME is very light -- about as light as most other brands' Light DME. If you use another brand, get a light. The only precaution I took with sanitation and the spices was to swab down my mortar and pestle with a bleach solution before crushing the coriander in it. If I remember correctly, the dried orange peel was from Spice Islands.

3.3 lbs. Munton & Fison Wheat Malt Extract  
2 lbs. American Eagle Amber DME  
1 oz. American Hallertau hop pellets (4.3% AA)  
1 pkg. Wyeast Labs #1007 German Ale Yeast  
1 oz. crushed coriander  
= oz. dried orange peel  
1 cup corn sugar to prime

OG = 1.038  
FG = 1.012

Bring 2 gals. water to boil and add extracts. Add 2/3 oz. hops when it returns to boil and boil for 45 minutes. Add remaining 1/3 oz. hops and boil 15 minutes. Cool and strain into 3 gals. cold water in primary. Pitch yeast and ferment at 65-68°F for about 1 week. Add coriander and orange peel to secondary and rack beer on top (either use a 6 gal. secondary or put a blowoff tube on it -- I clogged the airlock a couple of times before finally putting a blowoff tube on it).

I bottled mine after 10 days in the secondary. The beer came out light in body and color. The carbonation, light body, and citrusy flavors from the spices made for a nice light, refreshing brew. I don't know how it stacks up

to commercial brews of this type since I haven't had an opportunity to  
taste  
any.

Enjoy,

From: lincecum@med-biochem.bu.edu

Subject: Advantages of ascorbic acid?

I have been reading the forum for several weeks now and am impressed with the depth of experience and willingness to help fellow homebrewers with their questions.

I have just brewed my first all-grain barley wine and will be aging it for several months. Unlike most of my beers which get sucked down by my thirsty friends as soon as they are carbonated I am a little concerned about long term oxidation problems with the barley wine.

Will the addition of ascorbic acid (vitamin C) at bottling time improve the longevity of the beer? Also what are the general advantages and disadvantages of ascorbic acid addition? Much thanks.

Jack> I won't re-hash the whole argument here but in summary,  
Jack> not a single, UNARGUABLE advantage could be brought in  
Jack> defense of counter-flow for home brewers and most of the

Jack, I'm quite sure that in your case there is no\_such\_thing\_ as an  
UNARGUABLE anything\_ :-)

Jack> So, I hereby challenge the counter-flowers to start  
Jack> your engines....

Silent long enough I guess....

I would love to have stayed with my immersion chiller. It is easier  
to sanitize, use and store. The problem is that it simply did not  
work well enough. My tap water is barely below desired pitching  
temperatures most of the year. As long as the temperature  
differential between the wort and water is high, immersion chillers  
work great. As that differential decreases, the advantage goes to CF  
chillers.

The bottom line here (at least for me) is water conservation.  
My 50' immersion chiller used in excess of 30 gallons of water to  
chill a 5 gallon batch of boiling wort, and my pump driven 40' CF  
chiller uses less than half that, and\_ gets the wort colder. As a  
side benefit, I finally get the cornflake sized cold break that I  
never\_ witnessed before.

Also, remember, we all brew a little differently. What is ideal for  
one persons style is useless for another. I cannot think of one thing  
I could change in my brewery that would not demand some other  
compensating change. Every method has advantages and drawbacks, and  
each brewer must make his or her own choices.

From: mri10@mfg.amdahl.com (Michael Inglis)  
Subject: Growing Hops

I would very much like to grow my own hops this next season but I have a slight problem. I live in a Condo without a back yard but I have a very large porch that has access to plenty of sunlight (my other plants are very happy :). If I was to grow hops, it would have to be from some sort of planter box. I would have plenty of room to set up a vine path that would be adequate but my concern is the planting. Will planting the rhizomes in a planter box work? Has anyone else done this successfully?

Also, I brewed an all extract beer several weeks ago (my third attempt at an SNPA clone) and the OG was 1.030! (my local homebrew store packaged DME in 3 lb. bags and when I actually weighed them they came out to about 2 lbs. 10oz :( ) Guess where I'm not going anymore for my supplies? Anyway my FG after two weeks was 1.016!! I was a little scared as I'd never seen such a low gravity loss but I bottled anyway. What I have now is IMHO an excellent ale that has a pronounced buttery taste and goes down like water. The sweetness with a fairly aggressive hop bitterness combined to make a flavor that I never expected and it's great. Just goes to show that even an apparent disaster can come out smelling roses (figuratively of course). Anyone else had horror stories that have come out to be a surprisingly good brew?

Best Jim Busch commented on the idea of steam sterilization with a pressure cooker:

"Sounds dangerous to me. How do you know when it is empty?"

\* No more steam. Simple.  
\* How does a melting pressure cooker and stovetop smell?  
\* I've seen what a teakettle can do to a stovetop. Not a pretty sight!  
\*\*\*\*\*

John Adams said:

>Personally I make my own labels using a graphics editor, a ray-tracer, a good collection of gif/jpeg "clip art" of beer labels, and a color printer.

\* Sound nifty. I'd love to see 'em. Are those beer labels YOU scanned? Or is there a commercial source, or disk copy others can obtain?

>I would also like to find an outfit that produces custom beer coasters.

\* Here's a couple- from an old issue of American Brewer (summer '92)

American Coaster Co., 527 Wheatfield St., P.P. Box 710  
North Tonawanda, NY. 14120 (716) 693-6540

NOTE: These fellers are directed at BREWERIES- Bulk orders of 10,000. I just saw it in a magazine, and besides all my cousins work there (NOT! )

ADMAT Coasters Johnson city Tennessee,  
Phone (615) 434-2373 Fax (615) 434-2210

There's even a place which does taps! I might have to look into that one!

Labels? Creative Labels 7413 Pulaski Hwy, Baltimore Maryland 21237  
Phone (301) 866-4700 FAX (310) 866-5672

I hope I'm not being too commercial. I always get a flood of e-mail when I mention these kinds of sources, so I'm shortcutting this time.  
\*\*\*\*\*

\* Random Comments on Comments... (just a little bw...pain cave?)  
> With 3 cats in the house, rodents are not my concern :-)  
but they could get into that bag with no problem at all.  
\*If you fed the cats more often you might not have them stealing grain!

>put on the lid and throw in some hops.  
\*Better reverse that.

"Skip and go naked" sounds like a fun name for a drink. But it sounds like a spruced up SHANDY. Coors/Lemonaid/Whiskey. Hmmm. Skip the board games. Play naked twister with vegetable oil!  
\*\*\*\*\*

Mark said:

> You can at least get a sense of the aroma potential of your homegrown hops by using your nose, but there's really no practical way to know how much alpha acid is in there (without a lab analysis).

\* Oh yeah. Nothing like cutting them in half and rubbing your

nose and fingers in it. sticky sticky. Smells like fresh buds!  
Has there been a practical way of testing developed for the homebrewer?  
I know you can send them off...but I'll save my money and guesstimate.

Arf...you were trying to come up with a pH test weren't you?  
Didn't you say something about a colorimetric test? Any luck w/it?  
\*\*\*\*\*

anthony johnston cried about a broken carboy:

>I am sure that most of these precautions are obvious and well-known and  
the others may seem like overkill, but after seeing the results of a  
broken carboy...waaaaaaaaaaaaaaaaah.

\* Don't be cautious. Someone might pounce you. Remember homebrew makes  
you immune! KOH would simply run off you skin since you're filled w/  
EtOH!

\* No really....good advise. How big was the carboy? Did you shift  
temps  
drastically and suddenly? Was it scratched?

I once had a 1 gallon EtOH bottle (brown...nice!) that was full of cold  
spiced cider- happily fermented out- awaiting bottling. (~45-50 deg)  
I had splashed hot water on a barstool from bottle washing, then  
placed the jug on the stool. Just a little bit of hot water was enough  
to cleanly sheer the bottom from the rest of the bottle. I was able to  
rack the precious fluid out before moving the bottle. There must have  
been an adequate temp differential to shock the glass. I was blessed  
by the grace of my brew lord for the survival! One bottle remains.  
I think I'll have to celebrate halloween w/it! Pumpkin brew too!'course.  
BTW I still have the top of the bottle. Could make a good funnel.

Also: The one batch (in my early days) of beer which became explosive  
(scary experience, ~~SHUDDER~~) I had one bottle which broke/blew  
exactly the same way. The bottom sheered off cleanly. The top shot up  
into my underarm! At least it didn't shatter like the one in my car!  
(no one was in it at the time. Good thing.)  
The point here...The connection between sides and bottom is a stress  
point for bottles. Thin to thick glass is my guess. Be wary!

Subject: Beer Shelf Life

Tom Schwendler asks about shelf life. 3 months life sounds ridiculous to me unless there is something wrong with the beer. Award-winning beers are frequently 6 months old when judged. From my own experience I am drinking a beer that I made 12 months ago and it's superb: better than fresh when it was a little harsh. Most of my brews end up being 6 months old by the time the last bottle is drunk and none have shown any sign of going off.

From: edo@marcam.com (Ed Oriordan)
Subject: Questions

Did my first all grain last weekend. Everything went well, but now I have two questions. One on sparging the other on grain.

Sparging -

What is the best way to sparge. Should you?

- 1) Completely drain the bed, then sparge in one of the following ways?
- 2) Just match the additions to the drainings?
- 3) Sprinkle in all the water at once?
- 4) Others.

I have a feeling that 2 and 3 are going to be a tie. What's the difference besides my effort. As I see it all the water goes through the bed either way, and if you can maintain the temp why not do 3? Maybe, more weight so compacted filter bed? What about 1? On one hand I would fear compacting the filter bed, but on the other hand I would be getting the first drawings that I would assume would be extract rich. I used a rectangular cooler and slotted pipe manifold(fantastic tool), so I am not real worried about a stuck sparge, but I would think clarity could be a problem. Also method 1 would cause more shifting in the grain bed, perhaps more astringency?

For a 5 gallon batch I drained off 1 gallon of wort and recirculated this because it was cloudy. Was this correct? I ended up with clearer wort, but I am assuming that the first drawings contain the most extract, which I then poured on the top of the bed, and now it has to be washed through the entire bed and out again.

Grain -

As a full mash novice I want to stay with simple infusion mashes for a while. What kind of grain does this mean I am restricted to. I used Pale (2-row english). The day after I went to another brew store and they had two Pales(2-row from Germany and from America). Pale is Pale??? The grain from the second brew store had a lot less flour already mixed in (i.e. if you dropped a handfull of the english Pale you saw some flour dust) and appeared to be good clean grain. Will it be as modified as the english Pale? Is it an oversimplification to say Pale == you can do an infusion? I was reading Miller last night and he explains the difference between Pale, Mild, Vienna, Munich, Lager, Klages etc.. But what I want to know is, what can I infusion mash as a base grain for recipe (obviously not specialty grains and adjuncts)

Pale is Pale??? No adjuncts used currently, so I don't need extra enzymes.

Describe how to tell if grain is good? Miller goes into it some (or was it Noonan?), but what do you look for?

If you are gonna answer my questions I would love to hear how you do it, and especially why you do it this way and not this way. I don't want to just follow recipes or steps, I would like to know why I am going to do something.

Fun, fun, fun. If you are contemplating trying all grain, I would
recomend
a cajun cooker burner and a slotted copper pipe manifold system. They
made
the job a LOT easier. Also if you live near a drag-strip, you can slap
that
cajun cooker on the back of your car and campaign it as a jet dragster.
NASA called and said the crew of the space shuttle saw it. Man, is that
thing
powerful!!! Comes with a nifty recipe for a deep fried turkey (is it
just me
or does the thought of deep frying a whole turkey sound odd?).

Thanks

Subject: Pilsner extract

The following attachments were included with this message:

TYPE: FILE
NAME: PIL

Greetings,
A few friends and I will be running an experiment in recipe formulation where we are trying to match a style with extract brewing as well as all-grain. The problem: the all-grain version will require pilsner malt and the extracts I've been able to find (DME & LME [No, not Male extract]) are all based on Pale Malt. Does anyone out there in HBD-land know of Pilsner Malt extracts that are Unhopped and (hopefully) no adjuncts?

TIA,
Andy A

From: Mark Garetz <mgaretz@hopstech.com>
Subject: Hunter Airstats

Thanks to an alert by Kieran O'Connor, I have confirmed that the Hunter Airstat is no longer being produced and there are no plans for a replacement product.

For those that don't know, the Hunter Airstat is a reasonably priced "line voltage thermostat" that was originally designed to add thermostatic control to a room air conditioner. Homebrewers, however, have been using it to control refrigerators/freezers.

The Hunter was unique in it's price range featuring a remote sensor and digital setpoint and temperature readouts. Homebrew suppliers are selling them for \$30 to \$40, and hardware superstores (such as Home Depot) had them as low as \$19.50. The main disadvantage of the Hunter was that it only went down to 40 degrees F, not considered low enough by lager afficianados. But it could be easily modified to go lower, and instructions have been published in this digest.

Homebrew rumor had it that the Hunter has been discontinued due to a lack of reliability. Hunter denies this and claims lack of sales is the sole reason.

Hunter has no more inventory on this item, but some inventory does exist in hardware stores, and I would bet even more is still in stock at homebrew shops. The reason for this post is that if you were thinking of getting a temperature controller someday, or like me are a happy user of an Airstat and want a "backup" or two, now is the time to buy. Armed with the info that they have been discontinued, you may be able to get an even better price on any remaining inventory, at least from a hardware store. I went down to my local Home Depot and bought their remaining two units at \$15 each (one had no packaging and the other's package was pretty beat up).

Some enterprising homebrew supplier might want to contact Hunter about picking up the manufacturing rights and making them again (and possibly modifying the software to allow 30 F operation). Hunter is in Memphis, TN.

Note that you don't have to panic. There *are* alternatives. Williams Brewing in San Leandro sells a Penn line voltage thermostat that has been modified specifically for Williams, but Penn has "standard" models that will also work. WW Graingers has a few pages of these, of which a few are suitable for our needs and not too expensive. Most will need to have a line cord added. You can also check local heating/air conditioning parts suppliers. What you want is a "line voltage thermostat" that is designed for either "cooling only" or "heating/cooling" (the key words are the switch contacts "close on rise"). Sometimes they are listed as SPDT, which means single pole double throw and is a technical way of saying they work for heating or cooling. The switch contacts need to be rated high enough for your fridge (usually this is not a problem). And the temperature range needs to be right. You also want a "remote bulb" or "remote sensor" unit. A "snap action" or "bimetallic" thermostat would

need to be entirely mounted inside the fridge, not very practical.
Lastly, make sure the "differential" is in the 4 degree range or
adjustable to it. You don't want one with a 25 degree fixed
differential.

Disclaimer: I have no affiliation with Hunter, nor do I sell temperature
controllers of any kind. I just think that for the price, it was a great
deal, and I really like having the digital temperature readout on my keg
fridge. And no, none of my "spares" are for sale, so don't ask.

Subject: Grinding Wheat / Chillers

Robert Schultz writes:

> I attempted Phil Seitz's Belgian White Ale on the weekend. I now know what Phil meant by grinding 5 lbs of wheat on a Corona.
> How do the roller mills perform on the hard unmalted grains (wheat, rye, rice)? Barley and oats are fairly soft.

My homemade roller mill works fine crushing hard stuff like wheat. I use a special (simple) modification to my mill when I crush wheat. The mod is two blocks of wood which restrict the amount of feed onto the rollers. It allows the rollers to crush less grain at any instant. For example, if the rollers are 8" long, this takes the working length down to about 5", so only 5" of the rollers have grain between them at a time. Without this mod, crushing wheat causes the motor to stop (and this is a washing machine motor!). Wheat is indeed a tougher nut to crack than barley.

**

JS comments about immersion vs. CF chillers:

>The counter-flow "snobs" are simply wrong on this one.
(and other similar comments)

Jack, this is abrasive and counter-productive at best; its out and out flame bait at worst. The HBD will now be tied up with tons of inane arguing at a time when 3 day turn around times are commonplace. You were the one griping about the yeast FAQ because you couldn't get a quick turnaround from the HBD. This will tie up the HBD for much longer than one FAQ.

I brought up this subject for serious discussion, not flame wars. I appreciate your well thought out comments regarding versatility of the immersion chiller, but I would have appreciated more if you had tempered your comments to a civil level. Do you talk this way in person?

One of the great advantages of CF chilling is efficiency of the water used. Has anyone out there measured your cooling water? It took me over 30 gallons of cooling water with my immersion chiller, less than half that with my CF chiller. That's 6 times the volume of the beer just to cool it with the immersion chiller! This is a big reason I like CF chilling. Combining this with other water conservation methods can amount to a considerable water

savings in one brewing session. I'm not claiming one method beats the hell out of the other, just that there are pros and cons. You have to pick your poison.

>Somebody doesn't realize that methyl alcohol was intentionally added to "bathtub gin" during prohibition to increase its intoxicating ability. Poisonous, but it will get you drunk.

>The government arrests people who operate a still because they want their alcohol taxes. If they tell you that they do it for your protection, just remember that they told Indians the same thing when they took their land.

Well put. Just because methanol boils off when distilling, does not mean there is any to boil off in the mash. For a simple example, ponder making brandy.... You start out with a nice drinkable wine and distill it to leave most of the water behind. If there were enough methanol to cause blindness in the distillate, you wouldn't want to drink the wine in the first place. The same thing applies to whiskey mash. Methanol comes from petroleum or from distilling trees. That's why it's called wood alcohol. If you put trees in your wine, you might be in trouble.

The industrial world needs grain alcohol but has enough clout to avoid paying taxes on it. To keep everyone honest, Big Brother mandates that a certain amount of methanol is added to industrial ethanol to make it undrinkable. The bad guys put this stuff in booz because it is cheap and people got sick and might have gone blind.

There is nothing you can do to a still full of wine to make it produce dangerous quantities of methanol and you can consider a kettle full of whiskey mash just a very new "wine" for the sake of this discussion.
.....

Sorry but I lost the source line (bb Brian Bliss?) for the following..

>Subject: wyeast/spruce/distillation temps/and more...

>6) I still buy wyeast and try to use it for those batches which require a special flavor from the yeast. I wish there were an alternative... It would not take that much more work to provide us with a packaging that has a larger yeast population developed before you open it.

There is an alternative and its called culturing. However, it's sort of like all grain brewing, viz., sounds real spooky till you try it. Not only does it save big bucks but it becomes as much of an obsession as brewing itself.

You can do it in the kitchen in simple stuff or a lab full of equipment.
The
bottom line is, yeast is free, it's clean and you can produce any
population
you feel is needed. Check out the archives for my article on Culturing
for
Beginners.

<I am using Low Density Polyethylene tubing for transferring wort. It
is FDA
approved and has a temp range of -70 to 120F and it handles sweet wort
temp
just fine.

>I can assure you that my sweet wort is above 120F, so I wonder the
wisdom of
using 120F rated tubing in this manner. I use a cut off plastic turkey
baster.

As I was unable to find a 20 foot turkey baster, I had to take drastic
measures.

I cited the specification for the record and then pointed out that it
works
fine at "sweet wort temp" and presumed we all knew what that meant. The
specification is obviously very conservative.

Furthermore, I would be interested in knowing just what your sweet wort
temp
is as it flows through the tubing. I suspect it is a lot cooler than
you
think. By the time mine gets down to the kettle, it probably is around
there somewhere. The copper tubing at the end is to protect it from the
boiling wort not the stuff coming down from the kitchen.

> How do the roller mills perform on the hard unmalted grains (wheat,
rye,
rice)? Barley and oats are fairly soft.

I could swear I just answered this but it also appeared in Ulich
Stafford's
comments on his new mm.

Malted grain is friable and crumbly. When gently squeezed, it falls
apart,
exposing the malt to mash water. This is definitely not true of
unmalted
grains. If you have the strength to run it through a roller mill, the
best
you will get is something like thick oatmeal. As there usually is no
husk
involved, there is little advantage to a roller mill over a grinder. I

suspect, a Corona me be more efficient if your lauter tun can handle the
fine
grinst. That is, after all what they were designed for but it won't be
any
easier to crank.

Subject: Freezing Wort

Do you see any problem with freezing homemade wort (extract)?

Next weekend I am going to make another try at a Dopplebock. (This time with German Pilsner grain as the base, not 2-row in my quest for that malty sweet German flavor).

My lauter tun can not handle more than about 12-13 lbs of grain at a time. So this weekend I mashed 10 lbs. of German Pilsner. Boiled it down to about 3 gallons, put it in a 4 gallon kettle, covered the kettle and stuck it in the deep freeze.

I suppose there are more convenient alternatives to making your own extract, but I wanted all-german grain.

My plan next weekend is to mash the remaining 13 lbs of grain I will need to make this Dopplebock, thaw the "extract" and add it to the boil.

Anyone see any problems with this procedure. (Other than spending an extra brewday mashing grain?

Subject: Beer Drinks

Here's another beer drink to add to the list

1 oz of vodka

1 oz Southern Comfort

2 oz 7-up

1 oz sweet & sour mix

1/4 oz grenadine

2 cups of crushed ice. Blend all of the above in a blender till it resembles a slush. Pour into a 20-24 oz glass. Fill the remainder of the glass with your favorite beer. The drink was introduced to me as a Combat. Its a good one.

matth> shops I get supplies from. Jack did a good job on it. Most of
matth> the reviews I have seen have been pretty close to the mark
matth> regarding usability of the device. It gives a great crush but
matth> as many people have indicated the design could be improved upon
matth> some.

I feel that Steve made light of Jack's efforts because he complained
about the cost and said right after that he could do a good without
much effort (this is a paraphrase). A lot of other people complain
about the retail prices of equipment like Jack's and state that they
could do as good for a lot less. I was just pointing out why retail
prices are generally extremely fair and what really goes into making a

product, rather than a one-off copy of someone's design. If you make it yourself and it does not last or does not work quite up to snuff, then you generally don't complain. Jack and other inventors have to make a product which works well and lasts, which most of them do.

Subject: RIMS sparge techniques

I just did a trial mash in my RIMS system using manual temp control by turning the heater on and off by hand. When finished, I did the sparge, but because of the speed of my pump, it only lasted about 10 min. I can't control the rate of sparge by only introducing sparge water slowly because the pump does not do well with pumping dry and it does not go down to extremely slow either. I have heard of adding all the sparge water at once and recirculating for 30 minutes and then just pumping the resulting wort on out.

Any other ideas. My extraction rate was a rather poor 22 points per pound per gallon from domestic 2 row, if I go by Dave Miller's rate of 35 ppg. Residual grain was slightly sweet after sparge completed.

Thanks for the help.

> for clearer beer but no one had come up with any documentation to prove
the
> point.

Oh, I might point out that you can immediately start siphoning into
the fermenter without waiting on the immersion chiller to chill the
wort and THEN siphoning into the fermenter. But who cares about
saving time?

Moreover, after we all agree on the importance of sanitation, good
recipes, good ingredients, and decent equipment, pray tell what ISN'T
arguable in homebrewing?! Isn't that why we love this hobby? Because
of its diversity?

> Now, ponder the possibilities this allows. You have an infinite number
of

off
> the heat, put on the lid and throw in some hops. This hops is at near
boil
> temp which kills that herbal taste but the vapor and aroma can not
escape.
> When you chill it down, the vapor and aroma are re-absorbed by the
wort.

Re-absorbed by the wort, huh? I'm sure you can pull the documentation
out on that one, can't you, Jack? And while we're pondering
possibilities, ponder the reality of having the hop aroma absorbed
directly into the wort with a nice little hopback hooked inline
between your kettle and CF wort chiller. Works great for me at home
and my little brewpub in town.

All this is not to say that a well-designed immersion chiller won't
function fine when used properly. But "not one unarguable advantage
(can) be brought in defense of counter-flow for home brewers"?! Come
now, Jack. Methinks you've been dipping into your homebrew a wee much
this evening.

Cheers to one and all!

Subject: Re: steam

When I was in the US Navy, during the 1960's I was told that the difference between a fairy tale and a sea story was that a fairy tale begins: "Once upon a time..." and a sea tale begins: "This ain't no shit. ..."

As an electrician, I had occassion to spend a few hours, now and again, in the engine room, where electricity was manufactured by steam turbines. It was hot and noisy there, but one learned to read sounds. A pin hole leak in a live steam line has a special sound. Once heard, it is indelible. One stops moving. In the fullness of time, a person will reach out for a broomstick and begin looking for the source of the leak by passing the broomstick over and around the steam lines. When the broom stick is cut in half, the live, pinhole steam leak has been found.

Live steam is a very useful tool, but one which must be brought into play with caution and understanding.

This ain't no shit.

From: Jonathan Labaree <jonlab@igc.apc.org>
Subject: RE: Short spigot on Gott

Sandy Cockerham in HB 1260 asks about a too-short spigot on a Gott mashing setup.

I, too, added a spigot to a cooler and ran into a similar problem -- I drilled a hole for the spigot and found that the spigot's threading was not long enough to fit all the way through. By this time, I had to find a solution because I had just forked over a good 14 bucks for the thing at Sears. So I drilled a second hole in the outer skin of the cooler large enough to accommodate the spigot's largest outside diameter (I used a paddle bit which chowdered the thing up a bit, but it ain't exactly a Chippendale to begin with). Then I fastened the spigot on the inside skin. I had to remove quite a bit of the Styrofoam insulation. In order to prevent the insulation from pouring out, I filled the void with a product called "Great Stuff." This is an expanding insulation foam that comes in a can (the package says no CFCs, by the way). It's pretty gooey stuff and it doesn't take much to fill the gap around the spigot to seal in the insulation.

It works quite well, though you must be careful about preventing grains from getting in as the spigot will clog very easily. I use a rectangular plastic needlepoint screen (cut to fit the bottom of the cooler --) which I fasten to the exposed spigot threads with a bit of picture wire so it stays in place. I'm looking for a better solution to that problem, though.

[Credit goes to Alice and John @ Brewers,Asso.,
Portsmouth, NH for the needlepoint screen idea, thanks!]

<At the end of the growing season when the leaves have fallen or turned brown,
<cut the vines at the surface of the soil and if possible remove the twine.
<After cutting back the vines a layer of 3 or 4 inches of mulch and composted
<manure can be put over the exposed vines for insulation and nutrition during
<the winter.

I read in Brewing Techniques that if the vines are allowed to remain uncut at the end of the season, the rootstock will build up energy stores for the upcoming winter season, and be healthier next year. This is obviously not practical for big farms, but due to my inherent procrastination, it is exactly how my plants are now. Comments?

<The proper length of time for dry hopping is dependent on the temperature. At ale temperatures, 7-14 days of contact time is widely used. At lager temperatures, although little data is available, it seems obvious that longer contact times, on the order of 14-21 days, are called for. It is common to use 0.5 - 2.0 oz. or more in a 5 gallon batch, but as always it is up the individual's preferences.

OK, how does temperature affect hop aroma wrt dry hopping? This doesn't seem intuitively obvious to me. I also would point out that I have dry hopped 1 BBl batches in the primary (after high krausen and skimming) for a mere 3 days with excellent results, and I know of a local brewpub that has dry hopped with pellets (I use whole) for one day, filtered and served online the next, so this will work. The point is that dry hopping times vary all over the spectrum, and I suspect if a heavy hand is used in the amounts, time is less important. I'm still wondering about the lager comment???

Best,
Jim Busch

Subject: Spruce beer

I think of spruce beer as one of those seasonal things. I've only done it with new spruce growth in the spring. The color, texture and smell are all quite pleasant to work with.

The recipe I started with (Papazian?) said 1 quart of new spruce growth, but I just pick a plastic bag full. You will find that when you are communing with an actual spruce tree, you will not want to pick all the easily accessible growth, and you will get tired of getting scratched by the old growth before you have picked too much of the less accessible stuff.

I did one batch where I was less careful about not using any old needles. It had a much more aggressive and less delicate (although still not unpleasant) spruce character.

All this is more fun and probably less likely to lead to overspruced beer than buying bottles of essence at the home brew store. Of course, you can only do it in late May and June.

Subject: More on steam injection SAFETY!

In HBD #1259 we read:

>I'm relying solely on memory here, since I wasn't taking notes, but as
>best as I can reconstruct it, the setup is like this: An ordinary
>pressure cooker (about 2 gallon capacity, I would guess) is modified
>by removing the pressure release in the center of the lid (NOT the
>safety pressure release, which is offset from the center on this one)
>and replacing it with a compression fitting. From that is run a length
>of flexible metal hose (the kind used for a gas line to a kitchen
>stove, I think) about 4 or 5 feet long.

I hate to criticize a great idea, but if this description is accurate, it could be ****very dangerous****. The thingy in the center of the lid (a weight covering a small hole) is what regulates the pressure inside the chamber. (It basically works because the doohickey has a weight of 15 pounds for every square inch of hole that it covers. Thus if the pressure inside exceeds 15 PSI, the weight gets pushed aside a little, venting some steam, and thus reducing the pressure.) By modifying this, you are eliminating the pressure regulation of the pot! Sure there is still a safety valve, but this is set for a pressure somewhat higher than the cookers normal 15 psi operating pressure, also, if this valve becomes clogged (and it does happen) you now have zero pressure regulation! Add a little more heat to the cooker, and the pressure will go way up, until the kettle explodes violently.

Please, if you're going to try this, add the steam outlet somewhere else on the pot, but DO NOT MODIFY EITHER THE SAFETY RELEASE VALVE NOR THE PRESSURE REGULATOR!!!!

Lets be careful out there...
Kelly

Subject: PH malt / acid rest / carboy storage

RE: PH malt

The poster claimed to have problems getting his Ph in the appropriate range even with the addition of a large amount of gypsum.

I am no chemist but this sounds like a water chemistry problem. I don't know if the term "buffering" describes what is happening but something in the water is preventing the gypsum from lowering the Ph.

Brewers I know of with similar, but not as severe, problems with their private well water do the following.

Boil 7-8 gallons of water the night before brewing.
Let it cool over nite and let the percipitate settle too.
Siphon all but the last couple inches the next morning.
They also use a gallon of distilled water in the mash and the rest from the preboiled and siphoned suply thus diluting the offending ingredients.
Don't sparge to the limit, 1.010 temp adjusted, to limit tannin extraction.

They have also had water analysis done and brew styles that are appropriate for the water chemistry. There are ways of getting the water analysis done for free or near free. Many plumbing supply stores provised this service if you are shopping for a water treatment system.

Acid rest:

This step is described by Noonan in Brewing Lagers, most texts provide this information for theoretical completeness, it is rarley done in commercial brewing. The recent beer styles book on Wheat Beers also includes a discussion of multiple steps of acid rest as important in producing certain components of a wheat beers flavor and aroma. These all involve ezymatic reactions resulting in the generation of specific acids.

Carboy storage:

After cleaning I cover the carboy opening with a sandwich bag held on with an elastic band. I cover the carboy with a second large bag and store it on an open shelf.

Subject: Re: Homebrew Club Gone Stale? Probably not.

Your club is probably doing just fine, as long as you keep everything in some kind of beery perspective.

The Chicago Beer Society *STARTED* in 1977 as a beer drinking and socializing club, and wound up with a bunch of us weirdo homebrewers joining and taking over. We haven't taken over completely, and probably never will - the Chicago Beer Society continues to bill itself as a beer appreciation AND homebrewing club. The serious homebrewers operate as a committee within the club - with a lot of overlap with the aficionado segment.

Is this an entirely peaceful arrangement? No. There are periodic disagreements about the future direction of the club, and the answer to the question: "Which way will it go?" is usually "Yes." And finally, are we the ideal model? Probably not. But we are quite comfortable with the fairly large number of Chicago Beer Society events which are not specifically related to homebrew, as long as things stay in balance. For instance, this month, November, we are having our annual homebrew competition, the AHA-sanctioned Spooky Brew Review, and we are also having our annual International Tasting. I'll be judging at one, and indulging at the other.

I know I haven't answered your question; in fact, I may have made it more difficult to answer. Just another perspective, though.

Roger Deschner, Member, Chicago Beer Society.

<snip>

It would help make it easier to assess the source your off-flavor if you had described it a bit more. In any event, I see two areas in your technique that could cause off-flavors: 1) Hot-Side Aeration (HSA) and 2) slow cooling.

Both of these problems can be solved simply by building/buying a wort chiller. You should really avoid aeration of wort until you have cooled it below 80F (of course some oxidation still occurs, even at 80F, but 80F seems to be a generally accepted temperature). Oxidation of hot wort will give you off-flavors and darken the beer. The off-flavors associated with HSA are sherry-like and wet cardboard. The long time between the time that your wort stops boiling and the time that it drops below 140F is not good since DMS (a cooked-corn-like aroma) is being produced while the wort is between boiling and 140F. Finally, the long time between the wort dropping below 140F (or so) and the time that the yeast are really going is an invitation for infection. No matter how well you sanitize, you probably cannot sterilize your equipment (or the air around it) and something gets in. If you can have your cultured yeast eat up all the sugars and make some alcohol and lower the pH before the uninvited visitors get established, you can keep the off-flavors from nasties below the flavor threshold. A long, slow cooling of the wort is just an invitation for the nasties to get a jump on your yeast and to create enough off-flavors to be perceptible. Get a wort chiller.

A1.

Subject: Evergreens in beer

There has been quite a bit of discussion about spruce beer lately, with comments about hemlock (the evergreen) tea, and most recently an interesting botany lesson from Edward F. Loewenstein <SNREDLOW@MIZZOU1.missouri.edu> on the Pinaceae family. Every year when I make my annual Spruce beer I wonder about other evergreens - pines, hemlock, and especially fir. I have some balsalm fir and Douglas fir, but since all references are to Spruce beer, I've confined my experiments to the picea genus - Blue, Norway, White and Black Spruces. I never tried the spruce extract that you can buy; maybe too much of that can give you a solvent taste, but it is virtually impossible to get anything like that with fresh sprigs. Most of the flavor seems to be extracted by the boil - I don't notice much affect from late kettle additions or "dry sprucing". You can definitely make a beer that's too sprucy, but it's not unlike making a beer that's too hoppy - a lot depends on the preference of the drinker, and in any case the solution to "too sprucy" is the same as for "too hoppy": dilution with a more conventional beer.

Any insight on the use of evergreens besides spruce? Will I be forced to pilot brew a balsalm fir ale? What would Euell Gibbons have done?

From: Spencer.W.Thomas@med.umich.edu
Subject: Re: Belgian Special B (Matthew Rowley)

Brian comments that Special B would probably make a good start on a Scotch Ale recipe. Well, I had the same thought recently. Tasting notes follow.

Scottish 120/70

Made 3 gallons 120/- ("Wee Heavy") and 4.5 gallons 70/-

12 lbs Pale Ale Malt (Hugh Baird)
2 lbs Munich Malt (DeWolf-Cosyns)
1 lb Special B (DeWolf-Cosyns)

Single temp infusion mash @ 67C for 1 hour (1 quart H2O/lb)

120/-:

Sparge 4 gallons in two batches. I drained the mash tun once, then added a couple gallons of 77C water and drained it again.

Boil 1 hour, adding 1 oz Goldings at beginning, and finishing with 1/2 oz Goldings (10 min). (Target IBUs 35) O.G. 1096. Force chill, pitch YeastLab Irish Ale yeast from 1qt starter. Fermented at about 55F. At 2 weeks, gravity was down to 1032, and I pitched the slurry from another quart starter of YeastLab London Ale yeast. Tasted nicely malty and alcoholic. I'll probably pitch new yeast at bottling time, as beer this alcoholic seems to have trouble carbonating.

70/-:

Sparge 5.5 gallons (normal technique, keeping water about 1" above grain).

Boil 1 hour, with 1 oz Goldings at start and 1/2 oz at finish. (Target IBUs 24) O.G. 1038. Fermented at "cellar temp" (65F?) for 2 weeks, then "mini-kegged" with gelatin finings, as it seemed to still be a little cloudy. Finished at 1010.

Tasting notes: nice malty notes, with a medium-low hop bitterness (probably a little high for the style). Color medium amber. Easy to drink a lot of it.

I served this at a party for a Scottish friend who is leaving town, and I was a little nervous about its reception. However, they thought it was pretty closely on target, although the color was light. I got compliments on the beer from all the Brits (Scottish and English) present.

Subject: Basement Brewing

Mathew Harper asked for tips on planning an area in your basement for dedicated brewing. I do not have a dedicated area, but rather serves several purposes. One of the things I did put in was a range hood. I had heard from other homebrewers that they spend hours wiping down walss from all the moisture that is generated from the boil. The moisture is an open invitation for mildew and all types of creapy crawlers to take root in the floor joists.

I went out looking for a range hood at a garage sale and found one for \$10 at the first place I stopped. I suspended it from the ceiling with cables. I used a dryer vent package that includes the 4" hose and the actual vent itself that goes to the outside.

I used it fro the first time two weeks ago. Works like a champ. I really recommend it. Write me if you want to know more.

Subject: Wyeast Packages And Bursting

Drew Lynch mentioned he would be curious to see if the Wyeast package would burst. Thus my story.

I forgot about a package of Wyeast American Ale (don't ask me how, but I have small children). I ended up using some of my existing yeast stock on that batch. Two weeks ago, cleaning up around the computer (I keep them warm by wrapping in a towel and keeping near the computer until they get big), I found one that I had "burst" three and a half months earlier. "What the hey", I said, and pitched it into a starter anyway. The package was *less* puffed up than it would normally be at max--don't ask me why. The starter tasted and smelled fine and the beer tasted fine going into the secondary. I suspect the yeast suffered but pulled through like troopers. I *don't* think the current packages will explode under normal temperatures and pressures.

Subject: Hops FAQ, Postmortem

This is regarding the recently published Hops FAQ. I welcome all comments so that I may take one more shot at revising it before turning it over to the archives. Keep in mind, though, that it is a list of Frequently Asked Questions. The answers are generally available around the net, and were (mostly) NOT just dreamed up by me. I tried to present the "net.wisdom" side of most things, which doesn't imply, by any stretch of the imagination, that it is correct in every aspect. Most of the answers have been considered helpful my many, but in need of some discussion and changing. That is the purpose of active involvement in the HomeBrew Digest, not the purpose of the FAQ. Take it for what it is and discuss controversial topics on the HBD. I will be glad to discuss anything and everything in the FAQ, but I may or may not wish to make changes to it (editorial privilege?).

I welcome anyone who wants to take it, once archived, and revise it to your heart's content. I realize it is not perfect; never will be. It is the best that my current time and resources allow and I am happy with it. Comments welcome, but see my side of it. As always we thank you for your support!

I should mention that Glenn Tinseth from The Hop Source, unbeknownst (is that a word?) to me, wrote the bulk, if not all, of Part 1/5. He was not credited, but he will be in Rev. 3. Sorry, Glenn. My fault for not keeping better care of the sources of the info. I hope you don't feel too ripped off. In hindsight, separating the credits from each passage may not have been the best idea I've ever had.

Cheers,
Norm

P.S. To anyone who may consider doing something like this: I learned as much about hops in the last 2 months as I did in the last 2 years. Lots of work but worth every minute.

Subject: Beer Head/ Best Bitter Recipe/Pnts AAU Calcs?

Cisco (John Francisco)'s new sig.line says:
>May your beer give you great head!!!!

* Now that's kinky! I find it works better the other way around.
* Question: Does "liquid male extract" increase head retention?

Also- Thanks to the JOKER for offering such a splendid accounting of a typical workday in the life of Wyllie Coyote. I just hate it when I fall to the bottom of those canyons, especially when a big rock- or worse- LARGE pot of boiling wort- falls on my head. You think all that sounds bad- you should see what ACME has offered me to "smooth" my way through a brewday. Rocket powered Racking canes!

Ok, but really. I Brewed a Best Bitter yesterday...following (roughly) a recipe for an IPA type bitter I posted the other day.
for 12 gallons

Best Bitter:
14# 2 Row Pale malt (only had american on hand.)
1.5# 60L Xtal
.3 # Victory Malt
.5 # Wheat malt

BOIL: 2 oz Chinook (13% alpha)
2 oz Centennial (10%)
2 oz Cascade (7.3%)
These were all flake hops stored in freezer ~ 2 months (or more)

FINISH: 2 oz Cascade- homegrown. Smells YUMMY and fresh. Good xtal devpt.

German Alt Yeast (dregs from previous ferements)

OG 1.035. Temp 25 deg C.

Question: In calculating points what grains are included, or do you just use the WHOLE grain bill? I can see wheat, and munich contributing fermentables, but what about things like chocolate which don't?

Calculation: 35 sp.gr. x 12 gall. / 16.33 #'s = 25.72 pts/lb
Is this right? It seems reasonable to me. That's within the range I expect from my cooler/lauter tun. But I'm not sure If I got the equation right. (I always get confused...maybe ACME has a kit...hmm...scratch chin)

AAU's...(13 x 2)+ 20 + 14.6 = 60.6 => 25.25 AAU (5 gallon conversion)
QUESTION: Is this right? I need to dig up the HopsFaq and check.

This is gonna be one bitter mo-fo. But ooooooh my house smelled delicious after the 1.5 hr boil! Everything is hoppily underway this morning.

I think I need to try a RauchBier before I retire the BBQ&Smoker for the winter. Plus it seems a fitting celebration to my folks house surviving the Altadena fire last week. (what a nightmare!) That'll be MUCH stronger!

Subject: Plumbing

Well, it appears we have a real HBD plumbing problem on our hands. I scanned the HBDs for the last seven days and I was quite impressed. I expected to see at least 25% wasted space (wasted space defined as articles which apply not at all to homebrewing). The beer drinks thread qualifies (who would really do any of this to your homebrew?), as do the complaints about people's .sig files. Those two topics were virtually all of the badness on the HBD recently. I expect that amounted to less than 10% of the total HBD bandwidth, a wonderful S/N ratio, IMHO.

So, what do we do? Quit posting junk like this one? Maybe. Two-a-days are possible, although I don't know Rob's limitations nor inclinations. I did notice his change to Six-a-weeks. That is a good start and it may prove to be all that is necessary. It is the brewing season and that increases brewing questions, thus HBD traffic. I suggest no panics yet, use email whenever general interest is not served, and wait. I suppose we could ask everyone to use as much self-restraint as possible with things like "Are there any good pubs in XXX?", but as I said before the S/N ratio is still quite good. Long .sigs, orgasmic ones or not, should be avoided whenever possible. Other than that, I say, "Keep up the good work!".

Old Lucifer update: OG 1085; SG 1035 after 6 weeks. I may rename it Old Energizer Bunny (keeps going, and going,...). Pitched dry frog yeast this weekend (I'm a jerk, I know). Anyone want 5 gallons of all-grain liquid candy with 6% alcohol? I want my carboy back!

Subject: Another immersion chiller

I've been lurking for awhile, so I thought I'd finally break down and be sociable. I recently built my first immersion chiller, and it occurred to me that I may have done something marginally innovative (it could happen)

The chillers I've seen for sale seem designed to sit in the bottom of a pot. Mine hangs over either side, so that the coil is suspended near the top - where it's hot. The idea being that the cooled wort will fall to the bottom and encourage circulation, giving faster cooling without stirring. I've only used it once, but it worked well (faster than a bathtub full o' icewater)

For your viewing pleasure, I include the crudest possible ascii rendering of said chiller. It can be adjusted for different pot sizes by stretching or compressing the coils (refrigeration copper tubing).

From: WESTEMEIER@delphi.com
Subject: Keeping the club healthy

Andy Kligerman asked for input about keeping a homebrew club healthy.

Our club is very healthy, if growth is a good measure. The Bloatarian Brewing League (of Cincinnati) was founded by Ray Spangler, 1987 Homebrewer of the Year.

We are extraordinarily lucky to have the support of the Oldenberg microbrewery and Drawbridge Estate complex. They give us a meeting room each month at no charge, in return for putting on a couple of homebrew demonstrations each year for the Oldenberg Beer Camp.

It seems to me that the best method for keeping a club from degenerating into a beer drinking club is to have a well planned program for every meeting. The socializing part is great, but there has to be more. We occasionally do a "Dr. Beer" seminar to demonstrate specific off-flavors in beer, helping to educate members' taste buds. We also have an organized tasting each month, wherein members bring samples of their latest brews which are tasted by a panel of experts (and anyone else who cares to participate) with feedback provided as a distinct part of the meeting.

That lets everyone in on the secrets of evaluating beers, provides a useful function to keep the experienced members from being bored, educates the newcomers, and keeps things fairly organized.

We also invite local merchants to attend and give tastings of special beers, which is great advertising for them (and almost free) and a treat for us (as well as being educational).

We have various members give presentations on equipment construction, describe specific beer styles, discuss yeast culturing, etc.

Road trips are another great tool. We plan on a meeting place, then carpool to interesting brewpubs or other places of interest to homebrewers. These are very informal, lots of fun, and a nice supplement to meetings

It's also important to have something planned for each meeting that involves beginners as well as for the more advanced members. That can be an activity related to identifying a specific problem in a beer or maybe something about equipment or ingredients.

Make sure that your club leadership includes everyone in discussions, as beginners can be intimidated by a lot of the arcane that concern the more advanced brewers. Try to define highly technical terms the first time they are used at each meeting, at least when you have newcomers present. Don't criticize the efforts of beginners, but make them opportunities to suggest ways to improve.

Finally, use the mails. We have an 8 page monthly

newsletter that covers lots of ground, but you can do much the same thing with a single sheet of paper that describes what went on at the last meeting (for those who missed it) and what is planned for the next one. Many people need that kind of reminder between meetings.

Subject: The Two Millers

I have both of Dave Miller's books. He seems to have alternate grain bills for Dopplebock in the two books. In one he suggests 100% Munich as the main grain, in the other he suggests about 80% Lager/Pilsner malt and 20% Munich (about 3 lbs Munich). (and of course cara-pils and crystal).

I've been going with the Pilsner/Munich mix. Has anyone brewed with 100% Munich? Flavor profile? Results? Warnings?

... All, known to his friends as Captain Capper!

Subject: informal get together in San Diego Dec 7-10?

Any of you folks out there planning to attend the CAUSE '93 conference in San Diego on December 7-10, 1993? If yes, email me and maybe we could get together for brew or two.

The conference is being held at the Sheraton on Harbor Island. I have extracted the list of brew pubs in the San Diego area (circa 1991 ?). Any of you folks that are familiar with the area have any suggestions of must see/don't waste your time brew pubs????

Comments appreciated.

Rob.

Subject: Re: Hops FAQ

Since this Hops thing is a FAQ, I feel obliged to put on my Monty Python act and NIT, NIT....

> Subject: Hops FAQ, Part 5/5  
>  
> Name: CASCADE  
> Grown: US  
> Profile: spicy, floral, citrus (esp. grapefruit) aroma  
> Typical use: bittering, finishing, dry hopping for American style ales  
> Example: Sierra Nevada Pale Ale, Anchor Liberty Ale, Old Foghorn  
> AA Range: 4.5 - 7%  
> Substitute: Centennial

Centennial is a great hop, and certainly similar in some respects to Cascade, but they are not really \*substitutes\*. Centennial is much spicier, and contributes a different citrusy essence to the beer. I usually like to mix the two hops, and while Centennial is a pretty high alpha hop (~10%) it can still be used as a dry hop quite successfully.

>  
> Name: CRYSTAL (CFJ-HALLERTAUE)  
> Substitute: Imported Hallertau, Mount Hood, Liberty.

"Imported Hallertau" does not mean much today. The region the hop variety is grown in is what counts, as "Hallertau" hops are grown all over Germany as are Tettanger, hence the names, Hersbruecker Hallertau, Hallertau Hallertau, Tettang Hallertau, Tettanger Tettanger, etc.... I encourage brewers to use the correct terminology, as it is a real difference which hop a brewer uses in a given recipe.

>  
> Name: EAST KENT GOLDINGS  
> Grown: UK  
> Profile: rounded, pungent aroma

also "earthy"

> Typical use: bittering, finishing, dry hopping for British style ales  
> Example: Young's Special London Ale, Samuel Smith's Pale Ale

LaChouffe!!

> AA Range: ???

4-6%

> Substitute: BC Goldings, English Fuggles

There is none!!

> Name: HALLERTAUE HERSBRUCKER

Reverse, HERSBRUCKER HALLERTAU

> Grown: Germany  
> Profile: pleasant, mild aroma  
earthy, can be quite spicy, ummmmmmm, and quite aromatic, Pils anyone??  
> Typical use: finishing / dry hopping for German style lagers

only "German style lagers" brewed in the US are dry hopped :-) BTW, most german lagers are finished at 15 minutes to end of boil, not at the very end as many of us do. This, in conjunction with the whirlpool, will add bitterness, and aroma to the beers. Many german brewers dislike the very late additions of this hop.

> Example: ???

Pils.

> AA Range:3 - 5%  
sometimes less than 3, I currently have 2.3-2.6  
>  
> Name: HALLERTAU MITTELFRUEH  
> Example: ???

Sam Adams

>  
> Name: MT. HOOD  
> Grown: US  
> Profile: mild, clean aroma  
> Typical use: finishing / dry hopping for German style lagers  
> Example: ???

Mt Hood Ale??

> Name: NORTHERN BREWER  
> Grown: UK, US, Germany (called Hallertau NB), and other areas  
Now we got it right, Hallertau NB. NB grown in the Hallertau region of Germany.  
>(growing region affects profile greatly)  
Exactly!!  
>  
> Name: SPALT  
> Grown: Germany/US  
> Profile: mild, pleasant, slightly spicy  
> Typical use: aroma/finishing/flavoring

Bittering too!!

> Example: ???

Alt bier of course, thats the bittering hop commonly used.

> Substitute: Saaz, Tettnanger.  
Saaz???

>  
> Name: STYRIAN GOLDINGS  
> Grown: Yugoslavia (Fuggles grown in Yugoslavia), also grown in US  
> Profile: similar to Fuggles  
> Typical use: bittering, aroma for a wide variety of beers, popular in Europe  
> Example: ???

Belgium ales, Rochefort,

>  
> Name: CENTENNIAL  
> Grown: US  
> Profile: spicy, floral aroma, clean bittering hop (Super Cascade?)  
> Typical use: general purpose bittering, aroma, some dry hopping

> Example: ???

Sierra Nevada Celebration ale, Old Crustaceon Barley Wine (Rogue), Jim  
Busch  
New American Ales :-)

> Name: PERLE  
> Grown: Germany, US  
> Profile: pleasant aroma, almost minty bittering hop  
> Typical use: general purpose bittering for all lagers except pilsener  
> Example: ???

Sierra Nevada Pale Ale

This is good info, just nitting around here, lots to know about hops...

From: jim@n5ial.mythical.com (Jim Graham)  
Subject: Oatmeal Stout results!

Ok, it's been a few weeks now since I brewed my oatmeal stout, and a bit longer since I asked the HBD for assistance in this area. Well, we now have some results...and they're very \*GOOD\* results. :-) Thanks to all who provided me with valuable information that led up to this batch.

I also have a question regarding the sediment in the bottle, but I'll leave that to the end.

I went with the following:

6 lbs Oatmeal Dark extract (from William's)  
1 lb Dry American Dark extract (also from William's)  
1/4 oz English Fuggles (60 minutes)  
1 oz English Fuggles (30 minutes)  
1 packet Burton Ale liquid yeast (William's)  
corn sugar for priming, as always....

The recipe called for 4 oz of Lactose (add during last 10 minutes of boil), but I didn't have that, so I skipped it. :-) This recipe was what the guy I talked to a William's said would be closest to Sam Smith's Oatmeal Stout, so that's what I went with (he'd given me a slight variation of this over the phone---it included Hallertauer hops, which this doesn't).

Result: I'll do a side-by-side comparison with Sam Smith's Oatmeal Stout tonight, if I can find any (SS isn't easy to find, due to how expensive it is---the stores don't stock much, and they don't always stock it at all)

But just from memory, I'd have to say that it is either a very close match, or is dead on. And it's very, very good. Yummmm....

It's also particularly appropriate now, since we just got hit with the first real signs of winter (about a month early, too), and actually went into the 30s last night. Yuck! But, in the evenings, I have a nice oatmeal stout (served at proper cellar temps, thanks to the fact that the apartment isn't approaching 800F) to warm me up.

Ok, I mentioned a question.... This is the first time I've used liquid yeast. I've noticed that the sediment in the bottle seems to be a lot finer than normal (i.e., much smaller bits, and more of them). Is this a characteristic of the liquid yeast? Or is it just a characteristic of that particular liquid yeast? Just curious. Btw, I haven't really decided whether it makes pouring the beer easier or more difficult.... but you certainly have to pay a lot more attention to where the sediment is when you pour (my first glass had a bunch of sediment at the bottom).

Later,

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>  
Subject: Brass in the boil

Hi Group,  
I noticed the Brass post today, and I can come up with an answer I think.  
First, are you noticing ANY corrosion? Any roughening of the surface?  
IF your fitting is an alloy containing Lead (unlikely) that would be a  
big  
problem. The leaded alloys are UNS # C3X000 series. These alloys are used  
when  
increased machinability is desired.

Hopefully, the brass fitting alloy being used is Red Brass aka UNS #  
C23000  
aka ASTM B43. That alloy is all Copper-Zinc and will pose no health  
hazard. The  
zinc is in solid solution for this alloy and is not subject to leaching.  
Other  
alloys such as Admirality Brass (copper zinc tin) may be in use and are  
acceptable.

With Red Brass or Admirality Brass, any corrosion you may be seeing would  
not  
be toxic. Corrosion in this case may be the Brightening of the fitting  
during  
use, the same as your wort chillers.

-John Palmer  
600 laid off the Space Station last Friday, but fortunatly I made the  
cut.  
Invest in the Space Program, folks, tell your congressmen. It promotes  
good  
jobs through transfer of technology for a good future. It also inspires  
our  
children toward higher education. Keep America Strong.

From: dweller@GVSU.EDU (RONALD DWELLE)  
Subject: one-pot brews

I just met an older fellow (80+) who's been brewing forever. Offered a nice lager (a bit cloudy) which is all he makes. Among other things, he said that he never uses two containers (primary and secondary fermenters) but instead puts the whole batch in 5 gallon carboy, airlocks it, and then waits till it's all done. He said that using two fermenters (I use a plastic bucket, then a carboy) was foolishness and the best chance to get contamination.

Since all the procedure's I've heard about recommend two--a primary and secondary--this fellow's method seems peculiar.

I wonder if anyone else has experience using only a single jug.

Cheers,

Ron Dwelle (dweller@gvsu.edu)

From: Y Y Zed <fini@bigvax.alfred.edu>  
Subject: sterilization options/procedures

Hi all - I'd like to get some input on the methods you use for sterilizing/disinfecting equipment and bottles. I've been told by a few people that bleach is to be avoided due to the risk of residual bleach solution killing off yeast. An alternative is B-Brite, but I don't know how effective it is at killing everything off compared to bleach, which is very strong. I'm relatively new at the game, and since I like to experiment I disinfected the bottles for my first and second batches with rubbing alcohol and then rinsed well. The first batch turned out well, but the second had a weird aftertaste (due to bacterial infection, I assume). What's the best method for sterilizing mass quantities of bottles? bleach solution in a bathtub?

thanks -

Paul Fini

Subject: Frogs?/Cider/Scotch Ales

Norm says: "...have to punt (i.e. pitch a frog yeast).

And that's SG for the nitpicky coyote!:)")

\* Pardon my ignorance...What's a "frog yeast"?  
\* Norm...sounds like you can use FG pretty soon!

\*\*\*\*\*

>You Don't want cider with sorbate. Find an orchard and get  
>the fresh pressed- unfiltered stuff. Much worth it!

That's very good advice. \* (but of course!!!! :) )

\* I submit: I over-stated sorbate's effectiveness.

\* It inhibits yeast budding=reproduction. Bacteria don't bud.

\* A note on cider sources...and hg apples....There have been cases  
of E.coli infections from apples which had fallen, sat on the ground  
prior to pressing. E.coli may be a common component of the flora of  
your bowels...but it's better to keep it at that end, not at the other!

The point here...it may be safer to campden your cider, then pitch.  
Rather than try to rely on the normal flora of yeast/bacteria/other bugs  
which might reside in fresh cider. I'll be starting up this years cyser  
pretty darn soon (payday!!! pant...groan...)

Also: It's worth bugging your presser to inquire about the types  
of apples used. Many orchards will press what's on hand. That may  
vary from day to week. You might get a better deal if you:

1. Go in with friends and buy LOTS! We walk off with up to ~20gals!

2. Arrange to come in on pressing day. You get fresher cider, and  
you won't depleat their stock. Bargain and you might get a better  
deal. The best I've run into is \$2.50 / gallon.

\*\*\*\*\*

Eric Urquhart (eurquhar@sfu.ca)

Centre for Pest Management,\* Sounds like you'd have your work cut

RE: Noonan's Scotch Ale book \* out to deal with the likes of me!

\* I was quite pleased with it. The history is interesting...ok so  
I found the water chapter kinda boring...and didn't feel like he gave  
a good explanation of the process of double mashing...just assumed we  
knew all about it! The book passed around a couple of friends and  
resulted

in the finest products out of these brewers I've seen in quite some time.

I made a 90 shilling first runnings, and continued to sparge a 2  
penny.

I didn't have the exact ingredients called for, but was pleased with the  
result. A strong- malty sweet, deep rich brew. I must try it again  
soon.

I won't bother posting the recipe unless there is a call for it. (i did a  
recipe yesterday...)

One thing I found intersting was that the dark malt flavors came from  
roasted malt, not crystal. I always assumed it would be a heavily xtal'd  
grain bill. Not so. Also...I would've assumed good 'ol greg would've  
promoted the Decoction- being a master of it himself...ok at least a  
previous author on the subject.

I did find the book to be more clearly written than his Lager book.  
I think I still like Porter/Pale ale the best. Mr. Fix's Oktober etc.  
is also a very nicely written piece. I do find these books to inspire  
the desire to explore a style in greater detail. It also gives ideas  
on how to name your ferments...even if you drift away from the style a  
bit!

From: Jim Cave <CAVE@PSC.ORG>
Subject: Counterflow chillers

There has been considerable debate recently on the relative merits of immersion vs. counterflow chillers. While I do not intend to try and convince others to switch to the counterflow design, it is the one that I use for the following reasons:

1) About 50% of the beers (all-grain) that I brew are lagers. I prefer very cold ferments to these beers (45 F). For much of the year, I can get my beer close to this temperature with this design. During the summer months I use an additional coil (after the counter current) which runs through an ice bath. This drops the beer an additional 10 F. This rapid drop in temperature makes for remarkable cold breaks.

2) Much of the trub falls out in the kettle. I have a hop-back and a second screen in at the outlet-valve to prevent the occasional errant hop from entering the chiller. I give the wort a quick stir to generate a whirlpool. The counter-current flows into glass carboys. I then rack off the trub and into glass carboys (Yes I rack off the trub; the breweries I have talked to estimate that they remove 95% or more of their trub prior to ferment).

3) The unchilled beer remains well above 160F and is therefore sterile. Gravity checks can be rapidly made at the exit of the chiller and gently re-introduced to the boiler without fear of contamination.

4) When 2/3's of the wort remains in the kettle, I throw in hops for aroma (hot soak). This gives excellent aroma. A hop-back in-line with the chiller would be a better way to go but I have't come up with a rugged design yet.

5) With my boils, I always seem to end up with a gravity 4 or 5 points higher than target (and correspondingly less volume). I have recently come up with a gentle way of adjusting gravity. I fire up the sparge tank and boil water. This is introduced with a tube into the boiler with the beer (when the beer has nearly all gone through the chiller). This gently washes the hops and trub of fermentable extract.

One disadvantage that I see with the counter current chiller is that the Irish moss addition is less effective, as it doesn't really enter the collecting carboys. Consequently, the beer in the collecting carboys takes longer to drop bright than it otherwise would in the boiler. However, as I

mentioned, trub is also settled and filtered out in the boiler.

I guess you pays your money and takes your chances!!

Subject: SS Kegs

Thanks to everyone who responded to my questions about mashing/lautering. I located 2 15.5 gallon SS kegs, so I bought them with the intent of turning one into a mash/lauter tun and the other into a boiling kettle. I'll probably be doing 10 gallon batches by the new year! The mash/lauter tun will probably be of the EasyMasher variety, and the boiling kettle will have a spigot so that I can also use it as a settling tank.

Can anyone out there offer guidance in converting these kegs? I need answers to questions like: How should they be cut? Which end should be cut (on the valved end, I suppose)? Where on the keg should the cut be made (top or side)? How many inches from the bottom should I install the manifold outlet on the mash/lauter tun (right AT the bottom, I suppose)? How many inches from the bottom of the boiler should I install the spigot (i.e., How much sediment can I expect from a 10 gallon batch)?

Thanks in advance,

Ed Wolfe

From: gummitch@teleport.com (Jeff Frane)
Subject: Counterflow Wort Chillers

I only chime in because I don't want anyone to get the impression that just because Jack Schmidling is adamant he is also correct. There are a good many reasons why someone would choose a counter-flow wort chiller over an immersion chiller, that have nothing to do with scale. If Jack had come to my presentation last year in Milwaukee, he'd know that.

Briefly, my reasons are simple: it's faster, the wort arrives in the fermenter at the correct temperature without being unduly exposed to the air or sitting around in a kettle while I stir the damn thing, and <important> the only "stuff" that arrives in the fermenter besides the wort is some cold break, which precipitates out magnificently and from then on doesn't pose any problems, because IT WILL NOT BE REABSORBED INTO THE WORT. The wort does not have to be racked off the cold break.

That presentation, by the way, was published in the last volume from the AHA, and includes scientific references, instructions on how to build an inexpensive counter-flow wort chiller, how to siphon bright wort out of the kettle (hint: whirlpool), and a number of variations on immersion wort chillers, courtesy of the internet homebrew crowd.

But, once again JACK HAS SPOKEN. Be advised, however, that in the past Jack has spoken through his hat more than once. More than twice, for that matter. But I can see it now: "Real brewers only brew all-grain." "Real brewers culture their own yeast (although once upon a time liquid yeast was for snobs, remember, Jack?)." and now: "Real brewers use an immersion chiller." Pffft.

From: gjfix@utamat.uta.edu (George J Fix)
Subject: Hop Flavor

I have always had a strong preference for low alpha aroma hops, even for early additions for bittering. I find that they give (if fresh!) a clean and mellow bitter, which contrasts with the crude effects I pick up from high alphas.

There is a large literature on this subject. Perhaps the most influential has been the paper by Rigby which appeared in the 1970s (ASBC Proc., 1972).

He identified co-humulone as the hop resin that was responsible for the "high alpha taste". Bishop, et al (J. Inst. Br., 1974) reproduced these results, and in addition showed the isomerized fraction from co-humulone was foam negative. The other humulone analogs exert a positive influence on beer foam. All of this jives with my own brewing experiences. In addition, all of the high alpha varieties known to me have much higher co-humulone values than aroma hops.

Recently Wachesbauer (Berlin) has called these results into question. The original papers appeared in Monatsschrift fur Brauwissenschaft, although English translations can be found in the 1993 editions of Brauwelt. He brewed beers with each of the humulone analogs added as pure extracts. No differences in the hop flavors were detected, although his study confirmed Bishop's findings about effects on beer foam.

These findings are consistent with the work of Professor Narziss and his students. They have long insisted it is the hop oils that are the most important. While most of these are removed during the boil (and possibly the fermentation as well), residuals coming even from early hop additions have been measured in finished beer. They tend to have very low flavor thresholds, so their effect on taste may be way out of proportion to their concentration. In terms of the hydrocarbon fraction, they cited the ratio

alpha-humulene/ myrcene

as an important parameter. Values >1.5 were reported to give a "refined flavor" (for Narziss, flavor= smell and taste), while values <1.0 had the opposite effect. Some oxidation products such as beta-farnesene and trans-geranoil were also cited as negative factors. They reported the following:

KEY: Hmfr = Hallentauer Mittelfruh (German), S = Saaz , Cas = Cascade (US),
Clu = Cluster (US) (Ugh!), BG = Brewer's Gold (German) (Double Ugh!).
UNITS: mg/kg

| | HMfr | S | Cas | Clu | BG |
|----------|------|------|------|------|------|
| myrcene | 2642 | 1049 | 3194 | 2536 | 7767 |
| humulene | 5095 | 3512 | 4341 | 1689 | 5092 |

ratio 1.93 3.35 1.36 .67 .66
geranoil10 1253 80 186

The numbers speak for themselves. While Clusters are technically a moderate alpha hop, my experiences with them have been similar to those with BG, and in both cases the results have not been very happy ones. This is of course a highly subjective evaluation. What may be "crude" to one palate may be "complex and interesting" to another.

I talked to Glenn Tinseth on Monday (ordering hops from the new crop), and the values he reported look good. Particularly impressive are how well the new aroma varieties (Liberty and Mt. Hood) are doing vis-a-vis the above criteria. He mentioned that the European aroma hops from the 1993 crop will be available in ~month.

Glenn also noted that his sales of Styrian Golding have been very slow, and that many brewers are uncertain what to do with this variety. In this regard, permit me to cite Michael Jackson's new book (which BTW is excellent). He mentions this hop quite a few times, and notes it is highly prized in the UK both as a finishing and dry hop. I completely agree with this, and feel it does well in select lagers as well. It is certainly worth exploring for those who have not done so.

>
>- ---Frank
>haist@cogsci.ucsd.edu

Sounds like a great idea. I have used Papazian's formula for priming with gyle in a previous batch and it worked out just fine. The brew carbonated quite well.

Miller, on the other hand, suggests that priming with gyle or malt extract can be unpredictable. I have primed several times with DME and had no problems. I have only primed once with gyle so I cannot comment on its repeatability. Note, though, the reason I did not continue with gyle priming was because it was inconvenient, not for any performance-related problems.

On the other hand, one advantage to priming with either DME or gyle instead of corn sugar is that, if you prime with corn sugar the yeast will exhibit what is known as the Crabtree effect and (even in the presence of oxygen) will ferment (instead of respire) thus leaving oxygen in your bottles. If you prime with DME or gyle, the yeast will first go through a minor respiration phase, consuming the oxygen, before they transition to fermentation.

Subject: Chiller Tip, Second on Salvator

I have a small immersion chiller (used some copper tubing I already had) that was not working quickly enough. I connect the chiller to the kitchen faucet while the boiling pot is in one basin of a two-basin kitchen sink. What I did to improve the performance of the chiller is run the output back into the basin with the pot, and run a small siphon from the first basin to the second. The water coming out of the siphon is really hot! This cut my cooling times at least in half. (your mileage may vary - a decent chiller probably wouldnt gain as much from this). Much cheaper than building a new one! I also appreciated the tips about shaking the chiller to stir the wort (I'm going to try that next time), and installing the chiller in your kettle LID (The cops would really bust you for that setup ;^).

I would like to second the recent request for a Salvator type recipe . How do they make that stuff so sweet ? I thought it tasted of licorice (sp?) as well. Any time I try to make a high gravity dark beer it ends up becoming to dry (and sometimes even harsh) after a few months in the bottle. (Havent been able to maintain cold temperatures for real lagering yet ;(

This sig intentionally left blank.

Subject: No airlock activity & Black and Tan

In Homebrew Digest #1261 (November 02, 1993) SHAMAN@WHARTON writes:

;I'm a new brewer working on my second batch. I started this one 7
;days ago and so far there has been no fermentation that I can detect--
;the airlock hasn't bubbled once.

I had this problem in a recent batch. Turns out I didn't have the lid of
my
plastic primary snapped down tightly. It might have fermented just fine.
Look for other signs of fermentation such as a heavy sediment, signs of
krausen (foam), a drop in the specific gravity.

Also in Homebrew Digest #1261 (November 02, 1993) J. Michael Diehl
writes:

>I recall once having a "black and tan." I just wish I could remember
what
>was in it. It was a dark beer and a light beer floating on each other.
>Wonderfull drink, if I'm remembering it right. Any one know how to make
one?

Take a pint glass and fill it half way with Bass Ale. Finish filling the
glass with Guinness Stout. To prevent the layers from mixing while doing
this, pour the Guinness over the back of a spoon. Other variations can
be
made by varying the ale and stout used.

There is a Black & Tan available in bottles. It's put out by a brewery
in
Saranac, NY (USA). Obviously it's not layered. I believe the label says
they
mix one of their lagers with one of their porters and bottle it. Not a
bad
brew.

Subject: Making plugs from homegrown hops

Hi All,

The recent Hops FAQ has got me wondering again about hop plugs. For those of you who are not familiar with them, they consist of dried whole hops, compressed into a 1-inch diameter cylinder that's 3 or 4 inches long.

The plugs are segmented so that it is easy to break off smaller chunks. Plugs have the storage and convenience advantages of pelletized hops, and the advantages of whole hops in the boil (i.e. no pulp to clog filters, strainers, etc.). However, they are only available at a few places, usually only come in 5 or 6 varieties of imported hops, and are a little more expensive: \$6-\$7 for a 5-ounce package.

Now for my question: has anybody tried making their own plugs with homegrown hops? It seems like you would just need a press of some sort, and a mold to form the hops into a convenient shape (i.e. plugs). Any ideas?

Subject: Labels and Florida Homebrew Weekender

>> One comment on using Ammonia to remove lables, works great one them,
>> except, an Etna Lager lable, they use a rubbery glue, the ammonia
helps,
>> butt... let'em soak a day or two.

The easiest way to remove labels that I have ound is this. First, buy a large plastic garbage can with lid. You know, the Rubbermaid type. Then take about one cup of tri-sodium phosphate and put it into the garbage can. Fill the garbage can about 2/3 - 3/4 full of water. Add 1 cup of bleach, and mix well.

Next, as you get empty bottles, just put them in the can. After about one day, maybe two the labels will slide right off. Rinse well and their ready for beer. Labels with a layer of foil such as Negra Modelo, may take longer.

- - - - -

BTW, I got no response to my request for homebrewers in Florida to contact me if they were interested in a homebrewer's weekend meet. So, I'll ask again...

Is anyone interested in setting up a Florida homebrewer's weekend meet? I see possibly having the following:

1. Local venders. (The Home Brewery, Hart's, Best Brew, others)
2. A seminar for new brewers.
3. A seminar for advanced brewers.
4. A beer contest, if we can get qualified judges. Possibly merchandise prizes.

Who's interested?

Subject: RE: melanoidins

I just want to go on a bit about melanoidins... Please keep in mind that I am discussing points in Jones' and Millspaw's article and not any conclusions Norm Pyle may have come to as a result of them in the following.

npyle@n33.stortek.com writes, quoting Jones and Millspaw's "Beer Stability" in Zymurgy winter 1992:
> "Melanoidins are stable complexes formed at high (mash-out) temperatures, they
> are colloidal in nature and are powerful reducing agents giving an acid
> reaction in aqueous solutions."

Melanoidins can be formed at nearly any temperature, but they really take off at boiling temperature. You can (and do) get melanoidin formation in your malt extract syrup at room temperature, if you wait a bit. But they need to be in a "drying" or relatively low moisture environment to make it happen. Melanoidin formation, or nonenzymatic browning (NEB) as it is more generally known in the food industry, is responsible for a large number of reactions. Bread crust formation, meat browning, and baked potato character are all results of NEB. You can see that these are surface reactions, where water is being evaporated out of the food (a drying situation).

That's why microwaved meat is so unappetizing: there is very little NEB going on, so there is little of that roasted meat aroma and caramel brown color. Similarly, this is not the situation in infusion mashing. Decoction mashing, on the other hand, would seem to have more of the right conditions, and is noted for the malty character of the beers it produces.

Each combination of an amino acid and a sugar molecule forms a different melanoidin, so you can see that there are many thousands of possible resulting ones. Also, if the reaction is not strongly driven by the right situation (temperature, low moisture), it has a tendency to fall back into its component ingredients. Unless you have a long time, temperatures under 100C just won't produce a lot of melanoidins. Pale malt, for example, is kilned at 80C for a number of hours, and produces only small amounts of melanoidins. Darker malts, Viennas and Munichs, are dried to 10% moisture at 80C and then raised to as much as 120C to enhance the melanoidin formation and, therefore, color and flavor.

In infusion mashed beers, most of the melanoidin content is coming from the original malt and perhaps the boil, if a kettle is in use that isn't wetted by wort (where the metal temperature will get significantly above 100C and the wort will caramelize or undergo NEB).

> beer. Melanoidins formed at 170 degrees F (76.5 degrees C) are more stable
> than those formed at the lower temperatures of conventional mashing. Adding
> specialty malts only in the mash-out can make the mash more efficient by
> maximizing the formation of melanoidins, optimizing saccharifications and
> eliminating steeping vessels and/or grain bags."

I would really like to know why holding these grains back is necessary; the reaction is less favored at lower temperatures, so little of it goes on. When the situation becomes appropriate, there are still plenty of raw ingredients (simple sugars, amino acids) to continue. (Narziss, in "der Bierbrauerei" volume 1, claims that only a few percent of the FAN (free amino nitrogen, a measure of simple amino acids) and the reducing sugars are consumed in making even the darkest of malts.)

Subject: krausing

On Kraeusining...

I've been toying with the idea of krausing my higher gravity beers just before botteling with fresh yeast (not with raw malt extract as Charlie P claims is the way to do it).

My reason for doing this follows from reports of better carbonation of high gravity brews with fresh yeast at time of priming (this is bottle carbonation obviously). I have noticed that normal priming levels are unreliable for high gravity brews and often undercarbonate, and sometimes leave some bottles with very low carbonation.

I am a practical brewer however, and don't feel like bringing up yeast solely to krause. I do, however, tend to brew the same day that I bottle and thus have a starter ready to pitch anyway. BUT my worry is that this new yeast will like some stuff the old yeast did not, and in a high gravity brew will eat some more of the "unfermentables" leaving me with bottle bombs. (I tend to bring up different yeast for each brew)

I would like to keep from making an extra starter (but will if needed) so I was curious what experiences have been with using different yeast to prime than to ferment.. any bottle bombs? (with high gravity beer in particular)

also even with another starter, the possibility of mutations, or just young eager yeast seems to open the door for further attenuation, has anyone had trouble with bottle bombs when krausing with the same yeast?

Dave

Subject: Re: Sparging Questions

In HBD #1261 Ed asks:

- > Sparging -
- > What is the best way to sparge. Should you?
- > 1) Completely drain the bed, then sparge in one of the following ways?
- > 2) Just match the additions to the drainings?
- > 3) Sprinkle in all the water at once?
- > 4) Others.

I have made 3 all-grain batches (you can use that to qualify my answer) and have tried 2 & 3. My understanding is that with option 1 you run the risk of compacting your grain bed and may be more prone to a stuck sparge. I think option 2 is the way sparging is most frequently described and that is what I did for my first 2 batches. What I have gleaned from others is that the water level should remain at least 1" above the top of the grain bed and that water being added should not disturb the grain bed. I found that running the sparge water through a colander does a nice job of keeping the grain bed undisturbed.

On my last batch, I tried option 3; this has also been referred to as batch sparging. I put all the sparge water into a picnic cooler with a slotted copper manifold, added the mash and waited about a half an hour. Overall, it worked quite well but I would offer this caution. When I made my first two batches, I had not preheated enough sparge water so I did not get as much wort as I expected. When I did a batch sparge, I increased the sparge water and I overshot & had to stop draining before all the sparge water was gone - no more room in the brewpot and I was not ready to sign up for a 3 hour boil. Thus I ended up with a lower gravity wort than I anticipated (1.040 instead of 1.050; still quite respectable though). The reason there is any difference between the two methods is that when you add all the sparge water at once, the sugars are mixed pretty uniformly through out the sparge water. When you add sparge water as you drain off the wort, the first runnings will have more sugar in them than the last. Thus if you stop early, you have left fewer sugars behind.

Once you have your recipe down and know how much sparge water you need, I don't think it makes too much difference except that batch sparging will require less attention from the brewer.

Subject: Business Week Article

In the October 25 Business Week (page 95) there is a article in the "Developments to Watch" section about gene-splicing and how Shiladitya Dassarma (professor of molecular genetics at U. Mass (Amherst)) spliced genes from bacteria that float to oil eating bacterium that didn't so that these bacterium would stay at the water surface and keep eating oil. The article goes on to say how "Next may come reengineered yeast for beer-making. Dassarma says the yeast would float to the top of the vat to be skimmed off - so the beer wouldn't have to be filtered."

This will most likely work for lager yeast, but for ale yeast I would think that the dead yeast cells would reduce the available surface area for the live yeast cells to do there thing.

Subject: Going all grain,questions

I have some questions about all grain brewing, Hopfully I will be able to brew my first batch of all grain this weekend but first I have some questions.

I plan on using a cooler for a lauter tun, the problem I have is that my boiling pot is only 3-4 gallons.

My question is, can I make an initial wort of 3 - 3.5 gallons in the cooler and add more water to my fermenter after the boil to make a 5 gallon batch?

This is what I do for extracts and it works good. I realize that it's better to add water for the hole batch up-front but I don't want to spend alot of \$\$ for equipment until I know what I'm doing. Or should I just make a 3 gallon batch to start with?

How much grain would I use if I can add water to the wort later? Would I use enough grain for a 5 gallon batch up-front? Which is ? What would the brewer community recommand I do?

How much grain should be used per gallon of water?

What temp is good in the lauter tun and for how long?

Any info would be appreciated.. Todd I realize this info is available in books but I don't have mine a neighbor borrowed it? I hope I understand the process.....thanks

Subject: maplbrew.txt

I mentioned that I had a couple of maple sap brew recipes and several people asked for them...so here they are. Taken from a maple sap cook book found at a sappers festival.

SAP BREW #1:

Leona Foote - Warren , NH
Use the last run sap and boil down about half way. Boil checkerberry leaves, pipsis-o-way and hemlock tips separately and then add sap. Put in barrell to work, put in bung when fully worked. In the middle of summer, during haying, chill and enjoy. (sorry no amounts were available on the ingredients.

SAP BREW #2:

Althea Clark - Bridgewater, NH
1 lb. hops
10 lbs. malt
6 yeast cakes
2 oz. checkerberry
Boil down sap, 5 gal. to make 1gal.
Boil enough sap to fill a 50 gal. barrel. This is an 1885 family recipe and came with no instructions.
Good Luck!

Subject: On making bread (et al) from spent grain

Chris (dcm@kepler.unh.edu, HBD 1262, 11/3) asks about bread ideas from spent grain. Good question.

During a spate of all-grain brewing (ah those were the days) I'd wonder what to do with all the good-looking grain leftovers. I tried 'em as porridge with half & half and brown sugar. Didn't work. They were too woody, and they look better than they taste by themselves. After all, by the time they're leftovers, you've mashed & sparged out most of the flavor.

So I tried mixing quantities of the stuff into a basic bran muffin recipe.

Just substitute some of the grain for some of the flour (I played quantities by feel). I added lots of raisins to boost the moisture and counteract the woodiness. But I found the texture pleasantly rough (a delightful gastrointestinal massage). Most of all, I found the muffins completed the beer experience in a satisfying way. After all, if you eat the mash from whence cometh the beer you drink, you're living your beer. Beer: the complete food.

Bon appetit. --Jan (holloway@indiana.edu)

>intuitively obvious to me. I also would point out that I have dry hopped
>1 BBl batches in the primary (after high krausen and skimming) for a mere
>3 days with excellent results, and I know of a local brewpub that has dry
>hopped with pellets (I use whole) for one day, filtered and served online
>the next, so this will work. The point is that dry hopping times vary all
>over the spectrum, and I suspect if a heavy hand is used in the amounts, >
>time is less important. I'm still wondering about the lager comment???

I've been taught that virtually all reactions, physical and chemical, are quickened by higher temperatures (I'm sure there are exceptions). The process of dry hopping involves aromatic oils dissolving into solution and probably reacting chemically as well. Doesn't it seem obvious to you that higher temperatures cause this process to happen faster, and that lower temperatures would slow it down? When making tea, you can certainly dissolve the sugar quicker in hot tea than iced tea.

As far as quantities vs. contact times, it is also obvious to me that if you use more hops you can get away with less contact time. You have (at least) three variables (assuming a fixed amount of hop aromatics): time, temperature, quantity. Probably wort composition at that point has an effect as well. I was trying to give some guidelines, not write the New Brewing Bible.

Cheers,
Norm

From: David Atkins <ATKINS@macc.wisc.edu>
Subject: Hop Vines & extract storage

Jim Busch mentioned the practice of not cutting hop vines, allowing roots to store energy. Im no botanist, but Jim does make a good point. While my biology days were some time ago, I believe that the roots store many good plant things--such as chlorophylls, sugars etc--for their winter slumbers. When leaves and vines wither, these elements flow to the roots and await the spring.
If you do any leaf or vine cutting, as for any perennial, wait till they get all brown and dry before removing...or even wait till spring.

Extract storage: In planning for the days that I may not live near a homebrew shop and/or have not yet gotten into the swing of all grain full mash beering, could anyone offer tips on storing large quantities of liquid or dry extracts.

Thanks,

Subject: Distilling alcohol

With all the talk about leality and taxes and what not I thought I'd add in my \$.02. I worked at an ethonal plant for a while before coming back to school. In the plant we made beer in a continuous process. It was not batch. The alcohol content usually ran between 10 and 11%. I never tasted it, but I was told that it tasted OK. Kind of surprizing since the main ingrediants were corn starch that was converted to dextrose, water, and light steep water (the water thats left over after soaking on corn for a day and a half). Oh, and yeast. Some of the bear was run through a massive centrifuge that would separate the yeast from the beer. We then put the yeast back in the first fermentor tank. The first tanks we added air. This was supposed to help the yeast reproduce. The later tanks we did not add air. The yeasts were supposedly switching over and producing alcohol. We ran the 10% beer thru a set of distilation columns at 2000+ GPM. Fusel oils were removed from the process, at only a few gallons per HOUR. There was not fusel oil in the stuff. We removed it because if we didn't it would block the column. The fusel oil comes off in certain trays which depend upon the pressure (temperature) that the column runs at. After the regular column we distilled it up to 200 proof by adding cyclohexane. I was told that the 200 proof mixed 50/50 with water tasted like a very good vodka, but I never tried it. To be used in gasoline the proof had to be 199.4 (or was it 199.6?). The small amount of fusel oils could be added back in. When it was sold to add to gasoline it was denatured with 5% gas. This is so the BATF is happy and no one will drink it. If it was sold for industrial used it was denatured with 5% methanol. If it was not denatured it had to be sold to some that was bonded so that they would worry about the taxes. The taxes that are so high are not paid if the alchohol is not for consumpsion.

As far as distillation by a private individual, I have a friend that was making ethonal to run in his car. He got free starch, free wood to run his still, etc. The only thing he had to buy was alpha amalose to convert the starch. In order to run his still he had to buy a \$500 liscense. This allowed him to run the still and use the ethanol for personal use, ie on his property or in his car. I don't know if it meant he could drink it, although I don't see why not. He finally gave up. With the liscense and the alpha amalose as his major costs he could come out slightly ahead. After the novelty wore off and he got tired of putting major amounts of time into it he quit. So,....Distillation is legal for individuals, but it costs big bucks.

> whiskey mash just a very new "wine" for the sake of this discussion.

Yeast produce a number of alcohols during fermentation depending on the source of carbon (food), strain, ferment temp. etc etc. All alcohol causes intoxication and is poisonous-some forms much more than others. Lightin' distillations have been notorious for containing methanol. Why? 1-product adulteration by producers, 2-BATF scare tactics, ie. misinformation (anyone actually met a person blinded by an honest and clean home distillation? Or a jug of moonshine for that matter.
NOT
Sterno or Xerox fluid.) 3-poor distillation technique, or 4-Based on fact.
IMHO the real questions are: Does the fermentation of corn, rye or *other stuff* favor the increased production of methanol over ethanol? *other stuff* would be very significant.
I suspect the answer is yes. I also suspect that wine/brandy would be less of a problem in this regard.
Does the strain of yeast/bacteria (ie sour mash or whatever whiskey makers do) effect the increased production of methanol over ethanol?
Again I suspect the answer is yes. We all know what happens when beer fermentations are run at high

temperatures-high alcohol and other byproducts, some strains are much more prone to this behavior. Headaches are a symptom of this alcohol toxicity.

I assume that only GOOD, CLEAN BEER would make GOOD, CLEAN SCOTCH...Ah! a good question for Michael Jackson.

Distillation will concentrate only what you want it to by collection only during the temperature range that you want. Of course this is technique and equipment dependant. For alcohols, methanol comes off first (65C) followed by ethanol (78.5) propanol (97), water (100), butanol (117) etc. Don't drink the methanol, propanol or anything that boils higher. Don't ferment and distill garbage.

>Malted grain is friable and crumbly. When gently squeezed, it falls apart,
>exposing the malt to mash water. This is definitely not true of unmalted grains. If you have the strength to run it through a roller mill, the best you will get is something like thick oatmeal. As there usually is no husk involved, there is little advantage to a roller mill over a grinder. I suspect, a Corona me be more efficient if your lauter tun can handle the fine grinst. That is, after all what they were designed for but it won't be any easier to crank.

My last batch of lambik contained 20 lb Breiss 2-row and 10 lb unmalted wheat which was ground with *much* difficulty. The wheat was boiled for 30 min after which it was something like thick oatmeal. The kernals burst open and later vanished in the mash. Since the whole grain would cook (and burst) as well as the ground grain and probably still look something like thick oatmeal, my new attitude is *GRIND IT? NOT ME!*at least until I've tried it.

>From: ed fromohio <NEGATIVE3@unh.edu>

>HI, I was wondering if anyone has a recipe or idea for bread from the >spent mash....

I've tried it, but don't recomend it unless you are very careful to remove all those nasty little rocks that seem to slip into the grain on occasion. Ouch!

Did Wilt Chamberlain fake it? Oh.....but he *likes* basketball.

Subject: Re: Plans for Grain Mill

- - - - -
Dion Writes:

I feel that Steve made light of Jack's efforts because he complained about the cost and said right after that he could do a good without much effort (this is a paraphrase). A lot of other people complain about the retail prices of equipment like Jack's and state that they could do as good for a lot less. I was just pointing out why retail prices are generally extremely fair and what really goes into making a product, rather than a one-off copy of someone's design. If you make it yourself and it does not last or does not work quite up to snuff, then you generally don't complain. Jack and other inventors have to make a product which works well and last, which most of them do.

Jack's mill is a nice piece of work. My complaint about the cost doesn't counter the craftsmanship of the work. Jack however is making a profit in this mill. There's nothing wrong with profit -- if you want to pay the price. Most of the cost associated with the mill is in labor. The mill can be made much cheaper if you use your own time as labor. Furthermore, if you enjoy making things, the labor can be fun -- hence enjoyment becomes another reason to build the mill.

Jack's mill is nice, it's not the end all however. I'm sure we can put together another mill that will be better in some respects -- perhaps one of these respects will be manufacturability with a minimum number of tools. I have never intended to copy Jack's design, I would rather try to devise a mill that can be built with largely existing hardware. It would be nice if anyone could build it -- even w/o access to a decent mill and lathe. Then people will copy, improve, copy, improve, ad infinitum. It's always easy to build something with all the tools you need. I've always respected people who do things on a shoe string budget more than ones that do it by throwing money at it. People have been mechanically grinding grain since the 1400's (at least). I don't think they had stainless and carbide. Finally, Jack's mill isn't an invention, it's a craft. There's nothing that special or unique to it. It's simply a good piece of work.

I really don't understand Dion's hangup on building a mill. Please go throw water on someone else's parade. We are having fun over here.

I am still collecting ideas for parts of the mill. If there are any interesting ideas for the rollers I'd appreciate a note. It'd be nice to use parts that are available at hardware stores, etc.

Thanks,
Steve

Subject: Hunter Airstat

The Hunter Airstat is a relatively simple electronic device. It has some nice facilities which monitor the on time for the current day, previous day, and total usage as well as maintaining the the temperature. It also has a digital display for the temperature. And as noted previously in these tombs, has been discontinued.

The plans for a similar device are available for \$10 from JB Distributing. The plans show the details of a device which will control your fridge temp as set by the owner. It doesn't have the nifty display and monitoring features. JB Distributing says the circuit boards for this design will be available soon and they have the plans for a more advanced model on the drawing boards. They also have plans and circuit boards for other items like a digital brewers thermometer with a 30" probe (great for deep vessels of hot stuff).

From: c-amb@csc-sun.math.utah.edu
Subject: water adjustment questions

I have been going over my water analysis and Dave Miller's book to figure out what water adjustments I am going to need before my first all grain. However, Dave leaves out some quantitative information which I seem to need.

First let me give you the important numbers (3 year average):

Bicarbonate 251 ppm
Calcium 43 ppm
Sodium 5 ppm
Sulfate 12 ppm
Magnesium 17 ppm

Now, as you can see, the bicarb level is quite high. Moreover, there is not enough calcium to simply boil off the bicarbs. Thus, using Dave's formulas I have calculated that I would need to add approx 2 tsp. of gypsum for 5 gal. of water prior to boiling in order to remove the excess bicarbonate. This will also raise the sulfate level to 292 ppm and this is where I start to get nervous. Dave says that excess sulfate will add a dry edge to well hopped beers. Sulfate combined with sodium makes this quite harsh he tells me. This makes the hophead in me quite nervous. However, how much is too much? Because of my low sodium level am I o.k. with this high level of sulfates? Any info or pointers are greatly appreciated.

Thanks in advance,
Mark Alston

Subject: Chilling Out, Hops, Brass

I decided to scrap my original responses to the ad hominem comments on my remarks about chillers and try something completely different.

Not only do I have strong feelings about chillers but I also think the net.sense.of.humor needs a little thrashing. I sold my business and retired at age forty because I got tired of kissing the world's behind and making sure that nothing I ever said offended anyone, anywhere on Earth.

I make beer and beer stuff and participate in these discussions because it is fun and mutually informative. When things get boring, I inject a little fun but everybody has their own idea of what fun is. If people do not like my humor, that's life and I accept it. The fact that I refuse to use these things :) is part of the fun because baiting the humor impaired is right up there with sex as far as I am concerned. It might even be as much fun as "beer drinks".

I find that using expressions like "the Lighthouse of Wisdom and Truth" and the "World's Greatest Beer" is a great way to bring the real weenies out of the closet. I have little sympathy for people who take them seriously.

I will bite my lip (fingers) and keep my responses non-personal and offer the following summary of the current comments that are worth repeating:

1. If the claims of efficiency are correct, water conservation is a good argument in defense of the C/F chiller.
2. A KB type HOP BACK (tm) will only work properly with a C/F chiller but it remains to be proven that it offers any advantage over a immersion chiller with a tight fitting lid.

End of list. No one even claimed that they make clearer beer this time.

I refer readers to my previous comments for the counter arguments in favor of the immersion chiller.

>From: ed fromohio <NEGATIVE3@unh.edu

>Subject: Bread from mash recipe request

>HI, I was wondering if anyone has a recipe or idea for bread from the spent mash....

BEER BREAD

3 cups spent grain (wet)
1 cup flour
1 cup warm water
1 tsp yeast
1/4 cup sugar

Mix and let ferment in warm place for several hours or overnight.

Add 1 tsp salt and knead in or mix flour, one cup at a time, until the dough will not stick to the fingers. This will take about 5 additional cups, the amount depending on the water content of the grain. Then continue to knead or mix until a silky texture that does not stick to fingers is achieved.

Let the dough rise (covered) in a warm place for at least an hour or till it doubles in volume. Then form into loaves and let rise again. When doubled in volume, bake at 375 for 25 min.

I roll the dough into bars about 2" in diameter and about 10" long and just lay them on a baking sheet. If you bake full size loaves in bread pans, the baking time would probably be longer.
.....

Since getting a Corona, I now dry the spent grain and grind it up with the Corona to get a more acceptable texture. One cup dry and three cups water works out for the above recipe.

>From: Jim Busch <busch@daacdev1.stx.com>

>I read in Brewing Techniques that if the vines are allowed to remain uncut at the end of the season, the rootstock will build up energy stores for the upcoming winter season, and be healthier next year. This is obviously not practical for big farms, but due to my inherent procrastination, it is exactly how my plants are now. Comments?

No comments here, just the ULTIMATE TRUTH....

From the plant's point of view, it is best to allow it to grow until it goes dormant. The root stock continues to develop as long as photosynthesis is going on. Once it goes dormant or freezes, the vines are dead and it makes no difference what you do with them. There are practical and economic reasons for cutting them earlier but it does compromise overall vigor.

Subject: All-Grain FAQ???

With the recent proliferation of FAQ's, I've been wondering about a similar resource for grains. What I'm most interested in is some sort of comparative listing of the characteristics of various grains. Color, enzymes, and especially flavor/body profiles like those recently provided for hop varieties. Also interesting would be some sort of interaction guide, noting interesting or perhaps traditional mixes which achieve certain common goals in mashing.

Does anybody know a good book for this? Seems like the really excellent technical guides all focus on a single variety of beer, which is too restrictive (especially when I tend to throw style guides to the winds and INVENT)...

*Subject: airlines, porter, brewbup, Sheath and Vine

*
*Just a few interesting tidbits:
*Yesterday my wife tried to take 4 homebrews on American airlines
*out of Raleigh-Durham and was stopped at security. Although the
*bottles were capped, since they had no label she was not allowed to
bring
*them into the passenger cabin. They said they could be stowed in the
luggage
* but we declined, fearing depressurization problems.

My family's experience with transporting beers has been much smoother.
Ah,

but of course they were labeled. If yer gonna take them, slap a
commercial
label on it just to get it on the plane (in the plane.) I do, however,
recall
at least one occassion where bee> r> s were stowed in luggage on a
transcontinental flight (smuggled much Maisel's) with no ill effects.
Just
luck I ask the faithful? What say yinz?

* Re: Swan V. Taylor's request for info on brewpubs in the Chapel
* Hill area. There are none in Chapel Hill, one in Raleigh
(Greenshields),
* and one in the Winston-Salem area (Lagerhead or Loggerhead?) that I
know
* of. the one in Durham (aka:Weeping Radish,etc.) bit the big one!

*
Bummer. So far Weeping Radish is the ony place I've been to in the
states
that serves by the liter krug. (Then again, the MidAtlantic is lame for
good
drinking establishments.)
As far as I know, the one in Manteo, NC is still open (Manteo is on the
Outer
Banks, across the sound from Nags Head/Kill Devil Hills). Really good
German
style drafts, darts, German pub grub, etc. A great diversion while at
the
beach, and a beautiful drive across the sound if you do it at sunset.

Neophyte's question, if not adequately covered in the FAQ: what is the
benefit of mashing, what's> > generally involved, and what
distinguishes a
mash-out from a normal mash?

And does anyone else do much substitution of honey for other priming
agents?

In small quantities, it's wonderful! Even in large quantities it's really good, but you get a really sweet beer, one that bears little resemblance to what the indians called, uh, beer.

From: axl@cherry-semi.com (Al Lingley)
Subject: patio hop growing

I live in a condo style apartment and have had limited success growing hops on my deck. I used a 1x3x1 planter box and ran twine up to my bedroom window one story up. I would recommend using larger planter box, as I feel my plants are now root bound. I planted hallertauer which I have been told is a lower yielding variety.

The first year netted a few shoots about 7 feet in length, due to my planting late in the spring. Year 2 (this year) netted many 20 ft. vines and about 3 ounces of dried hops. My low yield was mainly due to Japanese beetle infestation.

About the only advice I can give is to water daily (soaking), and shake those vines at least once a day (beetles). I fertilized about every 2 weeks with Miracle Grow.

From: mberger@wellfleet.com (Michael Berger)
Subject: RE:Post boil wort handling

My thanks to all those who replied to my recent posting of questions regarding the handling of the post-boil wort and the off-flavors that can come of it. The answers were essentially unanimous and I have summarized the recommendations below.

After the boil is complete, the wort should be chilled using your favorite chilling technique. The hot wort should be exposed to air as little as possible in order to avoid the dreaded HSA (hot side aeration). HSA is a common cause of a "cardboard-like" off-flavor. A rapid chilling of the wort also reduces the risk of bacterial "action" that could cause other off-flavors.

After chilling is complete, the wort should be racked into the primary using a racking tube with a "copper scrubby" on the end to filter out hops and other solids in the boiler. At this time, the *chilled* wort should be aerated.

The primary should be a carboy instead of an open plastic bucket. You can set up the carboy as a "blow-off/by" for the primary. Your chilling method should have brought the wort temperature down to pitching temp so you should immediately pitch your starter.

Thanx again.

From: Paul Boor <PBOOR@BEACH.UTMB.EDU>

Subject: rice, the other light grain

Rice has been mentioned recently as a way to emulate "your bud". I advocate the use of rice in allgrain brews of all lighter type, and have used it lighten porters. It's not just for yaller-beers.

Good rice, like Indian Basmati, has a nice aroma as well. I use a half to a pound, cooked well and added to the mash with the regular grain bill. the amazing thing ishow it lowers the finishing gravity, like down around 1005 for a beer that might be expected to be 1015.

Rice is used by many commercial brewers, my favorite being The Utica Club Brewery in Utica NY, makers of such greats asSaranac Adirondack Lager. Try their beer if you get to upstate New York. The brewery has also done some nice contract brews in the past, jumpstarting such beers as New Amsterdam and Sam Adams (yes! the boston lager was orginally made in NY)

>Pale is Pale??? No adjuncts used currently, so I don't need extra
enzymes.

>Describe how to tell if grain is good? Miller goes into it some (or was
it

>Noonan?), but what do you look for?

When you say "simple infusion mashes" you probably mean "mashes with no
protein rest," right? You can do this with infusion mashing (raising the
temperatures with INFUSIONS of boiling water) or "stovetop" mashing
(raising
the temp with a heat source.

Whether or not you need a protein rest is dependent on how well modified
the malt is. Most modern malts that we get in the stores are well-
modified.

Perhaps some of the custom malts that A-B or Miller or Coors use are less
modified, but we certainly won't be getting any of that stuff normally.

You can tell how well modified a malt is by looking at how long the
acrosipire

has grown (I believe it was Noonan that described this in detail). What
you

do is rub off the husk on the acrosipire side of the grain and compare the
length of the acrosipire with the length of the whole kernel. If the
acrosipire

is 3/4 of the kernel length or more, then the malt is fully modified. If
it

is significantly less than 3/4 of the kernel length, then the malt is
less-

than-fully-modified. You need to do this on a couple of kernels and
consider

the average length.

Also, as you probably already know, more highly kilned malts (like Munich
malt)

have less remaining enzymes than the less kilned malts (like Pilsner
malt)..

Malts like DeWolf-Cosyns Aromatic is reported to be able to convert
itself

despite being a highly-kilned malt, whereas I believe that DWC Biscuit is
not

able to convert itself.

Andy writes:

extract brewing as well as all-grain. The problem: the all-grain version will require pilsner malt and the extracts I've been able to find (DME & LME [No, not Male extract]) are all based on Pale Malt. Does anyone out there in HBD-land know of Pilsner Malt extracts that are Unhopped and (hopefully) no adjuncts?

I think your best bet is perhaps might be Alexander's Malt Extract. It and Munton & Fison Extra Pale are the two lightest extracts that I know of.

The difference between the flavor of Pale and Pilsner malts is really just that the Pale malts tend to have a bit of caramel (just a bit) in the flavor, thanks to the higher kilning temperatures. I would suspect that these two really pale malt extracts will have used the palest malts the manufacturers had available. M&F is in England, so maybe the Alexanders may be the most Pilsner-like of the two. Another consideration may be to use German extracts such as Ireks Bavarian Light or Bierkeller Light, which are probably made from Pilsner malt.

Al.

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: AAU, IBU, and published numbers

I've been getting lots of use out of the hops FAQ, but I am left with a nagging question. I was trying to follow Pierre Rajotte's belgian ale recipes, but when using the formulae from the hops FAQ the numbers seem

way off. For example, one recipe calls for 7 HBU's or 22 IBU's of hops. Another calls for 10 HBU's or 30 IBU's. Now even being super conservative,

I get 10 HBU's is roughly equal to 38 IBU's. That's over 25% more! And using the equations unmodified, 10 HBU's is in the range of 48 IBU's, or 60% more. What gives?

Just so you can frustrate yourselves too, here are the (simplified) equations I've been using:

$\%Util = 13.11 + 13.86 * \text{TANH}((T-31.32)/18.23)$

$IBU's = \%Util * \%AA * Qty / Vol / 10$

Where: T is time in minutes,

$\%Util$ is in percentages (ie 0-100, not 0-1)

$\%AA$ is the alpha acid content in percentages

Qty is the quantity of hops in grams

Vol is the volume of wort in Litres

$\text{TANH}(x) = (e^x - e^{-x}) / (e^x + e^{-x})$, e being the mathematical constant epsilon, roughly 2.71828

Note the 13.11 value in $\%Util$, versus the 18.11 value in the hops FAQ. This is to convert to the modified utilization table presented by Mark Garetz.

> From: "Edward F. Loewenstein" <SNREDLOW@MIZZOU1.missouri.edu>
> Subject: Cutting hop vines

Jim,

Just read your posting on the homebrew net and hope I can be of some help.

Commercial growers of hops mechanically harvest their hops by cutting the vines off at ground line when the hops are ripe and separate the cones from the vines via a machine similar to a cotton gin. Of course some of the cones are a bit overripe, some underripe, but some allowances must be made for mechanization.

By picking the cones by hand, as most homegrowers do, you can pick all of the cones when they are ripe. Further, I have found that many hop varieties (Cluster, Nugget and Pearle) produce additional flushes of flowers following initial harvest.

Concerning leaving the vines in place after the end of the season. indeed, leaving the vines after picking the cones (while the leaves are still green) does allow the hop plant to produce and store extra carbohydrates in the root system for the following year. Once the plant senescens (leaves and vine turn brown), no additional benefit is derived. At this time, or shortly thereafter, it is wise to cut the vines and clean-up any fallen hop leaves from the area. The reason for this is that fungal organisms overwinter in and on the dead plant material and if left can infect/reinfect your plants the next growing season. Typically, downy and powdery mildew and verticilium wilt will follow this life cycle. Insect larvae such as aphids can also overwinter in infected dead plant tissue. I try to remove all hop leaves to my compost pile (located well away from my hop mounds), or if I have had a problem with an infection, burn any infected material (downwind from the mounds). I also use the dead vines to weave wreaths for Christmas decorations. My wife decorates these with dried flower arrangements. I've also heard of people selling these wreaths to craft stores.

Hope this helps.

> but we declined, fearing depressurization problems.

The cargo bay and passenger cabins of commercial aircraft are both
pressurized
and heated. From a structural point of view, with pressure differentials
dominating fuselage design, it's easier to pressurize everything between
the
forward and aft pressure bulkheads, the cargo bay included. (Bombers'
bomb
bays, by the way, which must be able to open at altitude, have all sorts
of
additional fuselage pressure structure that is unnecessary on commercial
aircraft.)

At cruising altitudes on commercial airplanes, this cabin/cargo pressure
is
maintained at about 11 psi; that which you'd experience at about 8000
feet
altitude. So, during the flight, an additional 4 psi would be added to
the
pressure differential already experienced by your bottle of homebrew (If
more
cabin depressurization occurs, you probably won't be worrying about your
homebrew!). That's not too large an additional load, considering that a
modestly-primed bottle of homebrew is already experiencing a pressure
differential of about 20 psi at sea level (This is according to my
back-of-the-envelope priming sugar calculation - maybe someone can
verify?).

So, taking your homebrew on an airplane, either in the cargo hold or as
carry-on luggage, shouldn't cause the bottle to blow unless you're
already
operating on the ragged edge of your bottle cap's safety factor! Given a
choice, I'd opt for carry-on luggage, since baggage handlers sometimes
lack
that delicate touch.

Subject: Steam injection (one more time)

Boy, am I sorry I ever mentioned this.

Please everyone, calm down and react to what you read, not what you think you read.

I know that high pressure steam is dangerous. That's why I specifically stated that this was low pressure steam. The 15 psi or less put out by a home pressure cooker is slightly dangerous, but only if it comes in contact with you or material that can't handle the temperature.

I know that modifying a pressure cooker's safety release valve is dangerous. That's why I specifically stated that we didn't modify it (that little valve with the weight on it is not in the center of this particular model).

Dan Listermann, who built this gadget, is still kinda computer-shy, so he can't handle direct contact yet. He 's beginning to get the hang of Compu\$pend, but isn't quite up to e-mail yet. That's why he asked me to post the original question here, as to whether anyone else had ever tried this technique. It appears that he's the first. OK, back to the drawing board, and he's working on a second version that will incorporate some more safeguards and be less prone to misuse. The fact remains though, that the initial attempt worked superbly when used with care!

Subject: Brewery Liturature

I'm interested in reading about the breweries that were around in the pre- and post prohibition area in the United States. Specifically historical accounts of Brewery size, specialty, even examples of their logos/labels.

I'm rather new to this group (this is my first posting :-) and I'm not sure if this topic was ever previously discussed, or in the archives. I'm looking for any titles of books or articles. Thanks group!

Subject: how I sparge

Ed asks about sparging:
> What is the best way to sparge.

Welcome to the world of all grain brewing!

Here is how I sparge (68qt cooler/copper manifold) (sorry about the steps :-). It may not be the best way, but I works for me.

1. Underlet mash with sparge water. I connect my hot liquor tank to the manifold outlet and fill the cooler to the brim. This will help raise the mash temp to mash out.
2. Add specialty grains if used.
3. Stir the mash for even temps.
4. Let sit for 15 minutes.
5. Connect pipe from cooler to brew kettle and draw off about 1 quart. I don't recirculate until clear but enough to remove the *big* chunks.
6. Carefully pour the quart on the top of the mash water.
7. Slowly drain sparge water into brew kettle.
8. I repeat steps 1-7 until I use all my sparge water or the gravity gets below 4P (about 1.020).

I find underletting the sparge water will help reduce HSA. Bob Jones and Micah Millspaw recommend underletting the mash for better beer stability in last winters Zymurgy and Norm Pyle restates Bob and Micah's article a recent digest.

The batch sparge is very easy and helps when I have other things going on (like wife, kids, house...). This was recommended by several other brewers in this digest.

Letting the mash sit for a bit (I use about 15 minutes) help settle the grain bed.

Chilling out with my counter-flow chiller,
rick

From: Ed Hitchcock <ECH@ac.dal.ca>
Subject: Re: Another immersion chiller

Steven Smith mentioned his 'hang from the edge of the pot' chiller, which sounds pretty cool. I would like to toot my horn once more and promote the joys of the planispiral chiller. It's a flat coil (like an electric stove burner) of 25' of 1/4" OD copper tubing, the last (outer) coil descends to the bottom of the pot as a support, and the in/out tubes hang over the side also for support. The disc/coil is suspended an inch or two below the surface. The cooled wort drops to the bottom, warm wort rises up the sides. I've never had to stir my wort to get it to chill properly, the convection currents are sufficient.

From: mlobo@sentry.foxboro.com (Michael T. Lobo)
Subject: easy wort chilling method

Greetings:

After reading todays HBD, I figured I'd put in my 2 cents worth regarding wort chilling. I take the KISS approach (keep it simple, stupid)

After my boil, I take the 20 qt pot and stick the whole thing into my bathtub full of cold water (my cold water is VERY cold). I keep the lid on and in about 30-40 minutes the temp is down to pitching temp & all I do then is transfer to the primary, pitch the yeast and have a home brew [:^)

regards,
Michael

Subject: Eisbocks legal

I've discovered some interesting information regarding the legalities of making eisbocks. There has been some question as to the legality of making an eisbock since it does involve a form of distillation. Well, a friend of mine who is in the process of opening a microbrewery (Ravens Ridge) here in Fairbanks had an opportunity to talk to somebody with the BATF. According to this person the amount of alcohol concentrated would be insufficient to, in their books, be considered distillation. Therefore, it is legal for homebrewers to brew eisbocks. Now you can brew relaxed, not worried and guilt free.

Cheers,

Scott

Subject: Clubs

A note about clubs. I recently moved and have been helping to re-energize our club in Syracuse, NY. It seems that the way to go is definitely to plan out in advance what will happen at each meeting. We are trying to have an educational aspect, then perhaps a tasting, and then the socializing part. These events are planned out 6 months in advance, and put in the newsletter for long range planning

Also, try to get free advertising. The local newspaper and the local weekly put in free ads. Also, the place we meet, Clark's Ale House, pays for 1/2 of any flyers, etc which have his name on it (as the meeting place). One other thought we got from the AHA annual book--we made business cards with our name and meeting place--they are in the brew shops and beer retailers. People can pick them up as a reminder for the meeting. They're cheap--about 20\$/500.

Subject: Cider

Coyote suggests a few ways to get apples/and pressing cheap - here's another: if there are orchards in your area there are certainly *abandoned* orchards in your area - these offer a bit more challenge, but lots of apples - for free (or almost, usually the owners are happy if you give them a couple of gallons of your sweet cider).

The advantages - this greatly reduces your price to the price of pressing (it costs us 60 cents a gallon - for something like 140 gallons this year). And you get more variety - in my experience it's the variety that makes for good cider.

From: dra@jsc-ws.sharpwa.com (Darren Aaberge)
Subject: Rye and Spruce

The last issue of Brewing Techniques has an article about using rye in beer.

Basically it sounds like you use rye as you would use wheat in a wheat beer.

This article has made me curious about using rye and I was wondering if anyone has tried it. If so, what's it like? Is it like wheat beer or is it totally different.

The article gave the following recipe:

8 lbs pale malt
4 lbs rye malt
1/2 oz Centennial (bittering)
3/4 oz Northern Brewer (finish)
1/2 oz Centennial (finish)
2 tsp Irish Moss
Wyeast 1056

Has anyone tried this recipe? Does anyone know of a source of malted rye? I checked my local homebrew shop (Steinbart's in Portland, Oregon), they didn't have malted rye but they did have flaked rye.

Regarding the recent thread on spruce beer, I have brewed spruce beer using fresh growths off of a spruce tree. The flavor you get from it does not remotely resemble pine-sol. From reading recent posts it sounds like the people who are using spruce essence are the ones with bad experiences. Maybe this says more about the quality of spruce essence than the flavor of spruce beer.

Diastatic Malt Extract is an extract with the ability to hydrolyze
starches
into simple sugars. This is what the enzymes in malted grains do during
the mash cycle of all grain brewing.

Date: Thu, 4 Nov 93 14:36:48 +0100
From: steve_t@fleurie.inria.fr (Steven Tollefsrud)
Subject: Convert to all-grain?

I've been brewing with extract (usually Munton) on and off for about 6 years. I started with Williams Brewkits when I lived in Phoenix, then quit for about 3 years when I lived in Munich, Germany (seemed a bit pointless because the beer there is cheaper than water and I was "researching" the beers, the breweries, and the biergartens, leaving no time for even extract brewing). My brewing stuff collected dust in a german keller for three years. Then I moved to the south of France a couple of years ago and found myself in a relative beer desert (well, Munich would be a tough act to follow no matter where I moved). So I dusted off my fermenter and brewkettle, hunted down the address of a homebrew supply shop in the UK and picked up where I'd left off in Phoenix. I started with some basic IPAs and Steam beers, and started experimenting with various grains and yeast types. The results were surprisingly well received by the French natives (a discriminating people, especially in matters of the palate). This was very encouraging.

A colleague at work turned me on to the internet and HBD about a year ago. I tuned in just about the time of Jack Smegmling's [sp?] holier than thou pronouncements along the lines that extract brewers are ignorant, lazy, and not worthy to share the same bandwidth with real brewers (all-grain). This was very encouraging/.

Even while I put in a couple of cents in defense of extract brewing, I knew, deep down in my heart, that I would eventually move on to all-grain brewing myself: the more I learned about brewing, the more fascinated I became.

My only reservations are:

- 1) Cost of grain: Homebrewing is unheard of in France. I have to have my extract shipped from England. As I'm paying shipping costs for 8-10 lbs of extract per 5 gal. it can add up. How much grain is required to make 5 gallons of all-grain (say OG 1050) and what is the typical cost of the grain (\$ or Brit. lbs)?
- 2) Time: One excuse I've always used for not brewing all-grain is that it is very time intensive. I'm repelled by the image of slaving for hours over a steaming kettle, though I never knew how much time is really necessary to do all-grain brew. With a feisty two year old running around the house, I have even less time than before. Are we talking half a day or a couple of hours?
- 3) Information sources: Just lurking around the HBD provides a lot of information. You guys (and ladies) are great! But I would need a good, detailed 'How-to' manual. The problem is that I don't have a homebrew store to go to and would have to order books in English through the local French bookstore, ie: without seeing the book first. If I were to buy one book that details the equipment and procedures, what is the best one to order? Why? (publisher please)

Subject: bottle sterilizing...

Paul asks about mass sterilizing bottles... Here's my 1/50 of a \$1...

I used to sink 2 cases of bottles in a bleach solution and rinse but MANOMAN is that time consuming and I suppose could quickly turn one off of brewing BEER!

Check your dishwasher to see if it has a sani-cycle setting. I have used my dishwasher for many (>10) batches and have yet to have any infections. I load up the bottom rack of the dishwasher with all the bottles upside down each on their own peg (it fits about 2 cases) and run through a cycle. I use the water-miser and sani-cycle settings. The sani-cycle setting, according to the dw manual, raises the water temp to >140F for the last 5+ minutes of the rinse. I don't know if water manages to get up into all the bottles but the hi temp seems to sanitize them just fine. Hopefully, you rinse your bottles out fairly well right after you pour the beer (a sure sign of a homebrew addict!) If so, the bottles should be pretty clean to start with (no furry trees rooted in the bottle!).

BTW, I do use a small amount of dishwashing detergent in the cycle and have had no problems with beer heads or off-flavors. But you would have to experiment since your water may be too hard or soft to completely rinse the soap away. (a hi-temp cycle with no soap works ok too)

I have not tried a batch in a dw without the hi-temp-setting so I don't know if it would be sufficient to kill the enemy.

So, If you're thinking of buying a new dishwasher, check to see if it has a hi-temp (sani) setting. It's worth the extra \$\$\$.

l8r,
Andrew

Subject: Decoction Mashing

Am I missing something here? Recently I asked how to develop that super malty flavor which comes from German Doppelbocks. Many people were kind enough to write me privately and suggest decoction mashing (along with low hop rates) as the answer.

Upon re-consulting Noonan's book on decoction mashing I am a bit confused. Simply put (although there appears to be nothing "simple" about it) it seems to me that Noonan suggests starting out with a low temperature for an initial dough in and then a temperature rise through each of the enzyme steps (protein, saccharification, mashout). It seems to me that he must be talking about mashing in a Coleman Cooler or something as the heat increases are brought about by removing some of the wort at each step, boiling it away from the grain, and adding it back to get the next temperature step. I suppose to a "cooler masher" this allows keeping the mash thick while raising temperatures.

I mash in a large canning kettle kept on a stovetop throughout the mash. By turning the stove on I can go through all the heat increase steps without removing ANY of the mash. Since the heat comes from an external source rather than hot wort or water I can keep the mash as thick as I want.

Am I missing something here? With my setup, won't I be accomplishing about the same thing as a decoction mash??

... 43 years old and still getting a keg out of life!

Subject: oxygen barrier caps

There was a question a few days ago on rcb about the proper use of the oxygen barrier caps. these caps are either sold as PureSeal or SmartCaps although I think the latter name may no longer be in effect due to some legal mumbo jumbo.

the caps have a substance which reacts with oxygen. obviously if the caps did not have some type of activation barrier, they would react with O₂ in the air and be useless. The caps are activated by moisture. therefore they should be kept dry before use. Each cap has the capacity to react with 1.2 ml (i presume this is at 1 atmosphere and a typical brewery ambient temperature). this equates to about 6 ml of air which aint much. in other words, if you boil these caps and activate them before bottling, you're wasting your money. the caps are properly used by capping dry and letting the beer activate the stuff.

there is no need to boil new caps of any type by the way. i used to do this but it's needless paranoia.

these caps really do lower oxygen levels in beer. as a result, the shelf life of beer is extended. this has some value to homebrewers but of course is of particular value to small breweries. it allows breweries like celis to be more flexible in the brewing schedule because it is now possible to store the beer longer and still maintain a fresh and delicious brew.

Subject: Extract storage

>Extract storage: In planning for the days that I may not live near a
>homebrew shop and/or have not yet gotten into the swing of all grain
full
>mash beering, could anyone offer tips on storing large quantities of
liquid
>or dry extracts.

Depends on how long you want to store it. My father bought 56lb of dried
malt extract. Very soon after, he gave up home brewing. The DME was in a
tough polythene sack, tied tightly with string, inside a strong cardboard
drum with a close fitting lid. I found it *13* years later, and that
persuaded me to start home-brewing.

On opening the bag, I found that the 56lbs DME had turned into 56-ish lbs
SSME (Solid Sticky Malt Extract). I assume that it had very slowly been
absorbing moisture, and compacting under its own weight, until it was one
rock-hard lump. I had to use a hammer and chisel to break it up. After 3-
4
hours I had weighed out about 50 1lb bags. There were chips of the stuff
within a 15 foot radius of where I was chiselling - thats how tough it
was.
However, I did then go on to make a dozen or so good dark malty brews
from
it and apart from an occasional excess of treacly taste, slightly lower
attenuation than expected, and difficulty dissolving it (even in boiling
water) I had no problems. Everyone loved the beer too.

Moral: Don't leave it 13 years in a bag in a cardboard drum.

Subject: George Fix Chill Haze Talk PART 1 of 2

Chill Haze and Fining Agents in Beer

Part 1 of 2

I was fortunate enough to catch George Fix's presentation at the 1993 Dixie Cup Milli-Conference. I even had a small enough hangover to take notes. George Fix spoke on chill haze and some recent work with common agents used to enhance beer clarity. I would call them finning agents. The work he presented is to be published in an upcoming sequel/update of Principles of Brewing Science. Since the good Dr. Fix scooped himself, I will try to convey the gist of his talk below including some tables of results. I am grateful for George's enthusiastic cooperation in proofing this posting. I have added further explanation and consulted other sources and as I felt was needed. I have also added editorial comments (you can tell where). Sorry to all for the delay but it was important for George to proof my note taking. This posting will be in 2 parts since the size is over 8k bytes.

This talk concerns the causes and treatment of chill haze that are not the result of some technical brewing error. We're talking about colloidal haze, protein/polyphenol complexes. We are not talking about:

1. Biological hazes caused by bacteria, non-culture(wild) yeast or mutant yeast.
2. Starch haze caused by the presence of gums like beta-glucans or unconverted starch. Over sparging, high sparge temperature or alkaline sparge water can all cause this kind of permanent haze.
3. Trace metals can also cause haze problems. Iron levels above 0.05 ppm or cooper above 0.10 ppm are common culprits. The most likely source is from your water supply. Your water character may be variable throughout the year. Seasonal haze problems may not be your imagination. Your water supply may also change sources (Norman's does). Check with your local water department at different times of the year to see if this could be a problem. Norman has found them more than willing to read off the most recent analysis over the phone (call the water plant, not City Hall).
4. Oxidation haze is cause by the time/temperature history of the beer after it has been bottled. Thermal abuse is the enemy here. The telltale sign is a dull lackluster appearance (not you and your drinking buddies; the beer). This problem is sometimes termed "European Import Haze".

We are talking about chill haze resulting from protein/polyphenol complexes (protein and tannins) and haze caused by yeast biomass. Note that chill proofing and reduction of yeast biomass are two separate things. Now, let's discuss some of the common fining agents.

Irish Moss

Irish moss is (according to Norman's dictionary) the dried and bleached seaweed of the red algae variety. The two most common species are *Chondrus crispus* and *Gigartina mamilliosa*. The active ingredient is called carrageen (carrageen) and is sometimes a synonym for the seaweed itself.

Irish moss is said to aid in precipitating coagulated proteins. It is normally added about 10 minutes before the end of the boil at the rate of 1/2 to 1 teaspoon per 5 gallons (by most homebrewers). Fix adds Irish moss at 15 minutes left in the boil. Some recipes call for a "pinch". The use of Irish moss has several advantages and raises some concerns for the (home)brewer.

Advantages:

1. Irish moss is a processing agent; not an ingredient. It will not survive the boil kettle. For this reason, it can be used under the "German Beer Purity Law".
2. Infections are not a concern since Irish moss is added during the boil.
3. A negative charge makes Irish moss selective for large molecular weight proteins.

Concerns:

Since proteins have important roles in the fermentation cycle and in the finished beer, any agent that removes proteins should give concern in the following areas:

1. Will it remove too many low molecular weight proteins (amino acids) and have a detrimental effect on the fermentation?
2. What effect will the protein removal have on the body, viscosity and head formation/retention of the finished beer?

The Punch Line

Sorry to say folks, but at the levels employed by "most" homebrewers, Irish moss has no effect whatsoever on chill haze, beer foam or body/viscosity.

So, I should give up using Irish moss? No way. The problem is not with the material but with the dosage. Irish moss dosage rates do not scale down linearly from commercial to homebrew brew length.

Norman's digression on scale up/down:

Malt or malt extract is an example of an ingredient that scales more or less linearly.

Ignoring efficiencies of size and equipment design, the amount you use (as dictated by desired initial gravity) can be easily estimated from the ratio of brew lengths to pounds of malt(extract). For instance, if your brewing buddy has a recipe for 10 gallons of Old Welding Glove Barley Wine that calls for 25 pounds of malt extract and you only wanted to make 5 gallons of Old Welding Glove, just use 25 pounds times (5 gallons divided by 10 gallons) equals 12.5 pounds. Scaling other things up and down is not always so easy. Sometimes assuming a simple linear relationship is way off.

And now, back to George:

Although it is not much of an increase (over what we normally use), the correct level seems to be about 1 tablespoon Irish moss for a 10 gallon batch. The result of experiments was a good hot and cold break. Fermentation with a "picky" yeast, Wyeast Bohemian Lager, produced little noticeable effects on body, beer foam or viscosity. Irish moss is available in several forms: large flakes, refined flakes and powder. Use slightly less powder than flakes. Rehydrate the flakes in plain water before using. DO NOT rehydrate the powder.

How good a job does it do? Let's talk first about units of haze. The American Society of Brewing Chemists has defined the following scale:

| ASBC Haze Units | Description |
|-----------------|------------------|
| 0 | brilliant |
| < 100 | very clear |
| < 200 | slight dullness |
| < 300 | see through haze |
| > 400 | murky |

Now, the next time you call your friend's brew murky, you'll know what your talking about. The DeClerk Test was used to evaluate various brews made with the different forms of Irish moss. The test is fairly severe: 5 days at 140 degrees F then 2 days at 32 deg. F and finally warm up to 50 deg. F and inspect the beer. The results are below.

| Batch | ASBC Haze Units |
|---------------------|-----------------|
| Control (no I. M.) | 400-500 |
| Powdered I. M. | 100-150 |
| Refined Flake I. M. | 150-200 |
| Large Flake I. M. | 170-200 |

As you can see, the proper use of Irish moss will help with chill haze in your brew.

End of part 1

Subject: George Fix Chill Haze Talk Part 2 of 2

George Fix Presentation on Chill Haze from the 1993
Dixie Cup Milliconference

Part 2 of 2

Isinglass

>From seaweed to fish parts. Isinglass is derived from the internal membrane of certain fish bladders (a Brazilian catfish and a Saigon kingfish). As you buy it, it is almost 100% collagen.

Isinglass has an isoelectric point of >5.0 and will have a positive charge in any medium whose pH is <5.0 (ie. in beer with a PH of 4.5). Yeast will have a negative charge. The rest is hopefully easy to figure out. Effectiveness may vary somewhat with yeast strain. Isinglass is most effective in reducing yeast biomass and is an excellent compliment to Irish moss. It is certainly better than beechwood chips or aluminum slats.

The dosage rate in the UK is 60 mg/l. Full effect will take about 48 hours. It is most commonly used in Great Britain's cask conditioned ales. George recommended 30 mg/l for a 5 gallon batch with preparation as follows. Drop the PH of 6.0 ounces of sterile water to 2.5- 3.0 PH with your choice of tartaric, citric or phosphoric acid. dissolve 1/2 teaspoon of isinglass. Hold in refrigerator over night. Do not let this material see any temperature above 50 degrees F. It will decompose and become useless. Norman has read other recipes and the directions on your package may be different. Siebel has isinglass already mixed with acid blend ready to go!

Those wishing to observe the German Beer Purity Law will have to lower the PH with the help of some critters. Norman wonders if those wishing to be vegans should leave all the cask conditioned ale for the rest of us.

Results of test brews treated as above in soda kegs with a 3 day contact time showed significant reduction in yeast biomass:

cells/ml in
mg/l isinglass dosagefinished beer
300.15 - 0.25 X (10)^6
600.01 - 0.10 X (10)^6

Other Possibilities

Polyvinylpyrrolidone, PVPP, or Polyclar is a positively charged plastic powder that works against the protein/polyphenol complexes. Tannins are adsorbed and fall to the bottom of the vessel where they can not complex with the

proteins. PVPP has no effect on foam or body but does reduce both hop bitterness and beer color. Add at the rate of 0.067 ounces per gallon of finished beer. PVPP may be added to the beer at the beginning of storage or mixed with diatomaceous earth in a filter.

Activated silica gel can also be used. It acts by collecting the proteins instead of the tannins. Norman assumes that Dr. Fix did not give it much air time because of limited availability to homebrewers.

Tannic acid has a large phenolic structure which selectively reacts with high molecular weight proteins. The bottom line is that this is the "active ingredient" in beechwood aging. Don't tell AB/Houston but there are those who say it does not work very well. Tannic acid has very little effect on beer foam.

Filtration

Now we're getting serious. Isn't this what the big brewers do? Norman remembers a good presentation on filtration by Steve Daniel from the 1992 AHA National meeting. It may be found (in written form) in the Just Brew It! book covering the meeting. Cartridge filters have gained popularity with homebrewers and if used with CO2 to push the beer will not cause aeration problems. Rinse your filter with sterile beer first.

Pumping the beer is another matter. Some pumps (Little Giant among them) have been found to introduce air. Air is drawn into the pump housing and vigorously forced into the beer. Not too good, especially when you thought you were improving your beer. Plastic filter housings can develop this capability over time and damage your beer. Fix prefers stainless steel (don't we all) but winces at the price (don't we all).

You may precoat the filter with sterile (cheap) beer and diatomaceous earth. Fix prefers a 3 micron stone (porcelain) filter cartridge over plastic (polypropylene).

Why a 3 micron filter? Consider what you are removing from your beer. That's right, a filter will impartially remove all particles above a certain size from your beer. A filter is a dumb device. In order to be smarter than your filter, look at the following table and then we will discuss.

Membrane filter results

| | Filter microns | | | | | |
|--------------------|----------------|------|------|------|-------|-----|
| Property | 0.22 | 0.45 | 1.0 | 3.0 | Cntrl | |
| Abs. Ext. (deg. P) | 2.25 | 2.25 | 2.3 | 2.43 | 2.5 | 2.5 |
| IBU (mg/l) | 26.1 | 25.9 | 26.2 | 27.1 | 27.5 | |
| Color (deg. L) | 2.9 | 3.2 | 3.9 | 4.6 | 4.6 | |

cells (mg/l) 000 1-10 10^5

The control beer is unfiltered so it gives a good idea of what you are starting with. There isn't much effect on gravity until you drop below 1 micron. Bitterness starts to be affected below 3 microns.

George interjects:

"Remarkably, IBUs are little affected by filtration. The small differences in the numbers reported are likely due to errors in measurement. I did these with the ASBC (chemical extraction) procedure, which is not as accurate as chromatography. Errors of the order 5% are not uncommon with the ASBC procedure."

Color takes a hit below 3 microns. Cell count is nearly zero at 3 microns. The results tell you that filtering to less than 3 microns is stripping color, flavor and body out of the beer. Three microns will not sterile filter (pediococcus is about 0.8 micron BTW) but it will leave the beer chill haze free but basically intact. You don't even want to know the degree to which some of the Mega brewers are filtering their beer. George told the sad tale and his time ran out. Next up was Paul Farnsworth to delve into cask conditioning but that will have to wait for another day.

As for me, I will revise my use of Irish moss as a result of this presentation and since I am an ale fanatic, I will try isinglass next time I keg (which will be soon).

Subject: Sticking to Business

I subscribe to HBD because I want to learn more about *beer, homebrewing, and DIRECTLY related issues*. What gives some subscribers/readers the idea that it is OK to introduce issues which are highly personal, have nothing to do with brewing good beer, and far too often resort to language which is almost certain to be offensive to some of us because it is vulgar and out of place in this forum?

Let's keep in mind that this is a *public* forum, and that not everyone has a tolerance for language which is crude in their judgment. In particular, maybe some of us need to re-think what we include in our signature line as well as how much space we are consuming with it.

It would also be helpful to me if headers or signatures gave a clearer indication of where the sender is located.

I look forward to continuing to receive HBD. I'm in the Department of Philosophy at the University of Georgia, and I've been brewing about twenty years.

From: npyle@n33.stortek.com
Subject: Kegs/Crabs/Salvator/Plugs/etc.

Ed Wolfe asks about converting some SS kegs for brewing equipment. I seem to recall some sage advice in the Zymurgy Gadgets and Equipment issue. Check it out.

**

Just curious: has anyone ever seen a crabtree? Our yeast apparently know a bit about it; you'd think a species as advanced as ours would know more than yeast... I've seen crabs of all types (except those scratchy ones!) and trees of many types but no crabtrees.

**

Jim Kent asks about Salvator:

> . How do they make that stuff so sweet ? I thought it tasted of
>licorice (sp?) as well. Any time I try to make a high gravity
>dark beer it ends up becoming too dry (and sometimes even harsh)
>after a few months in the bottle. (Havent been able to maintain
>cold temperatures for real lagering yet ;())

I think you said it right there, Jim. You need the cold temperatures to knock the yeast down, where they can't keep working on your sugars. You might work especially hard on sanitation, too, as any wild yeast or bacteria may break down some dextrans into maltose and the like. Then the yeast will take it from there. Cold filtering would help. Drinking it in the first 3 months works well, too. I have the same problem, BTW.

**

Tom Kaltenbach says:

> The recent Hops FAQ has got me wondering again about hop plugs. For
>those of you who are not familiar with them, they consist of dried whole
>hops, compressed into a 1-inch diameter cylinder that's 3 or 4 inches
long.
>The plugs are segmented so that it is easy to break off smaller chunks.

This either misleading or Tom has seen some plugs I haven't seen. The standard plugs come in 0.5 oz. bungs, approx. 1" in diameter, approx. 0.5" long. They are stacked, usually, in two columns of 5 (I think), packaged in foil for a total weight of 5 oz. My point is that you "break" off a known quantity of 0.5 oz of hops, not just some unknown "smaller chunk".

**

Todd Taylor, I'd make a 3 gallon batch to start. The problem with making a 5

gallon batch with a small kettle is that you will leave lots of sugar in the grain because you don't have the means to boil more liquid. Its not a disaster but its very inefficient. It is typical to use about 2 pounds of grain (or less) per gallon of beer, but it all depends on your goal OG and your extract efficiency.

Cheers,
norm

In HBD 1163 Dion writes:

```
|| I would like to make some labels for my bottles, but a little ||  
|| more creatively than I currently make with WordPerfect. A ||  
|| friend has Corel Draw and that would be fine, but I do not ||  
|| have several hundred dollars to spend on software. Can ||  
|| anyone suggest software for DOS or Windows, (or even X for ||  
|| that matter) which would be suitable to make *really* nice ||  
|| bottle labels with? Must have lots of fonts available and it ||  
|| would be really nice to be able to fit text into any shape ||  
|| (like in a crescent shaped banner). ||
```

Well, my first choice would be to ask my friend if I could come over and play with Corel Draw on his machine.<g> The next option, if you have Windows already, is to try the Windows Paint program. If you stick to black and white, you'll be able to get some decent artwork going for your labels.

The one thing that IS going to cost you some bucks is getting exactly that "fit text into any shape" feature. That is a most desirable feature, and I don't know of any low-end software that allows you to do that.

BTW, I suggest option number one. I'm doing some labels in Corel Draw right now (I was working on my design as I captured this HBD, so I mean RIGHT NOW), and placing text on a curve looks really spiffy and is lots of fun!

Subject: SS Keg Conversion, or How I learned to Love All-Grain. Part 1

All it took for me to convert from all-extract to all-grain brewing was stumbling across an orphan 1/2 bbl rounded stainless steel keg at a scrap yard. For, not only was I able to easily fabricate a simple brewpot from this keg, but an entire methodology for all grain brewing using a few extra contraptions in conjunction with the keg's faucet. Both the methodology for brewing and a detailed plan for modifying the keg are explained herein. But first, more about the keg itself.

The rounded type keg which I used is commonly known as a "Golden Gate"- type keg. This is to be distinguished from "Sankey" type kegs, which are characterized by their straight sides, built-in handles on top, and rounded top and bottom. Both hold 1/2 Barrel, or 15.5 gallons. While the flat-sided Sankey-type kegs have the advantage of built-in handles, they have the disadvantage of not having a built-in flat section on the bottom side for installing the drain faucet, as do the Golden Gate-type kegs. This may or may not be a problem if you are trying to repeat what I did, but there is no doubt that trying to install a faucet on the rounded bottom side of the Sankey-type keg may not work to well without first having a sleeve welded on. I do know of at least one person who managed to bang a flat in the bottom of a sankey keg so he could install the faucet with standard screw-thread plumbing fittings as I did.

So, with standard parts available at most any hardware store and simple tools (which if I didn't have, my neighbors or friends did), I was able to put together not just a big brewpot, but a simple, easy way to brew 10 to 13 gallon all-grain batches with little fuss and no welding. The only major new investment was for a Propane Burner. I of course had to move my brewery from the kitchen into the basement, and I located the burner under a window where a fan could vent the propane fumes, etc. Be warned, though, that the propane tank's label clearly discourages use of propane indoors. The keg conversion itself took one Saturday and cost less than \$20: In short, you cut a big hole in the top of the keg and install a drain in the bottom side using standard 1/2 inch I.D. standard thread plumbing supplies. I tried to bang out the hardwood bunghole, but it was in there so tight, I decided to just leave it be. No problems after 10 batches with that.

Because I used standard plumbing threads, with a nipple that extended out into the inside of the keg, I found that I could add removable accessories to the set-up so that in one vessel I could mash, brew, and even primary ferment. Only lautering would require the temporary transfer out of the keg into food buckets. For sparging, I used a standard toilet stand-off and attached a couple feet of copper tube, bent it into a pretzel, and drilled a series of 1/16th inch holes in it. This screws onto the inside of the faucet. I also fashioned what I call a "Trub Bypass", which is nothing more than another copper toilet floor stand-off with a

bend which I attach the same way as the "copper Pretzel". This allows me to primary ferment right in the keg so I can rack my beer directly from the faucet, bypassing the trub on the bottom of the keg. It works just great: input is adjustable from the very bottom of the keg up to about 7 inches above the bottom. I must rack as soon as possible off primary, though, to avoid infection. Also, this implies that I do not separate the wort from the cold break material before pitching. If this sounds distasteful, optionally you can use this trub bypass to rack off into another primary fermenter after the boil if you wish. If this be your preferred method, call the Trub Bypass a "Cold Break Bypass" instead.

The basic process I use for all grain brewing with my new toys is as follows: Crush your grain; install the Copper Pretzel, calculate your water requirements for mashing and put that amount of water in the keg, Heat sparge water with propane and mash-in. I find no heat is necessary to maintain mash temp, but I do wrap the keg in a camping pad. Next lauter out of the spigot into food buckets. You do need another source of hot water for sparging, such as hot tap water mixed with boiling water in food buckets. I use my old brewpot on the kitchen stove. Fwiw, I've never needed more than four food buckets for dealing with all this. Now, clean out the spent grains and remove the copper pretzel. Install the trub bypass and pour in the wort from the buckets. Brew as normal. Chill with wort chiller.

Option 1: Aerate, pitch yeast and cover the keg (I use aluminum foil). After fermentation stops, rack from the spigot directly into Cornelius kegs (I use a short section of sanitized garden hose fitted to the spigot to minimize aeration while racking). Or, rack into a bottling bucket, prime, then bottle. Option 2: after chilling the wort, let the break settle, then rack from the keg directly into carboys or fermentation buckets, allowing aeration during transfer.

If you use the keg as a fermentation vessel, you must get the hops out before you pitch. Simply use muslin bags. This also assures the plumbing won't clog up on racking. A friend who uses my system and prefers racking to primary just throws his hops in, but prior to attaching the Trub Bypass, fastens a Chore-Boy on the end with brass wire to filter out the hops. All sorts of fun experiments can be made, like centrifugal decanting ala the big boys.

Subject: SS Keg Conversion, or How I learned to Love All-Grain. Part 2

ASSEMBLING THE EQUIPMENT:

If you have trouble locating the parts in the list, it may behoove you go to a plumbing supplier first, as they are sure to have all the parts. The parts for the drain assembly are the same parts for a standard faucet you would see on the side of a house for a garden hose. The parts listed below are what I used; I chose brass fittings, but I see no reason why you couldn't chose any other standard material that can stand up to the heat from the propane burner. I found that keeping it as simple as possible worked well to my benefit since by selecting a standard plumbing thread, it allowed me to incorporate interchangeable and removable pieces into my design, making the whole process of brewing simpler and more relaxing! A friend prefers the Ball-type, lever-actuated faucets. These are a bit more expensive, but will definitely decrease the chances of clogging up the faucet. A good investment, but you'll have to use tubing other than a garden hose for racking as mentioned above.

Parts:

- 1 15.5 gal. Stainless steel Keg, Please obtain it legitimately.
- 1 1/2" faucet, flush-mount, brass. Inside-threaded. \$2.25
- 1 1/2" x 1" pipe nipple, brass, counter-threaded. \$1.17
- 1 brass nut to fit pipe nipple. Fits 11/16" wrench. \$0.75
- 2 washers, ~ID 1" ~OD 1 3/8". Galvanized. had these lying around.

Comments: You can substitute a faucet with the threaded nipple "built in", i.e. the faucet has an outside-threaded extension. The problem with these is that there is no flange for flush mounting against the outside of the keg. Ideal would be a faucet with a flush-mount flange and a built-in nipple extension with outside threads. I didn't bother asking for one at the plumbing supply shop since I had already bought the above parts.

Parts for optional Copper Pretzel and Trub bypass tube.

- 2 1' Copper floor stand for toilet or sink, w/ brass compression fitting on one end and flange to ID 5/8 on other. (\$2.25 ea.)
- 2 Feet of 5/8 OD soft copper tubing.
- 1 1/16" Drill bit. You'll burn out a couple drilling holes.

Comment: Feel free to use the "slotted pipe" method here, i.e., instead of drilling holes, hacksaw some slots. Also, many Homebrewers get fancy and build sparging devices analogous to really small septic leach fields. Knock yourself out.

Tools, etc.

- Flair pen.
- 11/16" wrench.
- Ear protection.

Eye protection.
Power Drill.
Drill bit, about 1/4", metal-cutting.
Reciprocating saw ("Sawzall"), preferably variable speed.
1/2 round metal file or honing wheel insert for power drill
Emory paper
3-in-1 oil.
Bimetal sawblade for reciprocating saw. (\$1.89)
7/8" bimetal hole saw. (\$6.97)
Mandrel for above to fit your power drill. (\$7.60)

Comments: Bimetal blades are a must for cutting stainless steel. You can

probably hack the drain hole by drilling a bunch of holes with the drill and then filing it round, but the \$15 investment in a good hole saw/mandrel is worth it, and can be re-used in the future for such things as installing a beer faucet in your fridge!

Use a reciprocating saw with variable speeds if you can find one. I found that at "6", my saw wouldn't cut at all, but cut through the steel like butter at "4".

From: Mike Peckar 05-Nov-1993 1303 <m_peckar@cscma.UNET.dec.com>
Subject: SS Keg Conversion, or How I learned to Love All-Grain. Part 3

Procedure for converting keg:

Mark off your opening hole with the flair pen. try to find a lid you can use and size the hole based on your lid. You only have a little cheese here with a Golden Gate-type keg. Drill pilot holes for the saw blade using 1/4" drill bit and 3-in-1 oil. Have a helper steady keg while you drill the top with bi-metal blade in reciprocating saw. Both you and your helper should wear eye and ear protection. Use oil liberally at cutting edge and rest the saw every few minutes to prevent overheating. Relax, have a homebrew. Smooth edge with stone or hone then emory paper. Mark hole for faucet from inside high enough up from bottom of keg so that the flange will clear the bottom. Drill out 7/8" hole, hone, sand, and install faucet, using washers & nut w/ 11/16" wrench. The drain hole must be made on a flat surface. If using the cylindrically-shaped keg, i.e., Sankey, which does not have a flat section for a drain, you will have to bang a flat with a hammer or otherwise force a flat.

Procedure for fabricating Copper Pretzel for mashing.

The Sparging device. Basically a thing that allows the liquid stuff to be separated from the solid stuff in the mash. The holes or slots face down. sweat or clamp a two foot section of soft copper to flanged end of stand-off. Drill holes on one side only. I made three rows of holes with each hole about 3/8 inch apart. Optionally, use a hack saw to cut slots perpendicular to the length of the tube every 3/4 inch or so. Saw only 1/3rd through the diameter of the tube. Hammer down the open end to seal it shut. Carefully bend the tube into a pretzel shape, keeping in mind the holes will face down, and bending the tube such that gravity will help drain the liquid inside the tube, i.e., the part of the tube closest to the crimped end should cross over the top of the part of tube closest to the brass fitting. Make the thing any shape you want: I chose this design because it doesn't require futzing with too many different joints and tees and elbows, etc.

Procedure for fabricating the Trub Bypass for fermenting in the keg.

This device will allow you to ferment your beer in the same keg in which you brew. It allows for the draining of the fermented beer off the trub. Or, use it to rack from the keg into primary bypassing the cold break. The floor stand is simply a copper tube flared to 5/8" at one end and molded at

the other, with a 1/2" female compression fitting at one end. It just screws right onto the protruding nipple on the inside of the keg. Bend it with care so that when attached to the nipple, the flared end sticks up a couple of inches from the bottom of the keg. I got a little fancy and bent it so it followed the contour of the bottom of the keg into the center and then bent up from there. Take care not to kink the tube too badly while bending. Adjust the intake height for trub or break bypass simply by bending it up or down to the desired height. With practice, you'll get a better idea on what height to set it at for particular brews.

Comments on the whole setup.

The biggest advantage is simplicity. A single vessel for all your all-grain and/or extract needs up to bottling. A lot of friends have expressed concerns about unsealed fermentations, but as long as pitching rates are good, and you resist the temptation to "peak", i.e., disturb the headspace, there should be no problem. An initial purging of the headspace with CO2 helps, too. The disadvantage to this system is the fact that since it is both a mash/lauter tun and brew kettle, the whole process takes longer, as you have to decoct into buckets and then wait while you rinse out the spent grains before you can start to brew. Also, since the sweet wort is sitting in buckets, you can't start heating up the wort before sparging is complete. To work around this, the next obvious step is a separate mash/lauter tun. Since you have already built the sparging device, the logical choice is another half barrel keg with faucet. With two barrels, you essentially have a traditional brewery, but there are myriad setups and possibilities for improving on this very simple basic brewing set up, like a pump system from sparge water transfer, uC controls, ad nauseum.

>From crush to pitch usually takes four hours.

Another important note. At first, I built an easymasher ala Schmidling, though I preferred to call it a "screen penis". I had a couple problems with this. First, sparging rate was poor at lower mash temps (compared to what I got with the copper tubing device); in fact, I had a couple of stuck sparges. Second, the device didn't have the physical strength to stand up to mash-in, i.e., it deformed, and once, broke off while I was stirring in the grains. It's rather difficult to solidly clamp a screen around a pipe, even when the pipe is outside-threaded. In Schmidling's defense, though, the device was very simple to fabricate and yielded satisfactory results when it did work, though I got no higher than 30 pts extraction. All things being equal, the copper tube yielded consistently better results, and, though it was a PITA to fabricate, it was well worth it.

Mike Peckar, the penurious, paltry, parsimonious, yet pedantic picobrewer.

End of HOMEBREW Digest #1266, 11/08/93

Date: Fri, 05 Nov 1993 12:13:45 EST
From: "Mark T. Berard, Dow Plastics, LAD, TYRIN* CPE R&D"
Subject: Distillation

Hi all,

Been watching about a month. Lots to learn, I can see. I'd like to comment on the distillation thread. See examples below. Mark Blunier describes the industrial preparation of 200 proof Ethanol, and Daniel McConnell

comments on boiling point of various alcohols. I'd like to add something to

this. AZEOTROPES. While I agree with most of what has been said in this thread,

i.e. if it isn't in there to start, you shouldn't be able to distill it out,

just knowing the boiling point of various alcohols isn't enough. Mark's company probably added cyclohexane to the distillation because water/ethanol

forms a well known azeotrope. That is, you can't distill off the last 4% of

the water. You have to add something else to break this up, distill off the

water, and then distill off the other ingredient. In his case, cyclohexane.

Commonly for "Absolute" Ethanol or "100%" ethanol, benzene is used. This will

need a tax stamp, etc, but it contains trace benzene, a well know carcinogen.

Not the greatest for drinking. Well, you say, 96% ethanol is plenty good for

drinking. True (?). But, water forms lots of three way azeotropes, including

one with methanol and ethanol! So you might think you are getting rid of any

"bad" alcohol after going over the boiling point of your various nasties, but

you might not be.

Happily you can't really hurt yourself if you mess up making beer, but you

could REALLY HURT YOURSELF (or DIE) if you mess up trying to make your own

distilled alcohol. So while most of the fears like "you'll go blind", (Sounds like what I've heard about other activities ;-) are probably just as

Daniel said, scare tactics, there IS some reality in there. I'd stick to making great beer! (If only I could. I'll have to keep working on that.)

-Mark

>Subject: Distilling alcohol

>After the regular column we distilled it up to 200 proof by adding cyclohexane.

Subject: Immersion Chiller

Just though I would toss my hat into the ring. I use a "Double Immersion Chiller". I have two copper coils, (1) 30' length <the main chiller in the kettle>, and (1) 20' length. I place the 20' in a bucket/pot that is filled with ice/water. The cooling water flows from my faucet to the 20' coil (in the ice bucket) to the main coil in the brewing kettle and out to the sink. I used to use a counter flow chiller (the copper-in-a-hose type) but found that I had to use a very high flow rate of cooling water and a very slow rate of wortflow to get the temp down to ~70F (50' of counterflow cooler). I now use less water (but have to use 2 bags of ice) and it only takes ~15-20 min to get down to ~75F with minimal cooling water flow. My counter flow chiller is now collecting dust.

Somebody had to come to Jack's defense ;-)

Subject: Greenplug

I saw this gadget that may be of interest to homebrewers like me who have many fridges and freezers. This device uses computer circuitry to work out how much electricity is actually needed to keep a motor running (it cuts up the sine wave in some way - ask an electrical power engineer). And not only does it save around 25-33% of electricity, the motor runs more smoothly as well (admittedly this was the demonstration motor with no load), and there is surge and brown out protection. It was \$31 in Builders' Square. I saw a similar device in a yuppy environmental catalog at home (amazing the junk mail fall out from certain magazine subscriptions!) and the price was around \$80.

Subject: Northern Brewer Hops

I received some e-mail asking if Northern Brewer hops suffered any of the deficiencies of Clusters or Brewers Gold. On paper the Northern Brewer hop runs circles around the latter. I have not personally brewed with it, however a few months ago Jeff Frane sent me a few of his brews which used Northern Brewers in a highly advantageous way. These beers were outstanding, and their hop character was a major factor. This hop also has a very good reputation in Germany as an early addition bittering hop.

My post in HBD#1264 had the following spelling errors:
(1) geraniol (not -oil)
(2) Hallertauer (not -entauer)
(3) jibes

We installed a scientific spelling program, but I often forget to use it.

Subject: hops/Ceils Grand Cru

Howdy, all,

In HBD #1264, George Fix discusses the advantages of low alpha hops over high alpha hops, using lots of formulas & stuff I got lost over. But initially he states he feels that low alpha hops impart a cleaner & more mellow taste. So, as a clarification, should larger amounts of low alpha hops be substituted for high alpha hops to impart these same qualities, or would I be defeating the purpose? What about using three times as much 2.5% hops over 7.5% hops to make a Sierra Nevada clone, for example?

Also, Spencer W. Thomas wants to know if Celis Crand Cru is a tripel. I don't think so; it's really considered it's own style. In M Jackson's NWGTB, he lists Hoegaarden Grand Cru (Celis' previous incarnation) as a separate style. I don't know if it's as strong as a tripel or not; it's about 7%.

Oh, back to George Fix & Micheal Jackson. What's his new book's name?

Happy brewin',

Alan, Austin

> > One is dry-hopped and the other uses a hop back.

Two things. Firstly I'd like to make sure that the order of the comment
doesn't confuse people. SNPA used the hop back, Liberty is dry hopped.

Notice I used "used" in the above sentence in reference to SNPA. I have
heard (but not confirmed, yet) that when they opened their new brewery
they were having major problems with the hop back and abandoned it in
favor
of dry hopping. So both may now be dry hopped. My brew club is touring
Sierra Nevada next weekend, so I'll get a chance to ask and confirm. I'll
report back. Also reported that the only beers now hop-backed at Sierra
are the Barley Wine and Celebration (Xmas Ale) because these are produced
in such relatively low volume that they can put up with whatever problems
the hop back caused for the short time involved.

Subject: Beer in Kuwait

I write to you all as a fellow lover of home brew. And I am in desperate need of help. Desperate. The predicament that I am about to describe is not for the beer-loving faint of heart. I find myself in a country where all alcohol is illegal. I've been able to make one small batch of lager with the most gracious help of a friend who flew in from Belfast with a couple of bags of hops and a can of malt extract. And I've been making do with wine (lots 'o grape juice available) and eth (home made still and lots 'o sugar). But you know as well as I that it's just not the same. I have no access to net news. And I have just received my first issue of this forum. It looks good. I would appreciate any info on:

1. Growing Hops
2. Malt processing
3. Alternative methods of brewing (ie. no hops - is it possible?)
4. Names and addresses of folks in the home-brew business (supply shops)

Places I have most access to are Long Beach, Sacramento, Albuquerque, and Boulder. Discrete mail order would be great.

Any input would be greatly appreciated. I will try to sift through some of the back issues on the above subjects but as the network here is somewhat precarious in terms of both functionality and real internet functions (like ftp), the more 'live' forum info I get the better.

As an interesting addendum to the lifestyle in this part of the country:
A 12oz can of Heineken costs \$15 on the black market.

Thanks

Subject: SS keg cutting

In HBD Ed Wolfe asked about cutting SS kegs,

EW> Can anyone out there offer guidance in converting these kegs? I
> need answers to questions like: How should they be cut? Which

Having just gone through this, I can give you some pointers. There are a lot of ways to do this (like using a plasma torch or having someone else do it), but this is what worked for me.

Rent or (preferably) borrow and in-line reciprocating saw. The best known of these is a Sawzall. A Sears or B & D sabre saw will work, using 10 times as many blades and 20 times as much time (plus you won't be able to find bimetallic blades). Then buy some (5 maybe) bimetallic 32 TPI sawzall blades. I could only find 24 TPI and it worked fine, but I think 32 TPI would work better. The blades must be bimetallic for heat dissipation or the blades will rapidly wear out.

Insert a large screwdriver in the spring loaded valve where the tap goes in the keg. WATCH OUT! The keg will be under pressure from the decaying beer contained therein. Gas and maybe a few drops of old beer will shoot out when you do this so cover with a towel first and avert your eyes!

Also buy a 1/4" tungsten drill bit. Use a nail set or punch to mark your starting point. Use the drill bit to drill 2 or 3 holes next to each other so that you have one hole big enough to insert the Sawzall blade. The saws are usually variable speed so begin slowly until you get the hang of it. The saws will also cut in circles very easily so I marked my cut line first with an indelible marker so I would know where to cut. I got the blades at Ace Hdwr.

EW> end should be cut (on the valved end, I suppose)? Where on the
> keg should the cut be made (top or side)? How many inches from

My keg has an upper rim into which cut-out handles had been formed. My first cuts were vertical on either side of each handle so that I could retain them for lifting. I cut down to the top seam on the keg and then cut around that everywhere except directly below the handles. If I had it to do again, I would not have cut on the seam, but rather cut out higher on the domed top so that the I retained more of the sidewall. You'll have to judge where to cut based on the construction of your keg.

EW> the bottom should I install the manifold outlet on the
> mash/lauter tun (right AT the bottom, I suppose)? How many

Can't comment, I only made a boiler.

EW> inches from the bottom of the boiler should I install the spigot
> (i.e., How much sediment can I expect from a 10 gallon batch)?

My keg has a domed bottom and a rolled rim similar to the top. I installed a 1/2" X 4" SS pipe nipple butt welded up to a 1/2" hole drilled into the bottom seam. This provides 1 gallon of liquid that I have to tip the keg to drain. This isn't a problem because there's

only one gallon in the keg when I'm tipping it.

The pipe nipple was threaded with 1/2" pipe threads. Ace had a brass ball valve with chrome ball for about \$6. A brass 1/2" thread 90 deg angle extension was about \$2 and a 1/2" pipe threaded hose nipple was also about \$2. These were also found at ACE.

The bottom rim of my keg fits exactly inside the top rim of my cajun cooker. This means that the bottom dome (inside the lower rim) is suspended about 4" above the burner of the cooker. The heat coming out of the burner is concentrated under the rim. I can get 8 gallons of 50 degF water to full rolling boil in 30 minutes, BUT I cannot burn my wort. I've had the burner up to it's full 160,000 btu and had a hell-of-a boil, but the boil is so vigorous that it doesn't stay in contact long enough to scorch. My reduction rate is something like 1 1/2" gallons an hour.

Subject: Homebrew Digest #1260 (Novembe

My point on judging, or rather having your (specialty) beer judged was simply that specialty beers (i.e. what ever the organizer's can't place in another category) will be judged more by the judges' likes and dislikes than any of the other categories. If I don't like "American Light", I probably won't judge it. I like fruit etc. beers and each beer that we tasted we took the time to savor and try and get into the head of the brewer and figure out what he or she was trying to achieve. This took a lot longer per brew than other categories, but it was worth it. Bottom line was, however, with specialty beers just because it doesn't get raves from the judges doesn't mean that it wasn't good. If you and your friends like it brew some more!

Subject: BATF Outlaws Steam Injection

This showed up in the local paper--

FEDS SIEZE HOMEBREW BOMB FACTORY

(AP Seattle) Investigators from the Bureau of Alcohol, Tobacco and Firearms led a massive raid on a homemade bomb factory in Tacoma, Washington last night. Accompanied by local law enforcement and a camera crew from the COPS "real-crime" (tm) television show, BATF agents stormed a residence during the early morning hours. The object of the raid was a bomb factory being run by a crazed local homebrewer.

Siezed in the raid were several large stainless steel vessels that were identified as bomb components, a coil of copper tubing and other parts of an illegal still, copies of a child porography publication identified as "Boy's Life", as well as several plastic bags of a leafy green substance identified by experts as "hop", a dangerous narcotic drug. The owner of the house, Mr. Charlie Poopazian, was taken into custody after his house was crushed into matchwood by a flame-throwing M472 tank disguised as an Avon lady. The massive show of force is expected to boost the ratings of the COPS show, if they can only get Mr. Poopazian to stop screaming and rolling around on the floor long enough to sign the necessary release forms. Mr. Poopazian was yelling over and over again, "It's only hops!" , according to an unidentified BATF who expressed satisfaction at being able to extract a confession from the suspect.

The bomb was made of heavy aluminum and fitted with large black bakelite handles. An unidentified source close to the investigation stated that the bomb marked a new turning point in international drug terrorism, since it appeared to operate on "cold fusion" principles. "This is the first known case of drug traffickers attempting to build a thermonuclear weapon", said the source, speaking under conditions of anonymity. According to this source, the bomb has been taken to a secret DOE facility known as "Area 51", somewhere in Nevada.

At a press conference after the raid, a BATF spokesman indicated that the target of the bombing was a mysterious organization known as "Z". The suspect had originally been the head of this crime syndicate, which is based in the Rocky Mountains. Mr. Poopazian was deposed after a national "crime conference" held in Portland last summer. "Our sources indicate that the suspect was planning the bombing to regain control of his crime empire.", the spokesman said. According to confidential sources, Poopazian was replaced by a cadre of yuppie women dressed in K-mart business suits.

Well, there you have it. The COPS show will be shown sometime around Christmas.

At the FBI (Fairhaven Boatworks Inc.), they use a steam generator

for bending wood. It doesn't have a pressure vessel, so it's probably an end run around pressure cooker modifications. The steam generator is just a coil of 3/8" copper tube over a small propane burner. There is a piece of stovepipe around the coil to trap the heat. The inlet to the coil is fitted with a needle valve and a fitting so a garden hose can be attached. The outlet is unrestricted and feeds the steam into a small rubber hose (which I think is automobile gas line.)

They fire it up and then slowly open the needle valve until steam comes out the hose. When it's properly adjusted, you get real hot steam. If the valve is opened too much, it starts spitting hot water.

I think Bob Stewart (descended from the sheep-stealing Scottish clan) built the thing. In which case, it must be a least a hundred years old, since Bob is around a hundred and twenty himself. Actually, nobody is really sure how old he is, but he was caught last week whistling at a newspaper picture of a local woman who had just turned 100. He was making inappropriate comments about "look at the cute young babe." Shar took Bob behind the warehouse and gave him 20 lashes with the cat-o-nine-tails, but she says that it didn't do much good, 'cause Bob seemed to enjoy it....

Sorry I haven't included a diagram of the steam generator, but the idea of drawing a coil with ASCII graphics makes me break out in a rash.

Paul.

Subject: Nasty Brews

Hey all,

I'm taking a course now on the genetics of human behavior, and we got around to alcoholism last Thursday. It's a four hour seminar, so we sometimes drift around the topic of the week. One of us mentioned the inescapability of drinking alcohol in the field (anthropologists we are), even

when what the locals drink may be foul beyond words. I ventured that I'd

drink most anything "homebrewed." Tales from the field then included fermented

milk and cream from no-longer Soviet Georgia (I said I'd drink it, not that

I wouldn't gag), homemade absinthe from Switzerland, fermented kelp from the Aran Islands. OK, absinthe isn't really nasty, but bitter. I added scrumpy to the list altho' I've never had any, and I've read of horseflesh

being added to beer in the American Civil War.

Now then. What other funky, nasty things find their way into our fermentors around the globe? Anyone ever tried fermented milk? I thought that was something only seen in the movie "Alien Nation" What about fish?

I've heard tell that various Eskimo people bury fish for months, then return

to eat it. I guess I'm not looking just for nasty stuff, but also odd things.

Any recipes'd be appreciated, either private e-mail or posting here.

We were also comparing rates of alcoholism to length of contact with alcohol. Native Americans are said not have had any alcohol (I find this hard to believe since natural fermentation is so common: i forgot a cobbler

on the kitchen sink over the weekend and came back to blackberry melomush a 'bubblin' away). What about Australia? anyone know of aboriginal beer drinks there? Hawaii? Didn't Cook make beer of breadfruit on landing, which

the Hawaiians thought foul? There was a Polynesian kava drink, but to my knowledge it wasn't intoxicating. Anyone know?

Thanks to all who provided info on Belgian Special B. I racked my Irish red into the secondary a few days ago. Used Guy McConnel's recipe with

a full pound of Special B. Perhaps it was a wee too much. We'll see in about

three weeks how she turned out.

From: phil.brushaber@lunatic.com (Phil Brushaber)
Subject: STRONG Pitching Rates in Lagers

I am here to testify! I have become a believer. I think I now have an appreciation of what people have been talking about when they espouse STRONG pitching rates (especially for lagers).

Last week I made a Dopplebock using Wyeast Bavarian. I started with the foil pack and eventually stepped it up to 1 gallon of starter. I pitched the whole thing after cooling the wort and got my usual, fairly strong fermentation after about 10-12 hours. In 12 days the wort went from 1.080 to 1.030. A couple of days ago I racked to secondary and saved the yeast slurry at the bottom of the primary.

Yesterday, I brewed another Dopplebock (wanted to change the recipe slightly) and used the 1.5 pints of clean, yeast slurry (no beer, no trub). This time fermentation started in about 3-4 hours. Again no surprise from what I have read.

Here was the difference. Normally I brew lagers at about 50[^]-52[^] to start and get about a 1-2" head. This time not only was the onset of fermentation quick, it was extremely vigorous. About a 4-5" head, actually necessitating a blow off tube on a lager. To somewhat slow down activity I reduced the fermentation temp to about 46[^]. No slow down in activity, still blowing off. I suspect that this will also be a quick total fermentation, perhaps something like 10-14 days versus the usual 20-30 I have been experiencing for lagers.

The opportunity came in brewing with the same yeast a couple of weeks apart. My guess is that one could not save this slurry very long even if refrigerated (2 weeks before autolysis?), so unless I am brewing with the same strain regularly it could make it tough to achieve the same effect. I feel certain that I am not getting the same amount of yeast out of even a one gallon starter that I am out of the slurry from a five gallon batch.

I'm a believer. I now know what "STRONG pitching rates" means. Now I want to know how I can re-capture the effect if I am not brewing with the same strain every couple of weeks. Thoughts?

... Bubble! Bubble! Bubble! My brew is in trouble!

Subject: Bad off flavor in beers

Ouch.

Not that I am worrying or anything, but I seem to have stumbled into my first brewing roadblock. A few weeks ago, I posted a message about my Old Ale that was having a vigorous second ferment about 2 weeks after it stopped fermenting in my glass primary. I went ahead and bottled it after it fermented out.

I tasted it this weekend and (not surprisingly) there was a bad flavor to it. Furthermore, the stout (which I racked to the same carboy after the Old Ale was done) had the same off flavor to it when I bottled yesterday.

The beer has a strong, medicine-like, alcohol-like, flavor to it. Like someone added some acetone to the secondary.

David Miller's book says this flavor can be attributed to Wild yeast strains or chlorine reacting with the wort. I imagine it could also be some sort of bacteria infection, also.

Has anyone experienced this type of horror before? I have to track it down before I can brew again.

I would appreciate any suggestions or comments that might help me out here.

Thanks!
Alex Ramos

From: arf@mcs.com (Jack Schmidling)
Subject: It aint easy being green

>From: gummitch@teleport.com (Jeff Frane)

>I only chime in because I don't want anyone to get the impression that just because Jack Schmidling is adamant he is also correct.

Yes, I know how Rush feels. It's just one of the burdens that the great and powerful must carry. People tend to believe the truth and that is very dangerous.

>There are a good many reasons why someone would choose a counter-flow wort chiller over an immersion chiller, that have nothing to do with scale.

Sounds like a serious challenge....

>Briefly, my reasons are simple: it's faster....

I have conceded that possibility but so is instant coffee.

> the wort arrives in the fermenter at the correct temperature without being unduly exposed to the air

This, of course, assumes that the kettle is open to the air which in a proper installation it is not. The immersion chiller should be installed in the lid to provide a sterile environment while cooling.

> or sitting around in a kettle while I stir the damn thing....

Not sure which of the Ten Commandments drives you to "stir the damn thing".

I turn on my chiller and come back in an hour or several or whenever convenient to transfer the wort. It makes no difference how long it sits there with a tight fitting lid on it.

>, and <important> the only "stuff" that arrives in the fermenter besides the wort is some cold break....

Now this one troubles me greatly. What happened to the "hot break"? I respectfully suggest that it is now what you call cold break. Not sure just what you are doing here or how you are drawing off the hot wort but everything that is suspended in the solution that can fit through your spigot/siphon/line and chiller, will end up in the fermenter.

For the record, I never said that was bad, just observed that if the wort is chilled and settled BEFORE transferring to the fermenter, it will contain less "stuff" than if the wort is transferred immediately after the boil.
I

can't believe you wish to argue that point.

>, which precipitates out magnificently and from then on doesn't pose any problems, because IT WILL NOT BE REABSORBED INTO THE WORT. The wort does not have to be racked off the cold break.

No argument. I have been wanting to ferment a batch on the whole mess without even transferring to a fermenter but I don't want to dash anymore
momilies at the moment.

>That presentation, by the way, was published in the last volume from the
AHA, and includes scientific references, instructions on how to build an inexpensive counter-flow wort chiller, how to siphon bright wort out of the
kettle (hint: whirlpool)...

But what about that evil demon, HSA?

>But, once again JACK HAS SPOKEN.

So why bother? No need for any further discussion.

> Be advised, however, that in the past Jack has spoken through his hat more
than once.

Who, me?

> More than twice, for that matter.

Now, that I challenge.

> But I can see it now: "Real brewers only brew all-grain."

YUP!

>"Real brewers culture their own yeast (although once upon a time liquid yeast was for snobs, remember, Jack?)."

Not sure what those quote marks are supposed to indicate but I never said
anything like that. I did not believe the stories about liquid yeast and to
a large extent, I still do not. I do however, believe that yeast can be eliminated as a source of infection if one cultures one's own yeast. I spent
a lot of time on the subject and my yeast article has made the process understandable to those intimidated by it. The arguing back and forth was
part of the learning process but never did I ridicule anyone for not using
liquid yeast.

> and now: "Real brewers use an immersion chiller." Pffft.

Again, you are taking liberty with the quote marks.

If anything, I implied that real brewers, i.e. commercial brewers use counter-flow chillers, but for reasons primarily based on scale.

Homebrewers who use counter-flow chillers do it because they like them for

some reason or other which has little or nothing to do with the quality of the beer they produce.

>From: Steve Seaney <seaney@ie.engr.wisc.edu>
>Subject: Re: Plans for Grain Mill

>Jack's mill is a nice piece of work. My complaint about the cost doesn't counter the craftsmanship of the work. Jack however is making a profit in this mill.

I don't want to beat this one to death but I would like to point out that I made the first mill in the spirit of the intrepid experimenter who would not take no for an answer. There simply was nothing available on the market and I wanted one. Having sold my real business and retired, I assure y'all, I had no intention of making more than one. Turns out though, that if you build a better mouse trap, people will indeed, beat a path to your door.

>I am still collecting ideas for parts of the mill. If there are any interesting ideas for the rollers I'd appreciate a note. It'd be nice to use parts that are available at hardware stores, etc.

The only roller I found practical is one used in Xerox machines. It requires a bit of ingenuity to make it work, but if you can find them in surplus stores, it will save you a lot of grief.

The conveyer belt ones will work for the passive roller but there is no way to put a crank on them. You can make them from water pipes, rolling pins and a host of other stuff for next to nothing and I admire people who do this.

For those who don't have the time or inclination, well... now there are alternatives.

Subject: Suggestion for Dion's inexpensive label software

A few HBDs back, Dion asked for suggestions for an inexpensive software package with Corel Draw like capabilities. In Saturday's HBD Mike Keller suggested draw that was included w/ Windows. My suggestion, if you can part with around \$89 is Harvard Graphics v2.0 for Windows. It is a presentation graphics package which includes a Corel Draw/Adobe Illustrator/ or Aldus Freehand *like* drawing program called F/X. It CAN have text flow along a drawn curve. Draw the curve, draw the line, select them both and choose a menu option... Done. The low price is an introductory offer so I am not sure how long it will last, so check Egghead, CompUSA or you favorite mail order house...

Subject: Spent grains = draff

Reading Clive LaPensee's Historical Companion to House Brewing last night, he claims that the spent grains are called "draff". I like it. Right up there with "wort" and "trub".

I haven't finished the book, but it seems to be an interesting combination of good information and out-and-out misinformation. It's the first book aimed at the home-brewer that has an in-depth discussion of malting your own.

I seem to recall that this book is available through the AHA; I bought mine from a local HB supplier who had picked up some copies on a trip to England.

Subject: cooling/chilling w/little w

cooling/chilling w/little water?
I've been closely following the chiller wars and, although all the designs seem fairly straight forward, I have a question:

Is there another method that doesn't require gallons upon gallons of water running from the tap to cool the wort? I'd rather not keep the local water authorities in business just to have quickly cooled wort.

Has someone come up with a chiller design that uses a closed system? Obviously you'd need a pump to circulate, but perhaps you could use ice as a heat exchanger for the chiller water? Does anyone know of a good cheap (and fairly quiet) pump for such an activity?

feel free to post or reply directly...

From: Spencer.W.Thomas@med.umich.edu
Subject: Need your help!

I'm trying to refine my "double sparge" method. (Yes, I know this is a historically used method, but there seems to be very little in the HB literature that will help me.) In order to be able to better plan these batches, I need to do some experiments involving the SG resulting from various liquor-grain ratios. The results I get will be valid for my specific setup, but may vary from the results from other mashing/sparging setups.

Here's my basic assumption: Given a particular ratio of water to grain in the mash, if it is fully mixed, and drained without the addition of any sparge water, then the gravity of the resulting sweet wort will be essentially constant throughout the draining (lautering?), and will depend only on the initial water-grain ratio. The amount you get out depends on the amount of water and grain you put in, of course, but the gravity shouldn't. (Initial experimental evidence is in favor of this hypothesis.)

If I can build a table of water/grain ratio <-> O.G., then I can easily plan my double sparge batches to get a desired gravity in both the first runnings batch and the second, sparged batch.

So, I'd like to ask my fellow HBDers for help in this endeavor. Here's what you'd need to do:

1. Write down the ratio of water to grain when you're ready to start lautering. Make sure the mash is uniformly mixed.
2. Take a (temp corrected) SG reading of the first runnings.
3. After a while, but before adding any additional sparge water, take a second SG reading.
4. If you're willing, drain the entire tun, and record the "final" SG reading and the volume obtained.
5. Send me e-mail with the following information:
 - a. Grain bill
 - b. Water/grain ratio (or amount of water added to the mash)
 - c. Initial lauter SG
 - d. Additional lauter SG readings (and volume of sweet wort at that time).
 - e. If you know, total amount of sweet wort obtained from first runnings.
 - f. Your lautering set-up (zapap, copper manifold, easymash, etc.)

I am planning to write this up for (probably) Brewing Techniques, if the method works as I expect. Any contributors will be acknowledged, of course.

Subject: Commercially available hard ciders.

I am conducting a survey of commercially produced hard ciders available in the US. Currently I know of the following:

Woodchuck, made in Vermont, two varieties: Amber and Dark.
Woodpecker, imported from the UK
Strongbow, imported from the UK
Dry Blackthorn, imported from the UK
Wyders, made somewhere in the Northwest?
Seven Sisters, made in Idaho.

Does anyone know of any others? If so, please email me directly. If at all possible, please include the following information:

Name of cider:
Name and location of brewer:
Where sold:
Price (for what quantity):
Style (dry, sweet, etc):
Carbonation (still, sparkling):
Approx alcohol content (mild -- strong):

Finally, if you got a chance to taste any, let me know what your opinion was.

BTW, I already asked the same question of cider-digest readers, but I only got one reply.

Thanks in advance. If there is sufficient interest, I will post a summary.

things
> being equal, the copper tube yielded consistently better results, and,
> though it was a PITA to fabricate, it was well worth it.

In deference to the concept of kettle mashing, I thought I'd add my
comments:

My converted SANKE 1/2 BBL. keg has a union welded to the outside. The
1/2" SS
union has the threads exposed on the inside of the keg so that I can
attach a
sparging manifold based built from 3/4" copper pipe. I use an adapter to
neck
the manifold down to 1/2" for connection to the union. The sparging
manifold
is based conceptually on the JSP Easymasher and has numerous slits cut on
the
bottom.

Using this device in my keg gives me the same extraction rate as a false
bottom
system and this mash/lauter tun arrangement yields extract in the 28-32
pts/lb
range. In short, my runoff was clear w/o the use of a screen on the
manifold
and I found multi-step infusion mashes to be easy to carry-out. I find
the
manifold fab'ed from 3/4" copper to be quite durable and tolerated
stirring
and being "whacked" (brewing jargon) with a wooden paddle.

Finally, IMHO an extraction rate of 30 pts/lb is quite respectable from a
home brewing perspective.

John> information on this topic.

Basically, everything people Emailed to me has been posted, but since
I get rec.crafts.brewing and a lot of readers of HBD don't, here is
the summary.

My criteria were (in order of importance):

cost (free is preferable)
DOS or MS Windows (X Windows acceptable, but not preferred)
able to fit text into a defined shape (like a banner)

Suggestions have been:

Arts and Letters - will do it all, but list price is \$699
Harvard Graphics - will do most, but list price is \$89
MS Windows Paint Program - free with Windows, but is such
a wimp, I used another option
Corel Draw - will do it all, but list price \$399
xfig - will do all expect text fitting, is free, but will
not run on my PC, thereby requiring I do the
label design at work.

Subject: sm-ALL Grain/ Sake

taylor@e5sf.hweng.syr.ge.com Todd:
wants to make all grain beer with a 3-3.5 boil pot? Don't think so.

> I don't want to spend alot of \$\$ for equipment until I know what I'm doing.

Or should I just make a 3 gallon batch to start with?

* "If you make it, you can brew. "

I think you're dreamin' to try to make a 5 gallon batch with a 3 gallon boil pot. You'd need MORE than the volume to boil: i.e. 6 gallons for a 5 gallon batch. Unless you want thin beer! There are cheap pots out there.

Someone's going to scream at this....but...Get yourself a cheap canning pot for \$5-\$20. Aluminum (cringe...) or ceramic coated steel. Check surplus stores. They are out there. Used resturaunt equipment stores can be good 2.

>How much grain would I use if I can add water to the wort later?

*Can't do that. You want the water to go THRU the grain. i.e. get sugars.

>Would I use enough grain for a 5 gallon batch up-front? Which is ?

What would the brewer community re"command" I do?

*You want on the order of 6-10# base malt (i.e. pale, munich, vienna.. etc)

for 5 gallons. Depending on how stron you want your brew.

Under your circumstances I would suggest a partial mash. Learn the process

on a smaller scale, then find yourself a bigger pot. There are advantages to a full volume boil even for the extract brewer- read "hop extraction"

*An example: Mash 4 # pale malt + adjunct grains (e.g. xtal) and sparge up to your 3 gallons. Add several pounds of dry malt extract, or liquid male (oops...I mean malt) extract. Boil...cool...add to carboy, bring up volume. Oh....hop the hell out of it of course! '^/

> >How much grain should be used per gallon of water?

* See above. Depends on what you want. American light, or Barley Wine.

>What temp is good in the lauter tun and for how long?

I realize this info is available in books but I don't have mine a neighbor borrowed it? I hope I understand the process.....thanks

* Biggest suggestion I can make is...GET YOUR BOOK BACK!!! You'll appreciate having it (if it's any good!). Borrow his boil pot while you're at it :), Maybe a couple homebrews, his wife if she's cute... nyuck.

Basics: Mash in- 50 deg C. 15 min, raise to 60-65 deg C for 1 hour. Mash-out at 70 deg C, sparge. Iodine testing is worthwhile until you have a system down that works for you. What are you sparging with? Mashing in? You want to maintain a constant temperature.

From: Bryan Kornreich <bkornrei@welchlink.welch.jhu.edu>

Subject: sake-brewing

> There is a sake yeast. I believe it's Wyeast, or maybe the other liquid

yeast manufacturer. (name???) I would think its a form of a wine yeast. The thing you need to do is mash the rice. You can't ferment straight rice. There are rice extracts on the market (Williams carries one). You could use some of the snail spit enzyme mix for your mash (commercial amylase). I've never done it. Never even tried sake, just heard "ugh"'s about the taste. But hey- whatever tickles your pickle.

Subject: HopShake/BrewLit/RyeMalt

tom@kalten.bach1.sai.com asked about making: Hop Plugs

*Question: WHY?

Pack 'em in CO2 purged mason jars, and store in a freezer. Making plugs will damage the cones, and probably knock loose a bunch of lupulin crystals. One of the BIG advantages of homegrown hops is the freshness, and the ability to control exactly what kind of treatment they experience.

Ok: I'll concede. Smaller space, easier measurement. eh.....

Idea for making them (I've done this with other herbs in the past) Get a tube- e.g. pvc pipe, and a plunger which will fit tightly. Maybe a dowel that will fit the ID of the tube. Stuff the length of tube with cones, then mash them down. You could hammer it or make a press using a car jack if you're so inclined. Pull the plug, and store. If you selected a proper length of tubing you could use it as a measure of the cones- i.e. make 1 oz plugs. Cones are not "pre-processed" as are pellets- i.e. not chopped up first. If you have a vacuum bag sealer you could put rows of them in bags, and stash away into months worth for longer term storage. Personally, I'm not going to do it with mine. I have a spare fridge in my basement where my kegs and hops reside. It is a dedicated fridge, and I'm quite content with that. Besides its on the tenants electric bill, so do I worry?

David Atkins <ATKINS@mac.wisc.edu>
Subject: Hop Vines & extract storage

>I believe that the roots store many good plant things--such as chlorophylls, sugars etc--for their winter slumbers.

* Um...er...chlorophyll in roots? Not likely. It's that stuff that makes leaves green. Sucks sunlight and turns it into useful energy- stored in sugars/starches...etc. (also makes leaves yellow/red in fall:) Most plant roots don't see too much sunlight. Try growing a plant in the dark and see what color it is. Not green! Chlorophyll is produced in response to sunlight. BUT roots do store nutrients. Their MAIN ROLE is uptake of nutrients from the soil and WATER. Desiduous plants generally don't photosynthesize in the winter months. They go dormant.

>When leaves and vines wither, these elements flow to the roots and await the spring. If you do any leaf or vine cutting, as for any perennial, wait till they get all brown and dry before removing...or even wait till spring.

* WELL....there is some truth in that...but...

As a plant senesces (dies) a number of phytohormones are produced and transported through the plant. Fruit ripening is a response to these phytohormones (giberillic acid, ethylene for example). But there are some negative shock responses which could occur due to frost damage. may do better to clip the vine at ground level, then add some good fertilizer (a good reason to have a healthy compost of grains!) into the surface soil. DON't overdo it- especially w/ chemical fertilizers. Read the directions! Follow them too! Use this approach rather than wait for

nutrients to flow down into the roots. The vines have already devoted the majority of their goodness in producing those fine fragrant buds we cherish so. By the time the plant is wilting it is time to give up the ghost and separate the vine from the root. The rhizome will continue to take up and store nutrients, so it is important to not treat the plant as being dead after the cones are harvested. Continue watering until the fall wet-up, or the ground goes cold and hard. You don't want the soil soaking when it freezes, but you also don't want the roots to starve and dry up before they go dormant. Feed them, cover with a good layer of mulch (peat moss, bark chips...your choice) and call it a season. I do not think leaving the vine intact through the winter is going to do any good, except the risk of fungal infections, or overwintering of pests in detrital matter. Keep in mind- part of the root's job is to supply water and nutrients to the entirety of the vine. After the vine is finished there has to be an advantage is separation- allowing root nutrients to stay down in the rhizosphere and be stored for the next seasons growth. Come spring, mulch in some more compost and keep covered from spring frosts as the new shoots start up.

NOTE: I have studied plant growth and phytopathology. I am not an expert, nor claim to be. I planted rhizomes this past spring so this is my first winter to deal with (for my hops). I have read Beach's book, and agree with much of what he covers. I have gardened fairly extensively for many years, and like to think my thumbs have a good color tone to them. For a first year's growth I felt I had a pretty decent harvest at least from the cascade. My plants generally treat me quite well, and I like to return the favor. Take my words as you will...just don't ask me anything about distilling. I don't discuss the subject anymore! :(

Subject: Counter Pressure Fillers - What am I doing wrong?

I've got the Braukunst Counter-Pressure Bottle Filler which, as far as I can tell, is just like the other CPBF's (Foxx, etc.). I've followed the directions (sanitize bottles, chill bottles, purge, fill, cap) and I still get way too much foam. The best I can do is fill a bottle with about 2-4 inches of headspace (after the foam dies down).

Obviously, I'm doing something wrong...what is it?

From: john.fix@hardgood.com (John Fix)
Subject: Yeast not starting (sniff)

I'm using Wyeast Munich yeast, and started the packet on Saturday AM. By evening, the packet was fully expanded (it was packed 11/3, so it was VERY fresh). Anyway, I boiled up one pint of water and a cup of DME, and pitched the yeast when the wort had cooled to about 80F... I couldn't find my old guidelines for making a yeast starter solutions, so I winged it.

Now, it's two days later, and the airlock is still quiet... there was some surface activity (i.e. the beginnings of yeast activity) and the airlock looked like it was getting ready to bubble, but basically it has done nothing. In the past, I've had bubbles from the airlock, and lots of foam in the bottle. I checked this am in my older recipes, and it looks like I used 32 oz of water last time.... could that be the problem (i.e. the S.G of the starter is too high for the yeast?).

Thanks!

> known quantity of 0.5 oz of hops, not just some unknown "smaller
chunk".

I stand corrected. I used plugs once a few years back, and my memory
could
be a little fuzzy. (It couldn't be the homebrew, could it? 8-) My
impression was that the 0.5 oz plugs were joined together (i.e. segmented
cylinder) but that was probably just the way they were vacuum-packed in
foil as Norm suggests.

However, Norm's observation means the manufacture of hop plugs would be
even
simpler -- has anybody tried it? Or does anybody know how hop plugs are
manufactured commercially?

This is incorrect, I just visited Sierra Nevada a month ago. They do
not use a hop back or dry hop the Pale Ale. They just put Cascade hops
in at the end of the boil. They do however dry hop the Bigfoot.

I made a beer last month from a 2 year old bag of William's Australian DME that had solidified into a 5 lb bag of toffee. I brought 5 gals of water to a boil and spent the next hour trying to get that sucker to dissolve. It finally did. Since I was expecting sh*t beer, I didn't write down anything like hop additions, yeast, etc. Well, the beer came out great and I'd like to reproduce it, but, so much for keeping records.

I appreciate Jack's chiller comments, even if I don't appreciate his "humor".
I guess your style of fun doesn't come across over the Internet, Jack. I know you won't do this, but you could always use the obligatory smiley-face to indicate you are chain-yanking. They look like this :-). They are many variations...

**

Mark Bunster asks:

> Neophyte's question, if not adequately covered in the FAQ: what is the benefit of mashing, what's > generally involved, and what distinguishes a mash-out from a normal mash?

Mashing gives the brewer control (or not) over the types of fermentables and non-fermentables in the wort. By changing the mash temperature, you can get a more or less fermentable wort. There are different ways to mash which provide different flavor profiles, etc. You can buy lots of different types of malt so your grain bill can have an infinite number of variations. The debate rages whether this is good: Tastes Great! Less Fun! More Control! More Time! More Fun! Less Control! Costs Less! More Equipment! etc.

As far as what's involved, you should get a book like The Complete Handbook of Homebrewing by Miller. Or just read the HBD for the next 6 months. A mash-out is the final step of the mash, where the temperature is raised (a debatable step in this forum). It is just one of several steps for all-grain brewing. Get the book.

**

Steve Tollefsrud writes:

> can add up. How much grain is required to make 5 gallons of all-grain (say OG 1050) and what is the typical cost of the grain (\$ or Brit. lbs)?

I get fairly poor yields with my all-grain beers, compared to other reports, but it is 25 pts/pound/gallon. Use this as your low end, and you come up with 10 pounds of grain needed. I suspect you are shipping about 7 lbs. of extract for the same beer right now.

> to do all-grain brew. With a feisty two year old running around the house, I have even less time than before. Are we talking half a day or a couple of hours?

We're talking about 5 hours for me, but you need not be present to win. At least for the mash, you can go do other things while the enzymes are working their magic. The hardest part for you (and me) is keeping the 2 year old out of it.

> If I were to buy one book that details the equipment and procedures, what is the best one to order? Why? (publisher please)

Buy "The Complete Handbook of Homebrewing" by Miller. I don't have my copy with, perhaps someone else can provide the ISBN, publisher, etc.

Cheers,
Norm

Subject: BREWING ORGANS

>From: Mike Peckar 05-Nov-1993 1252 <m_peckar@cscma.ENET.dec.com>
>Subject: SS Keg Conversion, or How I learned to Love All-Grain.

Nice article. With a few minor variations, it is pretty much my kind of brewing. It sounds complicated but the bottom line is one can jump into all grain brewing with a single piece of equipment.

I can't however, resist the urge to beg authors to have the courtesy of serializing long articles instead of hogging half of the Digest. Today makes the need for this even more obvious with two of them hogging almost all of it. I for one enjoy serials. Short articles hold my attention far better than long ones.

> Comments: You can substitute a faucet with the threaded nipple "built in", i.e. the faucet has an outside-threaded extension. The problem with these is that there is no flange for flush mounting against the outside of the keg. Ideal would be a faucet with a flush-mount flange and a built-in nipple extension with outside threads. I didn't bother asking for one at the plumbing supply shop since I had already bought the above parts.

The part you are looking for is called an "air cock". It has a flange to seat against the outside of the kettle and a male thread that passes through it for easy attachment to the female on the inside. They come in brass and range from 1/8" to 1/2" pipe sizes.

>Another important note. At first, I built an easymasher ala Schmidling, though I preferred to call it a "screen penis". I had a couple problems with this. First, sparging rate was poor at lower mash temps (compared to what I got with the copper tubing device); in fact, I had a couple of stuck sparges.

Not sure what you mean by lower temps or why you had this problem but it does not sound exactly like my design or the results experienced or reported.

> Second, the device didn't have the physical strength to stand up to mash-in, i.e., it deformed, and once, broke off while I was stirring in the grains.

Not sure what deformed or broke but again, I suspect it has something to do with the design. Mine is a SS screen rolled into a 3/8" diameter tube and is

as stiff as the 3/8" copper tubing it is clamped to. There is no way it will be deformed by stirring. If you made the assumption that big is better, you may have a problem if it was excessively long. Mine is only 6 inches long and only 4 inches protrude from the end of the copper tubing.

> Its rather difficult to solidly clamp a screen around a pipe, even when the pipe is outside-threaded.

Mine uses a SS hose clamp and that problem has never occurred on mine nor has it been reported with hundreds I have sold. There are, BTW, no threads on the pipe where the screen is clamped to it. Possibly, it is the fact that I use copper tubing and the SS screen digs into it firmly when the clamp is tightened. This might not be the case with steel pipe.

> In Schmidlings's defense, though, the device was very simple to fabricate and yielded satisfactory results when it did work, though I got no higher than 30 pts extraction.

I suspect lots of people would be delighted with yields like that and you are in the range where technique and measurement error cloud the issue.

Subject: Yeast blends

I've been toying with the idea of blending yeast strains to get 'novel' results. I have a passion for 1056 and pale ales, but would like to introduce another layer of complexity. My plan is to make a starter with both Wyeast 1056 and 1007 (American Ale and German Ale) - then brew the house Pale.

Is there a yeast guru on the net that would care to offer comments on this process? Is there any way to get repeatable results with this technique?

TIA...Glenn

From: Paul Slater
Subject: Brewing books
Steven Tollefsrud asks for details of a good book. I think the following is excellent, presenting information clearly and concisely without too much jargon, but with enough information on home brewing to create excellent beer.

Title: Home Brewing, The CAMRA guide
Author: Graham Wheeler
Publisher: ALMA books, a subsidiary of CAMRA UK (CAMpaign for Real Ale)
ISBN: 1-85249-107-8
Pages: 180
Price: 64.99 (pounds sterling) (1991 price)

The following chapter headings will give some idea of the depth of information contained in this book:

History of traditional and commercial brewing; brewing methods; brewing equipment; malt/malt extract/sugar; hops; yeast; water and water treatment; mashing and sparging; boiling and cooling; fermentation; finishing; cleanliness and sterilisation; recipe formulation; malt extract beers; mashed beers; lager; other brewing techniques; problems; making measurements; glossary; index.

I would heartily recommend it.

Subject: Hot Break/Hops in CF Chiller

Jack writes regarding use of a CF chiller:

> Now this one troubles me greatly. What happened to the "hot break"? I
> respectfully suggest that it is now what you call cold break. Not
sure just
> what you are doing here or how you are drawing off the hot wort but
> everything that is suspended in the solution that can fit through your
> spigot/siphon/line and chiller, will end up in the fermenter.

I wanted to comment that my boiler has a spigot several inches above the bottom of the kettle. My CF chiller attaches to the spigot via a flare fitting. Twelve to fifteen minutes after the boil is concluded, I begin runoff through the heat exchanger. By this time, hops and hot break

have settled below the level of the spigot and are not drawn into the runoff.

The price paid is the loss of a few quarts bitter wort: this can be reclaimed

and canned for use as starters if one is so inclined.

Subject: BSness/Low Alpha Hops/Chilling Out/Lawsuit!

It appears that someone has been offended by recent HBD discussions. So lets all stick to business now, and don't offend anyone, and make sure we don't get too crude and vulgar. As far as I can tell, this is the first post by this particular HBD "participant"; which isn't exactly pushing the forum in a positive direction. Now that is vulgar.

**

Alan in Austin asks for clarification:

>In HBD #1264, George Fix discusses the advantages of low alpha hops over high alpha hops, using lots of formulas & stuff I got lost over. But intially he states he feels that low alpha hops impart a cleaner & more mellow taste. So, as a clarification, should larger amounts of low alpha hops be substituted for high alpha hops to impart these same qualities, or would I be defeating the purpose? What about using three times as much 2.5% hops over 7.5% hops to make a Sierra Nevada clone, for example?

I think I can answer this one, and add some personal experience. Yes, you should use more of the lower alpha hops to achieve the same bitterness as less of the high alpha hops. As long as you add the lower alpha hops at the same boil times as you would have added the higher alpha hops, you will in theory, have the same amount of bitterness. It will just be a "cleaner", more pleasant bitterness.

>From personal experience, I brewed a Sierra Nevada Pale Ale clone with low alpha hops. SNPA uses Perle hops for bittering, in the 7 - 9.5% AA range. I used Mt. Hood for bittering, at 3.9% AA. Now I don't know how these two hops do in Dr. Fix's "ratio test" but I can say that my "clone" was a far superior beer to the original. It was very close in all respects, but the hopping I did was quite an improvement. This is the real joy of homebrewing.

**

George Tempel asks:

>Is there another method that _doesn't_ require gallons upon gallons of water running from the tap to cool the wort? I'd rather not keep the local water authorities in business just to have quickly cooled wort.

Lots of people use ice in one way or another, but I suspect that you will spend more \$\$s on electricity (and wear and tear) to run your freezer, than you will

on the water. I try to conserve, but you can't squeeze blood from a turnip (or something like that).

**

BTW, Jack's "easymasher" is described in at least one back issue of Zymurgy. I don't know who "invented" it first, but it sure would be fun to see the look on the judge's face in court. "It's a piece of pipe with window screen stuck on the end?" "Mash? Hot liquor? Loitering? Well, all that's illegal; you should be in criminal court, not civil court!" "You are suing for how much?" "Well, I've seen a lot stranger things come through my courtroom, I guess."

Norm

From: gummitch@teleport.com (Jeff Frane)
Subject: Re: Wort Chillers, Redux

Without trying to quote from Jack's posting responding to my posting...

Jack, I know the difference between hot and cold breaks -- they happen under different circumstances. I leave my hot break behind in the kettle because at the end of the boil I create a whirlpool (no problem with HSA, because I don't splash), and then draw the clear (very clear) wort off from *around* the mountain of protein and hop debris on the bottom of the kettle. The cold break is create as the wort passes through the chiller, and is deposited in the fermenter.

'Nuff said. My main point is not that my system is inherently the best - -- on the contrary, my point is that there are a lot of good reasons for using a counterflow chiller and that dogmatism has no place in brewing.

Keep an open mind, folks.

Subject: Siphon Wonder/Trub Effect

Subject:Time: 11:52 AM
OFFICE MEMO Siphon Wonder/Trub Effect Date: 11/9/93
I'm tempted by the recurring add in Zymmurgy to purchase the "Siphon Wonder from Down Under"(bla,bla,bla standard disclaimer). It's a pain in the neck to get a sterile siphon going even with a hose clip. I'd also like to use something like this to recirculate cold water through my immersion chiller instead of wasting tap water. Has any one had any good/bad experiences with this product? Would the flow be strong enough to cool 5.5 gallons of wort with any expedience ? Can I run a recirculating cooling system out of one bucket with ice water in it ? Will Underdog survive ?
-I remember reading somewhere in the NCJHB that trub inhibited ester production and fermentation but because of scale these things had little effect on the homebrewer. Will racking the beer off of irish moss settled trub significantly increase the amount of esters in an ale ? What will increase ester, production beside high gravity, warmer fermentaions, and ester happy yeast? Anything else?
-Oh yeah and best of trip award to Capital City Brewing Co.'s Alt for DC/Baltimore trip. Any really good Alt making tips also appreciated.
-thanks

End of HOMEBREW Digest #1268, 11/10/93

Date: Tue, 9 Nov 1993 11:08:00 -0500
From: carlo.fusco@canrem.com (Carlo Fusco)
Subject: need help with water chem

Hello Everyone,

After reading someone elses post about water chemistry I decided to look into my own water supply and it generated 2 questions. I am now hoping that net wisdom will shed some light on how to fix my problems.

Water parameters
York Region, Ontario, Canada

hardness 160
pH 8.0
Ca 38 ppm
Cl 4 ppm
Mg 16 ppm
K 1 ppm
SiO2 13 ppm
Na 22 ppm
Fe 1 ppm

They could not provide me with Bi/carbonate levels only hardness measured as calcium carbonate. Everything else is in trace levels.

Question #1

Is 1 ppm Fe to high? Miller states that it gives a metallic flavour, adds haze and hampers yeast activity. I have noticed that since I moved and switched to LabYeast from Wyeast that my fermentations are considerably longer and less vigourous, sometimes 4X longer.
[note: Wyeast is no longer available where I am.]

Miller states that Iron is not wanted in brew water. How do I remove excess Iron?

Question #2

Since they could not provide me with the bi/carbonate concentrations, I would have to figure them out. Using standard analytical methods I can calculate how much hardness is contributed by Ca, Mg, Fe, and Mn [the key contributors of hardnes]. Did I figure this out correctly?

hardness = 38 ppm Ca * 2.497 + 16 ppm Mg * 4.116 + 1 ppm Fe * 1.792
+ 0 ppm Mn * 1.822

Ca contributes 94.89 ppm hardness as Calcium Carbonate
Mg contributes 65.86 ppm hardness as Calcium Carbonate
Fe contributes 1.792 ppm hardness as Calcium Carbonate
Total calculated hardness is 162.5 ppm, which is pretty close to the 160 ppm reported.

Now assuming that all bi/carbonate is only associated with Ca and it is all removed by boiling as outlined in Miller. I should then have 0 ppm Ca left in the water and about 67 ppm bi/carbonate left in the brew water.

Will the addition of Gypsum prior to boiling remove the remaining bi/carbonate and reintroduce Ca to the brew water? How much Gypsum? Will the sulfate and sodium conflict and cause a harshness described by Miller?

Will Mg and Fe react like Ca and precipitate out after boiling? If so, will my Iron/hard water problem be fixed by simply boiling all brew water before using it.

Thanks for your help
Carlo <carlo.fusco@canrem.com>

From: REGINAH@SOCIOLOGY.Lan.McGill.CA
Subject: Re: Adding spices to beer

Hello out there--

I just brewed a Christmas Porter loosely based on Papazian's Goat Scrotum Ale recipe (if anybody's offended, blame him not me), using cinnamon, nutmeg, cloves, and ginger. In trying to figure out the amounts of each, I reviewed both Papazian's other spiced beer recipes and his section on spices. I found a confusing discrepancy. All the recipes direct the brewer to add the spices at the beginning of the boil, but the spice section says to add them 15 minutes before the end. I added all of mine at the beginning, figuring that for a Christmas beer, the more time the merrier, but am still wondering about this point. Any opinions?

Subject: Dry Hopping BUs???

I was reading the 1990 Zymurgy Hops and Beer Special Issue today and an issue came up that I haven't seen addressed directly. From the article, "Matching Hops with Beer Styles", Quentin B. Smith mentions "Occasionally I will dry hop using Byron Burch's formula for figuring total bittering units". Earlier in the article he mentions Burch's book "Brewing Quality Beers", which I assume is his source for this formula.

Does anyone have Burch's book? He is certainly an award winning homebrewer but I've never heard any authoritative word on IBUs from dry hopping. We have discussed the perception here in the HBD, but I don't think we have come to any conclusions. What exactly does Byron say about this?

Norm

Date: Tue, 09 Nov 93 16:28:00 EST

From: andrewb6@aol.com

Subject: Propane, natural gas, and toxic fumes. (Andrew Baird)

I recently built a burner for brewing. I built it for (and tested it with) natural gas. I've been reading literature on similar *propane* cookers and they all say for outdoor use only. I assume this is because toxic levels of hazardous combustion products are produced, and I'm guessing that carbon monoxide is the main culprit. My questions are as follows:

1. Is CO the ONLY gas/ byproduct I should be worrying about?
2. Is this a problem with both propane and natural gas?
3. When they say OUTDOORS ONLY, do I take that literally, or does an open garage qualify.

I've yet to use this burner for other than testing purposes, and I've been thinking about buying a CO detector before I brew, but if CO is not the main culprit, I may be wasting my time.

Incidentally, the burner can heat two kettles at once. Each unit produces 70 little blue flames that can be controlled so that the flame height ranges from approx. 1/8" to 1 1/8". I'm not sure how many BTU's it puts out, but I'm considering re-jetting it for propane and measuring output (it's too hard to weigh natural gas).

Any insight to these questions is welcome via HBD or private e-mail.

Subject: Head Retention problems

Has anyone else experience head retention problems when using malt extract as a primer? The one beer I primed with DME has no head on it at all! And it's a single decoction wheat beer! It should have loads of foam. I keep thinking that something in the extract may have goofed up the foaming. I've noticed some slight, oily-looking stuff on some of the un-hopped boils that I do for unhopped yeast starters. At any rate, I'm going to stick to corn sugar or reserved, sterile wort from the same batch.

Subject: Inadvertent Lambic

I made a batch of aborted vienna lager and the brew turned out to be infected from the new fermenter I was using (used keg). In the process of washing out the goo, some flat, ropy-looking stuff came washing out. It was the color of trub, sort of an off-beige and very stringy. I examined a piece of it and it was quite resilient with a faint acidy smell. Any ideas what that might be? I've heard of a pellicle forming on lambic beers...this stuff looks like it would form a covering on the ferment. By the way, the brew wasn't too bad and was salvaged by mixing with an over-hopped brew and dryhopping to freshen the taste.

Subject: Re: Nasty Brews

Rowley@kuhub.cc.ukans.edu asks about nasty brews, including drinks fermented with milk...

I know of two such drinks: kefir from the Caucauses and kumis from Mongolia. Kefir is a fizzy milk drink that contains a yeast and a lactobacilli. It is slightly sour and very refreshing. The yeast/bacteria colony forms a large clump that is simply amazing to behold.

Kumis is fermented mare's milk. I have never tried it. The "standard" method of preparation is to put your mare's milk in a leather bag and hang it outside your yurt. Whenever you or anyone else enters/leaves the yurt, you give the bag a good shaking.

The Romans used to ferment fish (cut up fish and let them rot (er--ferment)). This is the ancestor of Worchester sauce.

Charlie Papazian reprints an old recipe that uses a dead rooster as an important ingredient.

The Aztecs and Mayans drank pulque which is fermented maguay. Don't know about farther north. South America has a tradition of corn beer.

Subject: Plugging Your Homegrown

Tom Kaltenbach writes (in HBD #1264):

| ... Now for my question: has anybody tried making their own plugs with
| homegrown hops? It seems like you would just need a press of some
sort,
| and a mold to form the hops into a convenient shape (i.e. plugs). Any
| ideas?

The closest I've come is to cram as much as I can into baby food jars.
I can get 1/2 oz crammed into the smallest ones (2oz) and usually put an
even 1 oz into the large 6oz jars. It's convenient to have a pre-
measured
amount on hand.

I start out by measuring an amount of hops and putting them into a large
glass mixing bowl. Then I stick the jar down in the hops and stuff them
in with my hand.

There's not much room for air in there; and the lids are air-tight.
I keep them in the freezer.

Subject: zymurgy recipe correction

I just received the Special edition of `_zymurgy_` and noticed a serious error in my article. The article (about reviving old British beers) is fine. However, the recipes (on pages 40 and 41) seem to have suffered from the attentions of a gremlin somewhere between the translation to American (from the original English) and the final printing. Terribly sorry it happened, but the editors are aware of it and promise to print a correction in the next issue.

All of the recipes list ingredients for making "six US gallons" which is plainly wrong if you examine the quantities. In fact, the quantities shown are for making `_one_(UK)_gallon_`.

CORRECTION:

To make five US gallons, multiply all quantities by 4.2 (that's close enough). This should be obvious, but you never know....

By the way, thanks again to Geoff Cooper for making the article possible and the opportunity to have the delightful evening I wrote about.

Subject: A Primer on Czech Beers

A Primer on Czech Beers

A fresh Czech Pilsner, like Pilsner Urquell or Budweiser, is a stunning example of the level of refinement achievable in lager beer. Perfectly clean, crisp, and sparkling, these beers provide a venue to show off the two main flavor components of beer - malt and hops - with emphasis definitely on the hops. There are no traces of yeastiness, and fermentation by-products are kept to a minimum. The slow, cool fermentations, and even slower and cooler lagering produces a full flavored smoothness which can not be realized by any other means.

The pale lagers are always brilliantly clear and have a rich golden color. At 4 degrees Lovibond, they are a shade deeper in color than their Western European counterparts. They are typically served in tall, half-liter glasses, crowned with a white frothy head which extends well above the lip of the glass. The aroma, like the flavor, is purely that of malt and hops.

The prized hops of the Zatec region (Saaz in German) of Bohemia are renowned the world over for their noble qualities, and Czech brewers use them liberally. The flavor profile is decidedly toward the hop end of the spectrum. The extremely soft waters of Plzen lend themselves to copious hopping rates, allowing a clean bitterness to come through in the finished product. Hop aroma is achieved exclusively by late kettle additions; dry hopping is not employed.

The full bodied character of these 12 degree Balling beers derives from pale Moravian and Bohemian malts. Some of the malt sugars are caramelized during the triple decoction mash and lengthy boil, which deepens the color slightly and adds depth to the beers' character. The only fermentation by-product present in perceptible amounts is diacetyl. The concentration is low enough that it is not distinguishable as a buttery note, but instead it gives the beer a fuller palate. Even though the malt charge is quite substantial, its role is essentially that of providing a foundation for the expression of hops, the dominant element of Czech beers.

While the beers of the Czech Republic may not be as diverse as those of other brewing nations, the beers that are produced there are classics. They are the most imitated beers in the world, but most imitators pale by comparison. There are no finer Pilsners to be found anywhere.

Subject: Changes at Pilsner Urquell

Greetings Brewers,

I hesitated before sending this, since it's not strictly about brewing, and since the Digest is so crowded these days. But people have generally responded favorably to my travel stories in the past, so here goes...

Enjoy,
CR

Change is Brewing at Pilsner Urquell

These are tumultuous times in Eastern Europe. Communism is practically dead, the lines on the map have been redrawn, and some nations have plunged into bloody civil war. The former nation of Czechoslovakia is now split into two separate countries : the Czech Republic in the west, and the Slovak Republic in the east. Along with the change in government is an attendant change in philosophy; the people are opening up to the ideas of the west. Capitalism is taking hold, and there is a great deal of investment and rebuilding going on. Even though these are difficult times, a general sense of optimism toward the future prevails.

There are big changes at Pilsner Urquell as well, but that's getting ahead of the story. First, a little history. The story of brewing in Plzen goes back to at least the 13th century, when the burgers of the town were granted brewing rights by King Wenceslas. The breweries were typically large homebreweries, and for several centuries, the beer produced was pretty wretched. During the 19th century great advances in brewing technology took place in Munich, Vienna, and Copenhagen, and the citizens of Plzen set out to imitate the beers of Munich. In 1842, the new brewery was established, and although the beer produced there was not what was expected, it proved to be very popular. By 1870 the beers of Plzen were exported to Vienna, Paris, London and Moscow. The rapid growth continued, and by 1913, the brewery's output exceeded 1 million hectoliters, making it the largest brewery in Europe.

The 20th century has not been so kind to the brewers at Plzen. The first world war brought an end to their rapid growth, and the time between the wars was one of stagnation. The second world war put the Soviets in charge of

Czechoslovakia, and separated Eastern Europe from the west. During most of this century, the brewery's output has remained a constant 1.3 million hectoliters. The export sales of Pilsner Urquell generated a good deal of hard currency, but this was siphoned off by the communists. The brewery was unable to expand or modernize.

The Velvet Revolution of 1989 brought big changes to the nation and to the brewery. As capitalism was introduced, new ways of thinking were required. Suddenly they had to be concerned with capitalist concepts such as profit and efficiency. However, old habits die hard, and some of the old guard were unable to adapt. There was a lingering attitude that it was easier to cover oneself by writing lengthy excuse letters rather than solving a given problem. Unfortunately, the first true taste of capitalism that some employees experienced was being layed off!

A more positive aspect of the transition is that the brewery is now able to modernize and expand production, and they have tremendous plans for very carefully doing so. There is substantial investment in Plzen, most of it coming from bank loans that the brewery has taken on. They have installed 104 new stainless fermenters ranging in size from 800 to 3600 hectoliters, which more than doubles their fermentation capacity. To match this equipment, a new four story complex is under construction which will house modern filtration, kegging, and bottling equipment. This will be followed by a new brewhouse. Production projections call for 1.5 million hectoliters this year, going up to 2 million next year. Interestingly, all of this increase in production is aimed at the Czech market, which comprises the bulk of their sales.

All over the country, the larger breweries are investing and expanding, which of course means that we'll see a shake out of the smaller Czech and Slovak operations. Already, Pilsner Urquell has gobbled up the nearby Gambrinus, Domazlice, Cheb, and Karlovy Vary breweries. Undoubtedly more consolidation will follow.

This may not be as bad as it sounds. Even though it's always a shame to see smaller enterprises consumed by the big guys, at least the large Czech breweries have remained true to their traditions. Consequently, Czech brewing heritage does not have the large discontinuity that we find in America. Indeed, the American drinker would be surprised to learn that for the most part, the largest Czech breweries make the best beer.

Amidst all of this change, the brewers in Plzen are committed to keeping one thing constant, Pilsner Urquell itself. They fully recognize the value of their

150 year old reputation, and would do nothing to compromise it. To this end, extensive experiments have been undertaken to determine exactly which parts of the old process must be retained to preserve the character of their world renown brew. In side by side comparisons, their expert panel of tasters has found that there are no detectable differences between beer lagered in wood versus stainless steel. However, they have found that the primary fermentation must take place in the traditional open wooden barrels, or the character of the beer is changed. Thus the shiny new fermentation facility is reserved for some of their other products, but not for the original. Further investigation led to an interesting experiment with a surprising result.

A standard batch of Pilsner Urquell was brewed and fermented in the normal fashion, while across town at the Gambrinus brewery, a standard batch of the similar Gambrinus was brewed and fermented in its usual fashion. Then both test batches were transferred across town for lagering in stainless at the other brewery. Upon maturation and tasting, the panel was able to detect these beers as different from the normal beers. In effect two new beers were created, somewhere in between the originals. Thus it was concluded that the convenience of being able to lager Pilsner Urquell at either facility must be sacrificed for the sake of the beer's quality.

Every aspect of the modernization effort is being scrutinized very carefully. The brewers rightly feel they are compelled to modernize, but must proceed with utmost caution. They are simultaneously faced with the challenges of an unknown world, and a future that is wide open. Let's hope that the stagnation of the 20th century is over, and that Pilsner Urquell moves into a new era of growth and prosperity.

The author wishes to thank Mr. Jaroslav Rous, Technical Director of Pilsner Urquell, for his warmth and hospitality. His assistance in writing this article has been invaluable.

Subject: re: BREWING ORGANS

in reference to Jack Schmidlings response to my long post on SS kegs...

1. Air Cock, yes. thanks. I also didn't use the proper plumbing jargon to describe what I referred to in my article as a "stand off". Its called something else, I forget what. Again, its a one foot copper pipe with a molded end which a 1/2" brass compression ring fits over and a one inch flare to 5/8" I.D on the other side. Most hardware stores only carry these in PVC anymore, but better ones will have the copper type.
2. The "lower temps" I had trouble at were under 154 degrees. In later batches, when I would raise the temp at the end of the mash (Mashout) flow would increase significantly with my version of the screen sparger.
Any batches where the mash temps did not exceed this, it'd get stuck.
3. Yes, my design was very different than what you describe. I can see how the easymasher's copper tube provides support for the screen and a better clamping surface. Mine was simpler yet that that, though, being just a wrap or two of screen clamped to a 1/2" nipple. it was 3/4" in diameter and 9 inches long. Too long and too flimsy. It was easy, though.

>From: gorman@aol.com
>Subject: Brewpubs in/near Ithaca, NY
>
>Any info on brewpubs in or near Ithaca, NY?

Funny that you ask - I was going to post a notice today about the recent renovations at the Chapter House Brewpub. Well it hasn't really been a brewpub for the past few years. The owners used to brew the beer at the Vernon Valley, NJ location and bring kegs here to sell, but for a number of reasons I won't discuss, they stopped brewing there a few years ago. They did have the equipment to produce smaller volumes at their building here, but had decided to brew all of their beers in New Jersey due to economies of scale. In the meantime, their license to brew here had expired and the renewal was held up in the beauracracy in Albany until recently.

Now for the good news. The Chapter House brewing equipment was refitted to brew lagers, and at the same time, the number of taps was increased to a total of 30. At the moment, there are 14 commercial beers on tap, including Sierra Nevada (Pale Ale, Celebration Ale, Stout), Sam Adams (Lager, Ale, Winter), Fullers ESB, Watney's Cream Stout, and Paulaner Hefeweizen. Woodpecker and Woodchuck cider are also available, as well as several of the Yeungling and Catamount products. The house brews are gradually coming on line. Last night I tasted the porter (which was being carbonated) and thought it was very nice - it was a little hoppy for my taste, but it had some body and maltiness. By the end of the week, there will be a Maerzen (which I tasted while it was conditioning and found to be a little light in color and maltiness) and an Amber. I think the Clements are also planning to brew the Blond Double Bock which was popular when it was brewed in Vernon Valley.

The Chapter House is located on Stewart Avenue (the one paved with bricks), one block North of Buffalo Street (where there is a flashing yellow/red light) . It lies in between Cornell and the downtown area, so it shouldn't be too hard to find. On the other hand, there is street parking only, so you might have to park a few blocks away :-)

Have fun!
Scott

Subject: Old beer recipes in Zymurgy

I was reading the latest Zymurgy last night, and happened upon the old English beer recipes. (From the Durbin Park club??) Anyway, the quantities in these recipes are surely off (1.060 from <3lbs of grain in 6 gallons???) . If anyone has the correct numbers for these recipes, could you please post them in this forum? Thanks.

Date: Wed, 10 Nov 93 09:52:38 EST
From: Spencer.W.Thomas@med.umich.edu
Subject: sm-ALL Grain/ Sake

You CAN make moderate gravity beers with a small boiler. Sure, it's not recommended, and you leave a lot of sugar behind, but it can be done. Example: mash 10 lbs of grain in about 3.5 gallons of water, drain 2.5 gallons of "first runnings" at about 1.090. Boil down to 2 gallons, then dilute to 5 gallons at 1.045.

Yes, you'll get lousy extraction, yes, you'll get lousy hop utilization (but this is no different from extract brewing), yes you'll get some caramelization of the wort sugars. But it can be done.

Personally, I wouldn't, though.

Subject: More on labels

Since I am an enthusiastic label maker AND a big fan of appropriate technology, here are two suggestions for putting curved text on labels:

1) If you have access to a PostScript printer, get the PostScript manuals that are published by Adobe. They are known as the Red, Green & Blue books (clever graphics reference, huh?) The titles are PostScript Language Reference Manual (red), PostScript Language Program Design (green), and PostScript Language Tutorial and Cookbook (blue). I've used straight PS code for doing interesting things that would be impossible through many application programs. Also, you might want to look for CricketDraw, a Mac program. It was one of the earliest PS code generators out there. Used copies (*with* manual) may be cheap or free, since it has been superseded by Freehand, CorelDraw, etc.

- or -

2) Do what graphic artists have been doing for years, snip out your text and make a bunch of cuts most of the way through the strip of paper, so that you can bend it. This works best if you use a waxer, rather than glue, paste or rubber cement.

Impressive ASCII figure:

^ ^ ^ ^ ^ ^ ^ ^ ^ ^ ^ ^ ^ ^ ^
snip snip snip snip snip snip snip...

Paul.

ps. The miscreant in "BATF Outlaws Steam Injection" didn't sign the release, so we'll have to watch the COPS show with one of those blurry mosaic fogs over his face...

George Tempel asks:

>Is there another method that doesn't require gallons
>upon gallons of water running from the tap to cool
>the wort? I'd rather not keep the local water authorities
>in business just to have quickly cooled wort.

I use an immersion chiller and collect the outflow water into a 6 gallon bucket. When the bucket is full, I dump it into my washing machine and do a load of underwear. No waste! Incidentally, it takes about ~8 gallons of Texas tap water to cool 5 gallons to about 90 degrees. I reaffirm that giving the wort a gentle stir every minute or so greatly improves the efficiency of the chiller.

Ulick> does it save around 25-33% of electricity, the motor runs more  
Ulick> smoothly as well

A discussion went on about these in misc.consumers.house a while back.  
I had bought one and responded that I did not see a drop in my  
electric bill, but my fridge was quieter. The common consensus seemed  
to be that if you have an older fridge (more likely when it is a beer  
fridge, than your primary household fridge) you will benefit more from  
this device. Newer, more efficient compressors in fridges now will  
not benefit so much.

A couple of months ago, I signed up with my utility company for an  
energy monitoring program and last Friday, was loaned a meter. It has  
been hooked up to my fridge for 2 days with the Green Plug and now one  
day without. Definite quantitative results will be forthcoming  
tomorrow when the non-Green Plug test period is completed.

**Subject: multi-strain brew**

Subject: multi-strain brew

Glenn GANDE@slims.attmail.com writes:

>I've been toying with the idea of blending yeast strains to get  
>'novel' results. I have a passion for 1056 and pale ales, but would  
>like to introduce another layer of complexity. My plan is to make a  
>starter with both Wyeast 1056 and 1007 (American Ale and German Ale)  
> - then brew the house Pale.

I tried this a few years ago in a misguided (read non-controlled) experiment, back when I was doing more \*open\* fermentations. Misguided for two reasons 1) The ENTIRE batch was fermented with all three strains and 2) I made a pale ale that was WELL hopped. I used Chico, Whitbread and Whiteshield strains simultaneously pitched. The beer was good, but since I did not split the batch and taste each strain individually, obvious differences in taste due to the triple strain were not apparent. In addition, since I hopped to about 40 IBU, most of the flavor came from hops, and the subtle yeast nuances were lost. OK, maybe I wasn't so smart, but you can learn from my errors. BTW I repitched this after top cropping and later went back to single strains.

I would recommend that you use either 1056 OR 1007 and another yeast with MORE character. For instance the combinations 1056/1028, 1007/1028, 1056/1098 or 1007/1098 might be interesting. BUT be sure to due a pure culture ferment for each strain as well so you can do a three point taste comparison. As unpalatable as it might seem, try to keep the hop rate and dark grain contribution to a minimum.

Consistency in brewing has never been one of my strong suits (way too much tinkering going on at my house), but if you "brew the house pale" consistently and reproducibly maybe you can get a handle on the multiple strain effect without control experiments.

Please post re the results.

From: Steve Zabarnick <steve@snake.appl.wpafb.af.mil>  
Subject: Grant's IPA Clone?

I recently tasted a bottle of Grant's IPA and was amazed by its being a dead-ringer for an extract Pale Ale that I brewed this summer (my last extract before moving to all-grain). My recipe was based on an attempt at an Anchor Liberty clone posted by someone to HBD previously. Here is the recipe.

6 lbs. Light M&F DME  
1 lb. Crystal Malt (unknow Lovibond)  
2 oz. Northern Brewer (7.1 AA) for 60 mins.  
1 oz. Cascades (5.7 AA) for 10 mins.  
1 oz. Cascades (dry hopped in secondary for two weeks)  
Wyeast 1056

OG= 1.054  
FG=1.011

I'm curious about which ingredients cause these two brews to taste and look so similar. Does Grant's use Wyeast 1056? Do they use Northern Brewer for bittering? Do they dry hop? The only difference I could detect was a slighty different hop aroma; perhaps they don't dry hop with Cascades. I calculate almost 60 IBU's for my brew (this was a full wort boil); is this similar to Grant's IPA?

Subject: RE: Nasty Brews (Part 1)

In HBD #1267, Matt Rowley writes:

>I'm taking a course now on the genetics of human behavior,  
>and we got around to alcoholism last Thursday. It's a four  
>hour seminar, so we sometimes drift around the topic of the  
>week. One of us mentioned the in-escapability of drinking  
>alcohol in the field (anthropologists we are), even when what  
>the locals drink may be foul beyond words.

Ah, now you're speaking my language :-). Actually, not all of those  
beverages are "foul beyond words", although many are unusual by  
western standards.

>I ventured that I'd drink most anything "homebrewed." Tales  
>from the field then included fermented milk and cream from  
>no-longer Soviet Georgia.

Fermented milk is not so unusual. I'm sure you've eaten cheese and  
yogurt, the most common examples (although these are bacterial  
fermentations for the most part and contain little or no alcohol).

The specific beverage you're referring to is "kefir", a fermented  
milk which originated in the Caucasian mountains. Milk from sheep,  
goats, and cows is used in its preparation. Fermentation is  
accomplished by lactic acid bacteria and yeast, and the resulting  
beverage contains about 1% alcohol. A similar drink called  
"koumiss" is brewed from mares' milk by Mongol tribes of the  
Asiatic steppes.

>What about fish? I've heard tell that various Eskimo people  
>bury fish for months, then return to eat it.

I'm not sure about the Eskimos (who, along with the Australian  
aborigines, are thought to be the only known cultures without a  
history of alcoholic beverages), but the people of Southeast Asia  
have been fermenting fish and shrimp for centuries to create salty  
sauces and pastes. The fermentations are bacterial in nature and  
are controlled by the use of large quantities of salt.

>Native Americans are said not have had any alcohol ( I find  
>this hard to believe since natural fermentation is so common:

Fermented beverages were not widely used by native Americans, but  
examples did exist. The Apaches brewed a rather nasty concoction  
called "tiswin" from germinated corn, wheat, and jimson weedd  
(sometimes referred to as "Loco Weed", a poisonous plant of the  
nightshade family). Tiswin's rather potent effects resulted in its  
being outlawed by the federal government in the 1880's.

Native Americans in the southwest also brewed versions of "pulque"  
and "mezcal" from the stems and core (respectively) of the Agave  
or Century Plant, as well as "tesguino" from germinated corn and  
corn stalk juice. [To Be Continued]

Subject: Priming / concise \$.02

I plan to bottle my first lager over Thanksgiving weekend. Particulars since my post in #1240: Primary at 45F for 3 weeks, secondary at 45F since. Am I likely to need more yeast (after Wyeast #2007) for conditioning and, if yes, what type(s) are least likely to affect the character of the beer?

Also on priming, has anyone else heard of or have more info on the "Crabtree effect" described by Troy Howard in #1264? Sounds like a good reason to abandon use of corn sugar for priming on the face of it.

Private email please, given enough responses I will summarize to save bandwidth.

\$.02 - Humor: laugh or ignore it, "all business" is not a realistic expectation. Offensiveness: eschew self righteousness. js: sarcasm fails in print for those of us (most?) who don't know you offline.

**Subject: Counter Pressure Fillers and Foam**  
Full-Name: Gary S. Kuyat

After drinking litres of flat beer (you didn't expect me to THROW AWAY that foam?!?) and having beer colored walls, I have come to the conclusion that LESS is MORE when it comes to counter pressure bottling. I find that pressurizing over 25 lbs. at 40 degrees is too much carbonation, and too much foam. I had a tough time getting it through my head, that 20 lbs. at 40 is fine. I bottle at 10 lbs. or so after letting the beer "stablize" at 5-6 lbs. for an hour. If you can't tap a pint with a reasonable head, you won't be able to fill bottles without tons 'o foam. If I remember my Braukunst, their catalogue had a nice table refering to pressure, temperature and volume of CO2 dissolved. My tendency was, "The keg is rated to 160! Heh! Heh! Pump up the volumes!" But this is totally wrong. If only I had a counter pressure filling room!

Subject: Responses to college brewers

Hello brewers,

I have been inundated with messages in response to my post "College Brewers" (but would welcome more responses). Many have warned about either

drawing attention to the possibility of exposing underage brewers and thus

spoilng it for them. Believe me, I do not plan to write an article about

underage brewers, especially since a majority of the responses I received were from graduate students. I could easily write a story which only included student brewers who are 21+. It seems that the best thing I could

do is write an article and post it to the HBD, thus we can all benefit without causing undue alarm outside of the homebrewing community. I have already received several funny stories about college brewing experiences. If the digest's collective wisdom (!) believes that any article would be harmful to homebrewing's image etc, I may just keep all these stories to myself. Sorry for the bandwidth, but since questions were posted to the digest instead of being mailed to me directly, I thought it was appropriate.

Subject: b&t

Two notes on black and tan--

The one that I always see around town is Yeungling Black and Tan. Yeungling is out of Pottsville PA, and claims to be the oldest brewery in America (continually brewing I suppose). Anyway, it's a mix of their porter (not bad but nothing special, although \$3.99 a six for it is reasonable) and their lager (pretty smooth, and again decent for the money). They also make a light (better than Swiller Lite, but what isn't). around here it must be pretty popular, for you can get it on draft in at least 5 places i can think of offhand.

This will likely completely destroy any chances I have of gaining a good rep as a beer drinker, but I've found that a surprisingly drinkable B&T you can make yourself uses Guinness and.....

Pabst Blue Ribbon. Call it a Black and Blue if you like.

No, honestly!

From: snystrom@aol.com  
Subject: Hunter Airstat modifications

A few editions ago, Mark Garetz reported that Hunter will be discontinuing their airstat thermistor/sensor. Like many, I raced out and purchased one. NOW I'm looking for someone who would be kind enough to repost the instructions that will allow xthe Airstate chill below 40 degrees. They appeared in a back issue of the digest. According to Mark, it may have been a 10K ohm resistor in series with the thermistor/sensor, but he didn't save the posting. Any help would be GREATLY appreciated.

**Subject: artifical bubbles**

In reply to David A. Byars' question about force carbonating, I quote Schultz and Dooley:

Give it malt, give it hops  
It won't matter what you do  
It's not naturally carbonated  
If it's pumped with CO-2  
This is how we always felt, sir  
Those big bubbles are for seltzer  
Give me Utica, Utica Clu..uh...ub.

(those in upstate New York will know)

In regard to recent Black and Tan discussions Yeungling also makes a  
Black and  
Tan frequently served as a "cheapie " draft at bars in the NE, and also  
sold in  
16 Oz cans (?!?). It pretty good stuff on tap, a mix of their own  
Chesterfield  
Ale and Yeungling Porter.

Subject: SNPA hops/Books/Lawsuit!

Aha!!!!

You all looked at me funny when I posted questioning the hop nose of Sierra Nevada Pale Ale, back in January of 1992. I had said that the SNPA that we got here in the Midwest seemed to have lost it's wonderful Cascade nose. There was no SNPA available in December of 1991, but then the stuff we got in January was nothing like the stuff we got back in November of 1991. Now, Martin writes:

>...I just visited Sierra Nevada a month ago. They do  
>not use a hop back or dry hop the Pale Ale. They just put Cascade hops  
>in at the end of the boil. They do however dry hop the Bigfoot.

I believe that they did used to use a hopback, but had some trouble with it so they went to a finishing hop addition as reported by Martin.

And you all thought I was crazy...

Norm writes:

>Buy "The Complete Handbook of Homebrewing" by Miller.

I feel it's a good book, but still has quite a few errors in it. I recently re-read Papazian's "The New Complete Joy of Homebrewing," Miller's "The Complete Handbook of Homebrewing" and Noonan's "Brewing Lager Beer." While reading, I was scribbling my disagreements with the books in the margins and dog-eared the corners of these suspect pages. The book with the least dog-eared pages? Papazian's. Miller's and Noonan's were about tied, but had at least triple the number of suspect pages. I have been meaning to write a series of posts or maybe an article on these three books and my disagreements with them, but heck, I barely have time to brew, so it's on the back burner.

My advice is to buy all three, but read them in the order I listed above. After reading all three and brewing a dozen batches, you will probably scribble the same notes in the margins that I did.
