During the ongoing debate about the relative merits of iodine vs chlorine based sanitizers there has been quite a lot of data provided, some of which was either misinterpreted or misunderstood. I'll summarize the relevant data, explain more carefully the misunderstandings, and present some additional technical information.

Here's a list of the criteria by which to judge a sanitizer for homebrewers.

1. Effectiveness in killing bacteria, etc.
2. Reactivity with materials such as 304 stainless
3. Ease of use
4. Flavor, odor, and other effects of residues
5. Expense, availability
6. Personal safety

The distinction between the 2 sanitizers is most blurry with regard to items 1 and 2. Making a case for one over the other is much easier when looking at the other factors.

1. Sanitizing strength

Both chlorine and iodine sanitizers kill bacteria as a result of their oxidizing power. A strong oxidizer is a good sanitizer. Chlorine in all its oxidation states (dichlorine, chlorite, hypochlorite, etc) is a stronger oxidant than the corresponding iodines. In chemical terms, it is said that the redox potential of chlorine is greater than iodine. Being a stronger oxidant, chlorine sanitizers are expected to be more effective at killing bacteria. However iodine is also a sufficiently strong oxidant to work very effectively in killing stuff and thus, in a practical sense, the two cannot be distinguished in this regard.

The recommended dose for iodophor, which contains molecular iodine, is 12.5 mg/l (ppm). Since each iodine atom weighs 4 times as much as chlorine and it's the number of atoms that is important, then a chlorine concentration of 3.5 mg/l will give the same sanitizing effect. Household bleach is about 5% sodium hypochlorite by weight. So how much bleach do we need in each gallon to get the same sanitizing effect as iodophor. Incredibly only 0.02 ounce! That's 50 times lower than 1 oz/gallon, 25 times lower than 1 tablespoon/gallon. For those more familiar with teaspoons, you need only add about 1/2 teaspoon of bleach in the entire 5 gallon keg to achieve the same level of sanitation that iodophor provides! Furthermore this concentration is about 70 times below the known safe level for reactivity with 304 stainless.

By the way, both bleach and iodophor need only be applied for 5 or 10 minutes for sanitizing.

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Maybe a stupid question, but...

Like many people I'm paying more attention these days to getting adequate oxygen levels in my wort prior to fermentation. Some people are using aquarium pumps and stones for this job, and the current issue of BREWING TECHNIQUES includes a proposed setup with activated carbon filter to remove plastic-type flavors that might be induced from the pump and tubing.

It would seem to me, though, that the primary concern would be the introduction of bacteria or wild yeasts, since these pumps are really just inducing a flow of unfiltered outside air. This leads me to two questions:

- 1) Among the people out there who are using the pump/stone arrangement, is there any sense that higher levels of infection are a problem?
- 2) Is there a good filter, say 2-micron, that can easily and cheaply be put into the tube line to filter out evil organisms?

I was pondering these yesterday when I happened to wander into my local Trak Auto. Yes, folks, this is probably a stupid idea, but would an in-line gasoline filter work for this purpose? They're certainly cheap enough, and come in a zillion varieties that could easily be attached to the various hoses.

Looking at a few of these I was impressed at how similar they are in structure to larger-scale brewing filters. However, none was labeled with the level of filtration provided, and there's always the possibility that some nasty chemicals might be involved.

Begin a truly non-handly type person, could the more ept (as opposed to inept) out there provide any comments? Also, do those of you with all those supply catalogs see any useful alternatives?

Finally, I might add an aside to those who haven't yet considered this method of aeration: it appears that a new aquarium pump, stone, and tubes can be had for under \$15. In other words, not a big investment for some potentially quite beneficial results.

Thanks in advance for any comments!

Subject: Headaches

Certainly, the absolute amount of alcohol consumed is the #1 determinant of headaches and other unpleasant side effects. Nevertheless, I also have observed that commercial beers in EQUAL amounts produce much worse effects than homebrews. And, that the products of the large breweries are worse than those of certain microbreweries which do not add stuff to their products.

As I am a chemist by profession, I will NOT refer to this stuff as "C\*\*\*\*\*s". After all, every substance in everything in the entire universe is a "C\*\*\*\*\*". BUT, I know that several of the specific items added to commercial brews can have adverse effects on certain individuals - allergic reactions etc. So, I do not see anything odd in the reports of bad headaches from commercial product.

Don't consume much of THAT stuff myself, anyhow. Don't consume much at any one time, in fact. Probably better that way. P.

Date: Mon, 14 Jun 93 09:54 CDT  
From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: FILTERING

Judging from my experience and that of a brewer who posted an article to rec.crafts.brewing, there seems to be a problem with the filters being sold to the homebrewing community.

I won't name my source or his, other than to say they are not the same, in order to give them an opportunity to rectify the problem. I told my source and he is looking into it.

I purchased a filter system with a .5 micron filter and was very disappointed with the results, viz. no visible change in the turbidity of the beer after filtering.

Not willing to accept these results, I purchased a known .5 micron filter cartridge from McMaster Carr and ran some tests on it which convinced me that the .5 micron cartridge that came with the filter, most assuridly was not.

I ran a gallon of water with one oz (by volume) of corn starch through both filters and the results were strikingly different. The filtrate from the McMaster cartridge was sparkingly clear and the other looked about like a beer I would want to filter.

I then ran a batch of stubbornly hazy red wine through the McMaster filter and it emerged dazzlingly clear.

From a physical standpoint, the McMaster cartridge is several ounces heavier than the other and takes about 5 times as long to dry out after use. Furthermore, it is darker in color and made of cotton.

The McMaster catalog has a wide variety of filters and cartridges but what is notable is that the only string type, submicron filter is cotton. All the synthetic fiber cartridges are 5 microns or larger.

So, if you are having problems getting what you expected from your submicron filter, I suggest you run the above cornstarch test on your filter and if it does not come out clear, complain to your supplier or order one from McMaster-Carr.

The part number is 4411K91 and costs \$11.82.

This is a 10" cartridge. If you have the smaller one, you will have to look elsewhere.

Phone number is (708) 833 0300

A note on filter use.... It seems assumed that the filter will be used from keg to keg and forced by CO2. The one I have works very well by gravity alone, simply inserted in a siphon line from the carboy on a table to the keg on the floor with the filter standing on the table.

I also find that mine has a very large and persistent bubble that, unless purged with CO2, could cause aeration if not eliminated. The simplest way to eliminate it is to just run the filter backwards... by running the beer into the "out" connector and out the "in" connector, the canister fills completely and the bubble never forms. The filter will clog up faster this way but for the batch sizes we run, it is not relevant. It is also presumed that one would backflush the filter after each batch, which in this case is running clean water through it the normal way.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Stoudts Festival

Here is my completely biased and subjective opinion of this weekends second annual eastern regional microbrewers festival (Stoudts Fest).

For this years event there were two major changes from the way things were conducted last year. Firstly, there were three sessions instead of one and this was an excellent and neccessary move. Secondly, the food distribution was moved into the Stoudts biergarten area, away from the beer serving area. Both of these changes resulted in a more efficient and orderly event, and made the task of getting some food much easier.

Each session had 1,000 tickets sold. The last session that was added later than the first two, was almost sold out (~950).

Working from memory, there were approximately 25 microbreweries and brewpubs in attendance, with most serving 2-3 styles of beer. Attendees received a Festival tasting glass and a meal ticket for kraut, german wersts and some of Ed Stoudts excellent fresh bread.

Each session lasted 4 hours. Attendees were allowed to sample beers at will without additional cost during this period. The breweries were not paid for thier beers, but each brewery did receive a complimentary hotel room and all brewers and helpers also were fed a prime rib dinner between the Saturday afternoon and evening sessions. I personnaly believe this festival combines the best aspects of the Oregon Brewers Fest with that of the GABF: one entry admission, no competition medals, as many beers as each brewery wants to bring, and the added Stoudts touch of a good meal included in the admission price.

The other great thing about this festival is that I love the surrounding countryside. It is a great place to camp, bike and do whatever.

My personal favorites from the fest:

McNeil's Brewpub, Brattleboro, Vermont:  
This is a hombrewers paradise. The brewery is a 4 BBl operation, and the beers are genuinely hand crafted, unfiltered and produced with quality ingrediants.  
My favorite was the Helles Bock. A 16P beer, it is made with Moravian malt, and german noble hops, hallertau & tettngang. This beer is a hoppier version

of Sierras Pale Bock. A very good hoppy american bock.

Zip City, NYC:

Despite some negative press in the past I believe Bob Berg is doing a good job of making some pretty tasty lagers. If you wrote off this brewery in the past, give it another try.

Arrowhead Brewing Co, Chambersburg, PA.

The makers of Red Feather Pale Ale, the brewhaus is a typical Peter Austin

Associates design, using ringwood ale yeast, torrefied wheat flakes, the Austin hop perculator, and of course open fermenters. I am not always a fan

of the ringwood family of beers, but each time I have another Red Feather,

I am impressed by the clean snappiness and great hoppiness of the beer.

Of

all the Austin breweries, Arrowhead seems to be the one that controls the yeasts tendency to throw diacetyl.

Stoudts Brewing Co:

The success of this brewery continues. Ed & Carol Stoudt run a tight ship,

with the brewery and GM? run by Tom Rupp. For the festival, Stoudts had a

Festival beer, a Double Honey Maibock and an Oatmeal Stout. The Maibock is

amazingly drinkable for about 9% ABV. The real winners from this brewery were only found in bottles or on draft on Sunday: Export/Gold, and Bock.

Tom

warned me that the bock is thier best effort yet and it was a truley delicious

traditional bock. Also of note is the Adamstown Amber, a amber lager with

great malt/hop balance. Tom reminded me that he leans toward balanced beers,

so I avoided pushing my 45 IBU pale ale on him. Tom is in the process of a

considerable brewery expansion with 90? BBl Unis due soon , a new cold box

and a 30 BBl brewhaus to replace the current 15 BBl. The new sudhaus will be

steam fired as opposed to the current direct fired one. Hopefully, the character of the beers will remain the same.

Baltimore Brewing Co:

Yes I am a bit biased here, as most of my labor was devoted to pouring and

explaining these beers to fest goers. But, from feedback during all three

sessions, the Baltimore Weizen (mit hefe) was terrific. The characteristic

Paulaner weizen/banana esters were evident, and the 5% ABV made it a nicely

poundable beer. For people who will be in the Baltimore area, this weizen

is still available and will be followed by a Weizen Bock.

Notable missing brewery from last year:

Great Lakes Brewing Co, Cleveland. I spoke with the brewer, Andy, who was in

attendance despite his beers absence. It appears that success has reared its

ugly head again, and the brewery was unable to sacrifice the required kegs and still supply the pub and its accounts.

Thanks to everyone who helped make this a great festival, especially the Stoudts, Tom Rupp and all of the helpers who carried kegs and trash cans of water. See ya next year!

Good brewing,  
Jim Busch

Subject: Recipe for Jalapeno Beer

My wife wants me to brew up a batch of jalapeno beer!  
Yes, folks, it's true. We paid a visit to Fort Collins last week, to visit the \*three\* microbrewerys there, and to visit Coopersmiths, the local brewpub. Coopersmiths has, among their six always-available beers, a "Chili Beer," and my wife was wild about it. The beer \*was\* really good.

Extremely dry, light in color, with an immediately noticable pepper flavor.

No hop flavor at all that I could detect, just a very dry pepper bite.

Not

particularly hot, either.

Anyway, I thought that bringing a half-gallon home would satisfy her appetite, but no, we've polished it off, and she still wants me to brew up a batch.

So, does anyone have a partial mash or extract recipe for jalapeno pepper beer?

Date: Mon, 14 Jun 93 11:17 PDT  
From: Daniel A Connors <Daniel\_A\_Connors%~WHC110@pnl.gov>  
Subject: Large Scale Recipies, Hop Utilization, & In-keg Carbination

NOTE: Please post your responses or reply to me at the following address: gj\_vargo@ccmail.pnl.gov Thanks.

I have been brewing in 6 finished keg batches for a few years. I seem to have fallen into a rut as my beers generally end up as either a Golgen Ale, Red Ale, or Stout. All are very drinkable, but I miss the Belgian styles and others [i.e. (Chimays), Ayingers, and Felinfoils (SP)]. Will anyone please post or E-Mail me "PROVEN" large scale batch recipies (part of my reluctance to vary significantly from the "standards" is the cost of failure - an unsatisfactory product deterrs my experimentation).

Any suggestions on how I may vary my process are also very welcome. The following is a very generic description of the process:

- \* Bring 125 gallons water to 180 degrees F (gypsum added)
- \* Transfer to hot water storage tanks
- \* Begin mash-in of ~220 lbs (mostly two-row) at a strike temperature of 172-174 F (water pumped to bottom of mash-tun)
- \* Complete mashing over a 20-30 minute period, cover grain with 1-2 inches of water
- \* Cover mash-tun, rest for 1:15 minutes (grain core temperature is ~140-145 F at finish)
- \* Sparge (by pumping into sparge ring) with remaining water (~150-160 F); valve out to Lauter-back and pump back to kettle (last of wort has little sweetness if any); balance flows in and out
- \* Add additional gypsum, citric acid, and table salt; heat to boil.
- \* Boil ~35 minutes add first hop pitch (usually 12-18 oz. of high alpha hop pellets - Centennials/Cascades/Fuggels)
- \* Continue boiling for ~40 minutes add finish hop pellets (usually 8-11 oz.) apply heat for 3-5 minutes to assure wort turnover and hop mixing (Tetenger, Willamette, Fuggels, Cascade, Centennial)
- \* Run thru tube and shell heat exchanger to get wort to 78 F maximum (prefer 68-72 F); pump to two sterile fermenters
- \* Grab two 1/2 quart samples for yeast rehydration; take hydrometer and temperature readings to determine O.G.
- \* Pitch rehydrated Whitbread Ale yeast, Batch 18 (usually 1-1/2 to 1-3/4 oz. per 1/2 quart starter) warmed to ~85 F
- \* Primary ends 3 days later, wort pumped up to elevated secondary fermenters; allow to work 10-20 days
- \* Gravity feed to 15.5 gallon kegs (Golden Gate style) and bung
- \* Force carbonate by slowly adding co2 to bottom shank and gradually increase pressure to ~25 psi at 60 degree F over 3 days
- \* Chill thoroughly, reduce keg pressure to dispensing

pressure

Any comments, suggestions, reprimands?

Secondly, I'm down to my last 8 oz of Whitbread yeast any suggestions on a new variety that would compliment the above process or a suggested improvement. How do the hop utilization tables I've seen on the Digest fit the larger batches? And lastly, has any one developed a set of co2 tables out to the 60-70 F range and up to ~30 psi. Obviously, the saturation rate is slow at my household temperatures (they were off scale of the tables published in "The New Brewer" a year or so ago. Carbination suggestions are also welcome. Thanks for the patience and the extra bandwidth.

Sincerely,  
Dan Connors

From: akcs.chrisc@vpnet.chi.il.us (chris campanelli)  
Subject: Slugfest in the Sierras

It came to pass that the garden slugs had become too greedy. Peaceful coexistence was not working out. Plant damage was occurring at an accelerated rate and it wouldn't have been long until irreversible damage was inflicted. Granted, all creatures great and small have a place in the Grand Design but the time had come to give the slugs their walking papers.

For those who are not gardeners, beer is probably the cheapest and easiest slug countermeasure. The method is simple and effective. Submerge a small container into the ground so that the lip is level with the ground. Fill the container with beer. In effect you're making a lilliputian beer swimming pool. At night, the slugs are attracted to the beer (the malt me thinks). The slugs drink the beer, loose their sober composure and fall into the container. Having never taken swimming classes, the slugs drown. Are you listening, Kevorkian?

It was my intention to use homebrew because: 1) a bottle of homebrew was a small price to pay for slug abatement and 2) I don't have any Sam Adams(tm). Planning and executing the mass murder was easy until I opened the fridge. To my surprise there was no homebrew. None. Oh sure, there was Baderbrau Pils and Bock, Celis White, Edelweiss Dunkel, Sierra Nevada Pale Ale and Mackeson's Stout. But not one stinkin' bottle of homebrew. It seemed I was going to treat a bunch of freeloading gastropods to the good stuff after all. The question was which beer would be sacrificed. Choosing was going to be tough.

My mind quickly went into Beer Assessment Mode. OK, no way do the slugs get the Celis or the Mackeson's. Not the Edelweiss either. The Baderbrau Pils was exceptionally fresh and so was a keeper. Remaining was the Baderbrau Bock or the SNPA. The logical choice would have been the bock as it was getting old. But I was afraid some of the more un-adventuresome slugs, not unlike some humans I know, might not like "dark beer". So the poison of the day was to be SNPA. I felt this was a sound choice because if drowning didn't kill the slugs, the bitterness surely would.

From: pjd@craycos.com (Phil Duclos)  
Subject: Kegging supplies

Some of you may not be aware of a recent pricing change by a supplier of kegging equipment and supplies. About a year ago Foxx Equipment Company of Denver & Kansas City sent a letter out to homebrew clubs inviting them to pool their member's orders and offering wholesale prices to clubs on quantities of 3 or more of any item. This policy has changed.

The Deep Wort homebrew club was one of the clubs which took Foxx up on this policy and placed orders for a variety small miscellaneous parts for kegging. Popular items included both large and small o-rings for the kegs, faucet parts, shanks, and keg connectors. One member agreed to act as a focal point and arrange the orders. The orders typically came to about \$200. Quantity savings were passed along to the members and a lot of hard to get items got supplied. Some people ordered 1 item just because it was readily available through this service and unavailable otherwise even though there was no price break. Nobody ordered complete kegging systems or kegs.

When our latest order arrived we were surprised to find that we had been charged retail prices on all items, even those of quantity 3 or more. A phone call revealed that Foxx's policy had changed. The conversation also revealed the reasons for this change. Apparently few homebrew clubs responded to Foxx's offer. Those that did got a good deal. Those that didn't continued to look elsewhere for those parts or just did without. Foxx was less than overwhelmed with the response. Also some big homebrew suppliers complained. Apparently they felt that Foxx was competing with them by offering wholesale prices to homebrew clubs.

Now I get a lot of homebrew catalogs and pretty much know what's on the shelf in the local homebrew stores and I have NEVER seen the parts that we order in either place. I see complete kegging systems, kegs, regulators, etc. But faucet knobs, shanks, 1/4" barb gas disconnects, dip tube o-rings and the like, NEVER. And I think that I understand why. The homebrew suppliers have limited shelf space and capital and feel that its better to stock stuff which has a higher turnover. OK, sounds like a good business decision to me. However, to then turn around and complain to the supplier of these parts that they are in competition with them is ridiculous!

Well, there are alternatives and probably the easiest is to simply knuckle under and pay the higher prices. However, no policy is ever set in stone and the better solution, I think, would be to convince Foxx that there really is a market for quantity sales to homebrew clubs and that they

demand wholesale prices for quantity purchases. The way to do this is to write to the owner of the company at the following address and express your opinion:

Ford Mauer - Owner  
Foxx Equipment Company  
421 Southwest Boulevard  
Kansas City, Missouri 64108

If you're not interested, don't use this stuff, don't care, like higher prices or whatever, OK, don't bother. I actually think that there is a sizeable demand out there that has been thwarted by lack of knowledge and frustrated by lack of availability. If I am wrong, OK. I also am not attacking homebrew suppliers. They are great and work on slim margins and have limited capital and lots of competition, etc. They also don't carry what I need, so I see no conflict. What I am trying to do is make people aware of a opportunity that they have lost. I think that if enough clubs respond, Foxx will change their policy.

This isn't an endorsement for Foxx Equipment Co either. There are other suppliers such as Rapids, Superior, etc. Foxx has just been the one we have been dealing with, that's all.

Thanks,

phil duclos

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Oils

New Product Announcement

In my article in the Summer '93 Zymurgy (Boost Hop Bouquet with Dry Hopping)  
I talked about CO2 extracted hop oils. As the article stated, measuring the very tiny amounts of hop oil needed takes lab equipment and lab skills, beyond those of most homebrewers (but probably not beyond quite a few Digest readers). Anyway, the article states that I was working on a solution to the problem. It was supposed to have a P.O. Box where you could write me to keep informed of any progress. Unfortunately, they edited that part out.

To make a long story short, HopTech now has available CO2 extracted hop oils that have been formulated in a stable, water-based suspension that are easy to add to homebrew sized batches. It is calibrated so that 1 tsp of hop oil equals 1 ppm of hop oil in 5 gallons. Average usage, depending on the style of beer and your taste, runs between 1 and 3 ppm. We sell it in 2 oz bottles, enough to add 2 ppm to 30 gallons of beer.

We have three varieties available:

Premium British Blend, made with a carefully controlled blend of English and European hops that allows extremely consistent aroma characteristics from year to year. Very floral in character.

British Blend, very similar to the Premium British Blend, but the aroma characteristics are slightly less consistent from year-to-year, allowing a less expensive price.

Pure East Kent Goldings. Wow! The real thing. Very smooth and mellow hop aroma. Not nearly as floral as the two British Blends. This is rare, expensive and worth it. Limited supply.

For a HopTech catalog or to order, call 1-800-DRY-HOPS M-F or you can email mgaretz@hoptech.com. Fax is 510-736-7950. Or you can ask your favorite homebrew supplier to carry our products.

I've drunk the beer and brewed the kit. The beer is good and the kit is  
too,  
as kits go. Though it's a long way short of the original. The OG seems a  
bit  
high. I thought it was about 1055.

>  
> I am hesitant to use the yeast packet that came with the kit, but I'm

The yeast will be OK but if you want to replace it I'd suggest something  
like a London Ale yeast - not sure of the yeasts you have available. 1kg  
of  
white sugar is a normal ingredient of UK beer kits. It's to keep costs  
down  
and does nothing to improve the beer. Many people use two kits instead or  
brew half the quantity without the sugar. The can is probably 1.8kg.

You could boil it up with 4 pints of water and then add about 2 gallons  
of  
cold water. Take an SG and temperature reading. Aim for an OG of about  
1055-1060 and a temperature about 20C. You could add small quantities of  
hot  
or cold water and/or sugar until you get there. Pitch the yeast and  
follow  
the rest of the instructions on the kit. You should get a pretty good  
beer.

>  
> Any help? They classify Dogbolter(R) as a "strong ale".

Well, how do they \*acquire\* large numbers? <g>

There is an interesting article in one of the earliest books published  
("Beer and Brewing"?) with transcripts of the AHA Conference talks. It  
is  
how someone built a walk-in fermentation room. If I remember correctly,  
it  
was basically built with stiff insulation boards used in building houses,  
with an airconditioning unit inside. Pretty neat.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Fullers ESB

Jay,

I saw your fullers question in todays HBD and since I just returned from the brewery I cant resist answering the question:

<My question is, since you've evidently been to the source, which is closer to the product served at the brewery, the U.S. tap or the U.S. bottled?

Neither! In the brewery they serve Fullers ESB Cask Conditioned Ale. This is near the gravity of the draft US version but is cask hopped with K. Goldings Hop Plugs (just like homebrewers use).

An interesting point is that the UK bottles/cans and polypins are packaged with hop oil and therefore do not have hop parts floating.

Also, the London Pride Cask is 4.0 ABV while the canned/bottled version is 4.7. This is fairly typical in that you are expected to pound 20 oz pints in the pub.

<10# 2-row  
1/2# crystal, 60L - 90L  
1/2# carapils  
1# brown sugar, 60 minutes  
2 oz Fuggles, 60 minutes  
.5 oz Kent Golding, 30 minutes  
.5 oz Kent Golding, 5 minutes  
1.5 oz Kent Golding, dry hopped in secondary  
Yweast London Ale (1028) yeast

OG: 1048  
FG: 1012

There is no Fuggles in ESB or any of the Fullers beers. They use English Target, Challenger and Northdown. EKG is in the finish & cask hopping of both Chiswick Bitter (very good bitter) and ESB. BTW the kettle hops are Lupofresh( challenger, 91) pellets from Kent and Worscester. They "Burtonize" the brewing water using mineral salts. A single temp infusion is employed. The ESB is 1.052 OG (apparently this was reduced for the US market, according to a brewer I was drinking with in the Pub next door)

I was told they used to use sugar but this is no longer required with the new mash tuns. I missed out on the Maize part so I do not know, but I assume George has this correct. Try 5- 10 % in the mash. Skip the sugar, use caramel malts to get the color and sweetness.

Good brewing,  
Jim Busch

Subject: fermentation?...no not yet.

Hi all

I've got a question about fermentation. Specifically about Wyeast American #1056 fermentation. I pitched some of this stuff about, oh, 3pm on Sunday (~40 hours ago). So far, nada. Nothing but this sorta scummy looking growth on the beer surface. What the hell's going on here? I've used Wyeast in the past, but not the American Ale. The package swelled just fine and all that. Anyone got any ideas?

Subject: Phillmill

>From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>  
>Subject: Phil's Mill Report

>The early prototype version I used seemed to work well, i.e. gave a good crush, and Dan (Listermann) has tested this observation by sifting the grist through a set of brewery screens, and comparing the (weight) percentages left on each to published data for 6-roll mills.

I won't argue that he may have improved on the Corona grind but I have his published "data" at hand and am a bit annoyed at his attempt to claim that it is far superior to the crush that is achieved by the MALTMILL (tm).

His bar charts show that the MM and Corona are just about identical (bad) and the Phillmill and the large commercial mill are identical (good). Considering the source, I would suggest a less than unbiased evaluation was done here. His chart also shows that an improperly adjusted PM looks just like the Corona and the MM. This would lead one to the obvious conclusion that you can prove anything you want by diddling around with them.

I have never seen a PM but, having only one roller working against a fixed plate, would seem to be only a nominal improvement over a rotating plate working against a fixed plate as in the Corona. I won't argue with his claims about it but I would be more inclined to believe what Geroge Fix said about the MM than what a competitor says about it, viz....

.....

I received Jack's mill in Jan., 1992. Shortly thereafter it was taken to the Dallas Brewing Co. (DBC) for the test. The latter was done with a standard and well established screen sieving procedure. This is described for example in DeClerck, Vol. 2, pages 321-323. It in effect consists weighing out the grain fractions that are retained on screen meshes of diminishing width. The following is what we measured:

|    | ASBCscreengrains retained, % by wt. |            |
|----|-------------------------------------|------------|
|    | screen no.                          | width, mm. |
|    | MM                                  | DBC Mill   |
| 10 | 2.000                               | 1413       |
| 14 | 1.410                               | 1820       |
| 18 | 1.000                               | 3332       |

|      |              |      |     |
|------|--------------|------|-----|
| 30   | .590         | 2525 |     |
| 60   | .250         | 5 5  |     |
|      | 100          | .149 | 3 2 |
|      | Not Retained |      | 2 3 |
| ---- | ----         |      |     |
| 100  | 100          |      |     |

George Fix

.....

For the record, Listerman's published data shows the MM retains about 45% on the 10 mesh screen and about 50% for the Corona and 10% for his. I would think that any grinding type mill (PM/Corona), as opposed to a true roller mill, could be adjusted so that zero is retained on #10 screen.

I have no problem with healthy competition and it's nice to know that our hobby can support this kind of growth but telling fibs about someone else's products is not a good idea.

From: magdek@LONEXA.ADMIN.RL.AF.MIL (Kevin M. Madge)  
Subject: Dogbolter

In digest #1162 Joseph Gareri asks for some info on the Dogbolter homebrew kit. I've brewed the kit using malt extract instead of corn sugar. It's definitely a strong ale. An excellent brew; I recommend it. A friend of mine (Franz Haas) has had the real stuff in England. His comments are:

I tasted the homebrew version five years after my last long night at the Pheasant and Firkin (I believe it is on Goswell Ave, London) where I was a regular. The homebrew reactivated those long dormant neurons - this WAS the beer of my favorite local pub!! True to form and taste. We used 3lbs of malt extract instead of the 2.5lb of sugar. Good luck.

Franz and I have brewed with the package yeast.

From: Paul Boor <PBOOR@beach.utmb.edu>  
Subject: CDC sterilant

Yo all you high intensity Microbiology types out there in academia/  
industry --  
Here's a thread to tie one on with:

The Center for Disease Control (CDC) in Atlanta recently reviewed its  
guidelines for sanitizing IV needles (reviewed in the Morbidity and  
Mortality  
Weekly Report of two weeks ago). Several large urban areas have tried to  
get  
drug addicts to sterilize needles to decrease AIDS, despite the screams  
of the  
likes of Jesse Helms that fed funds should not be used for such projects.

..  
Anyway, CDC recommends 1/4 cup/gallon water for sterilizing surfaces,  
so I'm with the recent comment of R. Stueven: Why has the bleach  
concentration  
been plummeting? Who really knows, like percent kill of E. coli? I  
can't  
believe that 1 tsp in a keg will do it; that seems about like most urban  
water  
supplies.

But more importantly, should we be using two different bleach  
concentrations for our needles and our Kegs? Are homebrewers out there  
secretly sharing kegs? How effective are condoms in preventing the  
spread of  
keg-associated STDs??

Think about it, but right now I gotta run out to the kitchen to make  
sure my refrigerator light is still on.

From: adoval@stmarys-ca.edu

**Subject: Siphons**

Since the basic technique in siphoning is to get the tube filled with liquid (free of air) before it will flow freely, \_first\_ fill the tube with water, pinch one end, place the other end in the wort, lower the pinched end into a small container and release the water, which will draw out the wort behind it; pinch again when the water has passed through, and you're ready to bottle.

Subject: Re: All Grain Systems

Hi Brian,

I've been doing all grain since about Christmas, and have recently gone through several of your questions myself.

> + Boiling Kettle - what are the disadvantages of cutting up an old  
keg?  
> Is a false bottom necessary? For a 15 gallon capacity (10 gallon  
> beer batch) what should I look for in material thickness and other  
> features.

An old keg is the cheapest way to get 15 gallon capacity. The false bottom is not a requirement, but 10-15 gallons of wort or mash is \*very\* heavy, and you don't want to pick it up. Therefore, some kind of bottom outflow is nice, and will require some kind of filtering to prevent clogging. Also note that the barrel shaped kegs as opposed to the cylindrical Sankey kegs are harder to fabricate a false bottom for. If you want maximum capacity, and just cut off the very top of the keg, the hole resulting is smaller than the desired diameter of the false bottom. I am currently struggling with this problem. My first attempt at a false bottom failed miserably last Sunday.

> + Propane burner - Is 35K BTU's big enough? How long to heat 12  
gallons  
> of wort?

It will work, but more is better, to a point. If you already own this burner, go ahead and use it, and only replace it if it is insufficient. There are basically two main types of burner: 1) multiflame and 2) single flame. Type 1 usually has the best adjustability and gas efficiency and the lowest total heat output. Type 2 can approach 200K btu, has very poor adjustability and poor gas efficiency at a low heat level. What I recommend is actually a hybrid of the two made by King Kooker (KK does make all three types). It has about 20 individual flames, is nicely adjustable, and puts out 145k btu max. This is what I have, it will bring 12 gallons to a boil in 15-20 minutes.

Subject: Dispensing with Foam

I sent this post last Friday, but it seems to have gotten lost. Excuse me if it appears twice.

I have solved the problem of getting the right amount of foam when dispensing beer from soda kegs through a cobra tap in a unique way. As always, the trick is to get the pressure at the tap to down to just above ambient by matching the losses in the delivery line to within about 1 psi of the gauge pressure in the keg. You can size the line such that this happens, but what about resizing part of it by putting in a restriction? You can't place the restriction at the end (by regulating the flow at the tap), because the pressure drop is too abrupt. I have found, however, that you can place a restriction at the quick disconnect, to get part of the pressure drop, and let the line take care of the rest.

My Cobra tap has the usual 1/4-in ID tubing, with a 1/4-in flare nut on the end, which attaches to a ball lock connector. I placed a short piece of 1/4-in ID copper tube between the cobra tap hose and the connector using a 1/4-in flare union and two flare nuts. I then squashed the tube (nearly) flat to create a restriction. The flattened section is about 5/8-in long, and the flow passage inside is only about 0.020 in or so. With the regulator set for the desired volumes of CO<sub>2</sub>, usually 10 to 15 psi for me, it works fine. In fact, I adjusted the restriction by trial and error to get it to work properly. One could try using an adjustable restrictor (needle valve?) to accommodate various tank pressures. Maybe one of the entrepreneurs out there could make a killing supplying such a thing to the mechanically disinclined.

Subject: Basics/Twist-off Bottles/Bleach, Iodophor & Stainless

Sorry about some of this being a bit dated, but I've been very busy (and still am).

Bart writes:

>1) Is there an inexpensive source of malt extract in the USA ? Part of what

Yes, \$6.25/3.3# or \$11/6# in single quantities (email me for the source)

.

>2) Is there a market for used small scale brewing and kegging equipment ?

> looking for a used CO2 bottle, regulator, and hoses. Ultimately, > SOMEONE must want to get rid of their old equipment.

Not really. Most of us are in this for the long haul. There are low-cost solutions. Kegs can be purchased used and reconditioned (don't forget the poppets!). CO2 tanks are CO2 tanks and can be purchased from yard sales, fire extinguisher places, etc. Hoses and regulators are best bought new from either a homebrew supplier or from a beverage supplier -- see your yellow pages.

>3) I'd like to experiment with adding different sugars to my wort, > particularly brown sugar or molasses. Has anyone tried these ? > Any recommendations on quantities to try ? How about other > sugars and their effects ? Anyone tried dissolving a pack > after dinner mints into their wort ? Just kidding about > the last one !! You can stop grimacing now.

Hey, whatever floats your boat. There's been beer made from roosters (yes, male chickens). Molasses is pretty strong flavored and thus only really appropriate in any quantity in a dark beer. I used 8 fl oz in my last Imperial Stout and I could have added twice that. For a lighter stout, I think that 4floz to 8floz is about right. Brown sugar is just white (cane) sugar with molasses added back. You can use 1/2# to 1# in Pale Ales for interesting flavors. In a recent IPA, I added 2# of Raw Sugar from C&H. It was too much -- there is an underlying cidery tone to the beer which I hope will go away. This is from the sucrose and not from the "rawness" or "molasses" in the sugar. I'm planning to try some experiments with Sucanat(tm) as soon as I have the time. Given that there's a lot of sucrose in it, I would suspect that it's use should also be limited.

>4) I realize that sterility is very important. All of the procedures > that I've read mention that during racking, a siphon should > be used to transfer the fermented wort. However, I have > yet to figure out how to start a siphon without getting my > mouth on the end of the hose. Is there any way to > start a siphon without risking the contamination ? Or am I > just being too paranoid ? Will my batch be ruined ? And how > do you know that the light in the fridge goes out when you close

> the door ?

Don't worry about the fridge light, but do be concerned about sanitation. Poor sanitation is the only think (just about) that will make your beer undrinkable. Here's how I siphon:

1. Fill carboy or bucket with 5 gallons of water and 5 tablespoons of Household Bleach.
2. Hold the end of the siphon hose (which, by the way, was cleaned and rinsed thoroughly after the last use) up against the faucet and fill the hose with tapwater.
3. Shut off the plastic hose clamp (these is really make it easier and they only cost about \$.25) or pinch off the hose to keep the water from running out.
4. Stick the in-end of the hose in the Bleach water and let the water running out of the hose start the siphon of the Bleach water.
5. Pinch off the hose and stick both ends in the Bleach water to sanitize the outside as well as the inside.
6. Let this sit for about 10 minutes.
7. Dump out the carboy or bucket into another bucket for later use if you need it. While you are doing this, you need to keep the hose in a sanitary place -- I either hang it from the ceiling by a string or hand it to an assistant if I've got one.
8. Rinse the carboy or bucket well (this is the vessel you will be siphoning into) and rinse the outside of the hose -- don't let the Bleach solution run out of it... keep it pinched off! Larger diameter hoses siphon faster, but don't hold water well... I use a 5/16" OG hose. Put a gallon or so of clean water in the vessel -- if your tapwater is not sanitary, final rinse in boiled water or industrial beer and use a gallon of that in the vessel instead of tapwater).
9. Dip the rinsed hose (or racking tube, which is what I use -- it's just easier to keep the end of it at the bottom of the vessel) into the vessel and use the Bleach water to start the siphon of water through the hose. Let it run for a minute or so, but don't let it run out!
10. Shut off the hoseclamp or pinch off the tube and move it to the beer you want to siphon.
11. Use the water or industrial beer to start the siphon of the real beer. Let the first cup or so go down the drain, cause it's mixed with what you had in the hose.
12. The above was sort of the "siphon from one carboy to another" instructions. After you're done siphoning into the bottling bucket on top of the priming solution, don't let all the beer run out of the hose! Stop it right before the end and then you can use this liquid to start the siphon for the bottling too.

>OK, so now it must be obvious that I'm a neurotic miserly penny pinching >flake. What variety of beer would best fit my personality ?

All of them.

\*\*\*\*\*

Alex writes:

>I hope this question isn't too obvious. But I was wondering why most  
>literature on homebrewing that I have read says "DO NOT USE TWIST OFF  
>BOTTLES".

>I have used twist offs for about 10 batches and have not had any  
problems.

Twist off bottles are made for a different kind of capping machine than  
we use. In fact you can buy twist-off caps. The two reasons that I  
would  
recommend not using twist-off bottles are:

1. they are thinner glass at the top and are more likely to shatter  
during  
capping, and

2. the press-on cappers that we use are not the right kind for this type  
of bottle and there's a chance that the cap won't seat properly and there  
will be a leak (flat beer).

\*\*\*\*\*

There's been a lot of conflicting information posted regarding Bleach,  
Iodophor and Stainless Steel. I'm in the process of thoroughly  
researching  
the "bottom line" and will post (what I hope will be) the definitive  
answer  
when I have collected all the data from experts in the appropriate  
fields.

Stay tuned.

Al.

effective  
> against hangovers; I don't know whether any sound research has been done  
on  
> this

This inspires me. Having been an early contributor to the recent  
headache/industrial brew thread, no doubt a frequently arising topic of  
discussion, let me launch what is probably another recurring thread:  
hangover cures. Here's mine: it's common sense, and works wonders. In  
order of importance:

1) Water. Lots of it. As much as you can stomach before bed (at least a  
pint), put a pint beside the bed for when you wake up, and drink more  
(water, that is) after you wake up.

2) Sleep. As much as you can get away with. An extra hour or two will  
make a world of difference.

3) Acetaminophen/Caffeine/Codeine (8 mg) compound tablets. These are  
available over the counter in Canada. You have to ask the pharmacist for  
them. Generic brands are way cheaper than the Tylenol version. Take 2  
or  
3 upon wakening. The acetaminophen is easier on the stomach than  
aspirin,  
the codeine makes life much more pleasant (but can cause nausea in large  
amounts, so don't pop those Tylenol 3's you've been saving from your  
wisdom  
tooth operation - they have 30 mg codeine apiece), and as for the  
caffeine,  
see below.

4) Caffeine. Not only does caffeine have analgesic properties of its  
own,  
it also increases the analgesic power of acetaminophen and aspirin by  
something like a factor of two. Put on the coffee pot immediately upon  
awakening.

5) Cannabis. Seriously. Really helps take the edge off things. An  
effective analgesic, anti-nauseant, and appetite stimulant (see below).

6) Food. Don't starve yourself, cuz low blood sugar will only make  
matters  
worse.

Of course, there's always the hair-of-the-dog-that-bit-you school.... I  
haven't mentioned vitamin B, but I think it's pretty important too. I've  
found I get more of a headache from commercial natural brews that have  
had  
the yeast filtered out than I do from bottle-conditioned beer, be it

commercial or homebrewed.

Happy quaffin'!

From: STROUD%GAIA@leia.polaroid.com  
Subject: brewing capitol of the world

Every so often I see proclamations in this forum or others that make statements such as "Portland is Beer Heaven" or (as in yesterday's HBD) "Colorado (the brewing capital of the world)".

Please, let's not be so provincial.

It is very easy in the current renaissance-in-brewing atmosphere in the US to get wrapped up in our own little corner of the world and think that we sit on top of the best beer. But the truth is that we're not even close. There is high quality brew in this country, but there is also a \*lot\* more mediocre beer being made, whether you're talking the East Coast, the West Coast, or somewhere in between.

Beer Heaven (and the Brewing Capitol of the World) is undoubtedly located in Europe. I'd nominate Belgium for Heaven, Bavaria for the Capitol, with the British Isles and the rest of Germany as close also-rans. The USA is hardly in the race.

If you've been to Europe, you know what I mean. If you haven't been there, what are you waiting for?

Steve

From: CCASTELL.UNIX11@mailsrv2.eldec.com (CCASTELL)  
Subject: Re: Dogbolter

Joseph Gareri asked about Dogbolter. I have used it twice and have been quite satisfied both times. The first time I made it almost according to the instructions. (I was curious what it tasted like, never having been to any of David Bruce's pubs.)

The first attempt was:

4 lbs Dogbolter hopped malt extract syrup  
2-1/2 lbs corn sugar  
1 tsp Irish moss  
Brewer's Choice 1098 (British Ale) liquid yeast  
(in at least a pint of starter)

yield: 3 gallons

Bring 3 gallons of water to a boil. Add syrup and sugar, stirring vigorously until dissolved to avoid scorching. Boil for 15 minutes, adding Irish moss for final 5 minutes. Cool. Strain into carboy. Pitch yeast. Rack to secondary after about a week. After two weeks in the secondary, rack to a 3-gallon keg. Force carbonate. (I was in a hurry.) Chill to cellar temperature and serve.

This makes a Strong Pale or Amber Ale. I took this to a friend's Christmas party along with a 3 gallon keg of an all-grain stout. Both were completely consumed, but EVERYONE liked this as opposed to the slightly smaller group that liked the stout.

For my second attempt, I thought that I'd try a "Winter Warmer". I thought about using some specialty malts, but figured anything they might add would be overwhelmed by the malt and alcohol.

Winter Warmer

8 lbs Dogbolter hopped malt extract syrup  
3 lbs rice syrup  
1 tsp Irish moss  
Brewer's Choice 1056 (American Ale) liquid yeast  
(in at least a pint of starter)

yield: 5 gallons

Bring 5 gallons of water to a boil. Add syrups, stirring vigorously until dissolved to avoid scorching. Boil for 15 minutes, adding Irish moss for final 5 minutes. Cool. Strain into carboy. Pitch yeast. Rack to secondary after about a week. After two weeks, rack to 5-gallon keg. Force carbonate. Chill to cellar temperature and serve.

This makes a very dark Strong Ale. I took this to the same friend's Christmas party this past year along with an extract/specialty malt Christmas ale (spices, oranges, etc.) Once again, both were emptied. However, those who had thought the stout was too dark/heavy/chewy had no problem drinking this dark strong ale, which was quite dark and very potent!

Cheers.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Utilization

Glenn Tinseth and Bob Jones write about my hop utilization table. Bob would still like to see the yeast calculation separated from the boil time utilization, and Glenn basically agrees. Glenn goes on to say that the boil time has no effect on the yeast's absorption of alpha acids.

I agree perfectly with Glenn's statement. I was not meaning to imply with the table that there was a direct relationship between the effect of the yeast and \*the amount of alpha acid isomerized per minute of boil time\*. However, the table is NOT a table of percent alpha isomerized, but is a UTILIZATION FACTOR table. The utilization as it relates to IBUs in the finished beer. Just because Rager only put boil time in the table, doesn't change what it attempts to accomplish (I verified this by checking Rager's article just now). I have simply added another dimension to the table, for yeast effects. There is no special magic here, the yeast calculation is a straight percentage reduction or increase from the "average" value in the table (20% either way). Since you multiply this percentage times the "average" value, it makes no difference in the final calculation whether you combine the steps as I did, or do them separately as Glenn and Bob suggest. I was simply trying to make the IBU calculations easier by combining the step. (It also keeps Rager's formula the same).

I can see Bob's point that if the yeast adjustment value is wrong, the table will need to be updated. But as Glenn points out, that is inevitable anyway as we get closer to better utilization curves. Also as Glenn points out, there are many more factors to be considered other than boil time, gravity and yeast. Eventually, I'm convinced that the whole table will be thrown out in favor of a much more complicated formula that will take a lot of these other factors into account. If one wishes to separate the yeast adjustment factor out, then use the "average" value in the table and adjust your utilization up or down to account for the effect of yeast.

BTW, Rager credits not only Eckhardt for the calculations, but also Byron Burch and Dave Miller. Eckhardt only gets sole credit for the table of beer styles vs. IBUs.

Subject: Re: Dogbolter

Joe Gareri asks about Dogbolter. I've brewed this kit twice in the past few years and really enjoy the end result. Both times I used 2 cans (8 lbs. total) + 3 lbs. M&F light dry malt. My OG's were 1.054 and 1.059. It is definitely a strong ale (5-6% EtOH) with a full flavor and dark amber color. I used their yeast both times. I've since cultured and plated out some of the yeast and found no bacterial contamination (on YEPD plates). I vote yes, spark it up! (By the way, I'm an extract/specialty grain brewer with about 4 years/40 batches under my belt, and a graduate student in a yeast lab.)

Subject: How Long On Fruit

Brewers of Fruit,

I am interested in the experience of those having brewed with cherries. I brewed a Cherry Weiss with limited success last summer and am attempting at doing it better this year. I am using very tart cherries of which I pitted and froze about 30 lbs. last year.

In my current creation, I am using about 11 lbs. for a 5 gallon batch. The question that I have is how long a period time is it recommended to let the fruit sit on the beer?

I have already gone through primary fermentation and have racked the fermented weiss onto the cherries and would like to know how long it is that I must now wait. I am sure the answers will be all over the board but so be it. This is my wife's beer so I wanna do good.

I will post the recipe. I sought a sweeter end product so I it incorporates  
1 lb of crystal and 5 oz of lactose.

From: gjfix@utammat.uta.edu (George J Fix)  
Subject: Brewing Calculations

The June issue of Brewprint, the newsletter of the Boston Wort Processors, had a article by Bob Jones and one by myself containing numbers relating to the use of chlorine. I have got some e-mail asking how these numbers were derived, and the following is an explanation of the ones that appeared in my article.

The particular bleach I use has "Active ingredient: 5.25% sodium hypochlorite" on the label. The first term is clear, but the last ones are potentially ambiguous. I contacted a rep, and was told that the hydrated form of sodium hypochlorite is used to make this product. Referring to the CRC Handbook of Chemistry and Physics, one can see this is  $\text{NaOCl}\cdot 5\text{H}_2\text{O}$ . (Sorry folks I can not do subscripts!) The relevant molecular wts. are (in rounded form):

$\text{Na} = 23; \text{Cl} = 35.5; \text{O} = 16; 5\text{H}_2\text{O} \text{ (water of hydration)} = 90.$

This form of sodium hypochlorite thus has a mole. wt. of 164. The Cl fraction is  $35.5/164 = .217$ , and the OCl fraction is  $51.5/164 = .314$ . (I can not do superscripts either so valences are missing!)

I was also told that the term "5.25%" could be taken in the sense of vol/vol. Therefore, my bleach contains 52500 ppm in the sense of vols. The rep concurred with this number, although it must be said that storage of bleach at elevated temperatures can lead to lower values.

If one dilutes bleach by adding 1 ounce in 1 gallon of water, one will get a sodium hypochlorite concentration of

$52500/128 = 410.2 \text{ ppm},$

and a Cl concentration of

$410.2 \cdot .217 = 89 \text{ ppm}.$

(The OCl concentration is 128.8 ppm). Data published by Siebel suggests at these levels, 15 min. contact time is sufficient for bacteria relevant to beer.

In an earlier post I mentioned that I do not choose to use this type of soln. with ss eqpt. I meant this as a statement of personal brewing style, and did not put it forward as a scientific principle. The same can be said for iodophor. As a brewer I am sensitive to the active ingredients in these

products, which fortunately are always listed on the label. The products  
I  
feel comfortable with have iodine (1.75%) and phosphoric acid (18.75%) as  
the only active ingredients. They are widely used in commercial brewing.  
I can  
see how a toxicologist might feel more comfortable with a version where  
the  
phosphoric acid is replaced with fatty constituents used in soaps, but I  
see  
that too as simply an opinion and not a basic principle.

Roger Bergin, an award winning brewer and full time brewing consultant,  
is  
preparing an article on sanitation that is aimed at small commercial  
operations  
and serious homebrewers as well. He will bring the perspective of a hands  
on  
brewer, something this topic badly needs. This paper will appear in Vol.  
3 of  
Brewing Techniques. By the way, Vol. 2 will have an article by Martin  
Lodahl,  
which could turn into the most widely read and discussed article in the  
history  
of brewing. He deals with malt extracts.

To head off anticipated flames, let me state that I get paid \$0 for being  
an  
editor of BT, and authors get the same compensation.

George Fix

P.S. I talked on the phone with Mark Carpenter of Anchor yesterday, and  
found  
out that Diversity Chem. is not the only one making brewery grade  
iodophor.  
Bergin's article will contain a list of the relevant players for this and  
other compounds.

P.P.S. Cushing Hamlen > I still can get through via e-mail. Call me at

Subject: Subscription Problems // Japanese Beer Club

Fellow Brewers,  
First, and foremost, has anyone else out there been mysteriously dropped from the HBD distribution list for no apparant reason? I stopped receiving the Digest with issue #1158, Tuesday 8 June. For about 4 issues prior to that, I would receive 2 copies of the day's digest, then on the 8th, they just stopped coming all together.

I have been FTPing daily to keep current, but the procedure is getting tedious fast. Can someone who is "e-mail smart", or involved with the Digest's publication/distribution help me get straightened out again please, or is the solution just to re-subscribe and hope I don't get multiple copies daily?

Thanks in advance.

... Secondly ...

A colleague at work clipped out an article from a magazine and gave it to me the other day, I found it worth sharing. I don't know what publication it came from, or its date. So, obviously it is reprinted here without permission.

Japanese Pay \$23,000 to Drink Beer at \$78 a Pop

Beer-loving Japanese businessmen shell out a whopping \$23,000 just to become members of a club where they guzzle foreign brews--for nearly \$80 a bottle!

Beer made in Japan tastes so dreadful that big-wigs eagerly pour into Tokyo's Club Knox, where they can sip beer shipped in from Britain, Switzerland and Belgium.

In the ritzy club, the vintage beer from overseas is treated like fine wine, stored in a wine cellar and served in crystal glasses.

The oldest vintage in the club's massive collection is 1983 Samischlaus. The fancy Swiss beer is brewed just once a year in December.

The most expensive is a 1985 bottle of the British brew Gales Prize Old Ale-- which goes for \$78 a pop.

- -----End of Article-----

Sure glad we don't have to pay prices like that.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: RE:filtering with cotton

In the last digest, Jack comments on filters:

snip snip  
<Furthermore, it is darker in color and made of cotton.

It would seem to me that despite the improvement in performance that Jack found with this cartridge, the reusability of a cotton based filter would be low. What do you do to clean and store a cotton filter? I am not sure I would want to spend \$11+ on a filter that I would have to discard or watch get moldy. If you want a cotton filter, my local HW store sells one for \$5 and I used it successfully on a cask hopped barley wine and then discarded it.

I would also point out what I posted on rec.crafts.brewing: One must be careful of the point of conditioning that you filter. A period of cold conditioning helps to remove the bulk of yeast in suspension, and results in better filtration. Other important factors are the % efficiency of the filter used, and the flow rate. Too high a flow rate results in poor filtration with the cartridge filters.

I bought a 5 micron polypro filter from the filter store and it is a good filter for a polished beer, not a sterile filtered or crystal beer. Note I said 5, not .5!! Micro filtered beer is stripped of important beer constituents, that I definitely want in my beer.

<Not willing to accept these results, I purchased a known .5 micron filter cartridge from McMaster Carr and ran some tests on it which convinced me that the .5 micron cartridge that came with the filter, most absurdly was not.

I am not of the opinion that the Filter Store is misleading brewers as to the size of the cartridge. Why is the McMaster Carr filter a "known" size and the other not??

Good brewing (flame suit on),

From: mgerard@caen.engin.umich.edu  
Subject: Liquid Yeasts

I have a question about GW Kent's liquid yeast. I have been trying to use this liquid yeast recently because it's not expensive and readily available (at least in Ann Arbor,MI). Here's my question:

How big of a starter do you need and what is a "normal" lag time at 75 degrees? Also should I start with one big starter or should I start with a small starter (12 ounces) and then transfer to a larger starter (1.5 liters)?

I've used their yeast in four different batches now and it seems like I need to make about a 1-1.5 liter starter and let it ferment for 4-5 days before pitching to get a lag time shorter than 12 hours.

Any advice would be appreciated. Thanks,

Mike

From: an982@yfn.ysu.edu (Steven Zabarnick)  
Subject: Full wort boil

I finally took the plunge -- I did my first full wort boil this past weekend. I used a new 33 qt ceramic-on-steel kettle and a new Brinkman propane burner. The burner provided excellent control for the boil. I was able to bring 5 gals to boil in 30 mins, and I was VERY conservative about turning the flame up high.

My new immersion wort chiller (50 ft of 3/8 inch copper tubing) also worked well; it brought the wort to pitching temperature in <30 minutes.

I do have some comments and questions about the process, though. With 5 gals of water and 6 lbs of DME at a rolling boil, the 33 qt kettle was quite close to full. How does one do an all-grain boil in a kettle this size, where one needs to boil about 7 gals?

As I boiled out on the porch and set up to chill in the kitchen, I had to carry the full, hot kettle with copper tubing protruding. This was much more challenging than expected. Do most people avoid carrying the hot wort by chilling in place (using a garden hose)? During chilling the kettle cover does not completely seal due to the copper tubing; should I have used plastic wrap to keep out the nasties?

From: gjfix@utammat.uta.edu (George J Fix)  
Subject: Extract - Gravity Conversion

I have been working on a sequel to my book on brewing science, one that is more practical and quantitative in its orientation. A particular problem that I am facing is the need to find an alternative to listing the complete Plato/Balling tables relating specific gravity SG to extract E (i.e., % extract by wt. or if you like degree Plato). What I am looking for are formulas that can give a digit or so more accuracy than the "factor of 4" rule. Quite by chance I came across one. I have no idea where it came from, and in particular can not take credit (or blame!) for it. I mention it in the forum to solicit reactions. In any case here it is:

$$E = 668.72*SG - 463.37 - 206.347*SG*SG.$$

This one smells like a curve fit. I bet (this needs to be checked) that a linear fit of the Plato tables gives the factor of 4 rule, and the above is a quadratic fit of the data. Presumably it was introduced to capture the first nonlinear effects.

Example 1. Let SG =1.010. Then the above gives

$$E = 668.72*1.01 - 463.37 - 205.347*1.01*1.01 = 2.563.$$

The Plato Tables (17.5 C version) give 2.562.

Example 2. Let SG = 1.080. Then

$$E = 668.72*1.08 - 463.37 - 205.347*1.08*1.08 = 19.331.$$

The Plato Tables give 19.311.

One can use the quadratic formula to solve the above for SG as a function of E. Since we are only concerned about the first three significant figures in E, one step of Newton's method should give a reasonable result not involving square roots nor choice of sign. This gives the following:

$$SG = 1. + E/( 258.6 - .8796*E).$$

Example 3. Let E =20 P. Then

$$SG = 1. + 20/(258.6 - .8796*20) = 1. + .083 = 1.083.$$

This is the value quoted in the Plato tables.

Has anyone seen any of the formulas before? I am sure that at one point in brewing history they must have been "well known".

George Fix

To: POSTMAN --NASAMAIL

FROM: Dennis B. Lewis <dblewis@jscprofs.nasa.gov>  
SUBJECT: Miller Amber Ale

I recently had the opportunity to try a Miller Amber Ale and I would like to pass on a few thoughts: Get a freezing cold one and drink it as fast as you can. The beer tasted great while cold with slight fruitiness and some hop and malt flavor. I mistakenly thought the Amber Ale would taste better if a little warmer. As the beer warmed, I was treated to a rather chemical-like fuzziness on the palate that I could only describe as sucking on batteries. A homebrew buddy said that's the hop oil they use. Damn shame.

At our last homebrew club meeting, we had a rep from Miller come and present the Amber in full marketing glitz. Lots of FS and free beer. I got a small pamphlet entitled "AMBER ALE: Guidebook to Ales." This has got to be one of the most inane pieces of misinformation I have ever read. I'll pass on a few examples:

"You've probably heard that ales should be served at warmer temperature than other beers. Not true. The tradition of warm beer is a cultural oddity of England than a taste issue. In fact, if you've seen the Queen frown, it's because she just had some warm ale....."

I think everyone has heard the joke "Why to Brits drink their beer warm? Because Lucas makes their refrigerators." but this cultural oddity thing is unbelievable!!! I can believe that the Amber Ale should be served ice cold because it tastes awful at real ale temps, but that is no reason to skew the facts. The pamphlet goes on to say that their masterbrewers recommend that the ale be served between 44 and 48 deg F. Hmm, "masterbrewers" said that, eh?

"Authentic ales differ form lagers and other beers in several ways. First, ale is made only from a special ale yeast. Ales are also brewed at higher temperature than other beers and have a greater hop content. These differences give ale its rich creamy head and full-bodied flavor. Ales are also the original beer of Europe."

I thought ale yeast was the common stuff and lager yeast was the special one.

At least that's the historical development. I think they meant to say "fermented" at higher temps and not "brewed". And they really go out on a limb

with the original beers of Europe thing. I guess the Sumerians and Egyptians

don't count in our mass-produced, Westerners-only society.

I'd love to go on about this but I've already given it more thought than it

deserves. There's a nice little jab on the last page about beers with English

or Irish sounding names not being "authentic ales". I'm just waiting for the

response from the rest of the factory beers: something like Coor's Copper and

Bud Bold, igniting a whole new series of ridiculous sport-related ads.

Date: Wed, 16 Jun 93 11:40:17 cdt  
From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: headaches, reprise; fridges & freezers; Chicago suppliers

Greetings!

One of the things I find most enjoyable about HBD is the way a discussion of some topic of common interest majestically spins itself out over several days! It's a lot more informative than those TV miniseries, and considerably less painful than sitting through Wagner's Ring cycle to boot.

Let me focus the discussion on headaches a bit, if I may, by returning to the original intent of my question about headaches, which may not have been clear

..... first, I am interested in the comparison between homebrew and Budmilloors (1) assuming relatively equal amounts and (2) in terms of immediate effect rather than hangovers. The headache I got from Coors last weekend hit me immediately after the second beer, and did not produce a hangover to speak of the next day (I did my drinking in the afternoon). My head hurts just from the memory of it! Anyway, it would be my assumption that in this case neither the alcohol itself nor a dehydration affect would be to blame, but I would rather suspect some kind of allergic or other physical reaction to the beer's ingredients. I have never known 24 oz. of homebrew to give me a blinding headache, and it seems to soon after drinking to blame vitamin B depletion, dehydration, etc. Sound right to you?

Second, I have been interested in recent discussions of refer/freezer equipment. I am planning on haunting garage sales in the near future to pick something up for my basement so that I can begin brewing a lager here and there. I gather that a chest freezer with a temp controller is ideal for this since you can sit carboys right down in it. However, I might also like a place to store fresh whole hops, and for this I would like a plain ole freezer set at plain ole freezing temps. I don't see any way around the necessity of getting two units, but do any of you techno-wizards out there have another suggestion (for a not-very-techno-person?)

Finally, a friend of mine who lives in Skokie and does not have e-mail access wants to start brewing. Would anyone in the Windy City care to e-mail me vital stats of supply stores in the area (Alt. Garden Supply, Al's store, any others I don't know about), and TIA.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Re: Chili Beer

One of the advantages of running the Oregon State Fair competition has been access to winning recipes -- and the permission to reproduce them at will. The following beer took 1st Place in the Specialty Beer category, and is, I thought, a really tasty item. Ken Kane, of Portland, seems to brew nothing but spiced and fruit beers, and has gotten quite innovative and skillful at it. If memory serves, he's won this category repeatedly (including a pumpernickel beer and a sage beer).

"Green Chili Beeritio" -- 5 gallons

7# Alexander's Pale extract  
1# Dextrin malt  
1# Vienna (presumably Briess)

1/4 oz Kent Golding & 1/4 oz. Clusters after 5 min.  
1/4 oz KG & 1/4 oz. Clusters after 20 & 40 min.  
1/2 oz. Mt Hood after 58 min.

the grains are mashed at 122F for 30 min; 152F for 10 min; 158F for 20 min.

2 tsp. gypsum in 60 min. boil

2 whole, roasted Hatch Chilis & 2 oz. chopped New Mexico chilis  
(presumably in boil)

fermented at 65F for 10 days with Whitbred Lager yeast

===I realize there's a little information missing, but it ought to provide a good start -- and it was a really tasty beer, for those who like chili beers.

Subject: chili beer

Vincent Heuring <heuring@riker.cs.colorado.edu> wants to brew a chili beer.  
I'd always thought that I'd like to do the same, until I tasted one!! Just a week ago, I tried Ed's chili beer, each bottle with a whole Jalapeno in it. According to the label, Ed's is a microbrewery somewhere in Arizona (can't remember where), but the beer was actually made by a contract brewer in Indiana.(?) Anyway, I was excited to try this brew. I really like spicy food, and I'm not above eating Jalapeno's with a meal. However, this beer was so intensely hot that I couldn't get past the first sip!! What a surprise!!

Good luck with the pepper beer Vincent, but, as with any new spice, start off slowly, and increase the peppers with successive batches until you get a beer you like.

-----  
On another note, I recently took a trip to Phoenix. While there, I made a special point of obtaining various microbrews not available in Utah. (Except for Wasatch ales, the list of microbrews not available in Utah is identical to the list of microbrews. Utah is the real wasteland of beer!;-) There's a shop called Sportsman's, and browsing through there I felt like a kid in a candy store. The beer I liked most is Celis White. Wow!! What a cornucopia of flavors. I've been reading reviews of this beer on the HBD, and it was great to be able to confirm them personally.

Cheers,  
Chuck

From: Mark Taratoot <SLNDW@CC.USU.EDU>

**Subject: headaches**

Greetings.

There has been some discussion lately about headaches from commercial beer. Here is yet another data point. I don't buy beer very often anymore, but my housemate does. (I have gotten him into homebrewing, but he does not show as much enthusiasm as I). Well, he no longer buys beer in cans. He says he gets heacaches from canned beer. At first I thought that he just meant cheap beer. But it turns out that Busch in the bottle does not give him a headache but Busch in the can does. He thinks it has something to do with aluminum. Go figure.

From: Richard Stueven <gak@wrs.com>  
Subject: The Untouchables

Tuesday night on KTVU-20's presentation of The Untouchables (the real ones, with Robert Stack and Walter Winchell)... "The Cooker In The Sky", an episode from 1962.

See, these BadGuys got the idea to build a brewery on the sixth floor of this warehouse in Chicago, because nobody would ever look for a brewery on the sixth floor of a warehouse. They picked up three disassembled tanks at an auction for \$2500, after the previous bidder bid \$300. (These guys were serious!)

They got their "rice, malt, and grain" from a local grain mill, and they got an "in man" at the Water Commission.

Eliot Ness (Our Hero (feh!)) got wind of this operation, and watched some of the construction through the building's windows. He guessed the brewery's capacity would be "two thousand gallons a day", and that it would cost "two, maybe three hundred thousand dollars before he's finished". It would be the largest illegal brewery ever constructed.

The brewery was short on pipe, so Ness got them some through legal channels in order to help catch Mr. Big. Washington heard about this (by means of Ness sending in an expense voucher for the pipe...Your Tax Dollars At Work) and was not at all pleased.

The brewery was built in exactly thirty days, and the proud owner gave his cohorts a tour. When will the beer be ready? "Tomorrow, maybe two days." Apparently their products would be keg-conditioned.

To my delight, the tour was fairly detailed. Rice and malt flour were kept in two bins in the rafters. The grains were delivered pre-ground to minimize dust, and were mixed with water on their way to a steam-heated vat, where the beer was "cooked". After cooking, the beer was pumped to another vat, and hops were added while the beer cooled to room temperature. It then was pumped through a "chiller" into the fermenters, where the yeast was added. After fermentation, barrels were three-quarters filled with beer, and "the yeast foams to fill the rest", ensuring minimal spillage. (So I was right about the keg-conditioning!)

They had brewed a test batch in preparation for this tour, and they got ready to draw a pint just as Ness raided! (Holy cow, this is exciting!) Ness took the mug of pale beer, held it up to the light. "Good color," he said, and took a sip. "Green but good!" Then he opened the tap, and all the beer ran onto the floor. "Expensive beer...a quarter-million for one glass."

The punch line (read this in your best Walter Winchell voice): Five days later, Franklin Delano Roosevelt was sworn in as the President of the United States. The seventeenth plank of his platform: the repeal of Prohibition.

have fun

From: "JSDAWS1@PROFSSR" <JSDAWS1@PB1.PacBell.COM>  
Subject: yesst & motorized maltmills

A while back, I posted about an idea I had for holding yeast in a cornelius keg until brew-day and pitching the sludge in the bottom into the wort. I bottled it (an amber wheat ale) last Sunday and noticed a mild but very definite cloviness. Once before, I had done this, the only difference being that I forced the sludge under pressure thru my tapper (which had been sitting in the fridge for weeks) That beer was VERY clovy and because I had a gaping hole in my sanitation, i.e. the tapper, I wrote it off to that  
My question is; are those cornelius cans as sterile as i thought? I noticed the bottom is very rough and the lids have lots of crevices. Until recently, I just sloshed chlorine water thru them and rinsed with tap water with no problems ... now I pour boiling water in them and seal em' up but didn't for this cornelius-can starter.

Recently, a freind & neighboor bought a JS Maltmill <tm>. It's a WONDERFUL device and I definitely intend purchasing one.... but ONLY after I figure out how to motorize it. Any ideas? I'm the kinda guy who grabs the correct end of a screwdriver about 50% of the time so it's got to be an easy, off-the-shelf kind of solution.  
Thanx in advance.

| If it's good for ancient druids runnin naked thru the woods |  
| drinkin strange fermented fluids then it's good enough for me. |

From: "Bob Jones" <bjones@novax.llnl.gov>  
Subject: Air filters, yeast filters

On the subject of air filtration when using an air pump, plain old cotton will filter out all airborne critters. Just make the path length through the cotton long. People that use these aeration stones, how do you clean them? Someone posted several months ago a source to a SS stone, a much better choice.

Jack S. experiments with filters is very interesting. Micah claims he has seen no problems with head retention using the supposed .5um filter and I have seen poor clarity with it as well when pushing some beers through it.

I have attributed the poor clearing primarily to the quality of the malt I was using. Fix has recommended against this small (.5um) a filtration. Well maybe the .5um is really 5um and just what we want. To pull those hazes out (if protein) one should chill for about a week at about 35 deg f. Now those hazes that pass through the filter, they are from poor malt. I'd say switch malt manufacturers.

Jack, I would worry about cleaning and reuse of the cotton filter. The poly filters seem much better in this regard.

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: Pasteurizing Fruit

Hello brewmates,

What temperature is required for pasteurization and for how long?

I'm making a few fruit beers this summer and I want to pasteurize the fruit and add it to the secondary.

I was told that holding the fruit at 160F for 15 minutes will work; but I have also heard 140F for 10 minutes. Does anyone have the "real" numbers. I know there has been much research on pasteurization, but I haven't seen many references in brewing texts. (But then again, I don't have many brewing texts.)

Any chemists or food industry people out there who can help me out?

Thanks for any help,

-Alan

From: Eric Wade <ericwade@CLASS.ORG>  
Subject: Cornelius fittings, Air filters

#### PIN-LOCK VS. BALL-LOCK CORNELIUS KEGS

At the risk of starting a ball v. pin fight (sounds like bowling), I offer the following summary of the (sometimes contradictory) information I received to my request on cornelius kegs.

Ball-lock kegs are sometimes referred to as Pepsi type and pin-lock as coke. The price for the kegs is about the same for both. Fittings are interchangeable but the pin-lock fittings are more expensive.

Some respondents said that the ball-lock fitting required a special tool for removal while others said the pin-lock required the special tool. I invite clarifications by e-mail.

Some found advantage in the shorter pin-lock kegs (more head-space in the fridge), some liked the taller thinner ball-lock kegs.

Ball-lock fittings might be forced onto the wrong in/outlets on the keg, not so with the pin-locks. While both fittings might get gummed-up, the pin-locks are less likely to break if forced. Pin-lock fittings are also more secure when attached.

Ball-lock kegs are more easily vented, easier to dismantle, and might be more readily available than pin-locks.

To keep S/N level low I'll accept any further information, clarifications and arguments with the above by e-mail and will summarize for the Digest.

To all who responded to my initial request, many thanks. If I didn't include all of the information you sent me, don't think I didn't find it extremely valuable. I just wanted to summarize the pin/ball info.

#### AIR FILTERS

In HBD 1163 Philip Seitz inquired about aeration/oxygenation systems and filters. While I intuitively think the filter is a good idea (and the set-up illustrated in BT mentions filtering out pump stink), why would one be any more concerned with organisms from pumped air than from sloshing headspace air? Is it simply the larger quantities of outside air passing through the wort from the pump? Does the filtered and pumped air offer a cleaner source of oxygen than sloshing headspace air?

As far as sources of filters, Heartland Hydroponics' (800-354-4769) ad in the current Zymurgy offers "point 22 u.m." filters that fit aquarium tubing (stand. disclaim.). Does anyone know anything about these? Is this ".22 u.m." and is this a reasonable air filtration size?

I have read about the use of hospital oxygen filters for use in these type of aeration systems (Zymurgy gadget issue?) but that they are usually sold only in bulk. Any sources (homebrew mailorder, etc.) for smaller quantities of quality filters would be appreciated (Philip, please forward any useful leads!).

Finally, given a relatively dust-free environment, how often would these filters need to be changed?

From: John F Myers <John\_F\_Myers@ccm.hf.intel.com>  
Subject: Starting a Siphon

I've been reading the HBD for a few years. Over that time I've read and experimented with a number of ways to start a siphon without the worry of infecting my beer.

Mouthwash  
Wiskey  
Blood pressure bulbs  
CO2  
Water in siphon hose  
Just do it  
etc...

Then a year ago, by accident I broke my bottling wand and ... A mouthpiece was born! Just sanitize and mark one end you plan to suck on (for multiple transfers, it's easy to forget which end you used when you set it down), start the siphon and bend the siphon hose 180 degrees when fluid reaches near the end of the siphon hose. At this point simply pull off the mouthpiece, add bottling wand or what ever. IT'S SIMPLE, CLEAN AND WORKS GREAT!

One question I would like someone to answer.

Why does geletin lose it's clearing properties once it is boiled???

>From:

Subject: Re: sanitizers part I

Once again, many of the statements made by donald oconnor <oconnor@ccwf.cc.utexas.edu> just didn't sound right to me. As I'm no expert on the matter (and by now it's obvious that neither is don) I referred to an excellent text on the matter, "Disinfection, Sterilization, and Preservation", by SS Block. (Many thanks to whomever first recommended this book here.) With this in hand, I would like to correct some of the errors which were posted here.

1. Sanitizing strength

>Both chlorine and iodine sanitizers kill bacteria as a result of their >oxidizing power. A strong oxidizer is a good sanitizer. Chlorine in all >its oxidation states (dichlorine, chlorite, hypochlorite, etc) is a >stronger oxidant than the corresponding iodines. In chemical >terms, it is said that the redox potential of chlorine is greater >than iodine. Being a stronger oxidant, chlorine sanitizers are >expected to be more effective at killing bacteria. However >iodine is also a sufficiently strong oxidant to work very >effectively in killing stuff and thus, in a practical sense, >the two cannot be distinguished in this regard.

Sanitizing can occur by many mechanisms, only one of which is oxidizing. The sanitizing mechanism for Iodine and Chlorine are somewhat different, thus we simply cannot compare their relative sanitizing power by just comparing redox potentials. The only way to do it is empirically. Empirical comparisons show that Iodine has 3-6 times the sanitizing power of chlorine. However, the sanitizing power of chlorine (and to a lesser extent iodine) is dependant upon pH (being greater at lower pH), so even this must be taken with a grain of salt. Also, iodine is not deactivated by organic matter to the extent that chlorine is. Thus, when sanitizing 'dirty' equipment, chlorine may be quickly rendered useless, while the iodine will have much more "staying power".

>The recommended dose for iodophor, which contains molecular iodine, is >12.5 mg/l (ppm). Since each iodine atom weighs 4 times as much as >chlorine and it's the number of atoms that is important, then a chlorine >concentration of 3.5 mg/l will give the same sanitizing effect.

Household

>bleach is about 5% sodium hypochlorite by weight. So how much bleach >do we need in each gallon to get the same sanitizing effect as >iodophor. Incredibly only 0.02 ounce! That's 50 times lower than >1 oz/gallon, 25 times lower than 1 tablespoon/gallon. For those more >familiar with teaspoons, you need only add about 1/2 teaspoon of >bleach in the entire 5 gallon keg to achieve the same level of sanitation >that iodophor provides! Furthermore this concentration is about 70 >times below the known safe level for reactivity with 304 stainless.

Different studies will show different doses for "effective" sanitizing. For iodophor, I have seen the 12.5 ppm number, but 25 ppm is also used often. However, to get a sanitizing power from chlorine equivalent to 12.5 ppm of iodophor, 50 ppm of chlorine is generally recommended. (NOT 3.5 ppm.) 50 ppm would be about equal to 20 ml of Chlorox bleach per 20 liters of water. (4 tsp. per 5 gal).

We often talk about the S/N ratio here, but we owe it to ourselves to keep the "Fact/Fallacy" ratio as high as possible as well.

Keep on Brewin',

Kelly <k-jones@ee.utah.edu>

Subject: Colorado Micro Brewers Festival

To all Coloradans,

The Colorado Micro Brewers Festival is coming up on June 26,27 in Fort Collins. This is the first year that it has been extended out to two days.

I went last year and had quite a good time. The beers and crowds are plentiful.

There are also a few good brewpubs nearby at which you may take in a meal while quaffing. I don't have many details handy (other than to show up in

Ft Collins on those days with your drinking hat on). If there is enough (any)

interest, I can dig around in my morass (sp?) of brewing info and produce some helpful information. If memory serves, there are about 15-20

brewpubs

and micros represented (if not more), each of which has at least two of their

brews in tow. Simple math will tell you that there will be quite a lot of

variety represented.

Perhaps someone out there would like to sink a few with a few fellow HBD'er. Let me know. I'll be the one with rosy cheeks, glossy eyes, and a big grin:-).

P.S. - I am not connected in any way with the Festival or it's organizers. I am, however, one hell of a satisfied patron:-).

From: pohl@unixg.ubc.ca (Derrick Pohl)  
Subject: How much bleach for sanitation?

Re the recent HBD exchange on how much bleach you need for sanitation:

Papazian in The Complete Joy of Home-Brewing says you can actually get by with as little as 1/3 of a tsp. in 5 gallons cold water (minimum contact time 30 minutes). I use a teaspoon or a little less of bleach per 5 gallon carboy and a similar concentration for bottles, bungs, hoses, etc., and have never had a sanitation problem in over two years of brewing (over 15 batches, all with closed primary & secondary fermentation and liquid yeasts). Now all this assumes the equipment is spotless to begin with: organic matter (i.e. dirt and stains) uses up the free chlorine. To get things clean I use a solution of 2 heaping tbsp. baking soda per 5 gallons hot water for the fermentation residue in carboys, bungs and blowoff tubes, using a brush for any persistent mung (which there rarely is). The other equipment I just rinse with hot water after use, occasionally giving them the baking soda treatment. For truly stubborn stains and mold (which most often appear in the bottom of improperly rinsed bottles), I use that pinkish-purple chlorinated detergent that goes by various names: Choriclean, Diversol (I think).... It's the same stuff I used to use in the dishwasher when I worked at a restaurant during high school. It truly kicks butt, cleaning and sanitizing in one go, but is much nastier and more expensive than bleach and baking soda.

Just one set of beer-addled observations for your consideration....

Date: Wed, 16 Jun 93 21:30:38 PDT  
From: bill@oilsystems.com (Bill Vaughan)  
Subject: Jalapeno beer

Two years ago, Mary and I were visiting Phoenix and stopped at the Cave Creek brewery, where one of the specialties is chili beer. (It was jalapenos then, but I'm told they've gone to Serranos since.) We tried the jalapeno beer and found it quite mild, and absolutely wonderful with hamburgers.

Four days later, before returning to the Bay area, we went back and found the beer was substantially more spicy. On inquiring, I was told that the amount of spice was related to how long the beer had been in the bottles, because they use their ordinary golden lager and add a jalapeno in the bottle.

So how long had it been? The batch had been bottled on Tuesday, which made Friday's (which we liked a lot) 3 days old. They also said the heat continued to increase until the beer had been in the bottle about 60 days.

I brought some home. Sure enough, after a couple of months it was real killer beer. So bad you had to have another beer! (Without chile.)

I resolved to make some, but NO WAY was I going to put a pepper in the bottle, no matter how nice it looked. So I took a wild stab, guessing that

the effect might be linear (!): let's see, 1 jalapeno, 12 ounces, 3 days =

16 jalapenos, 5 gallons, 3 weeks. And that's what I did. Used my plain-jane

ale recipe, didn't hop it as much as usual, and threw 16 jalapenos into the

secondary for 3 weeks. (Blanched the peppers with boiling water to sterilize,

but did not cook them or cut them open. I would cut them open next time because they insisted on floating for the whole 3 weeks.)

After 3 weeks, I bottled the beer, and as a bonus had a dish of jalapenos pickled in beer. I would have saved them in the fridge but they didn't last that long.

The beer turned out very good. Mild heat, jalapeno flavor just right. The only problem is that the bottles tend to gush. Not infected, (the commercial bottles gush too), just some weird effect of the oils or proteins from the peppers. But gushing isn't a problem if you chill the bottles first, and this is not a beer to be drunk at cellar temp anyway.

So to answer Vincent Heuring's question, just use any light ale or lager recipe, and put 16 jalapenos per 5 gallons into the secondary for 3 weeks.

Or 32 jalapenos for a week and a half, if it's <really> linear, a hypothesis

I did not test.

Jack writes:

> I have no problem with healthy competition and it's nice to know that  
> our  
> hobby can support this kind of growth but telling fibs about someone  
> else's  
> products is not a good idea.

I have to agree with Jack - while I object to some of his political  
and philosophical stands, he does make a fine roller mill at a reasonable  
price. I was skeptical at first, but the yields speak for themselves.  
With a grain bill of 95% Munton and Fison Pale Ale malt and the rest  
crystal malt, I get an efficiency of 32, which is very close to the  
theoretical maximum of 34. For a typical weizen grain bill, my  
efficiency  
was 34, which again compares well with the maximum of 36 for malted  
wheat.

My only objection is that due to the high yields, I've been having  
problems overshooting my desired original gravities, but I think I  
can find a way to live with the extra maltiness ;-)

From: ron\_hall%80@hp6400.desk.hp.com  
Subject: JALAPENO BEER

Item Subject: Jalapeno Beer

In HBD 1163, Vincent Heuring (heuring@riker.cs.colorado.edu) asks:  
"Does anyone have a partial mash or extract recipe for jalapeno  
pepper beer?"

Well, following the advice of the HBD community, I have made  
two batches in the last year in which I put slices of jalapeno in  
a dozen or so bottles at bottling time. The first batch was  
a partial mash-based pale ale, in which I tried both 1/4" thick  
slices and 1/8" thick slices. The 1/4" slices were WAY too hot,  
and I happen to like spicy food (and drink) alot. The 1/8" slices  
were just right. I tried the 1/8" slices in a mash-based Steam beer  
recently and the spicing was about right. Use fat peppers so that the  
slices stick in the neck of the bottle when pouring, and try to  
leave out the seeds.

One problem I have had with this method is that I have had several  
"gushers". I am not sure if this is due to contamination on the  
peppers, or some reaction from the peppers themselves. I did not  
sterilize the peppers the first time, just rinsed them in hot water.  
On the second batch, I gave them a quick dunk in a bleach water,  
but did not want to get a bleach flavor in them so I kept it short.  
I would probably try a little longer soak in a very weak bleach  
or bisulfite solution. Any ideas out there?

The gushers do not have any off-flavors, just seem over-carbonated.  
By the way, Crazy Ed's in Cave Creek, AZ makes a very good chili  
beer using a whole pepper in each bottle. They are not jalapenos,  
something a little weaker.

Good luck.

comment?

Definitely!

I started with the Foxx CP filler, and after cutting my fingers to shreds, deforming the valve handles, finding the need for 4 or 5 hands at once, and generally becoming exasperated, I gave it up. I still wanted to do CP bottle filling, so I bought one from a very reputable homebrew supply store. Similar to the Foxx model, with similar results. Finally, I bought the BMP model and have been absolutely delighted with it. It's far easier and more convenient to use, does a superb job (OK, you have to get the knack of using it, but that only takes 2 or 3 bottles), and is well worth the price. It's also easier to clean. Incidentally, it was designed by Micah Millspaw, formerly a regular here. After demonstrating the BMP filler to two of my friends, they were both sufficiently impressed to buy one themselves. FWIW, I have heard that the CP filler sold by DeFalco is also excellent, but I have never seen it and can't vouch for it. All others I have seen are not worth much, IMHO.

Well if you are going to follow what the lambic brewers do then you are looking at around 6months. The pKriek I made last fall spent almost 6months on the fruit the flavour,aroma and colour were perfect[Well at least the cherry part-)] Give it time.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Re: Yeast pitching amounts

In the last digest Mike inquires about one of the most important issues in brewing, yeast growth/pitching quantity:

<From: mgerard@caen.engin.umich.edu  
Subject: Liquid Yeasts

<How big of a starter do you need and what is a "normal" lag time at 75 degrees? Also should I start with one big starter or should I start with a small starter (12 ounces) and then transfer to a larger starter (1.5 liters)?

The "professional" technique is to pitch a known quantity of cells, usually 12 million cells per ml for a 12P wort. Add 1 million for each degree P, especially with high gravity worts. Some Ale brewers pitch 1/2 this amount. Most of us have no convenient method of counting cells, nor is it required.

The practical method for homebrewing mortals is to step up the amount in a 10-1 ratio until an adequate amount of slurry is produced. If the yeast source is 30 ml of slurry, this can be directly pitched into 300ml of boiled/cooled wort. The 300 ml should probably be stepped up once more to result in 1-3 Litres of pitching yeast. With this amount, you are still only pitching in a 1-20 (or 3-10 litres) quantity for a 20L batch. With a healthy yeast, this will result in minimum lag time of say 3 - 8 hours. Remember that lag time is also a function of oxygen amounts in the wort. For this reason, many brewers inject oxygen to increase the yeast growth during the respiration phase (yeasts will absorb oxygen through the cell wall, using the oxygen, lipids and carbohydrates/sugars in a process called sterol synthesis).

If you are culturing yeast, start with a loop of yeast and pitch into about 1.5 ml of wort. Grow one day, pitch into 15 -50 ml of wort, wait one day, pitch into 500ml to 1 liter and wait until visible fermentation has begun to brew (1-2 days).

Some brewers prefer to wait until the starter has finished fermenting and pour off the still beer, pitching the slurry only. I have not found this to be necessary but many swear by it and have very good results with it.

When pitching slurry, the rule of thumb is to pitch between 1/2 and 1 pound of slurry per Bbl of wort, 8-16 oz into 31 gallons. When I use fresh slurry off a unitank, I have 2-3 hour lags when pitching this amount. If you can befriend a local brewery who makes \*clean\* beers, this method is unbeatable.

Good brewing,  
Jim Busch

From: mills 17-Jun-1993 0920 -0400 <ferguson@zendia.enet.dec.com>  
Subject: Grain Mills: opinions

I'm eventually going to be interested in getting a grain mill as I move closer to all-grain. One homebrew supply place I go to has a "corn mill" selling for about USD\$41.00 or so. It has a hopper (2# capacity) and a crank. Looking into the hopper is a rod that looks like a giant screw. It is easy to adapt an electric drill to this mill, which is a feature I'm looking for. This mill does let you adjust the crush.

I've heard a lot of talk lately on roller-type mills. I don't reckon that the one I saw was a roller mill. What are the pros and cons of different types of mills? Also, I've seen talk about the PhilMill and the Maltmill, what do these sell for?

Thanks,

From: aew@spitfire.unh.edu  
Subject: Amber Wheat Beer

I've been enjoying the HBD for about two years now and have always wanted to post one of my original recipes, but until now I wasn't sure that I had any that were up to the high quality standards that have been displayed herein the past. I think this one is finally good enough.

This recipe produces an excellent summer beer. Light in body, but with a nice hop Flavor and nose to make it enjoyable to drink. I also use this as the base for my fruit beers. With 5 lbs. of blueberries added to the secondary it is truly special!

Al's Amber Wheat Beer

Ingredients (5 or 6 gallon batch):

- 3.3# Can Mutton and Fisson Light Unhopped Extract
- 2.0# Bag of Unhopped Wheat Dry malt
- 1.0 oz. Cascade Leaf Hops (Boil)
- 0.25 oz. Cascade Leaf Hops (Flavor) Homebrew DigestH
- 0.25 oz. Cascade Leaf Hops (Aroma)
- 1 tsp. Irish moss
- 2 Packages Mutton and Fisson Ale Yeast

Procedure:

Remove 1 1/4 cup of wheat malt and save in zip-lock bag for priming.

Bring 1.5 Gallons water and Malts to a boil. When boil starts fully set your stove timer (watch, hourglass, whatever) to 45 mins. For leaf hops I don't use a hop bag, you can if it makes you feel good.

- 45 Mins: Add Boil Hops - 1.0 oz.
- 15 Mins: Add Irish moss - 1 tsp.
- 10 Mins: Add Flavor Hops - .25 oz.
- 2 Mins: Add Aroma Hops - .25 oz.
- 0 Mins: Pour through strainer and funnel (with strainer) directly into carboy with 2+ gallons of cold water as quickly as possible.

Fill to top with more cold tap water. swirl carboy to mix hot and cold evenly. Pitch yeast.

Notes. This could also be a blonde wheat ale if M+F malt was replaced with a lighter colored malt - say mountmellick unhopped light. Also, If you buy hops in 1 oz. packages you could boost the aroma and flavor hops to .5 oz. each. This shouldn't be too much. Or save the extra .5 oz. and make Papazians Avigadro's Expeditious Old Ale which needs exactly .5 oz of cascade hops!

Enjoy!  
Al

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Filters, Plato

>From: Jim Busch <busch@daacdev1.stx.com>

>It would seem to me that despite the improvement in performance that Jack found with this cartridge, the reusability of a cotton based filter would be low. What do you do to clean and store a cotton filter?

I let it drip for a day and then put it in the oven with just the pilot light and it dries completely in a couple of days. If kept dry, it is not much harder to care for than a cotton undershirt. Some folks have suggested just keeping it in the freezer but I would rather dry it.

> I am not sure I would want to spend \$11+ on a filter that I would have to discard or watch get moldy.

Neither would I and I suspect that I will get a lot of use out of it if properly taken care of but only time will tell.

On the other hand, I do not want to pay any price for any filter that does not do what it is supposed to do.

> If you want a cotton filter, my local HW store sells one for \$5...

I doubt that it is a .5 micron filter.

>I would also point out what I posted on rec.crafts.brewing: One must be careful of the point of conditioning that you filter. A period of cold conditioning helps to remove the bulk of yeast in suspension, and results in better filtration.

I took that under advisement but it does not affect the results of my cornstarch test. I was trying to evaluate two filters and as long as the conditions were the same, the results were valid.

>Micro filtered beer is stripped of important beer constituents, that I definitely want in my beer.

I am sure that is true but I do not consider these string wound filters to be absolute in any sense. My guess is that it just might stop more small stuff than a coarser filter but to believe that nothing over .5 microns gets through is wishful thinking.

<Not willing to accept these results, I purchased a known .5 micron filter cartridge from McMaster Carr and ran some tests on it which convinced me that

the .5 micron cartridge that came with the filter, most assuridly was not.

>I am not of the opinion that the Filter Store is misleading brewers as to the size of the cartridge.

First of all, who said anything about the Filter Store and who suggested anyone was misleading brewers? I specifically stated that I was leaving out the names to give them an opportunity to look into the problem.

For the record, I did not purchase mine from the Filter Store but I do not recall the source for the one in the article. It is my understanding that the Filter Store sells pleated filters and are therefore not relevant to this discussion about string wound filters.

I was simply reporting on the fact that I received the wrong cartridge with the filter I bought and laid out the method by which anyone can determine if he/she has what is expected.

> Why is the McMaster Carr filter a "known" size and the other not??

For the simple reason that the catalog listed it as .5 micron and the one that came with the filter was unmarked and I had not a clue other than the supplier's word that it was .5 micron.

He has since sent me two more that are marked .5 micron but they are exactly the same as the one that came with the original and hence, I do not believe the marking is correct.

>From: gjfix@utamata.uta.edu (George J Fix)

> A particular problem that I am facing is the need to find an alternative to listing the complete Plato/Balling tables relating specific gravity SG to extract E (i.e., % extract by wt. or if you like degree Plato).

>  $E = 668.72 * SG - 463.37 - 206.347 * SG * SG.$

>One can use the quadratic formula to solve the above for SG...

Perhaps I am missing something but it seems that if we all spoke the same language, this problem would go away.

If it is necessary or useful to brew in Plato or Balling, why not just suggest that whoever makes the ubiquitous homebrew hydrometer simply tune in and make a cheap instrument that reads in Plato or whatever is more useful.

As a matter of fact, it seems no more complicated than changing the cal chart inside the instrument and it could read all three scales.

From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>  
Subject: Re: Phil Mill Report

I was well aware of the circumstances and results of the testing done by Listermann comparing the Phil Mill's output to the Corona and the Maltmill, which I obtained from Listermann over the phone. I have not seen any sales literature from Listermann, except magazine ads. Y'all will note, please, that I did not attempt to compare the Phil Mill to the Maltmill in my recent post, because the testing done was obviously not rigorous. The Maltmill used was not the adjustable type, and hence could not be tuned to match anything, right or wrong. The Corona, however, is a known entity, and it is well understood that a compromise between damaged husks and poorly crushed grains must be accepted. I therefore chose to include that portion of the test results.

The data given by Fix comparing the Maltmill to a commercial mill is impressive, but it did not state (in the excerpt) whether the Maltmill used was the adjustable type or not, which would be useful information for any one contemplating a purchase. However, to restate the point I made previously, trying to match the particle distribution of multiple roll machines with single roll types may not be the best course of action because the mechanics of the crushing process are different. This is borne out by the Corona- the thing to worry about is the quality of the beer that results.

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: siphoning sanitation

Lately there's been quite a lot of talk in the digest regarding the use of proper sanitation while siphoning. I'd like to be the guy who says "Hey don't be so paranoid, keep it in perspective". I always start my siphon by sucking with my mouth, and have yet to discover an infection (knock on plastic keyboard).

Sanitation is relatively unimportant at bottling time. Relative to racking off trub, etc. before yeast is pitched, that is. The best way to prevent an infection problem is to pitch a large yeast starter. I'm not saying that it's OK to use dirty equipment, etc., just keep it in perspective. I'll bet that most of us would agree that you don't need to wash your hands with bleach while brewing, right? For me, the trouble of starting a siphon by any method other than sucking on it outweighs the benefit of increased sanitation.

Relaxing too much,  
Chuck

From: LPD1002%NYSHESCV.bitnet@UACSC2.ALBANY.EDU  
Subject: Cooling extract wort

Here's another one of those naive questions from a somewhat inexperienced brewer. I am an extract/spec. grain brewer. Usually after the boil, I would sparge the 1 1/2 gallons of hot wort into 3 1/2 gallons of cold water. This would still leave me with a temp too high for pitching. After reading the ongoing thread about a month ago on wort chillers, I started to wonder. Was my beer spending too much time at DMS temps? So for my last batch I took the brew pot off of the stove and put it into a sink that had been filled with very cold water and ice. I covered it and stirred the cold water around it for 10 minutes or so. Then I sparged into my 3 1/2 gallons of cold water. The beer turned out pretty tasty, so it wasn't infected. A little chill haze though.

Are there any problems doing this? Is it a waste of time for such a small quantity of wort? Should I just wait 1/2 hour before pitching or should I really not worry and do whatever I feel like doing that day?

Subject: Re: Keg Dispensing/How Long on Fruit/Sulfury Aromas

Martin writes:

>I have solved the problem of getting the right amount of foam when dispensing beer from soda kegs through a cobra tap in a unique way. As always, the trick is to get the pressure at the tap to down to just above ambient by matching the losses in the delivery line to within about 1 psi of the gauge pressure in the keg. You can size the line such that this happens, but what about resizing part of it by putting in a restriction? You can't place the restriction at the end (by regulating the flow at the tap), because the pressure drop is too abrupt. I have found, however, that you can place a restriction at the quick disconnect, to get part of the pressure drop, and let the line take care of the rest.

>  
>My Cobra tap has the usual 1/4-in ID tubing, with a 1/4-in flare nut on the end, which attaches to a ball lock connector. I placed a short piece of 1/4-in ID copper tube between the cobra tap hose and the connector using a 1/4-in flare union and two flare nuts. I then squashed the tube (nearly) flat to create a restriction. The flattened section is about 5/8-in long, and the flow passage inside is only about 0.020 in or so. With the regulator set for the desired volumes of CO2, usually 10 to 15 psi for me, it works fine. In fact, I adjusted the restriction by trial and error to get it to work properly. One could try using an adjustable restrictor (needle valve?) to accommodate various tank pressures. Maybe one of the entrepreneurs out there could make a killing supplying such a thing to the mechanically disinclined.

Well, it's a good idea, but then again, not really. The additional fittings and copper tubing are more areas for bacteria to hide and spoil your beer. The simplest solution is to slip some kind of pinch-type hose valve onto the beer line near the keg end of it. These are the plastic siphon hose shutoff clamps that most of us have on our siphon hoses. There are fancier ones with little wheels (like a rack and pinion) that are even more adjustable or the stainless steel ones that are used in labs. As Martin said, though, it needs quite a bit of hose so the restriction is not too close to the faucet so

it doesn't foam all over the place.

Frank writes:

>In my current creation, I am using about 11 lbs. for a 5 gallon batch.  
>The question that I have is how long a period time is it recommended  
>to let the fruit sit on the beer?

First of all, that's a good amount of Cherries -- you will get a decidedly  
Cherry aroma and flavor. I used 12 or 13 (I forget) pounds to make a  
5 gallon batch (actually it was 3.75 gallons of beer on 12 or 13 lbs of  
cherries WITH the pits) and it worked out very well (won a couple of  
awards  
even). In any event, I let them sit in the brew for three weeks in my  
fruit beer, but it's been something like 8 months for my pKriek  
(pure-cultureKreik). For a regular fruit beer, I think that 3 to 4 weeks  
(from my experience) at 65F is the proper amount of time.

>I will post the recipe. I sought a sweeter end product so I it  
incorporates  
>1 lb of crystal and 5 oz of lactose.

I used a couple of pounds of Belgian Caramel Pils and 8 ounces of Lactose  
in 15 gallons of finished beer and it turned out pleasantly sweet.

Some strains of yeast have a tendency to produce sulfury aromas during  
fermentation. There have been quite a few reports of this from Lager  
yeasts especially, but I'm sure that some Ale yeasts are capable of  
producing sulfury smells and still making great beer. Give it some  
time. I've had smells go away in the bottle too, but personally, I  
feel a lot better when the smell goes away in the ferementer.

From: bszymcz%ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: Rotten eggs, Fruit, Siphon

In HBD1164 Rafael Bussto asks:

>Help! after two days of fermentation a rotten egg smell is  
>coming out of my bucket. It is a continental light beer, nothing  
>special.  
>Should I discarded and start over or should I wait a little  
>longer?

Don't dump it yet! Sulphur compounds giving off a rotten egg smell can be a natural byproduct of the yeast during early stages of fermentation. If this is the case, just wait a few days and the rotten egg smell will go away. (I've noticed a rotten egg smell during early fermentation stages of a weitzen and with starters I've used with lager yeasts. In each case the smell went away after the primary fermentation and the beers turned out fine with no detectable sulphury aroma or flavor.) If the rotten egg smell is still strong after active fermentation has ceased, then consider dumping the batch, or using it as slug bait.

Also, Frank Dobner asks:

>In my current creation, I am using about 11 lbs. for a 5 gallon batch.  
>The question that I have is how long a period time is it recommended  
>to let the fruit sit on the beer?

>I have already gone through primary fermentation and have racked the  
>fermented weiss onto the cherries and would like to know how long it  
>is that I must now wait. I am sure the answers will be all over the  
>board but so be it. This is my wife's beer so I wanna do good.

Why not simply wait until the sugars in the cherries ferment out, which should take from 2 days to a week depending on your yeast and the fermentation temperature. Currently, I've been fermenting a strawberry-rhubarb ale (10 lbs strawberries + 1.2 lbs rhubarb) in which I used a similar process as you, (froze the strawberries, blanched in boiling water for a few seconds, dumped into a 6.7 gal carboy, boiled the rhubarb with 1/4 lbs DME and added on top of the partially frozen strawberries, shook, then racked from primary onto the fruit). You may not have as vigorous a secondary as me since I added a little DME, (my small blowoff tube clogged and I nearly had an explosion). Active secondary fermentation stopped after 3 days, (WYEAST 1056, 68F) but I didn't get to rack off the fruit until 7 days. I plan on letting it sit in tertiary a week or so to let the pulp which got through the siphon settle out.

Finally, on starting siphons, I have been using the following method when siphoning into a carboy. I use one of those orange carboy caps with the two tubes sticking out. In the shorter tube (where the air lock is suppose to fit) insert a piece of copper tubing (3/8 OD, about 1 foot long) so that some remains outside and some is inside the carboy. (If you are rereacking place a 5/16 ID plastic hose on the bottom of the copper pipe, which is long enough to reach the bottom of the carboy, to avoid aeration.) A section of plastic tubing is used to connect the top of the pipe sticking out of the carboy to a racking cane (I also use copper tubing for the racking cane). Insert the racking cane into the kettle with wort, or primary carboy with the

beer to be racked. Connect a 3/8" ID plastic hose to the smaller tube (blowoff) extending out of the orange carboy cap. The siphon can be started by either sucking on this hose, or attaching it to a hand pump (as I do).

I sterilize my copper tubing by baking in the oven at 350F for about 1/2 hour and let cool in the oven with the door shut. The carboy is sanitized using 1 oz bleach / gallon of water, and is rinse by twice adding about 1/2 gallon of pre boiled water, shaking and dumping. The plastic tubing is sanitized also by soaking in the bleach solution and rinsing with pre-boiled water.

FROM: Dennis B. Lewis <dblewis@jscprofs.nasa.gov>  
SUBJECT: Eric Warner's Wheat beer book

I recently purchased Eric Warner's book \_German Wheat Beers\_ and have found it to be a tremendous help in quantifying the mysterious tastes of German wheat beers. I have a question for anyone out there (maybe someone knows Eric..)  
about the recipe formulations in the back of the book. I calculated the extract required from the grain recipes to achieve the desired SG. In almost every recipe I came up with an extraction of 40 pts/lb/gal!

I think that these sound more like malt extract (heavy liquid or light dry) numbers. This is not a big problem, but I think the community should be aware of this and make corrections to their own grain bills before starting. One point of help for corrections is that Eric says the recipes are based on 83% extraction from the wheat malt (1.039 max) and 78% from the barley malt (1.035 max). (numbers in parens are mine)

Or maybe there is some super German malts that yield 40 pts!

I think we're missing the point here. The Data posted by george  
measures by weight the amount of grain passing through sucessively  
finer screens. It is a measure of the consistency of the crush  
of the kernel itself, which is important as far a stuck sparge go.

What is more important is how badly the mill shredded the husk  
material, and the analyses do not measure that. husk material is  
light, and will not show up (relatively) in the results, which  
are by weight. A well shredded husk can also be retained by  
the medium screens - it is the grain dust which falls though  
the finer screens.

The presence of extra grain dust does not cause extra tannin extraction,  
the big factor. It can make your sparge stick.

As far as the maltmill goes, I'm a satisfied customer.

From: Martin A. Lodahl <pbmoss!malodah@PacBell.COM>  
Subject: A Few Observations

In HOMEBREW Digest #1164 there were several items that "spoke to me." First, William A. Kitch seconded Kelly Jones' call for references in postings (with which I heartily concur), adding:

> ... This is not to say that opinions and anecdotal  
> evidence are not important. They are and should be posted but should also  
> be clearly marked as such!

I couldn't agree more. Opinion and speculation are grand precursors to knowledge, but aren't themselves knowledge.

Then Dr. George J. Fix caught my attention:

> ... Brewing Techniques. By the way, Vol. 2 will have an article by  
> Martin Lodahl, which could turn into the most widely read and  
> discussed article in the history of brewing. He deals with malt  
> extracts.

Wow! Well, I hope someone finds it helpful. At the moment I'm not sure if it will be discussed, or just dissed and cussed. We'll see, pretty soon.

> To head off anticipated flames, let me state that I get paid \$0  
> for being an editor of BT, and authors get the same compensation.

The compensation is getting to do the research the articles are based on, and getting to work with the people involved with the magazine, including Steve Mallery, a truly extraordinary editor-in-chief.

Finally, Steven Zabarnick set off my alarm bells:

> I finally took the plunge -- I did my first full wort boil  
> this past weekend. I used a new 33 qt ceramic-on-steel  
> kettle ...

This is the same kind of kettle I use, and I think it falls into the "best buy" category. They work great.

> I do have some comments and questions about the process,  
> though. With 5 gals of water and 6 lbs of DME at a rolling  
> boil, the 33 qt kettle was quite close to full. How does one  
> do an all-grain boil in a kettle this size, where one needs to  
> boil about 7 gals?

Very carefully. The tip that someone offered here about tossing a few hop strobiles or a couple of pellets into the wort before it begins to boil is a good one, and especially as boil approaches, the kettle must be watched closely. I always partially uncover the kettle at that point, both to avoid boilovers and control the mechanical action of the boil. If it becomes too vigorous, it will splash over the sides.

> As I boiled out on the porch and set up to chill in the  
> kitchen, I had to carry the full, hot kettle with copper  
> tubing protruding. This was much more challenging than  
> expected.

Dangerous, too. Remember, you're carrying a considerable quantity of boiling-hot, sugar-laden liquid, in a kettle whose handles are none-too-strongly attached. I suspect they're there for handling the kettle when it's empty, not when it's full. I had one handle come off of my kettle, at the best possible time: I was mashing in it, and as I began to lift it from the insulated box there was a sudden \*tink!\* ... Total fall was a couple of inches, and while the mash sloshed around a bit, none spilled. But it got me to thinking ...

> ... Do most people avoid carrying the hot wort by  
> chilling in place (using a garden hose)?

That's exactly what I do. I brew in the kitchen (to my wife's increasing annoyance), and have a quick-disconnect fitting on the faucet. I attach a short (10') hose to that, then to the inflow-side of the immersion chiller. The outflow I direct into the carboy I'm going to use as a primary, to which I've added some <insert favorite sanitizer>. After collecting that 6.5 gallons, I rearrange the hoses to use a small Teel pump to recirculate icewater, to do the rest of the chilling.

> ... During chilling  
> the kettle cover does not completely seal due to the  
> copper tubing; should I have used plastic wrap to keep out  
> the nasties?

This has bothered me since my first batch using an immersion chiller, but I've never done anything more constructive than fit the lid on the best way I could, nor have I seen evidence of infection because of it.

From: gjfix@utam.uta.edu (George J Fix)  
Subject: Units

I made an assumption in my chlorine calculations I forgot to mention. In particular, I assumed that a liter of solution weighed approximately one kilogram. This is not exact, but for chlorine solutions I believe it is reasonable. I was forced into this assumption because the Siebel data was presented in mg/l (units I prefer), while the best I could get from my bleach friends was liters per million liters. A sentence that was inadvertently left out of my post was " Lets assume that the 52500 ppm figure can be taken as 52500 mg/l". Sorry for the omission, and the confusion it caused.

I used 1 oz. per gallon bleach rate simply as a numerical example. This is what I have been using (on tubing), but I am very interest in the success John has been getting with half that rate. This is something I am going to check out in terms of my system.

George Fix

P.S. Takes to Anthony Johnson and Greg Troxel for asking about the units I was using.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: data point on molasses

Al's comments on molasses being better for dark beer are worth noting. I recently put 8 fl. oz. in a ginger beer with 6 lbs. Telford's Extra Pale extract syrup. It's too much! Hopefully more bottle conditioning will improve things. However, thinking back a number of HBD issues to the suggestion someone made that brown sugars and molasses have desirable aromatics that might be lost during a full boil, I put the molasses in for only the last 15 minutes. A couple of years ago I made another ginger beer with 8 fl. oz. molasses and only 4 lbs. of an amber extract. The molasses was virtually undetectable even by experienced palates. So I guess my limited experience suggests that when using molasses, if you want the aromatics, use VERY LITTLE during the last part of the boil; if you want a certain je-ne-say-kwa, dump it in for an hour and you can use more. And Al's probably right about sticking to darker beers anyway.

On the aromatic side, though, I used some "demarara" sugar - 1 lb. with 6 lbs. of a light extract - in a British ale last year which was really wonderful. I would not hesitate to accent the qualities imparted by that sugar by moving its addition closer to the end of the boil next time!

Subject: The Great Grain Mill Saga

I recently bought a JS MaltMill(r), the adjustable model, and have got a few things to say about using it for two batches. The first thing I notice is that the quality of the crush you will get is very sensitive to roller spacing.

When I got it from a local homebrew shop, the rollers weren't adjusted well at all, and the crush was MUCH too fine. Didn't look any better than a Corona, what with all that dust and small pieces of husk. Turns out the rollers were way too close together. I adjusted it to the recommended .060" spacing by using automotive feeler gauges. Which brings up a good point: you will not get repeatable results unless you use a metal gague for setting the gap. More on this later. Ayway, I was crushing DeWolf Two-Row, which of course came from a particular bag, and a particular lot-number. The .060" spacing was too loose -- many grains were just cracked in half, but not really crushed. I adjusted the mill, again with feeler gauges, to .057". This provided satisfactory results for the two-row, but was too loose for the CaraPils. I adjusted again to .055", and this provided great results for CaraPils as well as the two-row. But I think it'll be too loose for wheat malt, which I haven't tried yet. Just for fun, I tried .050, and .045 gaps, and the quality of the crush falls off (by visual inspection, no screens) pretty rapidly. Also gets real hard to turn the crank at these close gaps.

One big advantage I see to a mill like the MaltMill is that it trivial to reproduce roller spacings. You just turn the thing over, and stick in your feeler gauges. When I set the gaps, I placed the gauges in the center of the rollers, and turned the adjustemnt until there was just enough friction to hold the gauges in place. Then I tightened the set-screw, and checked to be sure the rollers hadn't gotten any tighter or looser. This takes about 30 seconds.

I tried using a drill to turn the MaltMill too. This absolves JSP of all liability associated with the machine, but I did it anyway. The drill is a very heavy-duty 1/2" drill, with 0 - 500 RPM speed. I figure I was running it at maybe 100 RPMs. The big thing is I think you get a better crush with a motor because the rollers are turning so smoothly. It IS easier to do, but I think the reason to do it is to get a better crush. I was told that Jack used to produce a motorized version.

Things that could stand improvement?? I think the hopper is WAY too small. But it'll be easy to make a bigger one from some scrap lumber. I was disappointed to find no bronze bushing in the eccentric "knob" that provides the adjustemnt. And the adjuster moves too easily when tightening the set-screw -- you have to be more careful than you might want to be. Some kind of metal clips that could fasten the mill to the top of the bucket would be good too.

My plans are to mount the MaltMill on a different base, add a permanent motor of some kind, build a bigger hopper, and come up with some kind of wire clip, like you may have seen on some shipping crates, to fasten the base to the pail. And then brew

LOTS of great beer. If the eccentric knob wears out, I trust that Jack will replace it. But I'd still like to see a bushing in it.

So, it seems there are now three price-points in the small-mill market now: \$40 gets you a Corona, \$80 get you a PhilMill, and \$120 gets you an adjustable MaltMill. Bottom line on the MaltMill?? From my point of view, I'd say if you don't mind the price, its a good machine, certainly better than a Corona Mill. There is even a certain retro-grouch homebrew supplier here in town who is impressed with the results I've gotten with the adjustable MaltMill. And you won't find a genuine roller mill anywhere near its price. ("Genuine" means "two rollers" IMHO) You can make great, award-winning beer with Corona-Crushed grain: I've seen it done. But its less ideal, for sure. The other homebrew supplier here in town has a PhilMill on order. I expect I'll go out and evaluate it, but I don't need two mills. And I'll bet I already have the Porsche.

Cheers,

t

From: Bill Flowers <waflovers@qnx.com>  
Subject: John Bull barley wine kit - what to do with it?

I was just given a John Bull "Barley Wine" kit as a gift. I don't want to look a gift horse in the mouth, but the problem I see is that this won't make anything like a real barley wine. The kit is a 1.8Kg can of hopped malt extract. The instructions call for combining this with 1Kg of "sugar" (of course, I'd use DME) to make up 14L of wort.

By my calculations this would have an OG of 1.057+/-, unless the syrup in the can is almost a solid (a can of DME maybe? NOT!).

While this might be a wonderful ale, it isn't even in the ballpark for a barley wine. Does anyone have any experience with this kit?

What I'm thinking of doing is cutting down on the water (I have a 11.5L carboy I could do it in) and increasing the fermentables to at least get it up to 1.085 (still low for a barley wine from what I understand, but it would be better), and some extra hops. Perhaps 1Kg of DME, 500g raw (whole) sugar and 20g Goldings. Do the initial fermentation with a good ale yeast and continue the fermentation with a (well started) champagne yeast.

Comments?

>+ Boiling Kettle - what are the disadvantages of cutting up an old keg?  
> Is a false bottom necessary? For a 15 gallon capacity (10 gallon  
> beer batch) what should I look for in material thickness and other  
> features.

Sanke keg works great. I find it hard to believe that false bottoms work well with bottom heat systems (e.g. propane burners) so I made a copper ring out of some 1/2"od tubing, ran it out the side of the keg through a compression fitting silver soldered as a bulkhead fitting. I did this twice: one with a large ring around the inner circumference of the keg, for the kettle: the slotted ring filters out whole leaf hops fine and for pellets, swirling leaves all the trub and pellet crud in a pile in the dome of the keg. I get all but about a quart of liquid out. The second one is an 8" ring centered in the keg and resting on the bottom. I use that for mashing and lautering. Again the slotted ring filters just dandy and I get excellent extract (100% of expected yeild on my second try). The kegs cost me \$10/ea at a recycling yard and I cut 10" holes in the top with a jig saw and a bi-metal blade (make sure you get bi-metal or you will be frustrated!).

>  
>+ Propane burner - Is 35K BTU's big enough? How long to heat 12 gallons  
> of wort?

In spite of what you hear people say, 35kbtu is more than enough. Bigger burners are just blowing heat around the side of your keg and wasting propane. A better solution is to make a heat shield that fits over your keg. I made mine out of some 24" flashing. The shield is about 4" bigger in diameter than the keg and the top is folded over to seal. With that in place it takes very little flame to keep 14gal at a roiling boil.

>  
>+ Wort Chillers - Right now I'm using a homemade immersion type. What  
> are the advantages of the other style?

From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: Acetaminophen and Hangovers

Derrick Pohl suggests taking a tab of Acetaminophen (the active ingred in Tylenol and several other similar products) as a pre-treatment for potential headaches.

This is probably not wise. One of the side-effects of acetaminophen is a certain degree of liver toxicity. This toxic effect is especially emphasized when taken in conjunction with alcohol. The studies I saw (several years back, sorry can't give the reference) suggested that in extreme cases (ie: heavy drinkers) the toxicity was sufficiently severe to produce more rapid liver failure than would otherwise be expected.

I personally have no problem with acetaminophen in general, but I don't think taking it for drink-related troubles is really advisable. P.

Date: Thu, 17 Jun 1993 18:27 EDT  
From: Phil Hultin <HULTINP@QUCDN.QUEENSU.CA>  
Subject: Bleach and Free Chlorine

George Fix discusses the amount of free chlorine produced in solutions of standard bleach. However, his assumption that the percent by weight of "Cl" in NaOCl can be used to give the amount of dissolved Cl<sub>2</sub> (no subs or supers on my machine either) is false.

The release of elemental chlorine from sodium hypochlorite is described by the equation:

Where I use <-> to represent the back-and-forth arrows symbolizing and equilibrium process.

Now, this equilibrium lies far to the right, which is to say, that comparatively little NaOCl reverts to free Cl<sub>2</sub> and NaOH in solution. Unfortunately, I don't have the equilibrium constant available at the moment, but consultation of "The Merck Index" 10th ed. entry #8463 reveals the statement:

"The hypochlorite ion in solution is remarkably stable."

Which is essentially saying the same thing I put in the preceding paragraph.

So, when George estimates the amount of Cl<sub>2</sub> in solution in his posting, he is grossly overestimating. The calculation of the true Cl<sub>2</sub> content is simple, if one has in hand the relevant equilibrium constant. The disinfectant action of bleach is largely due to the power of OCl<sup>-</sup> ion as a disinfectant, while the "chlorine" smell of bleach is a consequence of the extreme sensitivity of the human nose to Cl<sub>2</sub>: threshold for detection is 0.2-0.4 ppm.

P.

> bleach concentration been plummeting? Who really knows, like  
(stuff deleted)  
> But more importantly, should we be using two different bleach  
> concentrations for our needles and our Kegs? Are homebrewers out  
(stuff deleted)

I would guess that something you are going to stick directly into your vein, you would want to be PDS (pretty damn sterile). On the other hand, brewing equipment probably need not be quite as sterile, since it will soon contain an alcoholic, low pH substance overwhelmed by yeast. Controlling gross infections is probably good enough. In "Disinfection, Sterilization, Preservation" (SS Block), a concentration of 50-200 ppm available Chlorine is mentioned for sanitizing food contact surfaces. This works out to 20-80 ml Chlorox per 20 liters water (4-16 tsp per 5 gal). I'm not sure what the appropriate contact time would be.

> Think about it, but right now I gotta run out to the kitchen  
> to make sure my refrigerator light is still on.

More importantly, does your airlock really bubble when you're not watching it?

From: WESTEMEIER@delphi.com  
Subject: Mill results

Due to the interest in the introduction of the Philmill, I thought it would be useful to provide a bit of extra data.

First, a disclaimer: I belong to the Bloatarian Brewing League, and Dan Listermann, creator of the Philmill, is a fellow member.

Our club did a comparison, using standard sieves, of the crush produced by the Corona (properly adjusted), a MALTMILL (tm) (non-adjustable model), and a Philmill prototype (properly adjusted). The results differed rather substantially from the MM sieve results posted here in May by George Fix, but they tended to point to the PM as being somewhat superior. I am personally a satisfied owner of the MM, and I use it often. I have also been very impressed by the results I've seen throughout prototype testing of the PM. I believe they are both first-class, state-of-the-art examples of homebrew equipment. I've tasted beers made with both, and I've very carefully examined the crush provided with both. I honestly believe that anyone would be happy with the purchase of either one.

However, for those who require more hard data, Dan Listermann has told me that he will be bringing his set of standard analytical sieves to Portland with him, and will offer to conduct a "crush-off" with all comers. Seeing the results first-hand should persuade any skeptics.

Date: Thu, 17 Jun 93 21:48:32 PDT  
From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Oil ppm vs. IBUs

Russ Gelinas asked (me specifically) if the ppm of hop oil had anything to do with IBUs.

No. IBUs are \*roughly\* equivalent to the milligrams/liter of isomerized alpha acids in beer. The alpha acids are responsible for the bitterness in the beer. The oils from the hops are responsible for the hop character and aroma in the beer. Hop character is imparted by late additions of hops in the kettle and/or by steeping hops while the wort cools. Some hop aroam is also imparted by this, but it is a totally different aroma than you get with dry hopping. The aroma imparted by dry hopping resembles the aroma of the fresh hops. But no bitterness is imparted by the hop oils, whether added directly as an oil, or by adding hops late in the boil or by dry hopping.

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Racking off trub, etc.

As promised earlier during the "should we rack off of the trub" thread, here are results based on two batches I have made, a Steam (tm) and a Stout:

Steam (racked off of trub) was pretty good, very bitter and highly hopped. The beer tht was left over the trub for the primary ferment seemed to have some phenolic overtones, but was still pretty good. In all other respects, the beers were treated identically. Also, the beer left over the trub didn't seem as clear as the racked beer. No clarifying agents were used. (I usually use polyclar (tm?).)

The stout (a new recipe I invented which has black walnuts in it :) ) was not significantly different between the two batches. Both are opaque deep brown, almost black. No noticeable difference in taste profiles, but the unracked batch has a much more noticeable walnut aroma, probably from sitting in the primary with them for so long.

The bottom line is that I will probably continue to rack my beers away from the trub, esp. for those with a lighter flavor profile. The heavy ones I probably won't fret over.

-----  
About filtrations (esp. air filtration)

Has anyone out there in brewdom tried using Acrodiscs (tm)? These are disposable membrane catrtridges in a variety of porosities and sizes that are available through science supply houses (VWR, etc.) They are made to fit onto a syringe tip, but could probably be put inline with an air hose. Would not be suitable for liquid filtration, because they are only meant to filter small (several mL) volumes.

-----  
About flames and commercialism

Let's be polite here in our criticisms, and lets leave the advertising to the pages of Zymurgy, etc. If you find something so nifty-difty that you've gotta tell or you'll burst, why not just describe it in generic terms, no specific copyrighted names, prices, ordering information, etc. and just field the private e-mail. If I wanted commercials, I would watch TV :( !!!!!

Sensibly yours,

From: jpgareri@acs.bu.edu (Joseph Gareri)  
Subject: Dogbolter Revisited

In Tuesday's HBD (1162), I wrote in with questions about what to do with a Dogbolter kit. The response was, to say the least, overwhelming. I received 14 responses at last count. Some folks have asked for a summary, so I thought it would be in the interest of many to post it here.

The comments were all favorable about Dogbolter being a beer worth making. Everyone who commented on the product said that it was quite close to the commercial product and very high in alcohol content (estimates of >8%.)

Many suggestions were received about the supplied yeast. A few folks said they have used the yeast and have had very favorable results. The favorite substitute was London Ale yeast (Wyeast 1028) with Whitbread a favorite for dried yeast.

Virtually no one suggested keeping with the recommended 2 1/2 lbs. white sugar. Although it was pointed out that some sugar is very common in English bitters. Suggestions ranged from 2 to 4 lbs. of either light or amber unhopped dry malt extract. The kit makes 3 gallons, but nearly everyone suggested making it into a five gallon recipe by adding additional malt or even an additional kit! Yikes!

Additional hops were suggested to maintain the balance. Kent Goldings were the odds on favorite with Fuggles a close second. The recommendations were for 1/2 oz. (3-4%) per ounce of additional malt for the boil (60 minute boil was the most popular), and 1/2 oz. for the finish.

Allen Wright suggested 2 tsp. Irish Moss thrown in during the last 15 minutes to help settle out the cold break.

Conditioning was recommended according to normal procedures.

I think that's about it. I hope I didn't miss too much of the valuable info.

Thanks to all the respondents. I have saved all the text into a file that I'll keep for a couple of weeks. If anyone would like to see the unedited text, I'll happily mail it off to you.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: Aluminum cans

A brief article in the paper yesterday (Thurs, San Fran. Chronicle) mentioned a study done by a company in Austrailia. They found that the levels of aluminum from non-cola sodas in cans was six times higher than the levels found in those sodas from bottles. For cola sodas, the levels of Al were three times higher in the drinks from cans.

The sample size was something like 56 sodas, no absolute levels of Al were given although it said that the levels found were below acceptable health standards, and no other drinks were mentioned.

Is the "fear" of aluminum due to the possible relation with Alzheimers? Is this also the reason that all homebrewers recommend stainless steel pots and kegs rather than aluminum, or is there some heat distribution advantage to SS? Or non-corrosive advantage?

< a very good article on Miller's Amber Ale deleted to save space...>

Now, after talking about local pride in our microbrewers, this is really something to behold. Think about these things. Remember when we couldn't get Munich Lowenbrau anymore, because Miller started producing it under license? (Poetic license, maybe, 'cause it ain't Lowenbrau, and I have some more of the Munich product at home to prove it!). Then there was Coors and its "Killian's Irish Red", licensed from a brewer that hadn't brewed in nearly three decades. Now, Miller's at it again, attempting to brew a "micro-killer". To give it due credit, it isn't bad, \*as long as it is kept fairly cold\* (cold ale?), but it does raise some questions.

This is a very curious product: a top-fermented ("special" yeast, har har) ale that tastes worse as it approaches what a lot of us, as somewhat educated brewers and beer-drinkers, regard as proper ale temperature. Is this a point of pride? I realise that many Americans have a predilection for ice-cold beverages, but if a product is pitched to an "upscale" market-segment, why not go for the authenticity?

The "Amber Ale" marketing pamphlet is so full of outright lies and falsehoods, it puts a certain Boston (tm) Beer (tm) brewer to shame. "Warm beer of England" is a misnomer. It isn't warm, it's at cellar temperature - I don't think of 55 to 60 degrees F as warm! So much for Miller's "master-brewers" (aka "marketing men" who have little or nothing to do with actual brewing).

>"Ales are also the original beer of Europe."

Hee hee hee. So when is Miller going to make gueuze-lambic, using locally-occurring wild yeasts? I can't wait to see their mass-market version of Ninkasi. :-)

As long as we have the likes of Miller continuing to "educate" the public, we Americans will have a long ways to go before we can be justified in proclaiming our respective regions to be "Beer Capitol of the Universe". Homebrewers excepted, of course, since our brew-cellars are, in fact, the center of the universe. :-)

From: johng@adx.la.ca.us (John E. Greene)  
Subject: Miller ale.

It's a bit amusing to read about what miller has written about the differences between ale and lager. I was talking with the owner of a brewpub here in Manhattan beach and he said that when he took a tour of the Miller Brewery he noticed that their fermenting tanks for the lager were at 65 degrees. He tried to ask about this but they would not give him an answer. I think that in Miller's case the only true difference between an ale and a lager is if the yeast ferments at the top or the bottom.

Subject: mashing and other mysteries of homebrewing

Hi all

I have a question that's been nagging at me a while. Since I brew only using syrup extract, the job of mashing escapes me. I thought about mashing once, even tried it. My problem; how in the hell do you keep mash at a constant temp? This technique evades me. I tried my best to play spin the dial on my electric stove to "maintain the mash at 142 F for 7 minutes and raise to 151 F for 3 minutes" etc. etc. This was quite impossible I found, but I did the best I could. The resulting beer turned out ok, but I chalk it up to a stroke of luck rather than skill.

Would anyone out there like to enlighten me? Are these tuns I see for sale really worth it?

Oh yeah, thanks to everyone's help and consolation about my American Ale yeast problem. Things \*seem\* to be going nicely, but I won't really know until that first taste :)

cheers  
scott

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: hop extraction

It is written that a high gravity boil will provide less hop bitterness in the finished beer than a low gravity boil. All the equations don't take this into account until you get up to 1.050 or so, presumably the loss of bitterness at lower gravity is not significant.

So what happens if you boil the hops in plain water? Do malt sugars or proteins or such provide something necessary for bitterness extraction (iso-alpha acid conversion)? For extract folks or folks with small pots (on a stovetop), it would be easier to boil the correct amount of hops in some water and just strain them into the cooled wort. It would even help some grain brewers who have problems siphoning off the hops (especially with pellets) into the primary.

Of course, it can't be this easy. I was just wondering why not!

>  
You are fortunate enough to live somewhere where WYeast is testmarketing this strain. It is not related to the 3056, but is a true weizenbier strain from Weinhenstephan. I have brewed with it once (got the yeast directly from Dave), and it is a truly exceptional weizen strain. If responses are good in the testing areas, I believe WYeast will add it to their regular list.

I have had uniformly good responses on the beer; one knowledgeable importer (and several of his staff, who have reason to know), said it was the spitting image of Schneiderweisse. I say this not to puff myself up, but to assure you that you have your hands on the real thing.

Subject: Business opportunity, Devils

>From: "JSDAWS1@PROFSSR" <JSDAWS1@PB1.PacBell.COM>

>Recently, a freind & neighbor bought a JS Maltmill <tm>. It's a  
WONDERFUL  
device and I definitely intend purchasing one.... but ONLY after I  
figure out  
how to motorize it. Any ideas? I'm the kinda guy who grabs the  
correct end  
of a screwdriver about 50% of the time so it's got to be an easy,  
off-the-shelf kind of solution.

I have responded in private but I see here a business opportunity for  
some  
budding entrepreneur out there.

For reasons of my I own, I have decided that I do not want to sell  
motorized  
mills. However, there is a substantial market out there for serious  
homebrewers and small breweries that would rather make beer than  
motorize  
mills. At the present time (see comments below), there is no viable  
alternative to the MM for the low budget operation and someone who  
wanted to  
repackage them could start a nice cottage industry.

>From: Nick Zentena <zen%hophead@canrem.com>

> If you've never seen it [Philmil] then your post sure sounds  
like FUD! Why don't you ask someone who has seen  
both mills to compare? Na that would have cut down  
on your chance to advertise.-()

I don't think that was called for. My post was based on published data.

However, I now own a Philmil and can speak from personal experience but  
I  
think it would be more prudent to let the market speak for itself while  
keeping in mind that one must drive a VW to appreciate a Porsche.

As Perot likes to say, the Devil's in the details, and there is one  
"detail"  
that I will point out in light of the above discussion on motorizing  
mills.  
The PM has NO BEARINGS. The steel roller turns in a 1.5" hole drilled  
in the  
steel support housing. The manufacturer's suggestions on how to  
motorize it  
must be taken with a large grain of salt.

BTW, what's a FUD?

>From: "Bob Jones" <bjones@novax.llnl.gov>

has

seen no problems with head retention using the supposed .5um filter and I have seen poor clarity with it as well when pushing some beers through it.

> Fix has recommended against this small (.5um) filtration.....

I wonder if we havn't got an apples and oranges problem here. I never asked

George what type of filter he was using. He gave me the manufactuere and part number but not the type but I bought something else.

As there are many differnt types of filters, pleated, string wound, ceramic, flat, plate, just to name a few, it seems that we need to know which type we are talking about to get any sense out of this discussion.

I have little confidence in the numbers quoted for string wound filters and have no experience with any other.

Subject: re: Headaches

There was a post-thread some time ago about headaches. There are some substances, not higher alcohols / fusel oils, that some people are allergic to and causes headaches. Cheap red wine frequently has a lot of this. Heck if I can remember the name. If anybody has the last year's HBD in grep-able form, look back there.

Anyway... I wonder if the headaches correlate to the brewers who do fast high gravity brews (the so-called "beer concentrate") and then dilute it for retail distribution. This could have all sorts of strange things going on in the fermenter...

Paul.

Subject: re: 5 liter kegs

I recently purchased the 5 liter mini-kegging system advertised by Brew Ha Ha in Pennsylvania. I received the kegs in a box that looked kinda like it was made for them. The kegs are essentially metal cans made to look like little barrels. The order taker said the cans are plastic lined and the best way to clean them is with a bottle brush bent like a carboy brush. The cans are painted up with a logo, government warning, etc. They were used by a microbrewer called Happy Valley. The tap is a plastic snap on piece that has a knob to control the CO2, a screw on cap for the CO2 cartridge and a spout with dispenser knob. The keg has a 1" hole in the top and you put a rubber stopper containing a plastic plug into it. When installing the tap, you use the end of the tap to push the plug into the keg. It just falls into the beer. You fish out the plastic plug when the keg is empty.

I just used the kegs for the first time early this week. I only used 2 of the kegs and bottled the rest because I wanted to test how they worked and compare them to the same beer in bottles. Also, I have another batch in secondary that I will do the same thing with.

They are used much like a large keg. Use half as much priming sugar as usual, fill and plug the kegs. Set them aside for conditioning for 2-3 weeks. They are conveniently sized to put in the fridge beside the milk weather they are tapped or not. They are about 13" high with the tap attached. This was a little too tall for my fridge. I had to remove a shelf.

I tried "Force carbonating" one of mine. I attached a cartridge, turned the pressure all the way up and then shook the keg every few minutes for about an hour. I then put it in the fridge with the pressure on. The next morning, the beer was carbonated and the cartridge was empty. I attached another one and was able to dispense carbonated beer immediately. The cartridges are 8g seltzer cartridges. The warn against using CO2 cartridges for guns because they contain oil. It comes with 10 8g cartridges and extra packages of 10 are \$4.95. They will also accomodate a larger 16g cartridge but I don't know where to get those.

I am quite happy with the system even though I haven't used it much yet. If anyone wants more info, just e-mail me.

From: dspalme@mke.ab.com (Diane Palme x2617)  
Subject: Hop Report and Apple Weiss

Howdy Y'all!

Well, as the month of June speeds by (and my e-mail box fills with requests), I thought I would throw a quick hop update onto the HBD. Bear with me, I only get to visit the plants about once a week.

If you will recall, I planted three varieties of rhizomes, Hallertau, Tettenanger, and Cascade. I am \*thoroughly\* amazed at the speed and vitality of the Hallertau plant. I am anxiously awaiting the frantic phone call from my parents saying that they are being held hostage by this vine. It is truly growing in leaps and bounds! The Cascade is running a close second and is just about ready to train to a horizontal wire. These plants are quite stupid, however, in that they refuse to wrap themselves around a horizontal wire. They seem to be much happier running up the poles sunk next to the root. Hmmm. Maybe they just need a good talking to! As for the Tett, well, I guess the operative word here is "runt." It is not more than 4" high and moving \*very\* slowly. It receives the same care and fertilizing as the other two, but it just seems like it doesn't want to come out and play with the other kids. Any suggestions? As for the weather up here, it has been remarkably cool and quite wet the past few weeks. The temperature has finally started to move toward the 80 degree mark (on a relatively consistent basis), so maybe that has something to do with it. Nevertheless, I look forward to some kind of harvest in a few months. As a quick side note (directed to those of you who have been growing/harvesting/brewing with hops for the past few seasons), how does one calculate the alpha acid content in these hops? Is trial-and-error (read: Newton-Raphson method of interpolation) the only way to go? Any advice will be appreciated.

[switching gears]

I was fortunate enough this past weekend to attend the Beer Festival in lovely Kenosha, Wisconsin, and sampled a beer from the Cherryland Brewery in Sturgeon Bay, WI. It was an Apple Ale and was absolutely superb! Being the cider fan that I am, I was wondering if any of you brewers out there could

give me some net.wisdom on how to brew a good apple beer. I am considering using a standard weiss base and adding copious amounts of apples to the ferment. Standard practice seems to recommend something on the order of 4# of apples (Macintosh, Granny Smith, Washington), I prefer Courtland, to the wort after the boil is complete, allow to steep ~15 minutes, dump the mess into a plastic fermenter (or carboy if one can get the apple pieces through the opening) and then rack off of the fruit once the primary ferment is complete. Does this sound plausible? Any better recommendations for a base? Once again, any info/suggestions will be appreciated and a summary will be posted if there is interest.

Well, this concludes the monthly Hop Report and CFD on Apple beers. I apologize for the length of the posting, maybe I should do this more often!  
:-)

Thanks in advance ...

From: gjfix@utam.uta.edu (George J Fix)  
Subject: References on sanitation

The diversity of opinion regarding appropriate strengths to use for sanitizing solutions is reflected in the diversity of results found in the professional literature on this subject. For example, data that was produced for the general food industry (copies of which can be obtained from bleach producers) show that highly dilute sodium hypochlorite solutions can be very effective with selected bacteria. To cite an example, one study showed that a solution with a 5 mg/l OCl concentration yielded a total kill (sorry for the barbaric language!) of E. Coli with contact times ranging from 5 to 10 mins. With the bleach I use, a OCl fraction of 5 mg/l is achieved by diluting ~1 tsp. of bleach in 5gals., i.e., ~1/30 oz. per gal.

Different studies using different microbes found an altogether different situation. Permit me to cite the following, which appeared in a professionally peer reviewed journal devoted to brewing:

J. Sorenson, et al, "Pediococcus: Some Biocide Studies", Brewers Digest, January 1983.

This study looked at the effect of various halogens (chlorine, iodine, etc.) had on selected strains of pediococcus. The following is but one of their findings for P. pentosaceus, a highly feared brewery contaminant. They propagated this microbe, and then added sodium hypochlorite at various levels of OCl. Their criteria was very simple. They just observed if the microbes continued to grow (noted with a + in the below), or stop growing (noted with a -).

Exposure Time (mins.)

| OCl (mg/l) | .5 | 1. | 5. |
|------------|----|----|----|
| 75+        | +  | +  |    |
| 100+       | +  | -  |    |
| 150-       | -  | -  |    |

The condition of no growth is a minimal one, what we want is a complete kill. Nevertheless, I find the results interesting. It should also be pointed out that various strains of lactos and pedios vary greatly in their resistance to sanitizers. They also vary greatly in their effect on beer flavors. The very special lacto strain used by Celis yields a gentle and mellow sour, while P. pentosaceus produces, among other things, an extremely unpleasant acid flavor.

With all this diversity is it no wonder people disagree. BTW Brewing Techniques will carry two articles on sanitation. Vol. 2 is by Dr. Maribeth

Raines, and is oriented to beginning and intermediate homebrewers. Roger Bergin's article will appear in a later issue, and is oriented to advanced homebrewers as well as microbrewers. It should also be noted that all full length articles in BT are confidentially reviewed by professionals in brewing.

In a post that will come out, or already has come out, Phil Hultin argues that my chlorine calculations had a serious error. From the point of view of equilibrium chemistry he is absolutely right. In fact, this argument has been made to me a number of times in the past by professional chemists. The reason I do not accept it is that it is missing the biological connection. What is being asserted by me is not that OCl ions are completely disassociating, but rather as the calculated OCl fraction of the solution increases, so does the sanitizing power. Similar calculations were used in the reference cited above. Remarkably, while there is general agreement about the effect of chlorine being the oxidation of microbe cell walls, the actual mechanisms are still unclear. The observation that equivalent OCl fractions track strength is completely empirical. Thanks to Phil for interesting e-mail.

I find myself in the awkward position of having an embarrassing number of projects with late Aug. and early Sept. due dates that need an embarrassing amount of work if they are going to be successful. Thus I need to hide for a couple of months, and work my @\$% off. I hope everyone (especially Don O'Connor) has an eventful, fun, and rewarding summer. See you folks in Sept.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Those Pesky Siphons

In regard to the discussion (more or less perpetual) about starting siphons, I have a STRONG recommendation. Although I was initially skeptical about the need for such a device (having always used a turkey baster), I had a succession of problems starting siphons and broke down and bought a Sucker (TM). Jeeze, I think I've got the nae right. At any rate, the device is based on a large syringe, with a y-connector and check valves that ensure the siphon flow continues in the proper direction. It is not only useful -- unbelievably so -- for starting siphons, but can also be used for pulling samples from carboys, transferring the sample directly into a graduated cylinder, for example, for taking hydrometer readings. Because it's entirely made of plastic, it's easy to sanitize (I use iodophor).

Best of all, you can get it by asking right here on the net: it's made by the never-advertising-in-the-Digest Russ Wigglesworth. Send your inquiries to: rad\_equipment@rad-ma1.ucsf.EDU

This is an unsolicited endorsement. Really. I can hear Russ blushing all the way up here in Portland.

Date: Mon, 21 Jun 93 16:41 GMT  
From: Phillip Seitz <0004531571@mcimail.com>  
Subject: Mashing raw wheat for Belgian white beers

Some time back I posted a preliminary recipe for a Belgian white beer that I had brewed with some success. A number of other people went on to brew the same thing, and reported good results. That recipe called for 60% barley malt, 30% wheat malt, and 10% raw wheat in the mash, using a single protein rest prior to sacchrification. This works smoothly and the wheat requires no special preparation.

I can now report that I have successfully completed a mash of 50% Belgian pils malt and 50% raw hard red winter wheat (aka wheat berries). All grains were ground on a Corona mill, with no additional preparation. The mash schedule was as follows:

Mash type:Upward step mash

Water/grist ratio: 2 quarts/lb

Dough in: 95F for 10 minutes

Protein rests: 117F for 20 minutes  
122F for 20 minutes  
126F for 20 minutes

Sacchrification:150F for 10 minutes  
158F until complete

Technique:

1) All the water is added at dough-in. I should admit that my strike temperature was much too hot (115F), and that I overshot by about 8 degrees F. I therefore suggest using water that is 97-100F, which you can probably get straight from your tap. I used the dough-in period to adjust the pH, which required 3.5 teaspoons of gypsum. Usually I don't need any, but this is also the first time I've used a complete step mash instead of infusion, and I usually use less water per pound of grist.

2) Apply heat to raise temperature to first protein rest and let sit for 20 minutes.

3) Repeat for second and third protein rests.

4) Sacchrification temperatures were my choice--use what you want.

Astute readers will notice that this is exactly the mash schedule proposed by Eric Warner in his wheat beer book, but without the decoctions.

The most interesting thing about doing this was that I could actually feel the grist becoming less gummy with each rest. What started as a rather sticky, bottom-clinging mass that looked like wallpaper paste became a light, fluffy, easy-to-stir and clear mash of the usual type. I lautered with 175F water until the wort running out had dropped to 1.008, and collected 6.75 gallons @ 1.038, or about 27 points per pound overall from 10 lbs of grist. Lautering proceded with no problems at all, and may have produced a clearer-running wort than usual. There was plenty of

hot and cold break material in the kettle but I wouldn't say the quantities were unusually large.

Some warnings and comments:

1) Grinding 5 lbs of raw wheat on a Corona is the most effort-intensive thing I've done as a homebrewer. Like grinding putty. Think twice before planning a 10-gallon batch.

2) You will do a lot of stirring with this mash due to all the temperature steps. My brew day took an hour longer than usual, and lasted from 10 a.m. to 5 p.m. Effort-wise I'd say this is about equivalent to a single decoction mash.

3) While I'm not sure what an optimal crush for raw wheat might be, I was uncomfortable with the amount of flour produced when I set the Corona to grind chunks roughly similar to those from barley malt. I therefore used a grind that what I would consider somewhat coarser than optimal. Having seen what the protein rests can do, I'd grind finer next time, as the flour seems to take care of itself.

This batch included some variations in spicing from my previous effort, and most notably the use of some hand-imported curacao orange peel. Subsequent postings will deal with this, as it's too early to say what the results will be.

Thanks for assistance with this project go to Jim Busch, still the Sultan of Wheat Beers.

- > extraction of 40 pts/lb/gal!

Funny you should mention that. I tried his "Isar Hefe Weizen" last night. After coming up with a gravity closer to 1.045 than his 1.055, I did the same calculation, and got an overall expected extraction of 36.5 for his gravity. I actually got about 30. Maybe I should have sparged for 2 hours insted of 1!-) Ah well, next time.... (If I will ever spend the time required for that complex multi-step decoction recipe again!)

Subject: Light (Lovibond) Extract

Message Creation Date was at 21-JUN-1993 10:27:00

Greetings,  
I have a question for those of you out there who do not consider Malt Extract to be too trivial for comment.

I wish to make a beer with the lightest possible color as is possible with extract. The style is somewhat uncertain at this point in time. I may use it as a base for fruit beers, or it may evolve into a "lawnmower" beer, but mainly it's just an experiment to see how light in color it is possible to get while using malt extracts. (Someday, if I get the time and brewing partners, I'll do it right & get my light color by going all-grain.) I would like to use only barley & wheat for my fermentable sugars - no sugar, rice, or similar adjuncts.  
What suggestions can you give me for both liquid extract (preferably unhopped) and DME?

TIA  
Andy A

"Date: Mon, 14 Jun 93 20:12:44 PDT  
From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Oils

New Product Announcement

"In my article in the Summer '93 Zymurgy (Boost Hop Bouquet with Dry Hopping)  
I talked about CO2 extracted hop oils. As the article stated, measuring the  
very tiny amounts of hop oil needed takes lab equipment and lab skills, beyond those of most homebrewers (but probably not beyond quite a few Digest readers). Anyway, the article states that I was working on a solution  
to the problem. It was supposed to have a P.O. Box where you could write  
me to keep informed of any progress. Unfortunately, they edited that part out.

"To make a long story short, HopTech now has available CO2 extracted hop oils  
that have been formulated in a stable, water-based suspension that are easy to  
add to homebrew sized batches. It is calibrated that 1 tsp of hop oil equals  
1 ppm of hop oil in 5 gallons. Average usage, depending on the style of beer  
and your taste, runs between 1 and 3 ppm. We sell it in 2 oz bottles, enough to add 2 ppm to 30 gallons of beer.

"We have three varieties available:"

Look, Mark. You work, if I recall correctly, out of Emeryville, on the fringes  
of UC Berkeley, where programmers and users are as thick as grass. Surely you  
have absorbed, by now, the understanding that advertising on the Usenet, and  
through electronic media in general, is in bad taste.

Like bombarding every FAX you can find with an advertisement, it is, while  
economically attractive and technologically feasible, a shallow use of a media  
reserved for more important things than your worship of the almighty dollar.

Please stop advertising on the Home Brew Digest. Everyone knows you're there,  
if anyone wants information they can mail you.

Please note that I am, in general, as supportive of personal businesses, as  
anyone is. I've done it myself. But you are abusing this forum.

Has it occurred to you that, perhaps, Zymurgy dislikes covert advertising  
?

Cyberspace is relatively free of throwaways ( barring bounced email ).  
Let's  
all keep it that way.

From: pascal@netcom.com (Richard Childers)  
Subject: filtering - mechanisms & tolerances

Jack Schmidling notes :

"Judging from my experience and that of a brewer who posted an article to rec.crafts.brewing, there seems to be a problem with the filters being sold to the homebrewing community."

This does not surprise me ... there is considerable latitude in circumstances where one cannot directly verify the statements of the salesperson.

Recently I became interested in this topic, as a consequence of being introduced to a hand-pumped camping water filter ( in close proximity to some naturally-heated sulphur springs, the location of which must remain secret ) and became intrigued by the design of the filter.

Suffice it to say that, between the combination of poor design ( the filter came apart easily during regular use and did not have support for anything such as hoseclamps by which to secure it ), and questionable water contents ( giardia was the primary concern, but obviously other microflora and fauna exist, as well as sulphur and traces of human urine, since there's always an 'upsteam' )-:, I became intrigued with how much easier it might be to build and maintain one myself.

I haven't done anything tangible yet, but, noting that others have the same interest for similar reasons ( I had not overlooked the relevance of these filters to brewing, yeasts being a microflora ), I thought I'd point out to those interested, that the Fisher Company sells about fifty pages of filters, a wide range of architectures ( paper, cone, replaceable disks, cast plastic housings, etc ), pore sizes and tolerances ( some are tolerant of organic solvents but a few are not ).

The non-sterile versions are somewhat less expensive ( gamma ray radiation is a nontrivial procedure to maintain and administer, I'd guess ).

I've called Jack's source in Chicago for a catalog, I'm interested in seeing what they offer - the prices are much better - but given the question of if a filter of a given pore diameter is what it claims it is, dealing with a scientifically professional firm may be advantageous.

Incidentally, I'm not sure what the pore size of gas filters is, but it's

probably pretty big - those are intended to filter out grit, not biological entities. Petroleum macromolecules might very well be similar in size to microorganisms ( although, clearly, I am not knowledgeable in this realm ).

"I also find that mine has a very large and persistent bubble that, unless purged with CO2, could cause aeration if not eliminated."

Many of the Fisher Company filters have anti-bubble mechanisms built in.

Cole-Parmer might also have some good filters ...

From: "Michael Barre" <MBARRE@NOMVS.LSUMC.EDU>  
Subject: New brewer

I recently read Tom Kaltenbach's brewing notes from May 25 and as a newer brewer I found some helpful info therein( esp. the jug-aeration). Thanks for the notes, Tom.

I have finished my first batch, an Amber kit using Cascade hops and Superbrau malt extract from a supply shop here in New Orleans, and I am displeased with the results. The beer is very sharp with a metallic aftertaste, almost like a canned beer that has been cold, warm, and cold again. The shopkeeper tasted the beer and he says using liquid yeast instead of the dried (EDME brand) yeast, and pitching the yeast into cooler wort will take the bite out. My wort was 90 degrees.

Has anyone experienced this problem, beer with too much bite? What do you think of the remedies?

The beer fermented in a new, bleach-sanitized 5 gallon bucket; I think using a carboy so I could get some blow-off might also help. I will not be able to get fermentation temperatures below 75 degrees, at least not until November.

Thanks in advance.

Subject: Miller PR

Howdy,

Just a comment on Dennis B. Lewis' comments about Miller's Amber Ale PR brochure. You have to wonder what the big brewer's know about beer that isn't yellow. Last Christmas, Coors' winter beer was labeled as a stout, which is very interesting for something that was about the same color as Bass Ale.

Well, at least it wasn't "clear".

Date: Mon, 21 Jun 93 14:48 CDT  
From: korz@iepubj.att.com  
Subject: Sucking on siphon hoses

Over the years, several brewers have suggested that sanitation at bottling time is not very important and that sucking on the siphon hose with your mouth is an acceptable way to start a siphon.

I would like to again insist that this is very bad advise! Sanitation is important throughtout the brewing process. It is true that fermented-out beer is less prone to noticable amounts of infection, that does not mean that maintaining good sanitation is overkill. It is not.

Before I make the next few statements, I want to preface them by saying that I don't mean to put anyone down or to imply that any of these statements are directed towards any of the brewers who have recently or not so recently posted contrary to my advise on the subject.

The reasons that some brewers get by with less-than-ideal sanitation techniques include:

1. the beer is consumed quickly and an infection does not have enough time to produce detectable levels of off-flavors/aromas [this could not be done for some styles like Barleywine which require some aging.  
.. set a beer aside for a year and see if it gets overcarbonated or not]  
,
2. the brewer has been very lucky,
3. the pitching yeast is contaminated with bacteria and there is little sugar left for the bacteria introduced during the siphoning to eat and make off-flavors/aromas [a very dry, thin beer would indicate that there's an infection in there -- if each bottle was equally dry then that would indicate the infection was introduced early in the process: infected yeast, infected fermenter, etc. -- if some bottles are more dry than others, the infection was introduced later in the process: dirty bottles, infection introduced while bottling, etc.],
4. the brewer is unfamiliar with the off-flavors/aromas that can be produced and is actually enjoying infected beer, and/or
5. the brewer is not sensitive to the particular off-flavors/aromas (each person has a slightly different threshold for each flavor/aroma).

I'd like to add that during the 1st round judging in the national competition, I judged perhaps a dozen beers that had subtle off-aromas that were due to poor sanitation or infected yeast. This indicates to me that there are still a significant percentage of brewers who are lax in sanitation. These beers were not awful (actually only one was undrinkable) but the off-aromas were definately there, whether the brewer knew that they were or not.

If you like the beer you are making and are happy with your process, then great... more power to you. On the other hand, it's important to remember

that there are a lot of beginners reading and that it's best to not teach them anything except proper sanitation techniques. I've gotten quite comfortable with my fill-with-water technique and I would be willing to guess that it takes only 15 seconds longer than sucking on the hose (assuming that you were sanitizing the inside of your hose as I am).

From: Nir Navot <LCNAVOT@WEIZMANN.WEIZMANN.AC.IL>  
Subject: Anyone heard of BrewHeat?

I'm just back from the UK. The British seem not to mind using plastic in their homebrewing. They have a mashing apparatus made of a 20 lit polypropylene bucket with a 2400 watt heating element controlled by a thermostat which they call "BrewHeat" (forgot who makes it). You mash in it, sparge and boil (after the bucket is emptied). I guess you can also use it as your primary. I am about to construct one myself. Can anyone think of a good reason why such a bucket would not be such a great think to use???

Only problem for me right now is that they don't make 20 lit buckets here in Israel. Only 18 lit. I might have to resort to JS's EasyMasher tm in the end.

>stirred the cold water around it for 10 minutes or so. Then  
>I sparged into my 3 1/2 gallons of cold water. The beer turned  
>out pretty tasty, so it wasn't infected. A little chill haze though.

Chances are that you're right -- your beer is spending too much time  
at DMS-creation temperatures. 10 minutes is a bit short. I suggest  
you keep adding ice till the temperature of the wort drops to below  
140F and then add it to your 3.5 gallons of boiled-and-cooled-to-40F  
water.

This will give you a wort that is at about 70-75F and ready for pitching.

>Are there any problems doing this? Is it a waste of time for such  
>a small quantity of wort? Should I just wait 1/2 hour before  
>pitching or should I really not worry and do whatever I feel  
>like doing that day?

It's not a waste of time in my opinion. I'm a bit confused by your  
statement: "...after the boil, I would sparge the 1 1/2 gallons of hot  
wort..." Sparging is the rinsing of grains with hot (170F or so) water  
to extract the sugars out of them. Your statement implies that you  
have boiled your grains. This will not only give you chill haze, but  
also make your beer quite astringent (like chewing on grape skins).  
I suggest that you remove the grains when the water in the pot reaches  
170F and then add your extract. Also, when you are pouring the hot  
wort into the cool water in the fermenter, try to minimize splashing  
which will oxidize the beer. Once the temperature of the wort is below  
80F, you can then aerate the wort without significant oxidation.

> After reading the ongoing thread about a month ago on wort chillers, I started to wonder. Was my beer spending too much time at DMS temps?

After re-reading Darryl Richman's detailed account of the brewing process at Pilsner Urquell, I started to wonder if anything at all that we believe about brewing is for real.

PU allows the beer to cool down naturally, in large open pans, in a building with "large louvered windows on one long wall". It takes four hours to cool down to a range given as 122F to 140F at which time it is then cooled down to pitching temp with a chiller.

If this extended period at "DMS temps" is harmful to beer, someone had better tell the brewmeister at PU.

>From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)  
>Subject: The Great Grain Mill Saga

I responded to this privately, not realizing that it was copied to the Digest so now I have to do it publicly but I will edit it for public consumption.

>I recently bought a JS MaltMill(r), the adjustable model, and have got a few things to say.....

> The .060" spacing was too loose many grains were just cracked in half, but not really crushed. I adjusted the mill, again with feeler gauges, to .057". This provided satisfactory results for the two-row, but was too loose for the CaraPils. I adjusted again to .055", and this provided great results for CaraPils as well as the two-row.

This whole discussion about a thousandth of an inch here or there is just too anal for my style and view of reality. I have not adjusted my mill for six months and I typically use 4 or 5 different malts in a batch.

I am glad to see a customer who likes his toy and has the flexibility he was looking for but, for the record, I sell roughly equal numbers of fixed and adjustable and can only recall two customers who saw the need to upgrade.

>I tried using a drill to turn the MaltMill too. This absolves JSP of all liability associated with the machine, but I did it

anyway. The drill is a very heavy-duty 1/2" drill, with 0 - 500 RPM speed. I figure I was running it at maybe 100 RPMs.

Not only do I absolve myself of liability but I would also like to point out that powerful electric drills are not a good choice for powering a mill. They have tremendous torque and will destroy rollers if stones or other objects find their way into the mill. If a drill must be used, I would suggest a light duty one that will stall on a foreign object.

The method of choice is a separate motor, pullies and a v-belt adjusted to stall at the proper torque.

>Things that could stand improvement?? I think the hopper is WAY too small.

That is more of a shipping problem than an engineering problem. Try hanging a 5 gal bucket from the ceiling with a hole in the bottom and just let it run into the existing hopper.

> I was disappointed to find no bronze bushing in the eccentric "knob" that provides the adjustemnt.

The bronze bushing is in the roller where the action is. The knob has a hardened steel shaft that rides in the bushing.

You ought to check out the new Philmill. It has no bearings at all. The 1.5" roller turns in 1.5" hole drilled in the steel housing. It sounds like a train hitting the breaks.

The knob is only an adjustment and not a bearing surface. Although not milspec, it works and is consistant with keeping the cost reasonable.

>And the adjuster moves too easily when tightening the set-screw -- you have to be more careful than you might want to be.

I have made improvements in the knob to minimize the movement but as you bought it from a dealer, I don't know what vintage it is. As a result of your mail, we are now assigning serial numbers to every MM as it is manufactured to keep track of mods and improvements.

>Some kind of metal clips that could fasten the mill to the top of the bucket would be good too.

The preferred way of using the mill is to clamp the base to the end of a table with the business end hanging over the edge and the grain falling into the bucket.

>My plans are to mount the MaltMill on a different base, add a permanent motor of some kind,...

Much better idea than a drill. You can also screw the board down to a larger board with the front hanging over to avoid having to cut the rectangular hole

in the new board.

>If the eccentric knob wears out, I trust that Jack will replace it.

Of course.

>So, it seems there are now three price-points in the small-mill market now:

\$40 gets you a Corona, \$80 get you a PhilMill, and \$120 gets you an adjustable MaltMill.

There are at least 500 people out there with fixed mills who would argue that

you should compare the \$80 PM against the \$99 MM.

From: nexgen!bart@daver (Bart Thielges)  
Subject: Free B and Punks on Swill

Is the "Brewer's Yeast" that can be bought at a health food store simply the sludge from the bottom of a fermenter ? If so, does it make sense at all to dry my sludge and save it as a source of vitamin B ? Or is there something magic about the store bought yeast ?

The thought of saving the yeast for vitamin B came from the recent discussion of headaches and whether they resulted from yeastless factory beer. This weekend I was at a rather rowdy (ahem) music event. The only beverage I saw consumed was malt liquor in 32 or 40 ounce bottles. Yeow ! Ugh ! I'd bet that there were many headaches the next morning. How do they make that stuff ? Is it truly brewed that way or is extra alcohol added to skanky beer ? Not that I want to make some myself ("Here, try my latest homebrew. Its supposed to taste like King Cobra !"), I'm just curious.

Thanks for all those who responded to my previous message !

(1.035  
> max). (numbers in parens are mine)  
>  
> Or maybe there is some super German malts that yield 40 pts!

I look at Warner's numbers and see for the Isar Weizen recipe on page 105  
the following:

$(5 \text{ gallons}) * (55 \text{ SG pts}) / (7.525 \text{ lbs grain}) = 36.5 \text{ SG pts/lb.}$

I never see 36.5 SG pts/lb with my equipment. I brewed a Hefe Weizen a la  
Warner on 31 May, 1993. Three weeks after brewing, six days after  
bottling  
this beer took first in a local informally judged "light" beer contest. I  
was quite surprised that it was so well received. It even beat Jim  
Busch's  
Weizen and Wit. I voted for Phil Seitz's Wit (I think). So, I am happy  
with the  
quality of the advice found in Warner's book.

The recipe performed as expected for my set up with extraction of  
29 SG points/lb for a decoction. I use a 48 qt cooler with the copper  
slatted wort collector that we have all seen. I do not beleive that the  
geometry of the picnic cooler mash-tun (wider than tall) gives as good  
a grain bed, clarity, or extraction as I have gotten with the insulated  
Zap-Ap style (taller than wide). But, the cooler is more workable for  
14 gallon batches.

German Hefe Weizan

Goals:  
OG: 1.054  
IBU: 12

Yield: 14 gallons  
Color: light

Ingredients:

15 lbs Ireks Wheat Malt  
10.5 lbs DeWolf-Cosyns Pils Malt

2 oz 4.6% German Hallertauer Pellets (assume 25% utilization) 60 min  
Weiherstephan Weizen Yeast (96? 69?)

Results:

OG: 1.054  
FG: 1.010

Procedure:

- 1) Preboil all water, chill, and siphon off of sediment.
- 2) Mash in at 99F, hold for 15 minutes.
- 3) Boost to 122F, hold for 15 minutes.
- 4) Perform first decoction with thickest 40% of mash. Heat in 15 minutes to 160F, hold 15 minutes. Heat in 15 minutes to boiling. Boil for 20 minutes.  
Mix back into mash tun over 10 minutes.
- 5) Hold at 147F for 20 minutes.
- 6) Perform second decoction with 30% of mash. Heat in 15 minutes to 160F, hold 15 minutes. Heat in 15 minutes to boiling. Boil for 10 minutes. Mix back into mash tun over 10 minutes.
- 7) Sparge at 172F to collect 15 gallons.
- 8) Boil two hours.
- 9) After hot break occurs collect one gallon of speise (wort) for priming.
- 10) Add hops for last 60 minutes.
- 11) Pitch yeast at 58F. Allow temperature to rise to 65F over three days.
- 12) Bottle with 1 4/5 qts speise per 5 gallons.

This process took about 10 hours from start to clean up excluding pre-boiling the water. I am quite happy with this beer. It has a smoothnes that I have not tasted with my other Hefe Weizen's that I attribute to the unhopped speise. I found Eric Warner's book quite helpful and pretty much followed his guidelines verbatim. I was surprised at the very easy sparge. I did stir after one hour and recirc 1/2 gallon. The run-off was clear and I had no stuck mash problems.

Cheers, Rick

>My problem; how in the hell do  
>you keep mash at a constant temp?

First, a gas stove is much easier than an electric stove for mashing...you can turn the heat on and off immediately, without the long time lag associated with electric burners.

None of my mashes are ever isothermal. They slowly cool down, and I slowly warm them back up.

Some people put their mash tun inside an insulated box, or inside their over, that has been preheated (on the 'warm' setting) to keep it warm.

> Are these tuns I see for sale really worth it?  
Depends...do you want to do it manually or buy something to do it all for you...

That would be a *\*big\** improvement. Brewers resource has a single  
strain weissbier yeast too. Its about time for this improvement.

I've been lucky enough to get a sample of Weinhenstephan #66, a true  
weissbier yeast. The smell out of the primary was wonderful. And  
the taste of the spec. grav. sample had 4-vinyl guaiacol all over it.  
Even flat, it was delicious. This is a good yeast to use.

Subject: hot yeast, brewpubs in minn??

Hi people,, I have a question about boiling an extract wort and throwing the yeast in when the wort is around 85 to 90 degrees. I was told that this accelerates the process, but will it hurt the beer in any way. I started a batch late at night and didn't have time to let it cool to 65, 70 degrees. This was an ale...????? Everything looks OK.....

Can anybody give me a list of brewpubs and supply stores for homebrewers in the Minneapolis/St. Paul area???

Todd.....

From: steve@Pentagon-EMH6.army.mil (Steve Lichtenberg x79300)  
Subject: iodophor, chili etc

Greetings fellow brewers;

I have been following the recent threads on sanitation and thought it was time to add my \$.02 to the discussion.

I recently made the switch to using iodophor instead of bleach and have been very happy with the results.

I became very discouraged about a year ago as I ended up with three infected batches in a row :- ( I finally traced the problem to some grunge left deep in my wort chiller and had to replace the entire system. I use a counterflow chiller (really a coil of copper in a 5 gallon plastic bucket) and have had some difficulty in keeping hops leaves out of it.

The chlorine solutions I was using were not able to get the organic components off the chiller and still keep the sanitizing ability.

In addition to the infections, I blew out two cornelious kegs by generating pin holes in them from the bleach. This just got to be too much as kegs are difficult to come by. (BTW I have found the best way to obtain kegs is to find a restaurant that has either just gone out of business or has just switched their soda system to bag in the box. You will usually find several kegs sitting in the dumpster. The soda companies are reluctant to pick them up and the restaurant owners have no patience for the clutter.)

After I switched to iodine, I have had no more problems with infections and my kegs are in pristine condition.

- - - - -

The recent discussion on chili beer has proven to be interesting. I have not tried to make one yet but I do have some experience with making pickled jalepenos. I harvested about eight plants worth last year from my garden and sliced them with a mandolin (gives uniform thickness) to about 1/4". The peppers were then placed in a vinegar/brine solution and left to sit in the refrigerator. After about three months they were hotter than any other pepper I have ever tasted. The acid in the brine solution apparently has a multiplicative effect on the capsicum(sp) oils in the pepper. I would imagine that beer would fo the same thing.

THanks for the forum and the ability to speak my peace. I have learned more here than I probably could have anywhere else.

Subject: Cotton spun filters & efficiency

IN the last digest, jack comments more on filters:

>Jack S. experiments with filters is very interesting. Micah claims he has seen no problems with head retention using the supposed .5um filter and I have seen poor clarity with it as well when pushing some beers through it.

> Fix has recommended against this small (.5um) filtration.....

< I wonder if we havn't got an apples and oranges problem here. I never asked

< George what type of filter he was using. He gave me the manufactuere and

< part number but not the type but I bought something else.

George uses a 3 ucron, DE filter as he notes in the following mail:

Yeast cells vary from 5 to 10 microns. My own filter is a Zahm+Nagel cartridge which is precoated with DE. The cartiridges come in 3, 1, and .45 micron sizes. I use the 3 micron version for my own homebrew. We also use this size for BRD brew pubs.

< As there are many differnt types of filters, pleated, string wound, ceramic, flat, plate, just to name a few, it seems that we need to know which type we are talking about to get any sense out of this discussion.

And of course, DE!

>From more email: From tsand@helix.nih.gov Tue Mar 2 08:48:45 1993

I have been filtering my beers for about a year now and have pleased with the results.

There are two types of filter cartridges that are used for filtering beer.

The first type is a spun (woven) polypropelyne the other is a pleated polypropelyne. There is a big diference between the two. The spun polypropelyne has an efficiency rating of 90% (10% of the stuff you are trying to filter out will get through) the pleated plypropelyne has an efficiency rating of 99.9% (only 0.1% of the stuff you are trying to filter out will get through).

The spun cartridges also tend to leak due to the fact that the ends of the cartridge do not have a gasket on them. The pleated cartridges come with gaskets and don't leak. The spun cartridges also cannot not be reused as many times as the pleated because they tend to be harder to back flush. I have used both types and the pleated polypropelyne is far superior and is the one I would recommend.

< I have little confidence in the numbers quoted for string wound filters and

< have no experience with any other.

Exactly. They are not made for this purpose and as such I suggest using products intended for yeast removal.

Good brewing,  
Jim Busch

From: Paul Sovcik <U18183@UICVM.UIC.EDU>  
Subject: Re: Acetaminophen and hangovers

I have to reply to this, since I have extensive experience in acetaminophen toxicity (residency in an ER for 1 yr) and hangovers (used to drink Blatz)

Acetaminophen is OK to use for hangovers. It is toxic only in large amounts (over 5 gms/ingestion) and in hepatic failure (advanced cirrhosis). Avoid high dose long term use and suicide attempts and you'll be fine. In fact, it is better than aspirin or ibuprofen because you have less gastric upset, which is a significant part of a hangover. Don't take it before you go to bed, since its duration of action is only about six hours or so...

My remedy? Lots of water/OJ before bed. Enough sleep. Some kind of nutrition upon arising. More water. Tylenol 650mg. If its really bad, a Sausage McMuffin sandwich (grease is good-dunno why.)

From: krueger@comm.mot.com (Kevin Krueger)  
Subject: Short Original Gravity ... why ??

I recently made the Imperial Stout listed in '92 Minnesota HB Champs recipe book (from the net) and did not nearly reach the original gravity listed for the recipe. I know you don't have to be dead nuts on the recipe, but I was a ways off. The recipe stated an OG of ~1.1 and I reached ~1.07. This recipe used d.m.e. (9#'s) and some specialty grains (1/2# each of chocolate and roasted barley) and 3 oz. of Williamette hops for boiling and some Cascade for finishing. As I am getting more brews under my belt (and it shows!), I am more inclined to ask why and I would like to know why I didn't get a higher OG. I steeped the specialty grains from cold water to something near 140, removed them, added the dme and hops and boiled for an hour. Should I have boiled longer or was it possibly a function of the dme ? Are there any other factors that would reduce my OG ??

Kevin

From: "Anton Verhulst" <verhulst@zk3.dec.com>  
Subject: MALTMILLS - kegging pressures

I'm a VERY satisfied Maltmill owner. A recent HBDer mentioned the desire of motorizing his MM. If you brew 20 gallon batches this might be a good idea but for 5 gallon batches, why bother. The MM is very fast (much faster than the Corona) and besides, rocks are going to damage the rollers if you motorize it. When you hand crank you stop instantly when a pebble is encountered and no damage occurs. For large motorized batches, an occasional roller replacement might be a hit that you're willing to take.

Setting the MM adjustment with a feeler gauge to get consistent results is a very good idea. However, instead of measuring the spacing at the center of the roller I would suggest taking the measurement at the adjustable end of the roller instead for increased accuracy. Remember that only one end adjusts and the other end is fixed.

As for the small MM hopper capacity, this is the mill's only fault. Making a larger hopper is easy but I think that a mill of this caliber should have at least a hopper that can comfortably take 5 pounds of grain.

On another subject, a letter in "Brewing Techniques" stated that a keg saturated with 12 psi CO2 at 40F would contain 2.5 volumes (medium carbonation) of CO2. Can some one tell me that the pressure would have to be at 70F to contain the same 2.5 volumes?

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Belgian Malts: Pils -vs- ale

A few weeks ago I did my first partial mash and made my best pale ale ever. So I'm jumping right into my first all grain batch. I could use a bit of advice from y'all.

In his book Belgian Ales, Pierre Rajotte implies that that the basic malt used for most Belgian ales is a pils malt not an pale ale malt. I recall him writing that the pale ale malts are used for British ale contract brewed in Belgium. However, his recipes simply say "pale malt". Any way, I'm going for a Belgium double with the following recipe for 5 gals.

- 9 lbs Belgian Pils malt
- 2 lbs Belgian special-B malt
- 1/2 lb glucose
- 1/2 lb Piloncillo (Mexican brown sugar)
- 7 HBUs Bitter Hops
- 1/2 oz American Saaz finishing hops
- OG 1.065 (I hope)
- Chimay yeast

Any comments would be appreciated. My specific questions are:

- 1) Should I do a protien rest esp. considering I'm using a Pils malt?
- 2) Will I have DMS problems from the Pils malt? If so how do I minimize them?
- 3) I want some malt flavor in the finished beer. What temp should I use for sacrfication (sp?)?

> If you've never seen it [Philmil] then your post sure sounds like FUD! Why don't you ask someone who has seen both mills to compare? Na that would have cut down on your chance to advertise.-()

> I don't think that was called for. My post was based on published data.

Which part? Asking that you not criticize a product you had not seen or asking that an impartial person compare both?

I haven't seen any published data on the Philmil. If it's out there I apologize. But the fact remains you cannot be considered an impartial person when it comes to either mill. All the reports I've seen in the digest have been quite favourable of the mill. Including one from one of your customers stating the crush was better. What does this mean? Nothing yet. If your mill is truly better I'm sure that people will decide that. But for you to rip a competitors product won't help.

> BTW, what's a FUD?

Fear and uncertainty. There is no need to discuss the merits of a product if you can scare away your competitors customers.

Date: Tue, 22 Jun 93 11:37:05 CDT  
From: hinz@memphis.med.ge.com (David Hinz)  
Subject: Grain Mill comparisons

In yesterday's HBD, Ed W. writes:

- - - -

Our club did a comparison, using standard sieves, of the crush produced by the Corona (properly adjusted), a MALTMILL (tm) (non-adjustable model) and a Philmill prototype (properly adjusted). The results differed rather substantially from the MM sieve results posted here in May by George Fix, but they tended to point to the PM as being somewhat superior.

- - - -

So, what's being said here, by a friend of Phil, is that the PhilMill is marginally better, when at it's best, than a non-adjustable MaltMill. No mention of what type of malt (standard size, that the non-adjustable MM is set for, or big wheat malt, or what?), and so on.

It looks like a case of running a test to get the desired results. To use an adjustable PhilMill, an adjustable Corona, and a fixed MaltMill on grain of an unspecified size seems like the "experiment" was designed to come out with skewed results.

For the record, I don't have a mill yet, but when I buy one it WILL be an adjustable MaltMill (hi Jack!), unless something better comes along. The test results posted seem to indicate to me that the PhilMill needs help from a faulty test to look better than MM, so apparently the PhilMill isn't the answer.

If PhilMill is truly better, then posting the above test was more of a dis-service to the product than anything else, as it has thrown doubt in at least my mind as to it's quality. Let's compare apples to apples, not apples to kumquats.

Dave "Not buying it" Hinz

Date: Tue, 22 Jun 93 11:30:48 cdt  
From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: summer brewing

Brewsters,

I am wondering what people think about brewing in the summer, specifically regarding the increased danger of little airborne animals falling into your cooling beer.

I've only been brewing a couple of years. Two summers ago I just didn't brew because of the heat - my house does not have central air, and the thought of subjecting everyone to three or four gallons of boiling wort for an hour plus - well, I'm not sure I would want to no matter how thirsty I was and besides my wife would probably consider it grounds for divorce. Last summer I was away, so brewing was a moot point. However, last summer was unusually cool here, and although this summer seems to be warming up, we do occasionally get that nice cool evening that makes me think of all that beer in the basement that will be gone probably some time in August if I don't replenish the supply, stop having friends over, or somehow convince my wife that drinking is bad for her but not for me.

So, here is the question. If windows are kept closed during the wort-cooling period and I am otherwise extra-careful with sanitation, is this enough protection, or if my windows have been open at all that day, should I "worry" about the increased risk of infection? I should add that I do not have a wort chiller, but I have been using a pretty effective means of chilling which leaves the cooling wort exposed to air for maybe 30-45 minutes; also, I use liquid yeast in a starter solution and get strong starts in less than six hours.

TIA as usual for any scientific data, empirical observations, or momilies.

Subject: Hop growing

This is my second year for hop growing. I have one Cascade and one Tettenger.  
Last year the Cascade went wild and the Tett was a "runt". This year, the same thing is happening. I think the Tett is just a slow growing plant. Any others out there with the same experience?

As far as calculating the alpha acid content, I started with the typical content published in TCJOHB, then threw in an extra handful just to be sure. The beer turned out a little too bitter, so this year I'll stick with the published numbers. Anyone out there (like HopTech) have a curve of alpha acid content as a function of "ripeness" of the hops. ie: how important is it to not be a week early or a week late on the harvest.

On malt mills: I'm personally tired of the calims and counter-claims, factoid vs factoid, petty bullshit, cry baby, mine's bigger than your's, wanna bet, (tm), hocus pocus flim-flam. I don't see how we can stop it, but I sure am tired of it. Why don't you folks (and you ALL know who you are) give us a break?

> (2.04g) tells me the file I have is probably not a .zip file. What am I  
I  
> doing wrong? How can I get hold of these files?

The following is from the archive's index file.

Files with a .Z suffix are compressed with the "compress" program.  
To uncompress the .Z files, you'll need the "uncompress" program.  
If your system does not have "uncompress" there is a version  
available in pub/sources as 'compress.shar' (or via listserv by  
"get sources compress.shar").

Files with a .zip suffix are "zipped" with PKZIP or something  
compatible. You'll need the equivalent to "unzip" them.

Files with the .uu suffix are uuencoded binary files. They are  
usually files that have been compressed or zipped (e.g. \*.Z.uu, or  
\*.zip.uu). You will need the 'uudecode' program, available in  
pub/sources as 'uudecode.c' (or via listserv by "get sources uudecode.  
c").

Files with the .ps extension are PostScript files.

I hope that this helps.

>chiller, but I've never done anything more constructive than fit the  
>lid on the best way I could, nor have I seen evidence of infection  
>because of it.

I've always had a similar concern. Here's what I do.

I use two fresh pieces of aluminum foil over the top of the kettle, arranged in the following manner. I set my chiller inlet/outlet tubing so that they stick up in the middle of the kettle. I put the first piece of foil so that more than half of the kettle is covered, and hand crimp the foil over the lip of the kettle. I then put the second piece of foil over the kettle and arrange it such that the edges overlap the first piece and that there is sufficient "slack" to do some hand crimping of the foil around the chiller tubes. Crimp the edges of the second sheet of foil around the kettle first, and then around the chiller tubes to make the best seal possible.

Certainly it's not perfect, but it makes me feel a lot better than if the kettle were open or partially covered by the lid.

Cheers!

From: dra@jsc-ws.sharpwa.com (Darren Aaberge)  
Subject: Spruce Beer

A couple of weeks ago I asked about how to use spruce in beer. After getting some helpful hints, I brewed a batch of spruce beer. The recipe I ended up with is:

10 lbs american 2-row  
1/2 lb crystal 40l  
1/3 lb chocolate malt  
1 oz cascade hops (aa=7.6%, 60 min.)  
1 pint fresh spruce growths (30 min.)  
German Ale Yeast  
OG = 1.052  
FG = 1.010

I mashed all grains together and did a protein rest at 122 degrees for 30 minutes and then mashed at 148-152 degrees for 1 hour.

I bottled the beer last weekend and was able to sample a couple of glasses. You can definitely tell that there is something different about this beer, but if I didn't know that there was spruce in it I probably would not be able to guess that it was. Also, Papazian says that spruce beer tastes something like Pepsi, but I think that takes a big stretch of the imagination. There is no detectable hop flavor and very little bitterness in this beer. Next time I brew this beer, I will probably increase the hops a little. I think that I used the right amount of spruce.

One important lesson I learned is that the hops make a much better filter bed than the spruce needles. I brew in a keg with a copper manifold on the bottom for draining. Since I added the hops first, they settled first and made a nice filter bed. During clean up, I noticed that after I removed the hops, the needles kept clogging the copper manifold.

Here are some other things that may be of interest:

Scott Stihler says that you can also dry "hop" with spruce. He also says that he has frozen spruce growths to use later, but the flavor diminishes a little, so you need to use a little more.

Lisa St. Hilaire says she has also added white fir to spruce beer, which has a tangerine-like aroma, but says to avoid using white spruce.

So, that is about all I know about spruce beer. So far, it seems like a good beer that is definitely worth brewing.

>emphasized when taken in conjunction with alcohol.

Acetaminophen, or any other drug, is indeed nothing to pop on a whim. But  
I didn't say take it before-hand for potential hangovers. Only take it  
if

you really do have an established, wicked, morning-after head full of  
pain.

All I would recommend by way of preventative, night-before precautions  
is

lots of water, don't drink on an empty stomach, and don't drink so darn  
much (I usually manage to follow at least 2 out of these 3). Cannabis,  
if

you're so inclined, can also be effective as a preventative. Heck, it's  
a

panacea - wear it, smoke it, write on it, cook with it.... (see alt.  
drugs  
for more).

If you're waking up with raging hangovers often enough to have to start  
worrying about the long-term toxicity of acetaminophen, it's possible  
that

you're drinking a little too much. Look for other tell-tale signs such  
as

memory blackouts, mysterious unexplained bruises, missing items of  
clothing, a compulsion to hide bottles in eavestroughs or behind the  
furnace, getting fired from your job, or delerium tremens in the absence  
of

drink. Any or all of these clues might mean you have a drinking problem  
(other than the perennial problem of not brewing often enough). For the  
occasional over-indulgence, I doubt acetaminophen presents a serious  
risk,

but you could always take a.s.a (aspirin) instead which is also available  
in a caffeine-codeine compound.

Subject: Hot Cave Creek Beer, Microbrews

From: Steve Slade <sslade@ucsd.edu>  
Date sent: 22-JUN-1993 15:52:53 PT

Hi all

I was heartened to learn someone else thought the Cave Creek Chili Beer was too hot to handle. I proudly brought some to my brother's house for Memorial Day as an example of an unusual microbrewed beer. My brother, my wife, and I all tried this at the same time. Now, we all like hot foods, but this was way too much! I couldn't taste anything for a good 30 minutes after taking one sip. Maybe I got one of these 6 month old six-packs. Do they come with date cades?

<downshift>

Our next vacation will take us to the Seattle area. Microbrewery heaven at last! We'll be taking a side trip from Bellvue, WA (sp?) to Beaverton, OR. Any suggestions out there for a nice place to have lunch and good beer near the half-way point?

TIA,

Steve Slade

From: mdcsc!gdh@uunet.UU.NET (Garrett Hildebrand)  
Subject: commericals, bleach disinfectant.

In HBD # 1167, Tony Johnston says,

>About flames and commercialism  
>  
>Let's be polite here in our criticisms, and lets leave the advertising  
>to the pages of Zymurgy, etc. If you find something so nifty-difty  
>that  
>you've gotta tell or you'll burst, why not just describe it in generic  
>terms, no specific copyrighted names, prices, ordering information,  
>etc.  
>and just field the private e-mail. If I wanted commercials, I would  
>watch TV :( !!!!!  
>  
>Sensibly yours,  
>  
>Tony Johnston  
>Tired Chemist, Inspired Homebrewer  
>anthony@chemsun.chem.umn.edu

My two cents on this one: Not only do I read HBD to find out about the mistakes that every one else is making (so I can avoid them :- ) ; not only do I read the HBD so I can try new recipies; not only do I read the HBD to see old ideas put to new uses, and new ideas for old problems, but I also read the HBD to get data and opinions on products which I might think about purchasing, and to hear about new things which are offered.

I'd prefer to let people use the real name of products they have tried, tested or given up on, and I prefer to hear about new offerings. So let us not get too hasty about getting so generic that we might as well go back to reading musty old textbooks and hyped-up advertisements which only indicate how much money was spent on them.

On the other hand, some restraint, as has previously been voiced, is nice. Infomercials and roastings we don't need.

More sterilization...

- - - - -  
In the same HBD, Kelly Jones responds to Paul Boor with the observation that needles need to be, "PDS (pretty damn sterile)," while brewing equipment need only be controlled for, "gross infections."

I note that Kelly states that the concentration of 4-16 tsp per gallon is sufficient, and I work this out to be in the range of slightly over one, and up to five, tablespoons per gallon (of bleach). I'll bet that the range could be accounted for by adding the time factor, as was suggested by George Fix in the same HBD.

I agree. Here is another data-point: at a local day-care center I saw a sign posted at the sink which directed employees to clean all food preparation surfaces with a sponge using a solution of one tablespoon Chlorox per gallon. They just let the damp surfaces evaporate after cleaning.

I personally use 1/3 cup per 5 gallons. That is around five tablespoons (it is actually 5.3333 tablespoons). It seems to work well enough

without corroding either me or the equipment. However, I am looking forward to the article mentioned by George Fix which is to appear in Vol. 2 of BTW Brewing Techniques.

Lastly, for fun, in another peek at Kelly's post (or should that be, "ripost?")...

>> Think about it, but right now I gotta run out to the kitchen  
>>to make sure my refrigerator light is still on.  
>  
>More importantly, does your airlock really bubble when you're not  
>watching it?

Or listening to it? ;-)

From: mikel@netlink.cts.com (Mike Lemons)  
Subject: Iodine's Staying Power

I've recently started using iodophor sanitizer. I've experienced severe problems with the "staying power" of dilute iodine solutions.

I have some Blue Ridge iodine test paper that can be dipped into the iodine solution to determine the ppm of free iodine. I have found these test papers to be essentially useless. There are three gray circles on the vial that are used to compare the color of the test strips. The circles are composed of widely spaced dots, like a newspaper photo, and don't look very much like the color of the test strips after dipping in iodophor solution. The three circles correspond to 12.5, 25 and 50 ppm. The 12.5 ppm circle is so faint that wetting the paper strips with pure water will make them dark enough to match the circle. Using the other two circles, I cannot determine if a solution is closer to 25 or 50 ppm, only that it is in that range somewhere.

I have determined that the amber color change caused by the iodine itself is the best measure of how concentrated the sanitizing solution is. I have used the test papers to verify that when a solution turns clear, it is indeed free of iodine.

The first thing I did was to create a 12.5 ppm solution by mixing 5/8 tsp of iodophor solution with 1 gallon of water. In two weeks it had turned perfectly clear, just sitting in a closed glass bottle!

So I squirted some more iodophor into the bottle to take the concentration into the 25 to 50 ppm range. I have a clear plastic tub with a spring-loaded plunger that squirts sanitizing solution up inside of empty beer bottles. After doing 2 or 3 six-packs, the solution will turn totally clear. (I just rechecked some of the beer bottles and they look perfectly clean to me.) It's a real pain to have to keep stopping to look for a faint color change in your sanitizer to determine if it is still working. I don't think that dilute iodine solutions would last very long in an airlock, either.

I used to be able to sanitize all of the bottles for a five gallon batch with the same sanitizing solution when I used sulfites. To determine if the solution was still working, all you had to do was lean over it and take a breath. The coughing and searing pain in your nasal passages left no doubt as to its potency. (Yes, I've heard the rumors that sulfites are ineffective; That's why I switched to iodine.)

How do chlorine users test the concentration of their solutions?

Where does the iodine go? It can't evaporate because it's a solid at room temperature. Since I have to use higher than recommended concentrations to get it to last through a few bottles, I'm wondering if anyone has ever been able to taste iodine in finished beer?

Subject: Lambic Tasting III in Portland

Attention Belgian beer lovers:

This year's AHA conference in Portland will be the site of the third annual lambic tasting. The tasting will be run opposite the best of show judging so you won't miss any of the talks or social gatherings.

The 'menu' includes beers such as Frank Boon's Kriek, Framboise, Faro, and Gueuze, Cantillon Gueuze, Saison Dupont, Blanche de Brugge, and Rodenbach. I wouldn't be suprised if a homebrewed attempt or two showed up too.

For more information on the tasting send e-mail to

From: djackson@wv.MENTORG.COM (Darin Jackson)  
Subject: Foaming/Flat Kegged Beer

Hello all.

I recently purchased a keging system and made my own beer chiller. The chiller is 6' of 1/4" od copper tubing with 3/16" fittings on either end to connect in from the line out of the keg and to the line out to the cobra tap. I bent it into a shape that fits into my small cooler I dedicated to the task and was proud as hell of my \$6 portable chiller. Well, I'm having foaming/flat beer problems.

Over the last 2 years I have collected HBD wisdom regarding this phenomenon. This morning I read through it and my question was not answered, so here it is. When I connected the chiller to the line, I cut the 4' line connected to the cobra tap in half, half for the keg to chiller and half for the chiller to tap. I have 4' of 3/16 id hose and 6' of approximately the same id copper total, but the "smooth" part at the end by the tap is only 2'. I presume that there will be turbulence caused by the fittings from the copper to the hose. Is 2' enough to let the beer settle back down? I'm getting all head and almost no carbonation in the beer. I have tried dispensing with the gas disconnected, with 12 lbs of gas, with 10 lbs of gas and with 7 lbs of gas. And, of course, I drank all of the flat beer.

All suggestions will be appreciated.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: Protein rest

I generally make ales and do about a 10 min protein rest before heating the mash up to mash temps. I generally use 2-row from Briess with maybe a little dextrine malt or wheat and I add any other adjuncts with the mashout.

I bottled my last batch and the FG was about 1.009. OG was about 1.062. Talk about attenuation. One reason for the low FG was that about 30% of the fermentables came from honey in this batch. (I used "raw, wild mesquite" honey hoping it would not ferment completely and would leave a honey taste)

The other thing I'm wondering about is the protein rest. I was going to use a cooler to mash in this time, so I added the grains to some water so the result was a thick grist at about 53C. I ran to the store with a friend and one thing led to another and I came back in about two hours. The temp. had dropped a good bit, of course, so I went back to a stove-top mash (would have needed a lot of boiling water at this point to bring it up to 68C for mashing). What happens during the protein rest? If a lot of proteins were broken down or something, then there went my body and thus, the low FG.

I will wait a couple of weeks and taste it to see how it is.

Thanks for any help.  
- Bryan

From: rgarvin@btg.com (Rick Garvin)  
Subject: Anheuser-Busch buys Sierra Nevada

I was at the brew-pub in progress Bardo in Arlington, VA on Monday night. In speaking with Bill Stewart the owner (very wacky guy with bottle of Celis White in his hand) he asked if I had heard the rumor that Anheuser-Busch was in negotiations with Sierra Nevada Brewing Company for a take over. What!? He said that this rumor was completely unsubstantiated but came from someone in the industry.

I called SNBC today at 916-893-3520 and spoke with Peggy. She was surprised that the rumor had gotten to Washington, DC but she had heard it. She said that this was absolutely false. Now, our friends at the SEC do not like companies to deny these things if it is true. So, I beleive her.

Thank You God.

On a bad note, we have been getting some bad Sierra Nevada products on the east coast. I was given a 6 pack of SN Porter from State Line Liquors in Northern MD that had a metallic flavor. I also bought a 6 pack of SN Pale Ale in Alexandria, VA that had that exact flavor. Metallic flavors can have a number of causes (I am a AHA/HWBTA beer judge of 6 years) but I think that what I am tasting is beer that has been held at very high temperatures for long periods. Say, a railroad switch yard for 2 days in the sun. Now, this is just a guess. I hope that it is not a fermentation or process fault. Comments?

Cheers, Rick

Date: Wed, 23 Jun 93 14:57:42 EDT"  
From: Gary S. Kuyat <gsk@sagan.bellcore.com>  
**Subject: NJ Brepubs, Filters**  
Full-Name: Gary S. Kuyat

I wanted to give status on NJ's Brewpub legislation. It passed the Assembly unanously! The senate still hasn't voted on it, but with this kind of response from the Assembly, I can't see how it will fail. It turns out that you really can't tell when the Assembly or Senate will vote on a given bill, you just have to keep calling and asking. I will post again when I have more info.

On another subject: filters. I was reading about some not-so-good results with a so-called .5 micron filter. I purchased such a filter from the Braukunst, a mail order place (for me anyway). I want to start off by saying that the owner was VERY decent about the troubles I had, and offered to refund my money if I was dissatisfied. I would recommend him for all his other products but until he finds a new source for half micron filters, I would stay away.

I finally gave up after trying 4 filter elements. I ordered a similar kit from the Filter Store+. Their catalog shows the first element I used as 5 (that FIVE, not half) micron. The new element looked very different, and was rated at 99.99% efficiency. I believe that the Braukunst got shipped 5s instead of the .5s they ordered.

As I have said the owner of the Braukunst seemed to be TOTALLY HONEST and never attempted to blame me (and if he'd tried, I probably would have thought it was my fault!) He assured me that .5 microns would produce a crystal clear beer. He was right!

With the new element, the American Light Ale I filtered was COMPLETELY haze FREE! This was PERFECT! It didn't seem to filter out any taste, except a muddy, yeasty taste (probably from yeast!) The Filter Store filters were more expensive and the kit did not include disconnects for the keg. I think the Braukunst is worth calling, but make sure to ask if they have gotten new filter elements, from a different supplier.

If you have any question about the filter element you're using, I'd say it CAN'T be .5 microns. The beer should be totally, UNCLOUDY. Make sure to chill it to serving temp or lower before you filter it to get out any chill haze.

From: Barry\_Gillott@DGC.ceo.dg.com  
Subject: Zymurgy Skunk Article

Message:

Greetings all! I come to you for help. The manager of my local beer store is sincerely interested in my claim that fluorescent lights can produce skunkiness in some beers. I'd like him to read an article that appeared in Zymurgy some years back. I believe the year was 1989 or 1990, and the article was entitled something like, "Who Put The Skunk In My Beer?".

The problem is, I threw the issue out long ago and my AHA membership expired. I checked the local library and they weren't much help. It was unclear whether they'd do an inter-library loan on a periodical, especially if I didn't know exactly which issue.

Do any of you know the exact name of the article, and the exact date of issue? To really push my luck, would any of you be willing to fax me the article? I think it was around 4 or 5 pages.

If there are any takers out there, please contact me via email at my return address or [barry@wgn.ceo.dg.com](mailto:barry@wgn.ceo.dg.com) . Thanks very much.

> extraction of 36.5 for his gravity. I actually got about 30. Maybe I  
> should have sparged for 2 hours insted of 1!-) Ah well, next time....  
> (If I will ever spend the time required for that complex multi-step  
> decoction recipe again!)

I found exactly the same thing a couple of weeks ago too.  
I got curious about his numbers after making a batch of weissbier that  
didn't come in to gravity specs (I usually get 29-31 pts/lb/gallon) and  
ended  
up quite a bit shy of Eric's numbers.

For my second batch (last weekend), I modified Eric's grain bill to  
1) use what I had laying around the house and 2) use a realistic  
extraction  
rate.

Eric Warner has a recipe for a winning weissbier published in Zymurgy  
from  
last year. I wonder what he gets for extraction on his  
5 or 10 gallon batches...

As for doing a double decoction mash to make weissbier, it seemed pretty  
easy to do. It was easier the second time and I'm sure it only  
gets easier from here...

Subject: What valve/pipe fitting for SS keg?

After reading the HBD and rec.crafts.brewing for over a year, I have seen many interesting brewing processes/equipment picked to pieces. I must say that the information gained by this process has been both enlightening and helpful in improving my homebrews. Many thanks for the quality information found in this group! There is a topic that I have not seen picked apart yet, unless I missed it from an earlier time. What type of ball valve/pipe fittings can be used for a drain on a SS 15.5 gallon keg? What kind of metal can be used? I assume SS would be best, but what about brass or copper? What is the best inside diameter of the valve/pipe fitting? How long should the pipe fitting be? How high up should the valve/pipe fitting be placed on the keg? Basicly, I would like some input on what kind and how to attach the valve/pipe fitting to the keg. After extended use, what has worked for you?  
Thanks and hop until you drop.

From: Lee=A.=Menegoni@nectech.com  
Subject: Aquarium Pump Airation ala Brewing Techniques

I would like to construct an airation unit similar to the one in Brewing Techniques magazine. The author of the article mentions using a charcoal filter to remove rubber odors produced by the pump. During a recent trip to a department store I discovered an array of pumps from \$5 to \$25 dollars but could not find an in line fliter, the did have boxes of activated charcoal so making on seems to be a minor issue. My question what makes one pump better than another? Given the short duty cycle required for brewing versus in an aquarium, durability and noise would be the least of my concerns. I would be most interested in the pump that produces the least odor.

Please post to the Net I have had problems with incoming mail.

RE: Imperial stout that was too thin. I suspect that the recipe published was not identical to what was brewed, acommon problem with published recipes, or the volume info was incorrect.  
A beer with an og of 100 sg points \* 5 gallons = 500 total sg points  
500 sg points / 9 lbs DME = 55.5 sg pts / lb no way do you get this from DME

70 sg points \* 5 gallons = 350 total sg points  
350 sg points / 9lbs DME = 38.8 sg pts / lb this is more realistic DME yeild  
The contribution of the . 5 lb barley and .5 lb specialty grain would be minimal on total gravity.

If you want 100 sg points from this recipe brew a 3.5 gallon batch  
9 lbs DME \* 38.88 sg pts/ lb = 350 sg pts  
350 sg pts / 100 pts/gallon = 3.5 gallons

Any one have a good all grain Belgian Double recipe?

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: More Weizen Stuff

Reading the last digest shows that summer is here and many of us are working hard on wheat beers. Having just brewed yet another Weizen broadly ala Warners Isar, and reading the posts, I thought I'd comment on some of my latest frustrations with Wheat beers. First some notes on yesterdays material:

>From Rick Garvin:  
<(5 gallons)\*(55 SG pts)/(7.525 lbs grain)= 36.5 SG pts/lb.

<I never see 36.5 SG pts/lb with my equipment. I brewed a Hefe Weizen a la  
<Warner on 31 May, 1993. Three weeks after brewing, six days after bottling  
<this beer took first in a local informally judged "light" beer contest. I  
<was quite surprised that it was so well received. It even beat Jim Busch's  
<Weizen and Wit. I voted for Phil Seitz's Wit (I think). So, I am happy with  
<the quality of the advice found in Warner's book.

I never see this either. The Weizen that Rick "beat out" (ouch!) only yielded just under 30 pts/lb. I increased the pale malt and added a bit of Munich and last nights yielded only 28. Both batches were single decoction.

Eric's book is certainly a great asset to brewers, and Eric notes that you should adjust all grain bills based on the performance of your system.

Now,  
if I can just figure out the performance of my system with wheat malt, \*\$!%.

FYI:

Hefe Weizen #123, 6/23/93:

59% De Wolf - Cosyns Wheat Malt

38% De Wolf - Cosyns Pils Malt

2.5% De Wolf - Cosyns Munich Malt

.5% De Wolf - Cosyns Cara Pils Malt

13 IBU Hops, Whole Domestic Perle, 1/2 at start of boil, 1/4 at 60 minutes

1/4 Hersbrucker Hallertau Pellets, 15 minutes to end

~21 oz Weihenstephan 66, Weizen Yeast

1/2 Tbls Gypsum in Sparge, 1/2 Tbls in mash

OG 12P

I use a shallow SS lauter tun, with a perforated sheet false bottom, and grain bed depth of about 1 to 1.5 feet. Lauters great.

A question for wheat brewers: what kind of grain mill do you use, and how far

(fine) do you grind the Wheat? I am beginning to wonder if my extract loss

is due to not pulverising the wheat enough. Pound for pound I should be getting a much higher extract from Wheat, and I dont. An equivalent Pale Ale

single infusion gives me at least 13P.

Hey, Rick: You better bring that weizen to next months contest where we can have "BJCP certified judges" pick the real winner :-)! I just hope they dont allow Phil's Wit beer in the contest, the competition is getting too stiff around here!

Good weizen brewing,  
Jim Busch

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Belgium Tripple

Since my latest visit to Belgium last month, I am getting real anxious to brew an authentic Belgium Tripple. I thought I would consult the HBD for any tips or opinions on the matter. My goal is a simple one, reproduce Bruges Tripple. I am aiming for 9-9.5% ABV, light pale color, warming alcohol presence but not overtly evident alcohol.

So for say 10 gallons:  
Pils malt to result in an OG of ~18P (1.073/4)  
5-6 lbs glucose/sugar/candi mix (is this close?)  
~20-24 IBU Goldings/Saaz/hallertau/Perle/Liberty?  
Yeast???? LaChouffe, Westmalle, Duvel? Suggestions excluding Wyeast Belgium :-)  
A combination? I would assume a fresh bottling yeast is required.

So all you high gravity pBelgium brewers out there, what do you think?

Good brewing,  
Jim Busch

Subject: High Gravity Brewing

In an attempt to start a subject that I dont recall reading here in the fairly recent timeframe I am asking for opinions on high gravity brewing. What I mean by this is similar to what the big boys do: Brew a high gravity wort and dilute with boiled/cooled water into the fermenter. Now before you get all upset that this is not the way to make "real" beer, let me point out that I talked to a few brewmasters in the UK who did just this. In particular, the brewer from the Larkins Brewery (located in Kent, took a medal in last years GBBF), told me he brews his ordinary bitter to an OG of 1.055 and dilutes it down to 1.035 in the fermenter. I realize one needs to take into account the additional caramelization in the kettle with the increased sugar content, but has anyone done much of this. I am especially interested in the idea of brewing pale ales of OG 1.065-1.070 and adding water to result in a 1.055 in the fermenter. The entire fermentation would be at the lower gravity. An obvious issue is the pH of the water pushing the wort toward the alkaline side, would the wort be able to buffer a 10-20% water charge? Would typical Sierra Nevada ale yeast be able to work at a slightly more basic pH than a normal wort? IT would seem to me that since kettle size is normally the limiting factor in batch size, this would be a great way to increase volume of finished product. I am fortunate in that I oversized/over engineered my lauter tun to accomadate high gravity brewing, so working with the extra grains is no problem.

Comments/experiances?

Good brewing,  
Jim Busch

My condolences to your wife. The best place to look for beer is the  
"Strip",  
which is located on the Tahoka Hwy south of town, I don't remember the  
number  
of the highway, but if you take I-27? south Loop 289, you'll be on the  
Tahoka  
Hwy. I checked out the stores there my last few trips to Lubbock and the  
selection is pretty dismal. They do have a few imports, but not many.  
This is  
about the only place you can find package liquor/beer/wine there are a  
few  
other stores around the outskirts, but they are harder to find. You won't  
find  
any package liquor in the city itself. I do not know of any restaurants  
or  
bars that have a good selection of beer. Try to stay away from the  
"strip"  
Friday and Saturday evenings, the lines of cars going there can be a real  
pain  
in the A.

By the way, tell your wife there really is LIFE after Lubbock.

Sounds like chlorine and/or extra-hard water to me.

Did you boil ALL the water used in the brew (before you added it),  
and siphon off the precipitate?

Andy, from my experience and comments from my local supplier, American Eagle seems to be the lightest extract (both dry and syrup) on the market. Their amber DME seems to be the color of M&F et.al.'s light.

Seems to me you only helped the advertising cause by repeating the advertisement in it's entirety in an attempt to prove your point.

Speaking of Mark of Hoptech, I have a question about his recent Zymurgy article. The article says that dry hopping with pellets will take longer than dry hopping with whole hops. Why? I would think the opposite would be true since the lipulin glands are probably ruptured during the pelletizing process.

Charlie Papazian in TCJOH refers to the dumping of the wort through a strainer into the fermenter to remove the hops and any other particulates as sparging. This might be the source of the confusion. He also recommends scooping out

the specialty grains just prior to the wort coming to a boil.

> roasted barley) and 3 oz. of Willamette hops for boiling and some  
> Cascade for finishing. ... Are there any other factors that would  
reduce  
> my OG ??

I calculate that using that quantity of malt and grains to make 5 gallons  
would give you an OG of 1.075. However using the same quantity to make 4  
gallons would be 1.095, close enough to the ~1.1 the recipe quoted. And  
if  
you made 14L (just shy of 4 gallons), you'd get 1.102.

Perhaps this recipe wasn't for a "standard" volume?

**Subject: Chipotle Ale**

Subject: Time:11:42 AM  
OFFICE MEMOChipotle Ale Date:6/24/93

In HBD 1176, Dale HIGgs talks about a Northwest Brewery that has brewed a chili beer with chipotles (that smoked and dried jalpeno). The only northwest brewery other than Blongewicz's Garage Brewery and Beer Joint (I'll get back to that later) that has brewed a beer with chipotles, that I know of, is Rogue. Their beer is called Mexicali Rose. In my garage brewery I used 2 oz of whole or partially crushed chipotles in the last 15 minutes of the boil. It came out quite well I thought (must have been okay, everyone at the Uno de Mayo party drank all 5 gallons of it). And the warm smokey taste at the very end is just right for drinking. I've had Ed's also, and its good, for one or two, but not much more after that.

Anyway if you want the detail on the Chipotle Ale, just ask

Date: Thu, 24 Jun 93 14:07 CDT  
From: korz@iepubj.att.com  
Subject: Raw wheat/Extra-light extract/Superbrau

I was just on the phone yesterday with a food industry wholesaler regarding unmalted wheat. I had read from Jean-Xavier Guinard's book, *Lambic*, that the raw wheat that they use for lambieks is soft, white, low-protein wheat. Furthermore, he said that the protein levels were typically 1.8 to 2.1 percent total dry weight.

Now, this did not go over well with the wholesaler -- their wheat typically has 11 to 14% protein. I looked up the protein levels in DeWolf-Cosyns Wheat MALT and they were "10.61% total protein as is" and "4.85% soluble protein."

Hmmm? I don't think the protein levels could be that much lower in unmalted wheat -- malting cannot CREATE proteins, can it? I suspect that somehow there was a mixup in the protein levels in Guinard's otherwise spectacular book -- perhaps a misunderstanding by the brewers? Perhaps they were quoting soluble protein and less is soluble before malting?

In any event, the reason I really posted this was to point out that the lambiek brewers are using SOFT, WHITE wheat not hard, red wheat.

Just a data point.

\*\*\*\*\*

Andy writes:

I wish to make a beer with the lightest possible color as is possible with extract.

I've found that the lightest of the extracts are Alexander's and Munton & Fison Extra-Light. Both are syrups. I'd like to add that I've never made a beer from all dry extract, so Light DME might be even lighter, but I don't have any personal experiences to report.

\*\*\*\*\*

Michael writes:

>I have finished my first batch, an Amber kit using Cascade hops and

>cooler wort will take the bite out. My wort was 90 degrees.

Most often, metallic tastes come from your water. Not only iron is responsible for these flavors, but also a lot of Calcium and Magnesium salts in the water can give your beer a metallic flavor. Other possible culprits are metallic pots and (for all-grain brewers) poorly stored/old grain. I don't think that the yeast would make that much of a difference.

One other comment. I have heard that Superbrau brand extracts have a pretty high level of corn sugar in them. I have not been able to verify this from either of the two extract composition sources that I have (from old Zymurgy articles). I have brewed decent beer with Superbrau in the past, but if indeed there is corn sugar added, I would avoid the extract. You see, malt extract costs between \$2 and \$3 per pound. Corn sugar (dextrose) costs about \$.75 per pound. So

if you're paying full price, you might as well get all malt and add the sugar yourself if you want.

I suspect that it is Polyethylene (PE), not Polypropylene (PP). I have yet to see anything that's been made of PP that is food grade, so I suspect that it is not food grade. Since we're on the subject of Polypropylene and food grade certification, if you buy yeast in plastic vials, check what kind of plastic it is. I've seen yeast sold in Polypropylene vials.

-----

Date: Thu, 24 Jun 93 16:42 CDT  
From: korz@iepubj.att.com  
Subject: Polypropylene correction...

Jim Busch's post reminded me of one instance of food-grade PP -- those pleated PP filters. Are you sure the spun ones are PP also? In any event, I looked around a lot and called a lot and could not find a PP food-grade vial. Why not HDPE, you ask? Well, I wanted to autoclave it -- PP is autoclavable as is PC (Polycarbonate -- also not food-grade)

.

I settled on glass vials with PP caps that have fiber/foil liners.

Subject: Help rescue my first batch!

Last sunday, I started my first batch, an extract. I'm using a Laaglander Dutch Dark Beer kit. But I think I'm in for some problems.

My initial Gravity was only 25; I was told to expect 45, on the scale that is. I also expected a bit more vigorous bubbling. I had times when it didn't bubble at all, other times it did pretty well. Anyway, 2 days after pitching, My girlfriend and I tasted a bit of the wort. It tasted like watered-down sour grapejuice. I figured that maybe I didn't stir it well enough so after 2 more days, I stired it up real good and took a gravity reading, a 20. It still tasted the same, but I bet you could catch a buzz of it! ;^) Now I suspect that all of the yeast is dead. What do I do now? Thanx in advance.

From: bill@oilsystems.com (Bill Vaughan)  
Subject: Miller amber ale

Well, I never thought I would be defending Miller (ick) but...

Dennis Lewis writes:

> This [Miller pamphlet] has got to be one of the most inane  
pieces of misinformation...

from Miller: "the tradition of warm beer is a cultural oddity  
of England rather than a taste issue."  
...This cultural oddity thing is unbelievable!!!

Belgian ale and altbier are both served much colder than English ale.  
When I lived in Belgium, no one could believe I liked English ales --  
they would all say "What! that flat, warm stuff!" These were NOT  
Americans talking -- they were Belgians, Dutch, Germans and one Swede.  
Continental Europeans do not share the British taste for cask-  
conditioned  
55 deg F ale. (Nor do they share the American taste for ultra-cold beer.  
)

> "Authentic ales differ from lagers... in several ways. First, ale  
is made only from a special ale yeast.'

I thought ale yeast was the common stuff and lager yeast the special  
one.

Gee, no doubt in my mind Americans would consider ale yeast special. Sure  
seems Wyeast considers it as special as their lager yeasts, or they might  
charge less. :-)

> "Ales are also the original beer of Europe."  
I guess the Sumerians and Egyptians don't count...

I don't know if they count, but they are respectively Asian and African,  
not European.

All in all, I suspect the Miller brochure is mostly factual, just watered  
down (like Lite beer) for the American public. And any facts are better  
than the kind of B.S. the public usually gets from our megabreweries.

From: krueger@comm.mot.com (Kevin Krueger)  
Subject: Cherry Brew? from Door County

Since I am heading up to Door County (WI) this weekend for some S&R (surf and relaxation), my mind drifted back to last year when I had a chance to try a cherry beer from Door County called Cherry Rail. Has anyone else had this beer? Personally, it was a lame beer and it tasted like Miller with cherry flavoring.

After my first swallow, I knew something was up with this beer, so I really combed the beer label looking for any clues. Before I could even dip into my fish boil:@[, I found the problem. They brew the beer and then add cherry flavoring to the beer! What's up with that? Is that how they make their apple beer? In fact, I am curious if there any fruit beers on the market that actually use real fruit and not flavored extract.

Which leads me to my other question about bad beer. In our party, we all ordered the cherry beer and we all thought it was pretty lame. I was the only beer connoiseur (sp?) in the bunch, so that leads me to believe that it was truly bad. So how does a brewery stay afloat with beer that, IMO, was only drinkable because I had been in the sun all day?

BTW, I know it was brewed under contract at another house, but that doesn't make my questions not worth asking. The label said Door County Brewery and that was what I remember about it. That and the fact that I had to order a Dog Style to wash down my fish boil!

Kevin

From: rgarvin@btg.com (Rick Garvin)  
Subject: Belgian Malts: Pils -vs- ale

William Kitch published a recipe in HBD #1169 for a 5 gallon batch of Belgian Double that uses 2 lbs of Special B malt. Special B is over 200 Lovibond. I used 2 lbs in a 12 gallon batch of Brown Ale on Tuesday and it was VERY brown. I would recommend 1/2 or 1/3 lb of Special B. Maybe less.

I really do like the Special B. Tim Artz has gotten some weird comments back from contests using this malt. One suggested that his beer (Dunkel Weizen?) had orange peel in it when it had nothing but Special B as an addition to malt. It may take judges a while to get used to it.

Cheers, Rick

From: Cisco <FRANCISCO@lan.ccit.arizona.edu>  
Subject: foaming/flat kegged beer

I forgot to add that when you are dispensing through a coiled chiller that you not leave the CO2 connected overnight because it will eventaully cause more CO2 to go into solution. When using copper dispensing tubing make sure to thoroughly clean it after each use.

For those of you who like their ales served at traditional temperatures, my previous post several HBD's ago stated that the optimum dispensing pressure was 12 lbs (adjusted +1lb for every 2000 ft. above sea level) and the length of 3/16 id hose should be 4(1lb. drop for every four inches)\* compensated dispensing pressure. This is approximately 48 inches with a normal cobra tap or regular beer tap such as through a refrigerator door. A tower tap has a 3lb pressure drop across it and must be subtracted from the dispensing pressure before calculating tube length. All this info is for a dispensing temperature of 38 to 42 degrees. If you want your dispensing temperature warmer, say 45 to 55, there are two techniques that can be applied to adjust the dispensing pressure. Beer that is served warmer allows more CO2 to escape and increases the pressure in the keg. This increased pressure can be compensated for by 1).dropping approximately 2 lb in dispensing pressure or 2).adding another 8 in. of 3/16 id hose. You'll have to play around a little bit to get it just right but you should only have to adjust the pressure + or - 1lb. to tweek it in.

Hope this makes sense,

Hey! It's rumor time.

According to sources at the breweries, A-B did ask both Sierra Nevada  
and Anchor (and possibly others) what their selling price was, both  
declined.

According to sources in both the brewing and financial worlds, A-B is  
seriously considering buying Jim Koch's Boston Beer Litigation Company.

Subject: HBD advertising

I think the problem with online advertising is that it can't be avoided. When some HBD subscribers advertise their products and other don't, we all get to see the advertising, as we are, in a sense, a captive audience. I think this is where the feeling that computer nets. like HBD shouldn't contain advertising comes from/

For those who do use it to advertise products it is a cheap and effective means of communicating for business purposes. For those who use HBD to indulge their passion for homebrew, advertising can be a pain. Notice that some people have discriminated between the 'kinds' or 'degree' of blantancy in advertising. What we have here is a range of uses, and range of users, and no particular, spoken agreement of what constitutes acceptable use of a free medium.

The issue of advertising on computer nets. is similar to door-to-door sales--how much freedom do businesspeople have to talk to you.

some non-HB but definitely D thoughts for you

Subject: DMS and PU

A few days ago, Jack wrote about his Pilsner Urquell clone that was brewed as closely as possible to Darryl Richman's description of the way Prazdroj Pilsenski (I think that's the spelling?) makes PU.

Well, last night, I had a chance to try some of this beer. A good attempt, I must say! The bitterness was right on, the hop flavor was clean and accurate (Czech Saaz hops used throughout) and the malty smoothness was very close. Amazingly pale for a four-decoction beer. On the down-side, the Saaz nose could have been stronger and the DMS level was a bit high. This is coincident with my assertion that a slow cooling would result in increased levels of dimethyl sulfide (DMS)

.  
It was not too bad, however, and small amounts of DMS are acceptable in Lagers (perhaps, and I'm just guessing here, because the cooler fermentation causes a less-vigorous production of CO<sub>2</sub>, which (we know for a fact) will scrub out excess O<sub>2</sub> and DMS from the beer).

The beer had been fermented and lagered at 40F for a while (I forgot to ask how long). Perhaps a longer lagering (and maybe if it was lagered at 32F as in Pilsen) the DMS level would be a bit lower? Does anyone know if DMS can be reduced via lagering? Can someone check DeKlerck and "Malting and Brewing Science?" I've already checked "The Biotechnology of Malting and Brewing" by Hough -- it's not mentioned in there.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop aroma, alapha acid questions

As far as the difference between hop aromas in late hop vs. dry hopping, this is not something I came up with out of the blue. This is well documented in brewing literature like Malting and Brewing Science by J. S.

Hough et al as well as by the professional brewers that I have interviewed.

I can also taste the difference quite distinctly, even if you can't. It is the heat of the process (in the late boil) that changes the aroma profile. I'm also not sure of your statement that "dry-hopping certainly produces more aroma per ounce of hops added." Aside from the issue that

I feel that late hopping produces more of a "hop character" and taste than aroma, (let's just change the wording to "hop effect" for purposes of discussion), the heat of the wort will certainly extract more oils than cool beer, but the heat will also cause a lot to evaporate, and there is the

time factor to consider: Dry hops are in the beer a lot longer than kettle

hops or those in a hop back. The whole subject is quite complicated, and I'm the first to admit I have no clue what the real answer is. It would be

interesting to run some experiments to see the relationship of quantity vs.

time of late hop additions. I imagine there is an optimal time where the maximum amount of oil is extracted, but hasn't boiled away yet. It probably

looks like a bell curve: the longer the hops are boiled, the more oil is extracted, but the more oil evaporates. Shorten the time, less evaporation,

but less extraction. Also, longer time = more aroma change. The speed of wort cooling is also a factor. Somewhere in the middle, there is probably

an optimum point.

Mike Schrempp asks if I have a curve that would show alpha acids vs. harvest

time. I'll look and I'll ask some hop growers if they have any data and report

back. Meanwhile, I don't know that I'd worry too much. Not all of the cones

on your plant budded at the same time, got the same amount of sun, etc. So

unless you're willing to harvest each cone individually, there is going to be

quite a bit of variation anyway. In the real hop world, alpha analysis for

each lot of hops has to be done by sampling many different bales and coming

up with an average for the lot. Cone to cone, alphas (and oils) vary quite

a bit, even from the same lot. So again, I'm not sure I'd worry too much.

From: Darryl Richman <darrylri@microsoft.com>  
Subject: re: Wort Chilling

A quick note about the brewing procedures at Pilsner Urquell brewery and the relationship between their cooling technique and DMS creation:

While it is true that the hot, bittered wort at PU is cooled slowly in a coolship, which could engender a great deal of DMS production and retention from latent S-Methyl Methionine (SMM), one must consider that the preceding boil is exceptionally long and it is likely that most of the SMM has already been converted to DMS and then evaporated off (see Fix's "Principle of Brewing Science" for a lot more detail here).

Also, consider that DMS levels of 0.1 mg/l or more are typically reported in lager beers (3 times the flavor threshold), while ales generally have DMS levels below the threshold. \*Some\* DMS flavor is, in fact, a defining character of lager beers, and adds to the crisp flavor profile.

Subject: Advertising in HBD

Time to offer my own opinions concerning advertising in HBD.

The opinion has been advanced that advertising on HBD is a service, that it provides information brewers find useful. Where that argument fails with me is in the fundamental difference between information presented in the interest of profit, and information presented solely to share something useful or interesting. Having something to gain beyond good beer creates a conflict. A poster with a commercial interest in the question will find it quite difficult not to favor their own solution: when all you have is a hammer, everything looks like a nail. Some posters (Kinney Baughman, Glenn Tinseth, Russ Wigglesworth, Darryl Richman and others) have handled this extraordinarily well, from my point of view, and I read their postings with confidence. Others leave me with the uncomfortable feeling that at least some of their postings (and I can't always tell which ones) contain not real information, but its counterfeit. We've learned to expect advertising on the more conventional media to be less than completely reliable; for this quality to slip unannounced into this forum compromises the credibility of every scrap of information presented here, especially for the newer brewers who are less prepared to sort fact from factoid, and don't yet know who's selling what. The principle of "caveat lector" has always been useful here (mistakes, sometimes big ones, are made), but knowing that the posting you're reading could be an "infomercial" doesn't exactly enhance the forum's value.

Just one man's opinion.

From: WEIX@swmed.edu

Subject: Yeast differences!

Hi-

I am a novice brewer. So far my friends and I have made three batches with different specialty grains, hops, and extracts. I have been pretty happy with the results we get, but there is an odd overtaste (not really unpleasant but noticeable) to the beer. We have used dry Whitbread Ale yeast for all three batches. I know that different yeasts can give different flavors and that liquid yeasts come highly recommended, so for my next batches I will be using Wyeast

American

Ale(#1056), which supposedly gives a cleaner taste.

My question is: Does anyone have a chart/table/list of what characteristics

the various common brewing yeasts (Wyeast, Whitbread, Edme, Red Star) have?

I know that no one yeast is "better" than the others just different. I also know that different yeasts work better with different styles. Any info would be appreciated--company propaganda sheets are fine too. Will summarize results and repost to digest if sufficient interest.

Hoppy brewing, y'all!

From: Edward Croft <CROFTE@delphi.com>  
Subject: Local packys/Why so technical?

Wow, shortly after I stated that our local packys only supply the Budmilloors types of beer, one local packy changed. What a smorgasborg. I can now select from Sierra Nevada, Schell, Anchor, and even Cave Creek. It seems they may have been reading HBD. They also started carrying limited homebrew supplies. It's great, now I am able to try some of the great beers that I have been reading about.

-----  
Why so technical? I get HBD to get ideas on new brews, hear about taste tests, and get other peoples ideas on how to improve the process. What I have seen lately is more of a chemistry class on the properties of idophors(?) and chlorine. I can see relating the impact some of the chemicals have on our equipment, but don't you think it is getting a bit anal, when we start breaking down the composition of the chemicals so as to get the optimum cleaning for the least amount of chemical. Come on guys, I don't see the harm in a quarter cup of bleach to five gallons of water. It works for me. I don't need to know how or why. Why don't the chemistry majors come up with the proper amounts between them and then post the summary. I want to hear more about using wheat bases for fruit beers, or the proper way to prepare jalepenos for chili beer. I want to hear about the new mini-keg systems, and yes even malt mills. Though, we could lighten up a little with the advertising and sniping.

-----  
Sorry about the flamette, but it has been bothering me of late. It's just that I think we need to see more of the types of input like Allan Wright's Amber Wheat Beer fruit base in HB1166. I have been contemplating a fruit beer, and this may do the trick. But, Allan, blueberries in beer? Let me know how that turns out. Thanks for letting me get it out of my system.

From: Jim Grady <grady@hpangrt.an.hp.com>  
Subject: step infusion mashes

I am making plans for my first all-grain batch and have a few questions about mash/lauter tuns. I am planning on using the slotted copper manifold for a combined mash & lauter tun. I seem to have 2 options. Put it in my mash kettle and make an insulated box to help maintain the temp. or put it in a 12 gal. rectangular cooler. Miller, in "The Complete Handbook of Home Brewing," recommends the insulated box because it allows you to do a step infusion mash. I believe I have read in these electronic pages that most of today's malts are so well modified that a single infusion mash is fine for most styles. Most discussion I have seen concerns whether decoction mashes are worth the effort and they can be done in a picnic cooler.

So, what's the verdict? Does anybody do step-infusion mashes? What are the benefits? Does anybody who does single-infusion mashes think their beers [would | would not] benefit from a step mash?

Thanks for your help!

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Alpha Acids vs. Harvest

Mike Schrempp had asked if I (or anyone) had a curve showing the alpha acid content vs. harvest time, trying to find out if a week or two's early or late harvest would make a significant difference. I said in a previous post (which might be in this HBD, dunno since it's the weekend) that I would try and find out.

Looked in my books and literature and talked to a grower late last Friday. Despite the fact the most hop literature is oriented towards growing hops rather than using them. one would think the answer would be there. NOT! Neither did the grower have any enlightenment except to say "Why would you harvest your hops at the wrong time?" So it's like this: They don't harvest their hops before they're ready, so they don't care what the alphas are before they harvest them. And for this reason, no one seems to have studied it. They HAVE studied how the temperature of the growing season affects the alphas (with the only positive correlation being high temps in some month like May, well before harvest, but generally no conclusive results) and the effect of various fertilizers on alphas (too much nitrogen has a negative effect), but nothing I can find on harvest time. The literature also assumes that if you're a hop grower, you'll know when the correct time to harvest is, so they don't bother to mention how to tell when that time is.

Maybe Glenn Tinseth (who is on vacation, I seem to recall) can shed some light here because the folks that he has direct access to (like Gail Nickerson) are really hop breeders, not brewers. Let's hope he reads this when he gets back on-line.

Forgive me for a bit of a tangent here, but this is kind of like why there aren't really any good formulas for predicting bitterness based on all the variables. The reason is that commercial breweries don't change their process often, so that is in effect a constant. They also have a lab to measure (and tasting panels to confirm) the actual amount of bitterness they're getting for a given hop addition. They also have the luxury of blending batches to correct mistakes and get better consistency. So their "formulas" are based on a lot of trial and error with measurement and subsequent adjustment, with the knowledge that their yeast strain, fermentation temperature, etc. will all remain constant and can be tightly controlled. So do they care to have a formula that they can plug in lots of variables and get a reasonably accurate bitterness calculation? No. So we don't have one either (yet).

From: waltman@BIX.com

Subject: Czech Budvar

Earlier this month there was some discussion of the Czech "Budweiser". A couple of years ago the NY Times had a long article about them and A-B. The gist of it was that Budvar and A-B had signed an agreement in the 1930's dividing the use of the Budweiser name: A-B got exclusive use in North America, Budvar on the European Continent and everywhere else (including UK) was open. One interesting factlet was the A-B was using the Budweiser name before the current brewry in Ceske Budejovice was opened. This was A-B's claim to use the name.

As for Samuel Adams in Germany, it is the only American beer I have ever come across. (I had one at the Bier Museum in Heidelberg which was a bit of a sacrifice since they had Budvar on tap.)

Subject: Foaming beer from the keg!

From: BrewerBob@AOL.COM  
For: Mark Parshall  
Subj: Kegging - Foaming at the tap!  
Re: HBD1157

Mark,

I know this note is a bit after the fact, I've been away. Perhaps it will still be of some help to you with your foaming beer problem.

I think you may have two problems. The reason for the foam may be too high a dispensing pressure into too small a tube. A 1/4 inch ID tube will cause a loss of more than 1 PSI per foot so ten pounds at the tank will be about six pounds at the tap for a three foot hose. Smaller IDs will have even greater loss. A 3/16 will lose up to 3 PSI per foot.

The reason for low carbonation in your beer is improper method. You can not simply put the gauge at thirty pounds for three days. The guy that told you to shake was right about that. Try this: Be sure the beer is very cold. Attach your gas line and set the pressure to twenty-five pounds (for exact pressures for different styles of beer, see Miller's book). Now, with the line attached, you will hear bubbles in the tank when you tip it to it's side. After a few seconds, the bubbles stop. Now roll the tank on the floor and you will hear more bubbles! Keep doing this for about ten minutes or until the bubbles don't happen anymore or are very few with each roll. Now the beer has ABSORBED the CO2! With the pressure still at 25 PSI, disconnect the gas line and put the tank into the fridge for a day. Then bleed off all pressure, attach your gas line and set it at the serving pressure you need, about ten pounds for a three foot line. Oh, by the way, be careful with the CO2 tank when you do this. Do not set it on it's side! Be very careful that it remains upright or liquid CO2 may try to find it's way through your valve!

Good luck! BrewerBob

From: Phillip Seitz <0004531571@mcimail.com>  
Subject: 5 liter kegs--some complications

Like a number of people I recently purchased a set of 4 5-liter kegs from Brew Ha Ha (Pottstown, Pa, 1-800-243-2620). In general I have been happy with the set, finding it reasonably well made and easy to use. So far I've kegged one batch, a bitter. As with other kegs, Brew Ha Ha recommends using 1/3 to 1/2 cup priming sugar rather than the standard 3/4 cup for bottling.

When I kegged my batch I filled three kegs, and then reprimed and put the rest into bottles. The first two kegs worked fine, although the beer coming out was a bit cloudier than the bottled version. When I pulled out the third kegs several days ago, I noticed that one are of the top had bulged out, and that the corresponding area on the opposite side of the bottom had also bulged. The keg would no longer sit flat, and it was hard to get the dispensing mechanism hooked on.

This would seem to be a problem stemming from excessive pressure. However, the beer was a 1.037 bitter that I'd kegged at 1.006 using 10 grams of sugar, about 1/5 what Brew Ha Ha recommends for a standard beer. In fact, the beer itself seemed fine, and was not excessively carbonated. I could only conclude that there was a flaw in this particular can that was not visible, leading to a structural weakness.

I called Randy Martin, the proprietor of Brew Ha Ha, to see whether they'd be willing to supply a replacement. It appears there there have been some other, similar problems, although, none of these fit the description of my own. They are now recommending that all kegs be stored in a cool or cold place, that they be checked periodically (they say the plug will bulge out before a problem with the can itself develops), and that all kegs should be filled to within 1" of the top (not less, as more pressure develops). They also remind people not to use the standard 3/4 cup of priming sugar.

By the way, Randy said he's sending me a replacement. Assuming no additional problems develop I can still say that I'm happy with the system, and might even consider buying another regulator and possible another set of kegs.

From: lfk@veritas.com (Lynn Kerby)  
Subject: Re: Short Original Gravity ... why ??

Well I would suspect that recipe. Simple math reveals that the only way that OG could be accurate given the ingredients is that the batch size was 3.5 gallons, not 5. Your numbers sound right (see below).

9# DME (@ 1.039 pt/lb/gal) yeilds 351 pts  
1# dark specialty grains yeilds 20 pts (if you are lucky)  
total 371 pts

371 / 5 ~~ 74 or 1.074 (probably very close to what you got)  
371 / 3.5 ~~ 106 or 1.106 (probably very close to what was expected)

NOTE: '~~' means approximately equal

Happy brewing.

PS - It always helps to sit down with a calculator for a few seconds before taking a recipe as gospel.

SUBJECT: new beer options in SF

Two new developments have recently occurred on the San Francisco beer scene.

The first is a combination Japanese Dim-sum and microbrewery which recently opened in the Financial District, at 333 Bush (at Montgomery) called the Cafe Pacifica. The atmosphere can be best described as Japanese-corporate-yuppie. It's a small place, and the brewhouse is incredibly tiny. They produce three beers; a light ale which has a well-balanced malty sweetness and fragrant hop aroma reminiscent of Devil's mountain railroad Ale, an amber which is clean and kinda average, and a dark, which has a nice chocolate finish and is, I believe, an excellent porter. The food is good altho not traditional Chinese Dim-sum. Both the food and beer are reasonably priced, making it an excellent downtown lunchtime option.

Rumor has it that a wealthy Tokyo restaurateur wanted to serve micro-brewed beer in his restaurants, but the Japanese laws concerning brewing make it impossible for micro-breweries to operate there. Apparently, you must produce 50 kabillion barrels or more a year to brew in Japan, so he set his son up in San Francisco to begin brewing American beer for export to Japan (his restaurants anyway..). The pub is, apparently, a pilot brewery.

On another front, the new owners of the San Francisco Giants obviously appreciate good beer, because now in section 15 you can find a stand which specializes in micro-brewed beers. Anchor Steam and Anchor wheat are available on draught. SNPA, Anchor Porter, and Devil's Mountain Railroad and Devil's brew are available in the bottle. Section 15 is located roughly behind first base. While a bit pricey, it's not much more expensive than Schludweiler, and infinitely tastier.

| If it's good for ancient druids runnin naked thru the woods |  
| drinkin strange fermented fluids then it's good enough for me. |

Subject: Belgian Pils malt/ Dubble recipes

In HBD #1169 "William A Kitch" <kitchwa@bongo.cc.utexas.edu> queries:  
>Subject: Belgian Malts: Pils -vs- ale

>A few weeks ago I did my first partial mash and made my best pale ale  
>ever. So I'm jumping right into my first all grain batch. I could  
>use a bit of advice from y'all.

>In his book Belgian Ales, Pierre Rajotte implies that that the basic  
>malt used for most Belgian ales is a pils malt not an pale ale malt.  
>I recall him writing that the pale ale malts are used for British ale  
>contract brewed in Belgium. However, his recipes simply say "pale  
malt".

>Any way, I'm going for a Belgium double with the following recipe for  
>5 gals.

- > 9 lbs Belgian Pils malt
- > 2 lbs Belgian special-B malt
- > 1/2 lb glucose
- > 1/2 lb Piloncillo (Mexican brown sugar)
- > 7 HBUs Bitter Hops
- > 1/2 oz American Saaz finishing hops
- > OG 1.065 (I hope)
- > Chimay yeast

>Any comments would be appreciated.

For one, this beer is going to be \*way\* dark. Special-B is > 200  
lovibond.

This dubbel is going to come out darker than an inky stout (thumbnail  
says ~85 L). The Special-B is darn tasty, but 2 lbs may be overpowering.  
On the other hand, it might be delicious. What it won't be is a dubbel.

I've made a couple of all grain dubbels now, and have found a recipe that  
seems to be in the ballpark for the style.

- 8 lbs Belgian Pils
- 1 lb Belgian Cara-Munich
- 1 lb Belgian Aromatic
- 1 lb Munich
- ~1 lb Some kind of dark sugar (some day I'll find dark candi)

Hops are still under experimentation, but noble hops only. Saaz,  
Styr-Goldings, Hallertau.

>My specific questions are:

- > 1) Should I do a protien rest esp. considering I'm using a Pils  
malt?

I usually do with this malt, but a fairly short one. I hold it at ~123F  
until there is a layer of clear stuff floating on top. Usually this is  
about 15 minutes.

- > 2) Will I have DMS problems from the Pils malt? If so how do I  
> minimize them?

Dr. Fix wrote pretty extensively on the Pils malt in Brewing Techniques  
#1.

I have my copy at home but I seem to recall that this malt was low in DMS precursors for a European lager malt, but higher than a pale ale malt.  
I haven't experienced any noticeable DMS with it, but most of the beers that I've made with it have been pretty strongly flavored, maybe I missed it.

> 3) I want some malt flavor in the finished beer. What temp should  
> I use for saccharification (sp?)?

With 2 lbs of special-B, you are going to have lots of malt flavor, no matter what temp you use for starch conversion. In my recipe I use a fairly low temp rest (~30 minutes at 145F and ~60 minutes at 152) and count on the Munich/ Cara-Munich to make it nice and malty without being sweet or heavy.

We're both looking at 12lb/5gal recipes. In my (limited) experience this is the point where aerating the @#%@ out of it becomes really important. You can't begin to rely on splashing into the primary to do the job. Many methods have been discussed, but what I use is my son's little asthma medicine aerosolizing machine. Does an awesome job and has some built in filtration. I paid \$100 for the thing and my son uses it about once a month, so I get some use out of it too.

=====

A couple of thoughts of my own:  
In my continuing quest for the perfect substitute for Belgian dark candi sugar I thought about dark Karo Syrup <tm>. It's dark and almost all corn syrup, but what's the coloring from? If it's just partially caramelized corn syrup, it might be a good substitute? If it's just dye or molasses, I'm not interested in using it.

In the BT article on Belgian malts, Dr. Fix expresses concern about the differences between the fine and coarse grind extract amounts in the Aromatic.

What does this mean?

From: mikel@netlink.cts.com (Mike Lemons)  
Subject: Shake, shake, shake your wort!

I recently bought a 1 liter erlenmeyer flask to culture yeast in. I got two #9 rubber stoppers, one with a hole and one without. The stoppers nearly fall into the flask. A nine-and-a-half would fit better. I have always used sterilized cotton in empty wine bottles for yeast cultures, but the neck on this flask is too wide . . . I have to use an air lock.

First step: Break the internal seal on a packet of liquid yeast and sit it on top of an external modem, where it stays at 90 degrees F. When the packet swells up, make the starter.

I use 1/4 cup of dried malt extract. I fill the flask up with water to the 800 ml mark. (1000 ml tends to boil over.) I set it directly on my gas stove and turn the flame up pretty high. A long glass stirring rod would be useful for stirring, but I don't have one, so I use a plastic chopstick. I boil it for about ten minutes, put the solid stopper in it and set it in a sink full of cold water. (Isn't pyrex wonderful?)

After the mixture had cooled, I started to swirl it around to increase the dissolved oxygen in the liquid, when it dawned on me, "Why not shake it instead?" So I put my thumb over the stopper and just shook the hell out of it. I cut open the yeast packet and poured it in and attached the air lock.

The next day, I had a very vigorous culture with lots of bubbles. When I brewed my five gallon batch of beer, I cooled the wort and poured it into a plastic fermentation vessel with a tight-fitting lid. Since I have a solid stopper the size of the hole, I thought, "If it worked for the starter, why not the wort?" So I stuck the solid stopper in and shook up the whole five gallons! I poured the yeast starter in and eight hours later, it was bubbling like crazy. I've always had a problem with long lag times, even when using liquid yeast and starter cultures, but shaking the wort took care of it.

WARNING: Do not shake hot wort! It will oxidize into cardboard.

Repeat: Liquid yeast and starter cultures did not decrease my lag times.  
Wort Aeration did.

Subject: RE: Belgian pils, summer brewing

Hi All,

Lots o' good stuff in HBD#1169. William A Kitch writes:

>Any way, I'm going for a Belgium double with the following recipe for  
>5 gals.  
> 9 lbs Belgian Pils malt

>Any comments would be appreciated. My specific questions are:  
> 1) Should I do a protien rest esp. considering I'm using a Pils malt?

The Belgian pilsner malt is highly modified, a protein rest should not be necessary.

>2) Will I have DMS problems from the Pils malt? If so how do I  
> minimize them?

According to George Fix in his article on Belgian malts that appeared in Brewing Techniques, the Belgian pilsner malt is low in the precursor of DMS (can't remember offhand, SMM?), so this shouldn't be a problem, especially if you adhere to standard procedures for minimizing DMS.

The precursor of DMS is a gas that can be driven off during the boil. Use a vigorous boil, and leave the pot at least partly uncovered. When the boil is finished, chill the wort below 140F as quickly as possible. A wort chiller is very helpful here.

>3) I want some malt flavor in the finished beer. What temp should  
> I use for saccharification (sp?)?

Use a temperature at the high end of the sugar rest, say 158F or so, which favors alpha amylase activity and should give you a more dextrinous wort.

\*\*\*\*\*

Jonathan Knight writes:

>I am wondering what people think about brewing in the summer,  
>specifically  
>regarding the increased danger of little airborne animals falling into  
>your  
>cooling beer.

IMHO, this is far more problematic than controlling fermentation temperatures, which can be dealt with in a number of ways (fridge with external controller, wet t-shirt method).

>So, here is the question. If windows are kept closed during the wort-cooling  
>period and I am otherwise extra-careful with sanitation,

>I should add that I do not  
>have a wort chiller,

Jonathan, you've pretty much addressed the issues associated with warm

weather brewing. Pollen and wild yeast counts are higher in warmer weather, so being extra careful with sanitation and minimizing or eliminating air circulation during the wort cooling period are very important. Of course, using a wort chiller to get to pitching temperatures quickly is also very helpful. Also, if possible, try to brew on rainy days, when pollen and wild yeast counts are reduced.

>TIA as usual for any scientific data, empirical observations, or momilies.

I brewed about a dozen batches throughout last summer, with no infection problems at all.

\*\*\*\*\*

Douglas DeMers writes:

>I use two fresh pieces of aluminum foil over the top of the kettle, >arranged in the following manner. I set my chiller inlet/outlet tubing >so that they stick up in the middle of the kettle.

I built my chiller so that the inlet/outlet tubing are just inside the edge of the pot. With the lid on, there is only about 1/2" space left open, which I also cover with tinfoil.

>Certainly it's not perfect, but it makes me feel a lot better than if >the kettle were open or partially covered by the lid

Ditto. See eliminating air circulation during the wort cooling period above.

Cheers,  
Jim

From: rgarvin@btg.com (Rick Garvin)  
Subject: AHA National Contest

It was just yesterday that I was grouching about not having received my judging sheets back from the AHA yet. Well, today they arrived. I was pleased to find that three of my beers had been promoted to the second round: Barleywine, Imperial Stout, and Old Ale. The Old Ale won't impress anyone. I entered a fair 1.064 IPA in this category because it is a category that does not get many entries.

Overall the judges comments were consistent. This is something that has gotten better through the years. There was one style that had "xerox" comments. The two judges should have just signed the same sheet since the only difference between them was the name. As a judge I understand the balance that must be struck between collaboration and independent thinking. This problem was only apparent on one beer.

For each beer that was promoted a button was included that said "MY BREW KICKS BUTT" and "I'M A 2nd round Brewer." I can feel the beer snob in me preening. But, then I drank one of those Old Ales: "Too much hops" "Needs more malt" "Harsh Bitterness". And my favorite from judge Cliff Beringer "Good beer, harshness might prevent me from drinking more than 8 pints." Well, not a total loss.

Cheers, Rick

>Tripple.  
>I am aiming for 9-9.5% ABV, light pale color, warming alcohol presence  
>but  
>not overtly evident alcohol.

Here are some data points (I haven't got a complete original recipe  
but I've made some pretty succesfull near misses)

Koningshoeven tripel has pilsner malt exclusively (for 8.5% Alc. by Vol.  
)  
don't know about their hops. This tripel is very similar to the  
Westmalle,  
perhaps just a little more body.

West Vleteren uses a large proportion of 'Record' hops, a Belgian  
Northern  
Brewer variety (which I believe is again related to Hallertau) and some  
Goldings.

The Brugge tripel contains somewhere around 20% wheat malt (From memory,  
I haven't got my notes here).

>So for say 10 gallons:  
>Pils malt to result in an OG of ~18P (1.073/4)  
>5-6 lbs glucose/sugar/candi mix (is this close?)  
>~20-24 IBU Goldings/Saaz/hallertau/Perle/Liberty?  
>Yeast???? LaChouffe, Westmalle, Duvel? Suggestions excluding Wyeast  
Belgium :-)  
>A combination? I would assume a fresh bottling yeast is required.

>So all you high gravity pBelgium brewers out there, what do you think?

One of my best attempts was made using the following (again from memory,  
but  
then there isn't that much to remember)

Pils malt, for an OG of 1090 (infusion mash)  
2/3 Belgian Northern brewer 1/3 Kent Goldings, for a bitterness about  
half that of traditional Pilsner  
yeast cultured from West Vleteren (the dark red caps, like a dubbel),  
I expect Westmalle will also do (I haven't tried it)  
Fermented somewhat cool, as I wanted the malt to dominate (I think 63F)  
Bottled with some of the original wort. No extra yeast added but  
next time I might, because carbonation took three weeks.

The result was very close to the Koningshoeven tripel both in flavour and  
appearance, definitely one of my best top fermenting brews..

>Now, this did not go over well with the wholesaler -- their wheat  
>typically has 11 to 14% protein. I looked up the protein levels  
>in DeWolf-Cosyns Wheat MALT and they were "10.61% total protein as is"  
>and "4.85% soluble protein."  
>  
> ...I suspect  
>that somehow there was a mixup in the protein levels in Guinard's  
>otherwise spectacular book -- perhaps a misunderstanding by the  
>brewers? Perhaps they were quoting soluble protein and less is  
>soluble before malting?

Alternatively, someone is inadvertently quoting the Nitrogen content as  
protein - a plausible error given the correlation. The data I have on  
Baird's  
wheat malt is that it contains a maximum of 2.2% total Nitrogen.  
Remarkably  
close to your figures of "1.8 to 2.1". Just speculation though, but maybe  
worth checking.

Subject: Door County Beers

Howdy All!

In yesterday's HBD, I happened to notice an article about the beers of Cherryland Brewing, Sturgeon Bay, WI. It talked about how the beer was brewed and a fruit juice was added at bottling time. Now, I had the opportunity to sample some of Cherryland's Apple Bach at the Kenosha Beer Festival two weeks ago and I was pleasantly surprised. This stuff was good! Being the cider fanatic that I am, I was to the point of hijacking the truck and doing some serious imbibing. I also resolved to make an apple beer and the net wisdom seems to hold that making a hard cider and a very light beer and combining the two at bottling time might be the way to go. I am currently in the process of making my first cider and if it doesn't turn out quite the way I want, I may consider the mix and mash thing. Regardless, I wanted to make one more point. I found some bottles of the apple bach in the cooler at my local home-brew supply store and promptly purchased a six-pack. The stuff was awful! Absolutely no flavor of apples (smelled like 'em tho) and none of the crisp sweetness that so overwhelmed me at the festival. :- ( Any input as to why this happened? The beer is in big, brown bottles and looks like it was stored at room temp. If I can manage to drink the beer, I will at least get a set of nice bottles for my cider. Oh, and one more thing: the rest of the beers from Cherryland are barely passable. The Gold and Silver Rails are not all that exciting and the cherry beer seems to go the same way as the apple bach.

Hmmmm. Enough rambling for one day!

Prosit!

My most recent Weissbier (actually a Dunkelweissbier) had a grain bill of  
6  
malted lbs wheat, 4 lbs munich and 1 lb pils, and yielded 30 pts/lb/gal  
with  
a double decoction. (OG 15.5P - 1.062) No where near Warner's numbers,  
but still acceptable.

> OG 12P

I added about 13 IBU also, Hallertau Hersbrucker plugs and saaz pellets.  
The Weihenstephan #66 is a great yeast to use for a true weissbier!  
It really has the correct taste.

> A question for wheat brewers: what kind of grain mill do you use, and

Pale Ale  
> single infusion gives me at least 13P.

Wheat should give a much higher yield. but it doesn't seem to in my case  
either. The xtractions using wheat are not very different from those  
with  
just 2 row pale. My previous batch had a poor wheat crush and the  
extraction  
suffered (low 20s). To avoid problems with the mills at homebrew stores,  
I just bought a MALTMILL (tm). Haven't gotten to use it yet.

For my next weissbier (maybe a weizenbock for the fall) I'm gonna try and crush the wheat very well and hope that I don't have lauter problems (I haven't had any so far using a double decoction)

Jim Busch brings up an interesting topic: High Gravity brewing.

One concern that the big boys have is deaerating(sp?) the water before adding it to the beer but this is because they are adding the water at the end of the process instead of adding it to the fermenter.

>mean by this is similar to what the big boys do: Brew a high gravity  
wort and  
>dilute with boiled/cooled water into the fermenter.

I'm very interested in any recipes that call for this method of brewing.  
I'm also interested in hearing any methods, procedures, gotchas, hints,  
etc. that people use for this method.

Currently, I only have a 5gal brew pot which is not sufficient enough to  
do all-grain brewing. I want to do all-grain with a 5 gallon yield, and  
the aforementioned method might be doable for me.

I'm interested, in particular, in wheat beer recipes. I've made myself a  
Zapap lauter-tun as explained in "the book" that works quite well. I've  
done  
a few partial mashes with decent success.

A lot of food storage material is made of polypropelene. Much of  
the Tupperware(tm) like stuff, and juice jugs and so on. It's heat  
resistant and microwaveable. A lot of lab equipment is also PP, and one  
doesn't want plastic leaching into one's slant tubes...

From: sims@pdesds1.scra.org (Jim Sims)  
Subject: Homebrew adventures #8725784509

Well, last nite was either homebrewer's paradise or nightmare, haven't quite figured out which yet.

I got home just after 7 after picking up the kids from Karate, slapped together some spaghetti, and put some water on to boil for beer and filled the #2 washtub with water, bleach, and bottles.

About 8, I added the malt extract and then the hops to the boil while I started siphoning off the latest batch of double-light from the primary fermenter. While the next batch ( 3-1/2 lbs M&F Light DME, ~ 2lbs honey, ~ 1 oz fresh Hollertau hops, EDME yeast) was boiling (cept for the honey)I bottled about 35 bottles of the aforementioned double-light, trying to leave about 2-3 gallons in the pan for making some fruit beer.

Well, in order to have something to put that beer + fruit IN, I needed to bottle the fruit mead that's been fermenting for the last week :

(3 weeks in primary, racked to secondary [ (2) one-gal apple juice bottles and a gallon winejug] with (a) 1 lb plums, (b) 1 12 oz package frozen raspberries, and (c) 1 pint fresh blackberries)

This proved to be a challenge, cause the siphon was still sitting (primed) in the beer and I didn't think i wanted to try to start a siphon in those 1 gal jugs, between the "line loss" and all that fruit pulp, it didnt seem a good idea. So, I just poured the mead from the respective jugs through a strainer and funnel into the beer bottles. Yes, I know it oxegenated the mead a lot, but hey, sue me, OK? If it comes out \*awful\* I have something to blame besides my (otherwise) ineptitude...

I sampled some of the fruit i strained off the mead - mmmmmmmmmmm

After getting the mead tucked safely into some bottles (and a bit drooled on the floor ;-), it was time to add the finishing hops and honey to the batch of beer on the stove and let it steep for a few minutes and dump it off to the primary and put it in the (pre-chilled with a coupla frozen gallon milk-jugs of water) water in the sink.

Well, now there are dirty pots and pans everywhere and about 50 or so bottles of various fuit meads and beer, empty bottles, the #2 washtub with chlorine water soaking those 3 gal jugs, an empty plastic fermenter, a bit of mead and beer, and who knows what else on the kitchen floor.....

Back to the original batch of double-light beer that's been patiently waiting for its fruit. Cherries were on sale for \$.99/lb raspberries for \$1.19/pint and strawberries for \$.59/lb; so that's what I got - ~2-1/2 lbs of cherries to be pitted, about 2 lbs of strawberries to (whatever you call removing the stem-thingie) and chop, and a pint of raspberrires to chop up.

So now we've got bits of cherries and strawberries on the table & floor to go with all that other stuff and a big cutting board covered with fruit. After squishing the fruit into the three (separate) gal jugs, i added a gal of beer to the cherries and 1/2 gal to the strawberries and 1/2 gal to the raspberries (and added a rubber

stopper and airlock).

There was enough beer left to bottle 2 more beers of that double-light, and then loads of clean-up.....

I finally got done about 1:30 AM. Cant wait to try the results!

jim

Heh, heh. That would be a master stroke for J.K.: selling a brewery with virtually no brewing facilities (a virtual brewery?) to the mighty A-B. Considering that Miller has already shown us that it is perfectly capable of producing flavourful beer (it's just been holding back until the market was right, didn't you know that!? :-), I find it amusing to think that Budweiser, the master marketer of insipid pale lager, would consider buying Boston (tm) Beer (tm), something that is essentially a beer-marketing company.

Okay, enough with these rumours; I have something real. A-B has announced that it will purchase 5% of China's Tsingtao brewery, or 45 million shares, part of a semi-privatisation of Tsingtao. Source: Seattle Times business section, 28 June 1993, page 2. Seriously! Political repression may continue, but economic development and growth in the PRC continue to gallop along, and now the biggest American megabrewer is dipping its toes into the waters. Let's hope that this involvement with Tsingtao keeps them busy enough that they keep their hands off Budvar (aka the Budweiser with flavour). Look for even wider availability of Tsingtao in supermarkets across the land. (Didn't A-B already have some kind of interest in Denmark's Carlsberg, or was that import and marketing only?)

> Darin

Your problem is your dispensing pressure does not match the inside diameter and length of your dispensing line. I posted an article about how to calculate this a few weeks ago, email me if you want it sent to you. To make it simple, an inside diameter of 3/16 has a pressure drop of 1 pound for every 4 inches. You have 6 ft. of copper tubing and 4 ft. of plastic tubing(all with 3/16 id according to you). This translate out to 10 feet of 3/16 id tubing or 120 in./4 in. = 30 lbs pressure that is required to push the beer through the lines without the carbonation leaving the liquid. The cobra tap does not essentially have a pressure drop across it that must be taken into account if you open it FULLY when pouring. If you open it slowly then you are definitely causing the tap to influence a greater pressure drop through your dispensing line and foaming will occur. So get used to opening it quickly and fully.

Subject: Diluting beer ...

>Subject: High Gravity Brewing  
>  
>In an attempt to start a subject that I dont recall reading here in the fairly recent timeframe I am asking for opinions on high gravity brewing. What I mean by this is similar to what the big boys do: Brew a high gravity wort and dilute with boiled/cooled water into the fermenter. Now before you get all upset that this is not the way to make "real" beer, let me point out that I talked to a few brewmasters in the UK who did just this. In particular, the brewer from the Larkins Brewery (located in Kent, took a medal in last years GBBF), told me he brews his ordinary bitter to an OG of 1.055 and dilutes it down to 1.035 in the fermenter. I realize one needs to take into account the additional caramelization in the kettle with the increased sugar content, but has anyone done much of this. I am especially interested in the idea of brewing pale ales of OG 1.065-1.070 and adding water to result in a 1.055 in the fermenter. The entire fermentation would be at the lower gravity. An obvious issue is the pH of the water pushing the wort toward the alkaline side, would the wort be able to buffer a 10-20% water charge? Would typical Sierra Nevada ale yeast be able to work at a slightly more basic pH than a normal wort? IT would seem to me that since kettle size is normally the limiting factor in batch size, this would be a great way to increase volume of finished product. I am fortunate in that I oversized/over engineered my lauter tun to accomadate high gravity brewing, so working with the extra grains is no problem.  
>  
>Comments/experiances?

I'm not sure if many would recommend diluting a beer. However on a partial mash I was shooting for an OG of 58 and ended up with 90. I decided to bottle it and label it as an under hopped Imperial Stout. I did consider diluting it down to 58 but wondered when it would be best to dilute it. What would be the advantage of diluting the beer prior to active fermentation rather than during the secondary phase?

From: "Bill (W.R.) Crick" <heybc@bnr.ca>  
Subject: High Gravity Brewing

Jim Busch asked about high gravity brewing:

We've tried it with good success. We originally did a batch with no sparge, and 4/3 the grain bill ala George Fix's maltiness article in HBD year or so back.

This created Pilsener Noel Premium (PNP), which is a offshoot of Normal Pilsener Noel (NPN). PNP definitely had all the maltiness George predicted. Almost too much. The PNP is more like a Mai Bock, than a pilsener? So we decided to run the same grain bill, that is 4/3 normal, do a sparge, and boil down to a normal batch size. We watered it down 50%, that is total of 150% of normal batch size. Tastes great. I can't detect any bad artifacts of the higher gravity brewing, or the "watering down". No one else has commented on anything unusual either.

Subject: Bits and pieces

Hi ya'll!

Keith mentions:

>Charlie Papazian in TCJOH refers to the dumping of the wort through a  
>strainer  
>into the fermenter to remove the hops and any other particulates as  
>sparging.

And I disagree with the esteemed CP on this. While I'm not one who  
thinks you need to rack off the cold break before fermentation begins,  
I do believe you need to get as clear a runoff as possible off the hot  
break when going to the fermenter.

>This might be the source of the confusion. He also recommends scooping  
>out  
>the specialty grains just prior to the wort coming to a boil.

Hmm... The conventional wisdom here is to remove the grains at 170  
degrees to avoid leaching tannins into the wort. Waiting until just  
before the boil is too long.

Jack says:

> Hmm... Wasn't planning on going to Portland. Hate to make the trip  
>just to  
>keep him honest. Any volunteers to take a brand new MM for the GREAT  
>CRUSH-OFF?

I'll try not to fall into the camp of the humor-impaired here but the  
casual reader and, I'm sure Mr. Listerman, would take offense at the  
insinuation that Dan is a dishonest person. This makes two such  
swipes at Dan in as many weeks. And since he isn't here to defend  
himself, don't you think we can refrain from comments like this?

Nir writes:

>>I'm just back from the UK. The British seem not to mind using plastic  
>>in their  
>>homebrewing. They have a mashing apparatus made of a 20 lit polypropylene  
>>bucket

To which Al responds:

>I suspect that it is Polyethylene (PE), not Polypropylene (PP). I have  
>yet to  
>see anything that's been made of PP that is food grade, so I suspect  
>that it  
>is not food grade.

Al corrected himself later but I've been brewing for years with a  
product that is constructed of HD Polypropylene and I'm still alive.  
:-)

Jim asks about high gravity brewing...

I've been doing some high-gravity brewing at Tumbleweed for the first  
time in my life. Our biggest problem with it is adjusting for hop  
utilization. We had much better hop character to our beers when we

did full gravity boils. The hop back helps but, again, I got better results from the full gravity brews. Suggestions, anyone?

And then Carl says:

```
>To add my $.02 to the advertising debate; it strikes me as highly
inappropriate
>to advertise on this list. It is a waste of bandwidth for those of us
who are
>looking for an informative forum on tips and techniques. It also does
an
>injustice to those who voluntarily restrain themselves on the list and
actually
>PAY for their advertising. If a product is good, we will hear about it
from
>satisfied customers. 'Nuff said.
```

To which I say, "Amen, Brother". Discussion of products in this forum is expected and should be encouraged. But why not let the customers debate the various pros and cons of a product? I personally think the only time a manufacturer needs to say anything about his product publicly is AFTER a thread has run its course. At that point, one post addressing all the pressing issues would be appropriate. This endless harping, hyping, and mentioning of one's own products to keep threads running ad nauseum is in poor taste, to say the least.

But we've had this discussion before, haven't we?

Cheers!

```

From: rstya@mda.ca (Roy Styan)  
Subject: RE: More Weizen Stuff

The best I've done brewing weizen was to get a 34 pts/lb/gal yield. This was for a weizen bock, and was brewed with a triple decoction, including a 30 min. dough in and 20 min. acid rest. It was a loooooong day - about 11 hours. I now stick with a single decoction and my normal 30-31 pts/lb/gal, using the extra time to sample my wares.

My grain mill is a corona, powered by a 23 rpm motor. I think the low rpms give a better crush than one normally finds on these mills. It is left on the same setting for barley and wheat - breaking a kernel into five or six pieces. Although flour is evident, it does not caused problems with the sparge as long as I go through at least one decoction.

Dan: Please ACK getting this.

Competition Update:

There will be a HWBTA sanctioned competition at the Topsfield fair this September, entry deadline is September 8th. The cost is \$5 per entry or \$ 4 per entry if over five are entered. Prizes in the form of gift certificates and brewing opportunities at local micros will be awarded. Prizes will also be awarded to the first and second place club, a club must have at least five entries. This is a great opportunity to enter a competition, since entries can be dropped off in Topsfield there is no shipping cost. Lee Menegoni will be bringing entries to Topsfield for BFD members. If you have a brew your proud of bring it to the July or August meeting the judges in the club can help pick the appropriate category to enter it in. Remeber to save three for the competition.

Please contact Lee if interested he has entry forms and more details.  
Phone H: 603-881-5227 W: 508-635-6282

HWBTA is the Home Wine and Beer Trade Association.

Club Only competitions:

We need to set up a tasting date, entrants can submit more than one beer but only one per category.

August 9 entry deadline August 9

Weiss is Nice \*\* categories:

Berliner Weisse, Weizen/Weissbier, Dunkelweizen, Weizenbock

Its not too late, the BFD Yeast Bank has a few good cultures appropriate for the Fest style.

October 4 entry deadline October 4

Best of Fest \*\* categories:

Vienna- Amber to deep copper/light brown. Toasted malt aroma and flavor.

Low malt sweetness. Light to medium body. Hop bitterness "noble-type" low to medium. Low hop flavor and aroma, "noble-type" OK. No fruitness, esters. Low diacetyl OK.

Marzenn/Oktobertfest- Amber to deep copper/orange. Malty sweetness, toasted

malt aroma and flavor dominant. Medium body. Low to medium bitterness. Low

hop flavor and aroma, "noble-type" OK. No fruitness, esters

December 6 entry deadline December 6

Poignant Porter \*\* categories:

Robust Porter- Black. No roast barley character. Sharp bitterness of black

malt, without high burnt/charcoal-like flavor. Medium to full bodied.

Malty sweet. Hop bitterness medium to high. Hop flavor and aroma: none to

medium. Fruitness/esters OK. Low diacetyl OK.

Brown Porter- Medium to dark brown. No roast barley or strong burnt malt character. Light to medium body. Low to medium malt sweetness. Medium hop bitterness. Hop flavor and aroma: none to medium. Fruitiness/esters OK. Low diacetyl OK.

Date: Tue, 29 Jun 93 10:39:32 PDT  
From: nexgen!bart@olivea.ATC.Olivetti.Com (Bart Thielges)  
Subject: storing kegs and sanitizing fermeter lids

Here's a few of questions for the experts :

- 1) I haven't been able to find a good way to immerse my fermeter lid (a 5 gallon white plastic bucket with snap on lid) in the sanitizing solution. I can distort the bucket and jam the lid in part way, but this could scratch the sides of the bucket and besides does not totally immerse the lid. Also, I don't have any other vessel larger than the bucket. I've been splashing the sanitizing solution all over the lid in the hopes that the contact time is long enough. Is it ? Do I need to buy a larger soaking vessel ?
- 2) I've been kegging my beer (too lazy to clean bottles :-). So far, the one batch that I completed was consumed all at once during a party. However, I imagine that it would be nice to keep a keg around for longer periods of time. I use CO2 to pressurize so oxydation isn't a problem but I don't have enough `fridge space to keep the keg upright and cooled down for extended periods. Will repeated cycling between 45F and 80F spoil the flavor ? I'm not really concerned about any visual effects, only taste.
- 3) I bought a used and dirty Cornelius keg. I scrubbed the interior out as well as I could. Now, I'm worried whether there might be built up crud in the feeder tube or the hose fittings. Would you recommend disassembly and cleaning ? I've circulated sanitizing solution through all of these parts.

advTHANKSance,

Bart Thielges

Date: Mon, 28 Jun 93 15:42 CDT  
From: korz@iepubj.att.com  
Subject: How not to make fruit beer...

I have the fortune of having married into fruit trees. What I mean is, that my new in-laws have two cherry trees in their yard and they haven't been bothering to pick them, so I can have them for the trouble of picking.

Last year, I watched half of the cherries get eaten by birds and plotted a way to keep all the cherries to myself this year. This last weekend, I decided to build a cage around the trees to keep the birds out. The cherries on one tree were almost ready but on the second tree they were still quite green. I decided to build a cage around one tree and then move it over the other one next weekend when the cherries on the first tree will be ready to pick.

The materials for this project (1-by-2s, nails, staples and netting) cost me about \$40. Early Sunday morning, I set out to build the cage. The cage was to be 16 feet long and 16 feet wide and 10 feet tall. Note that this is much too tall to lift over the trees, so that to move it, one side would have to be disassembled and then reattached after moving. Basically, the design was a box frame made of 1-by-2s with "Bird-X" netting stapled to five of the six sides.

11 hours and a hundred mosquito-bites later, I can only say this must have been my stupidest project ever! After 10.5 hours of baking in the sun and getting chewed upon by mosquitos, I determined that I was building a large death-trap for birds (while putting up the netting, several birds flew into the netting and it was a matter of time before one of them got caught in the net and died) and that the benefits were not worth the costs.

Costs:  
Consider that the frame was simply nailed together and therefore damage to the wood from disassembly subsequent reassembly means that the lumber would only be good for maybe three years. Therefore, the cage would cost about \$8 per year in lumber, nails and staples. It took 10.5 hours to assemble this cage, would take probably 4 hours to move it and then another 10.5 hours to disassemble for winter storage. A total of 25 hours. Even at, say \$5.00 per hour, my labor costs were \$125. (Sure, I like to build things, but heck, I could also spend that time brewing!) Total cost per year: \$133.

Benefits:

I estimate that there are about 60# of cherries on these two trees each year.  
The birds get about half, so that the cage gains me about 30# of cherries.

That means that I would be getting 60# of cherries for \$2.22/lb, but I would have to pick them too! Not to mention, I've still got 15# left in my freezer from last year that I didn't have time with which to brew.

I spent the last 1/2 hour tearing down the netting down from the frame and next weekend I'll be taking down the frame. Chalk one up for experience.

By the way, it looks like a good year for Michigan Cherries. They are already in the fruit markets and are priced quite a bit lower than last year: already-picked are running \$1/lb, whereas u-pick last year were \$1/lb.

Date: Tue, 29 Jun 93 12:43 CDT  
From: korz@iepubj.att.com  
Subject: Specialty Products Intl. part 1

A number of weeks ago, someone posted the name of a supplier of inexpensive malt extract called: Specialty Products Intl. If you are like me, you called and recently got their booklet called "Home Beermakers Guide." This booklet was written "BY LEIGH P. BEADLE, AUTHOR OF THE BEST SELLER Brew\_It\_Yourself\_" a book that was "reviewed" (quite unfavorably) here on the HBD a few months ago.

First off, I'd like to post a disclaimer:

I am a homebrewing supply retailer and mailorder business owner which does not carry the products marketed by Specialty Products International, HOWEVER, these products are available to me for wholesale purchase, so it is by choice that I do not choose to stock them -- in other words, I am not really in competition with SPI. They would have my wholesale business if I felt they had a good product.

If you have received this booklet and are a relatively experienced brewer, then you probably got a few laughs out of it. If you are less-experienced, then you may have been confused by this book, which is the sole reason for my posting this review.

Pg1:  
"Hundreds of commercial breweries flourished in America around the turn of the century, and beer-lovers could choose from a variety of lagers and pilsners. There are now only 50 left and within a few short years there may be only five remaining."

Indeed, there were hundreds of breweries around 1900, but "lagers and pilsners" [sic] were not the only styles they brewed. Back then, ales were quite popular also and many styles of ale were available to the beer-lover. By the way, pilsners ARE lagers, just one specific style of lager. Fear not, the numbers of breweries in the US are growing, not shrinking.

"It takes only about thirty minutes to mix the ingredients, and a week later, another thirty minutes to bottle and cap, with nothing to do in between."

I'll address the boil time issue later, but unless you're not sanitizing and you're using 1/2 gallon bottles, bottling will take you over two hours.

Pg2:

"The single stage fermenter, developed since my previous books on home beer-making, is a great improvement in equipment. It is made of FDA food-grade polyethelene..."

Will the wonders of high-technology ever cease! Will you look at that! As a by-product of research done for the Space Shuttle project, single-stage fermenters are now available to us lowly homebrewers. By the way Leigh, that's "polyethylene."

Pg3:

"Since the fermenter is filled with CO2 gas the beer is protected against spoilage because spoilage organisms are air-bourne and cannot live in a CO2 environment."

Yes, unless you count Lactobacillus and Pediococcus and wild yeasts of perhaps 30 species from Hafnia to Bayanus, not to mention Cryptococcus which is water-bourne...

...seriously, molds and two species of acetobacter are the most common spoilage organisms that cannot live in a CO2 environment.

Pg5:

"Always let your equipment drain upside down to dry. After brewing your beer, rinse out your fermenter immediately after emptying it so that the beer does not have time to dry. The same applies to your siphon hose. This way, you will not have to sterilize your utensils each time you use them. It is a good idea to run a solution of Clorox and water through your siphon hose and also your fermenter after several batches, again using the above solution of one tablespoon of bleach to one gallon of cold water."

Well, I doubt even the beginners on the HBD can see what's wrong with this picture. Yes it's a good idea to rinse immediately and I feel that the concentration of bleach is right, but we all know very well that sanitation is the most important part of brewing good beer and everything that will come in contact with your beer should be sanitized (and rinsed in the case of bleach) immediately before use.

"If you rinse your bottles out with hot water immediately after emptying them, scrub them with the bottle brush and leave them to dry upside down and, finally, store them upside down in their carton, it will not be necessary to re-sterilize or re-clean them prior to the next brewing."

I would venture to guess that the author of this booklet has a gusher at least once in every ten bottles with these procedures. Again, it's great idea to rinse right away, but sanitation is required before use. By the way, that "sterilization" would require the equipment or bottles to be irradiated or autoclaved. What the author surely meant was "sanitized."

To be continued...

Al.

From: Domenick Venezia <venezia@zgi.com>  
Subject: Hangover prevention and treatment

Slightly suffering as I am at this moment from too much Barolo and Port (it wasn't a beer night), I thought I would share what I have learned from some decades of chronic overindulgence in various and varied fermentations.

Metabolism of ethyl alcohol (CH<sub>3</sub>-CH<sub>2</sub>OH) and the higher so-called fusel alcohols (CH<sub>3</sub>-(CH<sub>2</sub>)<sub>n</sub>-CH<sub>2</sub>OH) uses prodigious quantities of WATER and B-vitamins. If one arrives at an Emergency room dangerously intoxicated the first thing one receives is a mega-dose of B-vitamins in the butt or thigh. Since alcohol metabolism depletes one's store of B-vitamins it is very important for us steady imbibers to maintain high body stores of B-vitamins. This can be done through proper nutrition or through balanced, high quality, relatively high dose supplements. It is important that we watch our health because it may seriously affect our ability to drink! Maintaining good body stores of B-vitamins will reduce hangover severity by itself, but personally I pop a couple extra before bed on those nights when I've had a few.

For those of you who are serious physical exercisers (again, general good health increases one's ability to imbibe) know that dehydration leads to headache and nausea. In my opinion it is dehydration that causes these symptoms called "hangover". The solution is in fact a solution. Drink as much water as you can before you go to bed, and drink water through out the night. And I mean QUARTS! Now some of you may think that this would necessitate many nighttime excursions, and you are right. But it gives you the chance to drink more water, and given the choice would you rather be a little tired the next day (take a nap) or hungover?

Finally, Paul Sovcik recently mentioned a greasy breakfast will ameliorate a hangover. I also have found this to be true, though I take issue with the term "greasy". Let's just say "fat containing", such as an egg over medium with a thin slice of sharp cheddar on whole wheat toast.

In summary: serious drinking demands serious training and attention to general health and nutrition; take your B-vitamins; drink lots of water; have breakfast.

From: "Michael Barre" <MBARRE@NOMVS.LSUMC.EDU>  
Subject: Metallic first batch

Thanks Andy, Brian, and Al for your help. The water I used (tap water pulled from the Mississippi River) is definitely hard - 12 to 14 mg/l according to the spring water salesman.

Brian, I did not boil the water, but tried to remove the chlorine before adding the wort by filling the sanitized fermentation bucket with the 3.5 gallons of water two days before the brewing. I removed the lid from this bucket only two or three times during that time, to allow the evaporated chlorine to escape but keep the nasties out. I know two days in a bucket WITHOUT a lid is enough time to dechlorinate my water, from experience with fish tanks; but WITH a lid, I don't know.

Neither did I siphon off the precipitate. The s.g. had fallen from 1.048 to 1.010 (corrected to 60F) within 13 days, at which time I bottled it. I had a lot of precipitate (from hop pellets) in the fermentor. Do you think siphoning into a secondary fermentor would improve the flavor? Should I use a hop bag for the pellets?

Which reminds me, someone posted a question recently about shoving the flotsam back down into the wort. After a week of fermentation I uncovered the wort to scoop some out with my sterilized (boiled for 15 minutes) Pyrex measuring cup to test the s.g. At that time I pushed most of the scum from the sides of the bucket back into the liquid with my sterilized steel spoon. I don't know if that contributed to my problem, but I won't do it again.

When the Ozone man gets here next Monday, I will purchase a glass carboy with zero hardness (according to the salesman) spring water from him. I will use that water and use that carboy as a primary fermentor. I will purchase better (ale) yeast and extract. If I use pelletized hops, I will put them in a bag. I will jug-aerate the water. And, I will use the water-pan-towel-drape fermentator cooler.

I may or may not use liquid yeast, and may or may not siphon off into a secondary fermentor after the fermentation settles down.

Thanks again for the help.

I seem to recall some HBDers complaining that the American Eagle  
dry extract product had significant amounts of corn sugar mixed in  
with the malt. This would certainly make a light beer, but it may  
be better to stay with a quality extract, such as M&F or Laaglander,  
which claims to be all malt.

An OG of 25 and FG of 20 would result in a beer with less than 1%A.  
I suspect that your first batch is okay and that you forgot to  
correct the OG for temperature. For example, an SG reading of 25  
measured at 185F would translate to a SG of ~55.5 at 60F.

>Yeast???? LaChouffe, Westmalle, Duvel? Suggestions excluding Wyeast  
Belgium :-)  
>A combination? I would assume a fresh bottling yeast is required.

>  
I suspect the amount of sugar is too high by about a factor of 2. For  
10 gal., about 2-2.5# of straight candi sugar (if it's light candi), or  
50/50  
sucrose and dark candi would be just about right.

Yeast is a tricky subject. One needs a yeast that can tolerate the  
alcohol, but yet is not \*too\* attenuative. I've used Chimay yeast with  
some  
success (although I still haven't concocted a dubbel or trippel that I'm  
altogether happy with). The yeast was cultured dregs, not Wyeast Belgian  
(which may or may not be Chimay). I've gone as far as 9% with it,  
without  
having to employ fresh yeast at bottling (although your mileage may vary)

.

An acquaintence once tried to culture from the dregs of Duval. I strongly suspect one would have to plate it out, as the starter had a truly \*vile\* odour about it. He \*was\* careful, BTW. However, in a matter of a couple days the starter had a \*strong\* barnyard droppings odour. I've always wanted to try Wyeast European (1338?), but will defer to anyone who has employed it in a strong ale.

Subject: Belgian Tripel Discussion and recipe

Jim Busch asks about possible recipes for a tripel.

The Trappist abbey of Westmalle was the first to introduce the Dubbel and Tripel style. Their Dubbel (1060 OG, 6.5% alc. by volume) is a dark, amber-brown color with a rich maltiness and a hoppy dryness in the finish. A more impressive beer, and one that they are better known for, however, is their stronger beer called Westmalle Tripel. This is a very pale, strong (1080 OG, 8% alc.) ale, obtaining its fermentables from pilsner malts and candy sugar. It is hopped with English Fuggles, several German varieties, and Saaz. After several months warm maturation (50deg F) in tanks, it is re-yeasted and bottle conditioned, yielding a beer of great complexity.

Although Westmalle Tripel is the classic brew, other excellent varieties of Tripel include the Trappist-brewed Koningshoeven, and the abbey varieties from Leffe, Grimbergen, Isebart, and Bruges, among others. They all possess the similar Tripel characteristics of a pale colored, high-gravity, complex Belgian ale.

The exact recipes for the Trappist Tripels are generally a guarded secret. There are those who think that small amounts of herbs and spices are added as a flavor nuance. I know a person who thinks that camomile may be an ingredient, while Jan Knoop, owner of La Vierge, a specialist beer bar in Maastricht, Holland, suggested laurel leaves!

I had never seen a recipe for a tripel until a trip to Belgium & the Netherlands several years ago. There I found several copies of The National Beer Journal, a monthly newspaper published by the Nationaal Biermuseum 'De Boom' in Alkmaar, Holland. In the back of one of them was an article (in Dutch) about yeast, including a recipe for a Tripel.

The original recipe was in Dutch. Here is my translation:

\*\*\*\*\*

Tripel (2.6 gallon): Recipe by D. Walsh

35 oz munich malt  
53 oz pilsner malt  
1.2 oz amber malt  
10.6 oz brown sugar

2.5 oz light candy sugar  
1.4 oz hops (see varieties mentioned above)  
0.11 oz coriander seed  
0.07 oz dried orange peel  
yeast

Procedure: Make a thick mash at 131 deg. F and hold for 45 minutes. Add boiling water until the temperature is 145 deg. F and hold one hour. Raise the temperature to 162 deg. F and wait another hour. Hold at 172 deg. F for 15 minutes. Sparge to collect 3.6 gallons of wort. Bring to a boil and add most of the hops, boiling them for an hour. The sugar, coriander, orange peel and a handful of the hops are boiled the last 5 minutes. Starting gravity is about 1080.  
\*\*\*\*\*

Notes: I have made this beer a couple of times. It yields a beer of lovely complexity. This recipe makes a beer that is borderline too dark for style and I would simplify it by substituting all Pils malt for the darker grains. Also, use corn or candy sugar for the brown sugar if you wish. The hopping rate seems about right if you use low alpha noble hops like Saaz and EK Goldings. The number of IBU's that Jim suggested is somewhat lower than in the above recipe. Some experimentation here may be necessary for your own personal taste.

I think that the spicing is a necessary ingredient and adds interest to the final product. Note that it is used only at the nuance level and in quantities so small that you should use a gram scale for accurate measurement. Do NOT overdo the spices if you use them, you only want a subtle touch.

As for the yeast, you are somewhat limited to what you have available. I agree with Jim that Wyeast Belgian isn't appropriate (too banana-y). I have experimented with Westmalle yeast cultured out of a bottle brought back from Belgium, but it behaved as if it were a bottling yeast. Duvel is also reported to be a bottling yeast. I think that La Chouffe would be a good yeast to try, as might the Celis yeast if you can get your hands on some (they use it for their Grand Cru). Has anybody given the Corsendonk Monk's Pale Ale yeast a try?? The range of yeasts from the New Belgian Brewing Co. in Colorado might also be of interest if you can get your hands on them.

So a 10 gallon batch might look something like:

22.5 lb Belgian pilsner malt  
3.25 lb corn sugar  
2.8 oz Saaz leaf hops (alpha ~ 3)

2.8 oz EK Goldings (alpha ~4.5)  
12.5 grams coriander seed  
8 grams dried orange peel

Assuming 30 pts/lb for the malt and 44 pts/lb for the sugar, you should  
get an  
OG of ~1.080.

Good luck and let un know how it turns out.

Perhaps the brewmasters and food chemists at Anheuser-Busch have worked so hard to remove all traces of beer flavor from their "beer" that they have forgotten how to brew real beer. Actually, the fact that the industrial megabrewers are taking notice of beer with flavor is a good sign. All we have to do now is to encourage the good brewers to keep giving A-B the finger.

From: macdonald@alvax.enet.dec.com  
Subject: Electrim Bin

A few years back I bought an Electrim Bin in Canada. It's a heat resistant plastic pail capable of holding about eight or nine U.S. Gallons, made in the UK. It has a built in heating element, with a thermostatic control with a scale of 1 through 10 I think, with a mark for "boil". I have used it with what I think of as "mixed success" in both mashing and in boiling the wort. In both cases the source of the problem seems to stem from the inability of the heating element to maintain a steady temp. For example, in boiling the wort, it will shut down for a minute or two, the wort will settle back, then it will start up, and the wort will froth and bubble furiously etc etc.

Now, the advantage is that, with the portable Electrim Bin, in the warmer weather I can do mashing and boiling out in my garage, away from the kitchen, where I get complaints from other family members about the odors associated with brewing. I love the odors; the rest of my family do not. They love the final result, just don't like the odors associated with brewing, particularly the hoppy stuff that goes with the boil.

The last brew I made with it was an extract "Canadian Ale" that had the target OG, fermented out in primary and secondary as expected over about 12 days total at normal temps, but wound up with a strong off taste that I can't identify in words, not bad enough to trash, but only good enough for me to drink, and then goes best with some other strong taste, like chile or a pizza with onions or some such.

Also, this batch is a suspect in the "headache" department, though I am still tracking that down as a try a few more bottles.

I haven't kept accurate records, but my sense is that brews I have made with the Electrim Bin have not been as good as stuff I have mashed and boiled on the stove where I seem to be able to keep a steadier temp.

I'd be interested in hearing of other people's experiences with the Electrim Bin.

I have just become a HBD reader in the last three months, so don't know if this is a topic covered somewhere already in the conference. In any case, your experiences would be helpful. I don't want to try using it again if others have also had bad experiences with it especially in boiling the wort.

Regards,  
Bruce MacDonald

Subject: NJ Brewpub News

The bill (A-2354/S-614) to legalize brewpubs in the Peoples Republic of New Jersey has passed the Senate (35-1) and will now go to Gov. Jim (the tax man) Florio for final signature.

I do not know how the original bill was compromised to get through, but there were rumors of very low volumns, no distribution outside brewpub and

a copy of the Pennsylvania law where a brewpub can only serve what they make (ie no other beer, wine or hard booze). The public statement read "The measure (A-2354/S-614) would create a restricted brewing license for places where beer and ale may be produced and sold for consumption and would dedicate the tax proceeds to the prevention of alcohol and drug abuse".

I believe the license fee will be \$1000 and \$500 more for every 1000 barrels to a max of 3000 barrels. One person can only hold 2 licenses and the resident municipality can bar brewpubs, but the brewpub can appeal to the ABC (Alcohol Beverage Control) following a public hearing (ain't politics fun!).

NJ figures it will raise \$22,700 in annual fees based on the national averages of 5 brewpubs producing 950 barrels each.

Three cheers for the sponserers of the bill - John H. Ewing (he also sponsered the homebrew bill that passed last year and came down to NJ's first homebrew contest and had a couple), Walter Kavanaugh and Jack Penn all republicians from Somerset County.

From: Darryl Richman <darrylri@microsoft.com>  
Subject: re: High Gravity Brewing

Jim Busch asks about experiences with high OG brews that are diluted in the fermenter. This is what I do when I make Mild. I recently brewed 12 gallons of wort at about 1.068 gravity and then immediately boiled and cooled an additional 13 gallons of water, to make a total of 25 gallons of Mild at an adjusted OG of 1.032. Caramelization is one factor here, it allows more sweetness to be retained in the final beer (and a higher final gravity -- mine finished at 1.011). Along with caramelization comes increased melanoidin formation with the concentration of reducing sugars and amino acids. This will tend to emphasize the malt character in the beer. (Decoction mashing can have an even bigger role here.)

As Papazian notes in one of his recent columns in Zymurgy, going through the primary at a very high gravity can really enhance the production of esters, leading to a more characterful beer even when diluted in the secondary (or at packaging).

>seen yeast sold in Polypropylene vials.

Al, Al, Al! Don't be so frightened of plastics. Plastics are our  
friends. :-)

Seriously, there is nothing that says that PP cannot be food grade. I am  
holding in my hand right now a drinking cup (actually a beer glass from  
a St. Pat's Day beer wagon) that is Polypropylene. It is made by Comet,  
item PF14, from Chelmsford, MA.

I also don't think that PP yeast vials are going to poison a 5 gallon  
batch.  
Even if the plastic had serious leaching problems (which I doubt), the  
dilution  
after several starter solutions in which the yeast slurry is pitched,  
would  
make the concentration extremely small.

>Jim Busch's post reminded me of one instance of food-grade PP -- those  
>pleated PP filters. Are you sure the spun ones are PP also? In any  
>event, I looked around a lot and called a lot and could not find a PP  
>food-grade vial. Why not HDPE, you ask? Well, I wanted to autoclave  
>it -- PP is autoclavable as is PC (Polycarbonate -- also not food-  
grade).

>Al.

So you bought a filter that was marked food-grade? Hmmmm. Mine from the  
Filter Store Plus was not marked in any way other than their part number.  
Maybe you bought from another source.

Anyway, polycarbonate, also known as Lexan (TM) can be food grade.  
Cuisinart  
food processor bowls are made out of it. Also check out the Superior  
Products Catalog. Many, many of their measuring cups, storage tubs, and  
beer pitchers are made of polycarbonate. The good thing about  
polycarbonate  
is that it is damn near impossible to break the stuff; it holds up much  
better  
than acrylic, and survives industrial type dishwashing.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Zymurgy Article Correction

Keith A. MacNeal asked why my article on dry hopping the recent Zymurgy stated that less hop aroma was extracted from pellets than whole hops. The sentence that probably caused the confusion reads (on page 45): "You will want to use whole hops as opposed to pellets, otherwise you'll still have to let the beer sit with the hops for about two weeks..."

I guess there was a typesetting mistake. The sentence was actually two sentences and should have read:

"You will want to use whole hops as opposed to pellets, otherwise you'll have hop particles in your beer as you drink it. If you force carbonate the beer, you'll still have to let the beer sit with the hops for about two weeks to allow the hop oil to be extracted into the beer."

Of course I wrote this before I discovered that there actually were hop bags that keep the pellet particles contained.

Also, later in the article I say, "Pellets give a better aroma yield because the lupulin glands have been crushed, releasing the hop oil."

I'm going to write to Zymurgy and have them print a correction. BTW, they don't believe in having their authors proof the galleys.

>Subject: What valve/pipe fitting for SS keg?

> What type of ball valve/pipe fittings can be used for a drain on a SS 15.5 gallon keg? What kind of metal can be used? I assume SS would be best, but what about brass or copper?

I spent a lot of time thinking this one through both from the standpoint of the ideal for my own brewery and for something for sale to others with minimum tools or time.

The basic problem presented by everything available is that they are made with tapered pipe threads. Kegs, kettles, etc. are not heavy enough to provide reliable fittings to pipe threads so they must either be welded or a compressing fitting must somehow be arranged.

If one has the tools, this can easily be done by rethreading the parts with straight threads and the two pieces simply screwed together with the keg wall in between and a leakproof and structurally sound fitting results.

As re-threading is difficult enough, I have chosen brass parts over SS but either is appropriate. To further keep it simple, I use parts with 1/8" pipe size because people are more likely to have a 3/8" drill bit in their tool box than much larger ones.

My system consists of an aircock with a male thread that passes through the kettle and a female connector screws on this from the inside. To this is attached the removable copper tubing/ss screen via a compression fitting. For detailed info, email for "easymasher".

>From: Jim Busch <busch@daacdev1.stx.com>  
>Subject: High Gravity Brewing

>I realize one needs to take into account the additional caramelization in the kettle with the increased sugar content, but has anyone done much of this. I am especially interested in the idea of brewing pale ales of OG 1.065-1.070 and adding water to result in a 1.055 in the fermenter.

As I now have a ten gallon keg and only a ten gallon fermenter, I brew and

ferment 8-9 gallons and top off the keg with boiled water at keggling time.

The end gravity is easy enough to predict and adjust for. I don't see any reason to ferment the water and I need the head space in the fermenter.

I don't think this is quite the same as the infamous "beer concentrate" of previous discussions but it is dangerously close. The key lies in what went into the "concentrate" and if it is strictly Reinheitsgbot, when the water is added seems incidental.

>From: korz@iepubj.att.com  
>Subject: DMS and PU

>A few days ago, Jack wrote about his Pilsner Urquell clone that was brewed as closely as possible to Darryl Richman's description of the way Prazdroj Pilsenski (I think that's the spelling?) makes PU.

>Well, last night, I had a chance to try some of this beer. A good attempt, I must say!.....

>The beer had been fermented and lagered at 40F for a while (I forgot to ask how long).

Two weeks primary and two weeks secondary and about a week in the keg.

> Perhaps a longer lagering (and maybe if it was lagered at 32F as in Pilsen) the DMS level would be a bit lower?

I suspect that time is more important than temp but have no way of checking

both. I did bottle a sixpack for tasting in about three months which is what

I recall PU does before shipping.

>From: Darryl Richman <darrylri@microsoft.com>  
>Subject: re: Wort Chilling

>While it is true that the hot, bittered wort at PU is cooled slowly in a coolship, which could engender a great deal of DMS production and retention from latent S-Methyl Methionine (SMM), one must consider that the preceding boil is exceptionally long and it is likely that most of the SMM has already been converted to DMS and then evaporated off (see Fix's "Principle of Brewing Science" for a lot more detail here).

For the record, I boiled this beer for 4 hours just as in your article. I started with 16 gallons of wort and ended up with 7 gallons of beer.

> \*Some\* DMS flavor is, in fact, a defining character of lager beers, and adds to the crisp flavor profile.

As a sequel to the story, we had lunch Sunday with the Parsons from the Malt Shop at Edelweis where PU is on draft.

I bottled two bottles of my clone just before leaving and ordered 4 glasses of PU and two empty glasses and did a real live comparison.

The color was identical. My beer was a bit harsher (for lack of a better term) and the DMS became more obvious if a small amount was left to warm up in the bottom of the Pilsner glass.

We all agreed that the PU was at least marginally better but that repeating the experiment in three months would definitely be informative.

>Japanese Pay \$23,000 to Drink Beer at \$78 a Pop  
> .....

> Beer made in Japan tastes so dreadful that big-wigs eagerly pour into Tokyo's  
>Club Knox, where they can sip beer shipped in from Britain, Switzerland and  
>Belgium.

(Bear in mind, especially Markham, that I know this is a quoted article, so I'm commenting on \*it\*. No flaming diatribe is intended. Thanks for the excerpt, Mark.)

Beer made in Japan tastes "dreadful"? Funny, it tastes like competently-made, lightly-hopped lager to me. There may be some quirky terminology, like "draft" for unpasteurised beer in bottles, or "stout" for pale lager beer with a bit more body than some, but hardly "dreadful", especially in comparison to some of the American industrial beerlike liquids. And then there's Sapporo's "Black Beer", which is most definitely \*not\* dreadful. Sounds like more brewing chauvinism at work here.

>Sure glad we don't have to pay prices like that.

Yeah, so am I. So are most Japanese, 'cause they don't always. I friend brought back a bottle of Budvar/Budweiser, bought at a specialty drinks-shop in Okinawa. He paid an obscenely high Y320 for it - an astonishing \$2.50 a bottle! Yow!

Seriously, the article was interesting, if for no other reason than to display a bit of good old Western cultural bias ("Gol durn, them Japanese sure pay high prices. How can they afford anything?"). The average consumer in Japan deals with high enough prices for many things, but beer is not usually that outrageous, and imports can be found, often in surprisingly good condition and at not-exactly-astronomical prices. On the other hand, a bunch of businessmen with a bit of extra money on their hands seem to have found a novel - and fun! - way of getting rid of it, and at least they're drinking some good beer - although I'm not sure about paying \$78 for a 'vintage' bottle of Gales Prize Old Ale! On the other hand, those entry dues sure are high. Not surprising in a country where business associations often blur the distinction between commercial and social interests, and where memberships in such associations are often perceived as being more valuable than gold.

ObHomeBrew: Because of the Japanese quirk of not letting one brew beer unless one is going to make at least two million hectoliters, an enterprising importer is selling homebrew equipment and kits, with instructions to heavily dilute the malt extract, or to only use a small amount, so it makes a legally "non-alcoholic" beer. Of course, anyone who

actually buys the kit receives subtle verbal advice to ignore the instructions if a proper batch of homemade beer is desired ^\_^.

From: Darryl Richman <darrylri@microsoft.com>  
Subject: re: Raw Wheat protein content

Al Korzonas asks about the correspondence between JX Guinard's quoting of unmalted wheat protein at 1.8 to 2.1 % and the reality that all wheat, malted or otherwise, has more than 10% protein. JX Guinard is apparently quoting the amount of "amino nitrogen," which is often interchanged with protein, and not the protein itself.

(In a very simple chemical assay, protein is made up of carbon, oxygen, hydrogen, and nitrogen. It is the last item that distinguishes it from a carbohydrate, so the nitrogen content of an (organic) substance is taken as a figure of merit of its protein content.)

The ratio of nitrogen to protein mass is reckoned to be 6.25, so the equivalent protein to 1.8-2.1% nitrogen is 11.25-13.75%.

Subject: "Belgian Ale" and Grand Cru

Message Creation Date was at 30-JUN-1993 08:02:00

Greetings,  
I just finished reading Pierre Rajotte's <Belgian Ale>. Great book, but it left me with some questions:

1. Where can I get "Candi" sugar in the US? Any mail order places? If I can't get any candi, any suggestions for suitable replacements? I suppose I could always plan a field trip to Belgium to buy my own 50 lb bag ...
2. It seems like the yeast selection is of paramount importance, yet the book just talks about using an alcohol-tolerant strain. Aside from the Wyeast strain, what recommendations does the net have for appropriate yeast strains?
3. How do I introduce a second yeast? In his Grand Cru recipe, Pierre states, "This recipe is great for two-yeast fermentation. First fermentation takes place with a weak attenuating yeast. In the secondary fermenter, add a second wild type, or different higher attenuating yeast." Aside from leaving my secondary fermentor outside in the hopes of pLambic fermentation, what should I use for a "wild type" yeast?  
How does the second yeast accomplish its aeration phase? Hasn't the first yeast already used up the available oxygen in the wort? Should I just pitch with a HUGE volume of yeast and not worry about yeast propagation?
4. It appears that primary fermentation temperatures are fairly high, while secondary fermentation takes place at relatively low temperatures (for ales). Any comments from people who've attempted these styles?
5. Finally, just how long will I be required to bottle condition my attempt at a Grand Cru? With all the sugar, I get the feeling it might take awhile to smooth out the flavors.

TIA

Andy A

From: "John Shane" <JSHANE@clover.uvm.edu>  
Subject: maple in beer

Hi..

I tried to send this directly to the person who asked about maple in beer, but got an undeliverable mail return, so I thought I'd send it here:

I am a homebrewer and (note the state I live in) a maple syrup producer. YES you can brew with maple syrup. A good ballpark conversion is to remember that a gallon of syrup weighs 11 lbs with a solids concentration of 66% (66.5% in Vermont, ...God we're independent cusses) most of which is sugar of some sort, mostly sucrose. Essentially, you can assume 66% sugar, all of which is fermentable. Syrup gives an excellent flavor to all beers (in my opinion), but some basic advice concerning syrup grades: Fancy (Grade A Light Amber in all states but Vermont (did I mention that we do thing our own way?) is VERY delicately flavored, and will be overwhelmed in almost any beer; Grade A Medium Amber is darker and less delicate, probably good in most lightish recipes; Grade A Dark Amber is darker still, will leave a more perceptable flavor, Grade B is even darker, good for beers with more robust formulations. As a first try, you might want to consider brewing "Rocky Raccoon" in "THE BOOK", replacing the honey in the original recipe with an equivalent (by sugar content, not syrup volume or weight) amount of medium or dark amber syrup. Adjust further attempts to taste. NOTE: unless you spend every waking hour during spring at blast-furnace temperatures boiling sap (about 40 gals sap to 1 gal syrup) to get the liquid gold yourself, this will wind up being a very expensive habit. Good Luck (let me know what you think!).

Subject: Use of Erlenmeyer flasks in brewing

Mike Lemons wrote on the subject of using a 1 liter Erlenmeyer flask and a solid # 9 stopper in yeast culturing:

>"I use 1/4 cup of dried malt extract. I fill the flask up with water to >the 800 ml mark. (1000 ml tends to boil over.) I set it directly on my >gas stove and turn the flame up pretty high. A long glass stirring rod >would be useful for stirring, but I don't have one, so I use a plastic >chopstick. I boil it for about ten minutes, put the solid stopper in it >and set it in a sink full of cold water. (Isn't pyrex wonderful?)"

Pyrex (tm) is wonderful all right, but it is still possible to break it by going from a flame to cold water too rapidly. I'd try to ease the temperature transitions a bit, air cooling the flask for a few minutes before moving it to not-too-cold water. What really concerns me is the practice of stoppering the flask hot and putting it into cold water. If the stopper fits tightly, that will create a partial vacuum in the flask, and standard thickness Erlenmeyer flasks (or any other glassware that has a flat bottom or flat sides) can't handle vacuum very well (you can get thick-walled filter flasks that look like an Erlenmeyer and are made for vacuum use, but they aren't meant to be heated, so that doesn't help). Better to let clean (filtered?) air into the flask as it cools than to run the risk of imploding a flask full of very hot solution. That WILL ruin your whole day.

Happy brewing, Gary Meier

>>>> JORGENS\_DAVID@Tandem.COM writes:

>> Has anyone tried using "real" maple syrup in any recipes?  
>> Are the sugars fermentable? Does anyone have any recipes which  
>> call for maple syrup? How much per five gallon batch should be  
>> used?

I made a batch using grade B maple syrup (about the same price as malt at a local coop food store), used about 3lbs, with 5.5lbs amber M&F malt syrup.

Used the generic 5 gallon beer recipe, except I messed up badly in hop choice/usage, and it was overhopped. That problem has mellowed out, and it

now tastes like a mildly sweeter sierra nevada pale ale, or (pick your favorite amber) hopped up with a nice maple after taste.

Some book (I think it was CJoHB) mentions not to use this much maple. Grade

B tastes similar to grade A (the standard stuff), but definitely doesn't compare well in a side to side comparison (a bit more water and a tad less sweet).

Don't overhop! hops + maple is an interesting combination, and probably isn't for everyone (some friends like it, and others start making gagging noises... typical.)

Brewing is after all a science. It can be treated as an art, but for the best results, you must understand that it is a science and that things that you do at one step will have an impact on another step.

I see a mix of levels here in the HBD. There's nothing wrong with that. I prefer to see the technical side. There's a plethora of literature out there geared towards the general population and not enough good technical info, unless you get into the peer reviewed brewing journals.

> but don't you think it is getting a bit anal, when we start breaking

FROM: Dennis B. Lewis <dblewis@jscprofs.nasa.gov>  
SUBJECT: Yeast culturing slants

I've had a bit of trouble with my slants recently. The poured and cooled tubes look great, but when I inoculate one, the solid wort begins to shrink and pulls away from the sides of the tube. In one case, some yeast got down in the bottom of the tube behind the wort plug and when I opened the cap to relieve some of the pressure, the pressure crammed the wort slug into the neck of the tube!

I don't have my notes, so I don't remember how much agar I put in the wort. (15 gm in 0.5L sounds vaguely familiar.) Could my problem be too much agar? Maybe I should fill my tubes more full so that there is a significant plug at the bottom of the tube. The tubes were clean, but maybe I should give them an acetone bath prior to filling and sterilizing to remove any trace of oils or dust. I'm open to any and all suggestions.

Subject: Blueberries, sparge setups

Edward Croft <CROFTE@delphi.com> says:

> Allan Wright's Amber Wheat Beer fruit base in HB1166. I have been  
> contemplating a fruit beer, and this may do the trick. But, Allan,  
> blueberries in beer? Let me know how that turns out.

Why not blueberries? I made a blueberry brown ale last year that turned out quite nicely. The berries gave the beer a subtle, wine-like character that was very pleasant. The recipe was posted in HBD #926 (July 18 '92) if you're interested.

Jim Liddil <JLIDDIL@AZCC.Arizona.EDU> and "Mark S. Nelson" <mnelson@eis.calstate.edu>, respectively, ask:

> I obtained a straight sided keg from the scrap metal yard this weekend.  
> Now I want to turn it into a boiler/lauter tun. Has any one ever  
> mounted an EasyMasher(TM) on a keg? What other manifold setups work  
> well that can be easily removed?

> I'm a kit brewer second in the feild ready for the grain. Please give me  
> your best advice, I really would like to know how to construct the best  
> system.

There are a number of different lautering options: an easymasher, a slotted copper pipe manifold, a false bottom, a separate double-bucket Zapap-type as described in Papazian. The subject has been covered at various times here, maybe it's time for a monthly FAQ?

Anyway, I favor the slotted pipe setup, since it's completely removable, doesn't require you to drill a hole in your pot, and can be disassembled for easy cleaning. I posted plans in HBD #1099 (Mar 17 '93). The description of the EasyMasher(tm) were originally posted by Jack Schmidling in HBD #754 (Nov 4 '91), and there was a lot of discussion and diagrams during March '93.

From: Domenick Venezia <venezia@zgi.com>  
Subject: WANTED: Fuller's, Full Sail recipes

I'm new to this list and generally new to home brewing, though I have much experience imbibing. I'm looking for recipes for two of my favorite beers, Fuller's Ale, and Full Sail Golden. There's a Full Sail Amber in Cat's Meow 2, and although it is an excellent beer (after at least a month in the bottle) it is pretty far from Full Sail Amber (except the color is right on). I would prefer all grain recipes, but I'll certainly take what I can get. I'm not sure whether posting your responses (I hope there are responses) to the list is appropriate or not, but you can always contact me directly.

So far I'm enjoying the list, though there is considerably more of it than I had anticipated. I have noted that a lot of requests for brewpubs in various locations are posted, and just for the record, I live in Seattle where there are many excellent brewpubs, microbreweries, and ale houses. I would be happy to recommend some if anyone is traveling through.

From: ROSS@mscf.med.upenn.edu  
Subject: Papazian Lambic

Date sent: 30-JUN-1993 13:03:56

I read the appendix concerning Lambic homebrewing in Papizian's new edition of the Joy of Homebrewing, and it sounded very interesting. Basically he suggests warming your dissolved malt extract, pouring into a fermenter, adding some crushed malted barley (to contribute bacteria), and allowing to stand overnight causing souring. The next day you put this back into your brewpot, and brew as normal. He suggests fermenting with regular ale yeast and then adding *Brettanomyces lambicus* and *bruxilles*.

Has anybody actually tried his method. I've been quite successful with many of his other methods. As I only have the time to do extract brewing, his method sounds interesting.

Does anybody know of any sources to purchase the lambic cultures? I know that Alternative Garden Supply (800-444-2837) has *Pediococcus cervisiae* and *Brettanomyces lambicus*. They sell for \$7.45 each plus shipping (I don't know how much the shipping costs). Is this a reasonable price or can I find a better price elsewhere.

Also, if I wanted to experiment and try some small batches, how long can I keep the unused portion of the cultures if kept in a refrigerator.

**Subject: Pressure/temperature relationship**

Someone a couple of issues ago asked what would be the proper pressure to get the same volume of CO2 at a temperature of 70F.

At the risk of getting technical, there is an easy solution given by the ideal gas law. Holding volume and mass constant, the pressure is equal to the original pressure times the new temperature all divided by the original temperature. That is:

$$P2 = P1 * T2 / T1$$

This does not take into account the solubility of the CO2 in the beer, but it should be close enough for your needs.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: HBD soul-searching

In response to Martin Lodahl's post on advertising (and the recent discussion on same), I find the HBD to be one of the best sources on homebrewing techniques, gadgetry, etc, largely because of the sheer amount of information as well as the varying backgrounds of the contributors and the give-and-take nature of the forum. I am not myself a terribly advanced brewer, and as such I wish to point out that Martin's concern for the new brewers taking HBD as gospel (with regard to infomercials etc.) is well worth noting but perhaps overemphasized. From the moment I started reading this forum it was perfectly obvious to me that not everyone knew what they were talking about (with all due respect, y'all). I would think it would be absolutely foolish to read one post on the HBD about any product and run right out and buy the thing. Personally, I prefer to wait for the same topic to recycle itself two or three times (an inevitability here) to consider the subject adequately before making any decisions involving the purchasing of equipment. In the meantime, I still make pretty good beer! Also, I personally don't mind having merchants and manufacturers as contributors, as I find their perspectives valuable; and I'd rather have a straight-out commercial than an insidious thinly-veiled info-mercial, as long as it is done BRIEFLY and IN GOOD TASTE. The taste issue seems to me to be the central one, and many of us obviously have differing ideas as to where the boundaries of good taste may be; but here I would say that if the digest is to continue to be successful, we should continue to be self-policing in this area. The bottom line? I have to throw my hat in the ring with those who do not favor a "ban" on any advertising in the HBD. At the same time, the "industrialists" among us have to understand that they need to make their comments here within the boundaries of brevity and good taste, or folks like me may be turned off and become quite uncharitable with respect to the leeway given to commercial considerations.

Regarding Edward Croft's complaints about overly-technical posts, I have to disagree, for reasons similar to those which cause me to be lenient toward the commercially-inclined. It has also been perfectly obvious to me since I

started reading the digest that there is FAR more information in here than I will ever use. So if some chemists want to get into an arcane discussion I don't understand very well, it's O.K. with me. I can either flip past the articles in question, or just scan for the conclusions without wading through all the data. No, I haven't seen anything to make me change my mind about 1/4 cup chlorine bleach per 5 gallons either, but I am happy that the recent discussion has made me re-think that aspect of my technique a bit. The bottom line? I am damn glad that there are a lot of people reading and posting to the HBD who know a lot more than I do! That's why asking questions to the combined wizardry of the HBD can be so fruitful. If the people who know more than I do (PWKMTID?) were to be constrained to talk down to my level all the time, what would be the point of their contributing to the digest? They are in it for their own edification as well as mine.

To summarize: for me, the more information in the HBD, the better. I don't care whether the info comes from those with commercial motives or those with Ph.D.'s in organic chemistry. In it's present format and tone, I find I can sort out the info I can use pretty well.

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: freezers, maple syrup

For those of you who have chest-freezers with top-opening designs, how do  
get  
the full carboys in and out w/o breaking your backs?

\* \* \* \* \*

There seems to be an abiding interest in maple syrup in the HBD. I  
haven't  
done it, but have often thought of priming a light ale with it. I'm not  
crazy about using large amounts in the boil because of the cost and  
because  
it seems that such a delicate flavor would be destroyed that way. Can  
anybody report on how much maple character is imparted by priming, and  
how  
much syrup to use for this procedure?

Jonathan Knight

| In my wanderings I've managed to pick up a large upright chest freezer  
| for cooling my kegs, as well as eventually becoming a beer cooler.  
| Unfortunately for me, the shelves are fixed, as they are actually the  
| cooling elements..

I have a friend who was given an upright freezer with fixed shelves  
(cooling elements). What he did was remove the door and build an  
extension  
out of wood and insulation. It is now about 2.5 times as deep. The  
original shelves in the back of the freezer now hold beer and wine  
bottles  
and kegs and carboys are in the front extension part. I think he put  
one shelf in the middle of the extension so he could have two levels of  
kegs and carboys (I only looked in it once).

The original freezer has no trouble keeping the larger volume cool enough  
for fermenting (ales and lagers).

Total cost: \$100

From: "David C. Skeldon" (CCAC-LAD) <dskeldon@PICA.ARMY.MIL>  
Subject: CO2 Regulator

I'm currently setting up a keggung system for my beer and I was wondering if there was any reason why I can't use my O2 regulator from my oxy/acetylene setup. If threads are the only problem then I could come up with an adapter but I don't know if there is any difference in the regulator itself.

I was also wondering how long a 5 lb CO2 bottle lasts. I picked up a catalog from superior and there was quite an array of different size bottles.

Thanks for all of the tips/suggestions/help that comes from this forum.

Dave Skeldon: Owner, Operator, and Brewmeister of Wooddale Brewing Co.

>lately is more of a chemistry class on the properties of idophors(?) and  
>chlorine. I can see relating the impact some of the chemicals have on our

I personally enjoy all types of posts from the most basic beginner questions to the yeast metabolic pathway posts. Restricting posts to only practical information (i.e. excluding theoretical discussions or the science of brewing) would be a great loss to most of us. Some beginners will always be overwhelmed by highly technical discussions and some veterans will always be bored by questions like "why should I aerate my wort?" However, unless we continue to cater to both beginners and experts:

1. we'll lose the experts who answer the beginner and intermediate questions, &
2. we'll lose the beginners who will be tomorrow's experts.

>how or why. Why don't the chemistry majors come up with the proper amounts  
>between them and then post the summary. I want to hear more about using wheat

This is what should be done in all cases of high-tech disagreement. As soon as we see an issue getting to be debated on the digest, let's take the issue off-line, debate via email, come up with a resolution and then post that.

>bases for fruit beers, or the proper way to prepare jalepenos for chili beer.  
>I want to hear about the new mini-keg systems, and yes even malt mills. Though,  
>we could lighten up a little with the advertising and sniping.

All one needs to do is ask. If anyone wants to hear more about a particular subject, just post a question -- someone's bound to have some info.

BrewerBob writes:

>I think you may have two problems. The reason for the foam may be too high a  
>dispensing pressure into too small a tube. A 1/4 inch ID tube will cause a  
>loss of

Yes, but I think you have it backwards. If the beer is foaming, then either the beer is overcarbonated, or there is too much pressure when the beer comes out of the tap -- you therefore need to INCREASE the pressure loss through the tube. Either increase the length of the hose or decrease the inside diameter. A very good writeup on this whole subject is in the 1992 AHA National Competition Transcripts by Dave Miller. Just to summarize his article, the proper way to design a kegging system is:

1. choose your beer temperature and the amount of carbonation you want,
2. read the proper CO2 pressure from the table in the article or from HBD backissues,
3. account for pressure drops across valves and set your CO2 regulator accordingly,
4. subtract the losses for faucets and towers from the keg pressure,
5. subtract the losses for keg-to-faucet head (the height difference),
6. subtract the losses for altitude (see HBD backissues), and finally
7. determine the proper size and length of hose so the total loss through the liquid line is equal to the keg pressure.

Another alternative is to do steps 1, 2 and 3 above and then use any hose length and diameter you want, but add an adjustable restriction in the liquid line (e.g. an plastic pinch clamp), near the keg, and use that to create the proper amount of loss in the liquid line.

Regarding force carbonation, you can begin at a higher pressure, but in eventually, you will need to use the tables to determine what pressure you need to use for the temperature you've chosen. Be careful when you lower the pressure at the gauge (release the pressure in the keg first) or you will get a lot of foam and some may travel back up your CO2 line towards the regulator.

>yeast?

At 90F, Wyeast #1007, German Ale, would probably have completed fermenting an average-gravity wort batch, which CITSnow is. 3 days is not an uncommon fermentation time for such a warm temperature. If you can, try to use a lower temperature since the likelihood of off-flavors is increased as the temperature increases. 90F will not kill your yeast unless it is a sudden increase from, say, 50F. By the way, a quick, violent fermentation has been called a "Flash Ferment."

individual  
>preference. I realize that IPA's should be strong and quite  
aggressively  
>hopped, but I didn't know one way or the other about dryhopping. Anyone?

Every judge has their preferences, but the bottom line should be the  
style descriptions for the particular competition. Most competitions  
simply use the AHA guidelines. To the best of my memory, the AHA  
guidelines  
say that a hop nose is acceptable in an IPA, but not required.  
Personally,  
I like IPAs with a hop nose (within reason) and if I was judging two  
beers  
that were identical in every other way, I would score the one with hop  
nose a bit higher. In general, I feel that if a style says that hop nose  
is acceptable, the beer will score higher if it has a reasonable amount  
of  
hop bouquet.

Subject: Talk Techie!

Salutations!

I, for one, enjoy the input these scientists [create and share with the HBD. As an English and Comp Sci major, I don't have near the expertise to calculate flavor profiles or create/critique mathematical formulas for color. I remember once seeing a study someone did about UV rays being transmitted through different color glass. The author included a graph! Great stuff! It is said: Farmers make wine; Engineers make BEER! This is not simple sloppy work we are doing here. We are modern day alchemists!

Yes, I don't understand much of the Brew Techie stuff, but as I make an attempt to do so I learn more about what I am doing and therefore become better at my craft. Indeed, most everyone with access to this forum is in some way connected to some kind of technology--often people working in Universities.

In short, I like the Brew Techie stuff. Thank you and keep up the good work!

From: Eric Wade <ericwade@CLASS.ORG>  
Subject: Legalizing Homebrew

In HBD 1171 Dick Dunn asked when (exactly) was homebrewing legalized. Although he asked for e-mail replies, I did the research so thought I'd take the credit;-).

26 United States Code sec.5053(e) reads, in part, "Beer for personal or family use.-- ... any adult may, without payment of tax, produce beer for personal or family use and not for sale." The section goes on to mention limits (essentially 100gal/person, 200/household). This was enacted as part of an excise tax amendment, Public Law 95-458, 92 Stat. 1255, sec.2(b)(1). The legislation was signed by President Carter on October 14, 1978 (124 congressional Record 38781). Although I don't have the exact time the President signed it, it essentially became effective retroactively to the first moment of the day he signed the legislation (see Sutherland, Statutory Construction, sec.33.10 and 1 USCA sec.106b, note 3).

Also in HBD 1171 Edward Croft calls for less technical postings. While much of the idophor/chlorine concentration thread was above my head, I have no objections. I like to see a variety of information at all levels.

If I don't want to read about blueberry wheatbeer maybe someone else does.

Finally, I'd like to second Martin Lodahl's comments regarding the commercial aspects of HBD postings. There are several contributors who have a financial stake in the homebrew market who manage to keep their postings limited to bettering the process of homebrewing without pushing their products. I, who have no financial interest, would feel comfortable recommending a product if I felt it improved my beer, but I might get a little squeemish about it if I was a close personal friend of the producer.

My \$.02 for the day.

From: korz@iepubj.att.com  
Subject: Re: Westmalle yeast/Styrian Goldings/DMS/Nitrogen levels?

Jim Busch asked about the possibility of using Westmalle yeast.

Westmalle is bottled with a very unattenuative bottling strain and not the primary fermentation strain. It would not be usable for much else besides bottling.

\*\*\*\*\*

Someone else (sorry again) wrote:

>Hops are still under experimentation, but noble hops only. Saaz,  
> Styr-Goldings, Hallertau.

Styrian Goldings are neither noble nor are they Goldings, actually. The only three noble hops (this was confirmed from various sources in the Brewer's Forum) are Hallertauer, Tettnanger and Saaz. Styrian Goldings are actually a Slovenian variety of Fuggles. They are a distinct hop in every sense from both Fuggles and Goldings, but are not related to Goldings other than by name.

\*\*\*\*\*

Another Jim writes:

> According to George Fix in his article on Belgian malts that appeared  
>in Brewing Techniques, the Belgian pilsner malt is low in the precursor  
>of DMS (can't remember offhand, SMM?), so this should'nt be a problem,  
>especially if you adhere to standard procedures for minimizing DMS.  
> The precursor of DMS is a gas that can be driven off during the boil.  
>Use a vigorous boil, and leave the pot at least partly uncovered. When  
>the boil is finished, chill the wort below 140F as quickly as possible.  
>A wort chiller is very helpful here.

You are right in every sense except what is driven off (even your memory has not failed you -- it is SMM). It's the DMS that's created that is driven off in the boil and during the vigorous part of the ferment, although I don't think that either SMM or DMSO (the two compounds that DMS can come from) are gasses.

\*\*\*\*\*

Geoff writes:

Subject: pop bottles

I have seen postings here and in rec.crafts.brewing that mention using plastic 2-liter pop bottles for bottling beer instead of regular old glass bottles.

I bottled one 2 liter bottle worth of my latest, just for an experiment. If it works out, I may do it again.

My question is, how successful is this? When you pour out of the bottle, doesn't all the sediment get kicked up into the beer when you put it back? What can you do to avoid this? Also, doesn't the beer go flat after resealing like pop would? I have a pump gizmo that is supposed to keep pop from going flat (you screw it on instead of the cap and pump air in to pressurize the bottle). Is this gizmo necessary?

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Re : Belgian triples

Belgian triples are not a style I brew myself, but there is an interesting issue of when to add the sugar, if any. With my wines, I've got into the habit of adding a concentrated syrup on about day 5 of the ferment. I may be deluding myself, but I fancy that I get a smoother result that way (ie, fewer byproducts of fermentation). Of course, these byproducts could be just what you want with some styles of brew.

Subject: kegging and temperature

Bart Thielges writes:

"....I don't have enough `fridge space to keep the keg upright and cooled down for extended periods. Will repeated cycling between 45F and 80F spoil the flavor ?"

I can't answer the flavor question but I do have a solution for the fridge space. I bought a small 1.7 cu. ft. (it's long past time for the U.S. to go metric) "dorm sized" fridge and a cold plate. A cold plate is a bunch of stainless steel tubing buried in about 15 pounds of casted aluminum. I keep the keg outside the fridge and have a 1/4" line going into the fridge which is hooked up to the cold plate. The out line from the cold plate is 8 feet of 3/16 tubing attached to a cobra tap mounted on the fridge door. The beer is cooled on demand.

Why 8 feet of 3/16 tubing? For a keg to maintain 2.5 volumes of CO2 (medium carbonation) at room temp requires about 29 psi of pressure. The long tubing is needed to drop the pressure to the proper dispensing pressure so that you don't get too much foam. 8 feet drops the pressure by 24 pounds and the cold plate and the tap drops the rest.

I want to thank John Francisco for his article of a few weeks ago recommending the use of 3/16 tubing to "gracefully" reduce pressure. I was skeptical but admit that it worked better than I could have imagined. It turned my glass of mostly foam into a proper glass of beer with a nice head.

Also, thanks to the 10 or so people who supplied me with CO2 saturation tables when I requested them on HBD. This is a GREAT forum.

From: U-E68316-Scott Wisler <swisler@c0431.ae.ge.com>  
Subject: Defending your cherries

My parent's cherry tree bore fruit this year for the first time that I can remember. I also eagerly awaited the ripening, thinking of a nice cherry brew. I ran into my mom a couple weeks ago and she told me the tree was picked clean overnight - not a single cherry left. She was understandably angry and thought someone came and took them. She considered calling the police ( Please help me officer, someone picked my cherries in the backyard last night and I'm pretty darn upset about it), but couldn't decide how to phrase it so she would be taken seriously. A relative from Michigan said it was birds and draping the tree with cheescloth would do the trick. I'm glad the previous poster decided that 2x4's wasn't such a good idea. Sounds like an engineer with tunnel vision - it happens to the best of us.

On another note, regarding forced aeration. Any of you SCUBA divers out there might consider that dry, clean, and filtered air in your tank. Your low pressure bouyance control inflator attachment might be adapted. I wouldn't go buy a SCUBA tank to aerate your wort, but if you've got one...

Scott Wisler

From: "JSDAWS1@PROFSSR" <JSDAWS1@PB1.PacBell.COM>  
Subject: high-gravity brewing

high-gravity brewing is, I think, very common to beginning brewers. For four years, I brewed 5 gal. batches in a 4 gal SS pot from Costco. I could boil up 3.5 gal of wort, but pre-boiled 2 gal. of water and added it to the fermentor prior to boiling the wort. My Barleywine is fine recipe in the current issue of Zymurgy is testament to the fact that you can brew perfectly good beer with this method. I have freinds who still brew this way (some with even smaller brewpots) and they are making very drinkable brew.

When I went all-grain, I bought an 8 gal. enameled pot and wouldn't go back. The old pot now boils mash & sparge water. The two biggest effects I've seen from high-gravity boils are increased carmelization and decreased hop utilization. But IMHO, high-gravity brewing is a perfectly acceptable way of getting by with a small brewpot or increasing the batch size without investing further in equipment.

| If it's good for ancient druids runnin naked thru the woods |  
| drinkin strange fermented fluids then it's good enough for me. |

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: high gravity brewing

The question I have re. high gravity brewing is whether it is better to dilute before fermentation or after. The main difference as I see it is the effect of high gravity wort on the yeast, moreover on the yeast by-products. Maybe I have this wrong, but doesn't high gravity affect yeast in the same way as high temperature, ie. increased production of esters, phenols, etc., all those "fruity and spicy" things? Another factor is that alcohol level in the high gravity fermentation may kill the yeast, leaving a high final gravity. This may actually be a good thing, as the subsequent dilution will not result in a beer that is too dry.

As a data point, my last batch was a high gravity ferment, split between Belgian ale yeast and Wyeast steam beer yeast. Both fermented from 1.060+ down to 1.014. The Belgian was diluted with .5 gallons of water at kegging, the steam had 2 gallons added. Both were very favorably received. I think I posted the recipe in the HBD a week or 2 ago.

Yes, Glenn, but you didn't mention how to do this... the easiest way is  
to boil and cool the water and then siphon it around as if it was beer  
(so you don't re-introduce the O2 you boiled out).

my  
>question is, will having that large air space be a problem?  
>Does anybody have an opinion about using fresh cherries versus canned  
ones?

I used canned cherries once and there was no aroma left in them. I think  
that fresh is the way to go. By the way, to make 15 gallons of  
raspberry/  
cherry beer, I made up 10 gallons of light ale and then added 5 lbs of  
blanched frozen cherries and 5 lbs of blanched frozen raspberries into  
each of three 5 gallon fermenters. I then siphoned 3.3 gallons of the  
light ale into the three fermenters. USE A 1.25" BLOWOFF TUBE OR YOU  
WILL HAVE AN EXPLOSION THAT IS NOT VERY PRETTY (RED GUNK ON THE CEILING)  
!  
Incedentally, raspberries are much more flavorful than cherries and the  
cherry flavor was not really noticable. 13# of cherries in a 5 gallon  
fermenter is what I used for my pKriek. So for cherries, I recommend  
about 3# per gallon of base beer and for raspberries, about 2# per gallon  
of base beer.

>himself, don't you think we can refrain from comments like this?

I never thought I'd be disagreeing with Kinney and defending Jack, but  
I think that Dan took the first swipe at Jack when he started  
distributing  
a test that compares the Corona with the MaltMill and the Philmill.  
In the test, Dan uses a non-adjustable MaltMill and the results appear  
to show the MaltMill as being about par with the Corona and the Philmill

about par with a textbook crush. I don't think that Jack literally meant to say Dan was dishonest. I've spoken with both Dan and Jack about each other's mills and there is definately a rivalry going. The good part is that the consumer will be the ultimate victor in this battle -- more competition means either lower prices or better quality products or both.

[By the way, screen tests don't tell the whole story -- they don't measure how much pulverized husk material is in the flour.]

From: korz@iepubj.att.com  
Subject: Specialty Products Intl. part 2 of 4

This is part 2 of my review of "Home Beermakers Guide" by Leigh P. Beadle.

Pg6 INGREDIENTS:

"The beer is made from six basic ingredients: water, malted barley, brewers corn syrup, bops, sugar and yeast."

Hmmm? I guess Leigh hasn't heard of Reinheitsgebot (or even Rheinheitsgebot ;^). The fact is that brewer's corn syrup is an adjunct which is quite a bit cheaper than malt extract (\$0.74/lb for dextrose versus \$1.77/lb to \$3/lb for 100% malt extract). Some brewers, most notably the Belgians, use it to make high-alcohol beers without excessive body. An all-malt beer with the alcohol level of Scaldis (Bush) would be like 10w40 motor oil! No, I'm afraid that in this case, it's just to lower the price and raise the profit margin. Excessive corn or cane sugar in a beer will make the beer taste cidery.

"Brewers corn syrup gives body and alcohol and aids in head and CO2 retention."

Typical dextrose-based corn syrup is 100% fermentable (it's all glucose) and thus will only add alcohol and a cidery flavor. It will actually reduce body and reduce head retention. I've never heard of CO2 retention -- perhaps something to do with flatulence. If the syrup does include some dextrans, it will increase body and head retention, but I would venture to guess that production of this type of syrup would be more expensive than malt extract production and thus plain dextrose is probably what is used.

"SUPERBRAU INGREDIENT MIX The malted barley, brewers corn syrup and hops are already blended in the correct proportions in the 3.1 lb can for a well balanced beer. The unique feature of this mix is that you can vary the flavor to exactly your own taste in beer. To do this, you simply extend the boil in Step 1 beyond the standard 2 minutes. A two minute boil will give the flavor of an American premium beer. If you prefer a more European flavor, I recommend a high boil for 10 minutes (watch for boil-over)."

Wow! What a concept?! Seriously, a two minute boil will not give the wort time to isomerize the hops (yes, those lumps in the syrup are hops!), boil off any chlorine in your boil water or coagulate proteins, which can result in hazy beer. I also suspect that they are Chinook hop pellets because that is the only hop pellet that they sell. Chinook hops have been reported here in HBD and other forums as having a harsh bitterness and flavor.

"SUGAR Note that the can mentions the use of either corn or cane sugar. Both give the exact same result so use ordinary cane sugar. It is cheaper and readily available. (For a low alcohol beer of 2%, simply leave out the 2 pounds of sugar in Step 1."

Note also, that in addition to the corn syrup in the can, your are also instructed to add another 2 lbs of cane sugar. I would venture to guess that this brings the maltose level of your wort well below 50%. I would also suspect that at this high a level of corn products, the yeast may have some nutritional trouble with this wort.

Stay tuned...  
Al.

I have a sponge set aside for just sanitizing my fermenter lid when I use the plastic fermenter. With a rubber glove on, I use the sponge to sponge-down the lid. I do this for about 5 minutes then rinse. Actually, if you don't overfill your fermenter the kraeusen will not even reach the lid and if you keep the lid clean, you don't really need to do have it as sanitized as if it was going to be in contact with the beer.

>2) I've been kegging my beer (too lazy to clean bottles :-). So far, the

The temperature changes are not really the problem once the beer is carbonated, but at higher temperatures, the yeast autolyse faster and you may get yeasty or sulphury flavors.

>3) I bought a used and dirty Cornelius keg. I scrubbed the interior out as

> through all of these parts.

I recommend replacing all the rubber in the keg. Most have 7 rubber parts:

the BIG O-RING, the two poppets, the two small o-rings you see on the outside and the two o-rings that slip over the two gas and liquid tubes and sit between the flare on the tubes and the keg (actually, the bottom half of the connector bodies). Oh yes, and I recommend also replacing (if you can) the over-pressure saftey valve. It has a rubber gasket also.

For an ale, I would say no. They spend so little time in the fermenter, that the benefits of a secondary are outweighed by increased risk of infection (especially in the summer) and aeration.

>Should I use a hop bag for the pellets?

I do, but then I also add 10% to Ragers numbers because of it. I add another 10% if I use pellets or plugs.

> Which reminds me, someone posted a question recently about shoving the >flotsam back down into the wort. After a week of fermentation I

I recommend against this. Either Conn or Goeff (sorry, forgot who) collected some of this scum and checked to see if it was soluble in water with (I believe) a little bit of ethanol. The verdict was that it was not soluble. I'm quite sure it's mostly hop bits and hop resins that were extracted from the hops, but did not become soluble.

> through all of these parts.

I'm one of the you-can't-be-too-careful-when-it-comes-to-cleaning-old-kegs  
kinds of guys. One of the results of the great o-ring debate was that  
sometimes you get burned with old o-rings and sometimes you don't,  
depending on whether that old keg had sprite or rootbeer/coke in it. If  
you don't know, toss all the rubber parts and rebuild to be safe.

You DEFINITELY need to disassemble and clean. Personally, I've found  
that  
nothing beats boiling up 5 gallons of a hot B-Brite solution, pouring it  
into the keg and letting it soak. After filling the keg, press the  
little  
valve on the liquid side of the keg and the sterilant solution will fill  
the dip-tube and clean it, too. If you don't, the dip tube won't get  
cleaned and that COULD be very bad for your beer.

Most homebrew supply shops carry rebuild kits. Alternative Beverage in  
Charlotte, NC does for sure. 1-800-365-2739. And I'd imagine Al does.

To: homebrew@hpfcmi.fc.hp.com

Subject: Got a recipe for a Duval approximation, anyone?

A Belgian beer imported to the states called Duval (trans. 'devil'?) has always caught my tastebuds just right. I checked my notebooks/cookbooks and the Cat's Meow, but I didn't stumble across anything that claimed to approximate this one.

How does one go about trying to duplicate a given beer? I don't think my tastebuds are in the league where I can hoist a class and then pencil a recipe. How about you? Have any of you either found a recipe for a Duval-clone or created one and stashed it away in your notebook?

From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>  
Subject: hops storage

Wizards of Wort:

I plan to try using more whole hops in the near future. I have read the info in the hops catalogues of Glenn Tinseth and "Mark from HopTech" - really good info in there, by the way, thanks guys! - and I am beginning, sadly to \*worry\* about storage. I have the freezer space, so temperature is not a problem. Oxygen, on the other hand, is. One of these gentlemen recommends storing unused whole hops in a CO2-purged mason jar; the other recommends "investing" in a vacuum-sealer.

I have neither CO2-capability nor a vacuum sealer. I know CO2 systems are pretty expensive, but I don't know a thing about vacuum sealers. Can anybody enlighten me? I really don't want to sink a lot of dough into new equipment right now. If I plan on using the hops all up within a short period of time will this be o.k.? How long can they sit in a freezer in a non-O2-free environment and still be reasonably fresh? If I can't count on using them up within a short period of time, should I just go with pellets for the longer shelf-life? Please, no pellet-vs.-leaf wars here - that isn't what I'm interested in. Glenn and Mark, if you're listening, I'd love to have you clarify the info on storage in your catalogs, and I'd like to hear anyone else's \$.02 worth as well.

A final question on whole hops: when I used them before I had the devil of a time siphoning the cooled wort out without getting all clogged up, unless I used bags to contain the hops. Are bags o.k. or is there some evidence they cut down on hop utilization? If it is preferable not to use bags, what tricks do people have for siphoning w/o clogging?

Hmm... seems like I have a lot more questions about brewing when I'm not doing any. Maybe now that several of you have encouraged me to go ahead and brew on those cool summer nights, I'll get back to business and stop asking so many questions.

Subject: zymurgy article

As editor-in-chief of zymurgy magazine, I am currently in the final stages of refining the articles for our 1993 Special Issue. The theme of this year's Special is the traditional brewing techniques of England, Germany and America.

I am currently looking for someone to cover two subjects in the English culture section:

1 Homebrewing in England -- an overview of what it is that makes this brewing specifically English. This could include trends, popularity, styles, etc., and

2 English Brewing History -- For the other two cultures, this subject covers the basic history and includes ingredients, development, style, trends, etc.

I know you all are the experts, so I am turning to you for assistance! If you're interested, either send me a note through C\$S (75250,1351) or call me at (303) 447-0816. Deadline for these articles is the week of July 20 and length is up to the writers -- I just want the subjects covered.

I look forward to hearing from you!

All the best, Elizabeth Gold

This is such a good observation. There are many simple, yet unanswered, questions posed to the HBD. These are the kinds of questions that one would think were answered years ago by a brewing scientist working for a big brewery. But your observation hits it right on the nose: the big brewing scientists are busy answering questions that are more appropriate to "big brewing". As small scale brewers, we have quite an opportunity here!

Subject: Small Batch too much air? NO!

Salutations!

Someone wrote in July 2nd's HBD wondering if 3 gal of beer fermenting in a 6 gal carboy would cause problems. I assume the person was worried (GASP!) about oxidation. The CO2 produced by the beer is heavier than air and will blanket the brew. No need to be concerned. I would recommend using a starter batch of yeast to get the fermentation going faster. Good luck!

>If I use pelletized hops, I will put them in a bag.  
>I may or may not use liquid yeast, and may or may not siphon off  
>into a secondary fermentor after the fermentation settles down.

First a disclaimer. Although I do sell hop bags that keep pellet particles contained, I'm about to *\*not\** recommend them for Michael's usage.

I assume your problem with the hop pellets is the particles getting into your finished beer and that you want to use a hop bag to prevent this from occurring. While this will certainly do the trick, it will also cause other "negative" effects. Most importantly, your hop utilization will suffer (meaning that you'll get less bittering power). Also, there are many benefits to be had to the wort by having the hop particles (whole or pellet) thrashing around in the wort during the boil (help with protein coagulation - aka the hot break) is the main one. Sorry I can't give you a number on how to adjust your utilization downwards, there are just too many variables, which brings me to my next point: The hop particles will expand quite a bit when they get wet, so make sure you don't over-fill the bag while they're still dry. To give you an example, we sell a 4x6" hop bag and we recommend only 3/4 of an ounce maximum amount of hop pellets in that bag (which is a *\*lot\** smaller than 4x6" when dry). This amount of hops will expand to fill the whole bag. Utilization will suffer because the wort can't get to the hops easily.

Anyway, I recommend you do use a secondary and rack carefully. The two step racking process should leave all of the pellet particles in the trub layer on the bottom. This is instead of the hop bag. The hop bags are great for dry hopping, but I don't like them for the boil. Also, your racking techniques will improve with time. The key is to have a reliable way to suspend the end of the racking tube just above the trub layer. I use a rubber stopper

that fits in my carboy with two holes in it: One for the racking tube and the other I use to force CO2 into the carboy (at \*low\* pressures) to push the beer into the secondary (I use a soda keg for the secondary). If you don't have the CO2 around, you still need the second hole to allow your siphon to work. There are these orange carboy caps around that do the same thing, but make sure they fit your carboy before you buy one (mine didn't!). You can also use Kinney Baughman's BrewCap system if you want the cadillac system. Lastly, I have had success with the racking tube securely rubber-banded to a clothes pin (with some extra rubber bands to make it close tighter) and then clip this to carboy neck. The problem with all of these is that you usually can't see the end of the racking tube once it's in the beer. The answer: a ruler. Measure from the top of the trub layer to the carboy neck's top, and then measure your racking tube to figure out where on the tube you'll have to line up with neck top. As the beer gets close to the tube bottom, you can usually adjust the tube bottom downwards now that you can see it, so err a bit on the high side when setting the tube depth. BTW, I have found the "orange racking tip" thingy to be essentially worthless. Ditto Fermtech's \$2 racking tube clothespin.

About the scum: You're right. Don't do it again. This could be responsible for all of the "off-tastes" in your beer. The scum has a lot of hop alpha acids, beta acids and tannins in it, and will also affect your calculations for utilization if you put it back in the beer (you'll get more bitterness, but you don't want it, trust me). If you want a shock, taste some of it.

Liquid yeast: Yes. Make the switch. You won't be sorry.

Date: Thu, 1 Jul 93 19:15:35 PDT  
From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Mash Question, Crazy Grain Mill Idea

Having just made the switch to all-grain about four batches ago, I have a question for the more experienced mashers:

I have always adjusted the mineral content of my water "to style" using gypsum, epsom salts and sodium chloride. Since going all grain, I have adjusted the mash water and sparge water in proportion to their volume, without any regard to their pH - mainly because the pH test strips I bought (pHydrion 5-7 range) are junk and I haven't bought any replacements yet. Basically I decided not to worry about it.

I have always gotten decent extractions (except my first batch because I didn't grind the grain fine enough). My latest pale ale got around 32 pts/lb/gal. I just did another batch, but decided to leave out any mineral additions to see if it would make any difference to the taste of the beer. Things proceeded fine but my extraction was down around 28.5 pts. Could the higher pH of the water (because I didn't add any gypsum) make that big a difference, or was I just lucky before? BTW, I use EBMUD water, which is pretty good quality "soft" water and I use a single infusion "picnic cooler" mash/lauter tun. Mash temp for both batches was around 154F, sparge temp of 170F.

Grain mill "crazy" thought:

The other day while waiting in an office supply superstore for some copying to be completed, I was wandering around and happened into the "paper shredder" section. One happened to be at the right height for me to look down into its jaws (it was on top of a trash can). I had always assumed these things had blades in them, but they actually have little wheels that look like 1/4" wide mini rollers from a malt mill, grooved and all. The spacing between the rollers seemed about "grain width" and I wondered if one rigged a suitable hopper if these things could be used as a motorized grain mill? The model I saw had plastic rollers (may not last too long with grain) but some of the more expensive models had metal rollers. The cheapest ones were in the \$50 range, the most expensive around \$100.

Now: Not wanting to sneak a handful of grain into the office supply store to try them, does anyone on the Digest own one of these things and be willing to try some grain and report back? If it works, this might be a nice already motorized malt mill for not much money.

(Warned you it was crazy)

Mark

> have forgotten how to brew real beer. Actually, the fact that the  
> industrial megabrewers are taking notice of beer with flavor is a good  
> sign. All we have to do now is to encourage the good brewers to keep  
> giving A-B the finger.

My first reaction was "right on!" but then I had a second thought. Here  
are some data points:

Jim(tm) Koch(tm) and his gang of contract brewers did a truly wondrous  
thing for this country. They made a very high quality beer widely  
available to the mass market. That's GOOD!

The last time I passed through the Denver area, I drove out to Golden  
and had some fresh Coors Winterfest at the brewery tasting room. It was  
absolutely outstanding. Even when I see it at my local supermarket, it's  
not bad, and that's GOOD.

Miller is apparently trying to do the same thing on a larger scale  
with their new Special Reserve Amber (disclaimer: I haven't had the  
opportunity to try it yet, so the jury is still out). Again, that's  
GOOD (at least from the reports I've been seeing).

The last time I heard a statistic, all the microbreweries and all the  
brewpubs and all the homebrewers in America put together only made  
a small fraction of one percent of the output of the big 3. They have  
nothing to fear from us, and the renewed interest in GOOD beer can  
only help the big guys by making their "pasteurized processed beer  
product" more popular.

So far, the big guys haven't done anything to the little guys in  
this country except recognize the competition and try to compete  
fairly. Since positive reinforcement generally works better than  
negative, maybe we should be telling the big guys how much we appreciate  
their efforts to improve quality. Saying "I'll buy this new product  
you make" rather than "I won't buy this old swill you make" seems like  
it would have a greater effect.

And yes, I think it's essential that A-B keep its grubby fists off  
the real Budweiser Budvar brewery!

Subject: Orange peel in Belgian brewing

Steve Stroud's excellent post in Friday's HBD prompted me to write regarding on ingredient that he mentions: orange peel.

I think the concensus is that brewing Belgian-style beers is tough to do, and I'm sure that anyone who's seriously worked on this has had more than their share of disappointments. I know I have. It's therefore with some regret that I must add another complication: there's more than one kind of orange peel being used in Belgian brewing.

The one we are most familiar with, at least by reputation, is curacao or bitter orange (the latter term actually being more common). In its dry state the peels look like they're made of plaster, and dirty to boot. The dried peels are quite stiff, and are more likely to snap than bend. When broken they give off a fleeting but enticing aroma of Cointreau, and when nibbled are noticeably bitter. Brewers who buy the peels in large quantities get them in hunks that represent about 1/4 of a single orange's peel. Bitter orange peel is also available in European herb and spice shops in smaller chips, and can be bought by the gram. I have yet to find it here in the U.S. (and believe me, I've called just about everywhere), and usually people don't even know what I'm talking about. The only people who do are very experienced cooks, who use the peel for certain Provencal meat dishes. I believe these oranges are grown in Spain and Northern Africa.

The less-known orange is called sweet orange. In fact, I strongly suspect that it's not too far from your standard, grocery store orange. These peels come to brewers in spirals, the kind you'd make if you were trying to peel an orange in a single shot. These are more orange colored than the bitter orange, less dry, less aromatic when crumpled, but are also less bitter and more orange-tasting.

I recently was able to bring back a small supply of each from Belgium. The guidelines I received from brewers there are to use the bitter orange in moderation, up to a maximum of 1 gram per liter of finished beer. I think the average use is closer to 0.5 grams/liter. The sweet orange can be used more liberally.

So, what do these do for your beer? We're still in the early experimental stages, but it appear that the sweet orange is what imparts any acutal "orange" flavor. On the other hand, the bitter orange gives no orange flavor or aroma at all, but if I'm not mistaken does provide a very noticeable but mellow bitterness--not herbal at all like hops. I recently made a white beer using only the bitter orange--.75 grams per liter to get its full effects--and found it to be sort of richly bitter but absolutely lacking in orange character. I added the zest of two oranges to teh secondary.

The bad news is that the bitter orange appears to be impossible to get over here, although if you can bring some back it will probaby last you quite a while. The good news is that if you can't get the sweet orange you can probably substitue Sunkist zest without losing too much.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: In defense of Jim Koch

First of all thanks to some excellent tips on high gravity brewing (esp D. Richman), and on Tripples. It is subjects like these that keep craft brewing interesting and exciting long after one has become "advanced".

Of note in the discussion is what I believe is a major factor in producing high gravity beers and diluting them, that is fermenting the product at the desired OG and not adding water to the finished ferment. I am not doubting the experience related on the diluted Pils, but I agree with the concept of a cleaner beer if you ferment at the desired OG as opposed to fermenting and then adding water to the keg. Obviously, if one is aiming for more esters, a high gravity ferment will help.

Tripples: I think the best advice is to use all Pils malt, and 2-4 lbs of sugar noble hops and a clean high gravity yeast. We are currently experimenting with LaChouffe so this is a definite possibility. A test of Duvel and Westmalle cultures might be in order also.

In defense of Jim Koch:

Despite the well known negative aspects of the BBC and its relations to other craft brewers, I want to praise him for building a world class brewery in Jamaica Plains. While I have not personally visited the site (yet), a noted brewmaster friend has just returned with rave reviews of the equipment and dedication of the staff. Apparently both kettles are fired allowing full decoction mashing to be done. The variety of beers produced here is enough to make any homebrewer at home. Apparently a super bock of some 40% ABV was made and stored in old Jack Daniels Whisky barrels! The report indicated a distinct "whisky/oak" character in the sample. The brewers are free to experiment and get feedback from the clientel. It is in this way that some really good recipes are developed and only after adequate market tests are then contracted out. From a pure brewers point of view (no buisness men around) this is what we need more of in small craft breweries in the US. It takes some risks to produce some winners.

Good brewing,  
Jim Busch

PS: I am interested in personal experiences with home made and dispensed cask conditioned ales. If anyone is using isinglass and a beer engine, email me with details and experiences. Thanks

Subject: High gravity brewing

All my beers are high gravity brewed.

I'm an all grain brewer without the 10 gallon stainless pot. I have one of those 5 gallon (or is it 33qt?) enameled pots. I mash in a 3 gallon Gott round insulated picnic drink cooler (can only hold 9 lbs of grain, if I was buying one rather than using the one I already had, I'd go for the 5 gallon version). I sparge in the same cooler using a false bottom.

Due to the small size of my mash tun, I tend to have thick mashes. My process is to put all the grain in the cooler, and add mash water to fill it up, stirring along the way. I almost always do a protein rest, then put it all into my brew pot to bring it to mash temp. This process lets me maximize the water in the mash (since I fill up the cooler) and lets me stir the whole thing well (in the brew pot).

I usually get 28-30 points per pound (a new brew unit, the ppp?), with the lower rates for high temperature sweet mashes, and high rates for lower temp drier mashes.

I recirculate til clear, then sparge with lots (note no measurement) of hot (75-80C) water, and keep going until the brew pot is nearly full of sweet wort. After the boil, I usually have about 3 - 3.5 gallons of wort which I cool using a counter flow / ice bath chiller. I top up to 5 gallons in the fermenter.

Due to the limitation of 9 lbs in my mash tun, my OG's tend to be below 1.055, but at the 3.5 gallon stage they are as high as 1.075. I don't make any corrections for hop utilization, etc.

I like my beers, so I guess I have the perfect brewing system (BrewPerfect tm?).

Mike Schrempp

If I can't even smell my own bad breath, how can I tell if my beer is bad?

From: jdg@cyberspace.org (Josh Grosse)  
Subject: re: Electrim Bin

In HBD 1173, Bruce MacDonald complained that he doesn't like the beers he makes in his Electrim Bin, and complains of an off-flavor. He wonders also if temperature control may affect it.

Well, I've bin a Bin use for a couple of years, and have been able to make beers without detectable flaws in it. I use a grain bag for mashing and sparging. Bruce didn't say if he uses one as well. If he doesn't, and he isn't stirring continuously, non-stop, without a break, he can scorch grain against the heating element. This may be the cause of the off-flavor.

I don't have problems with temperature control. I mash in approximately 3 gallons (imperial), regardless of the size of my grain bill. I stir fairly regularly during mashing. I've stopped using iodine to test my mashes, and every sugar rest runs for 90 minutes

I've also improved my sparging, which now gives me 34 points / us gallon, by ensuring that the grain bed is fully compacted in the bag. I drop the level of wort way down, untie the grain bag and let it settle on the bottom, watch my wort slow to a trickle and clear completely. I then add the wort back in and add sparge water as needed. A sparge now takes 2 hours or more.

If your off flavor is "wet cardboard" or "sherry/winey", your problem may be oxidation caused by aeration of the wort when it's still hot. If you transfer your wort from an un-grainbagged Bin to a lauter-tun, using the spigot, and you "pour" into a lauter tun when mashing on the stove, this difference in procedure could be the source of your problem.

From: jdg@cyberspace.org (Josh Grosse)  
Subject: Bringing beer into Canada

In HBD 1171, Fred Waltman (waltman@bix.com) asked:

>I have a family re-union this summer in Sault Ste. Marie, ONT., and I  
would  
>like to bring some homebrew. Is there any particular problem with  
importing  
>homebrew into Canada or should I bottle it all in old Coors bottles with  
the  
>labels still on <grin>? I would assume that I would have to pay duty  
just as  
>if it is store-bought beer.

This spring I talked to Canadian customs and was told the following:

If it's for your own consumption, and you stay longer than 24 hours, you  
can bring 24 12-ounce bottles with you free of import duty. If you are  
bringing it in as a gift, you can expect to pay between C\$10 and C\$13/  
case,  
depending on value determination. Store bought beer is easy to value,  
homebrew  
would depend on your declaration of strength, I suppose. (Standard,  
premium,  
super-premium? Alcohol/vol? Starting gravity? Customs officer whim?).

Were I you, I'd call Canadian customs in S.S.M. before going, get the  
name  
and title of the person you talked to, and \*bring\* that persons name with  
you when you go, just in case. What I was told may have no bearing on  
what  
happens to you at that border (I'd checked with Customs in Windsor).  
What-  
ever you do, be sure to declare your beer.

From: lfk@veritas.com (Lynn Kerby)  
Subject: Re: Lauter Tun Manifold

>  
>I have a question that I hope someone can answer. I am making a manifold  
for  
>my lauter tun with copper pipe in which I will make small cuts with a  
hacksaw.  
>The question I have is do I make the cuts face up or down or does it  
matter?

>  
Just made one myself a couple of batches ago and I am pleased so far. I  
made  
mine with the cuts facing down, but I suspect that it really doesn't  
matter  
all that much. I suppose I could turn it over and find out sometime.

Are you making a manifold with tees, endcaps, elbows, etc or just a coil  
of  
3/8" copper tubing with some slots cut in it? I went whole-hog and build  
a  
manifold from 1/2" hard copper pipe (I think I saw the original idea on  
the  
HBD a few months ago) that uses 4 tees, 2 elbows, 4 endcaps, some  
reducing  
couplings, a vent pipe riser, and a siphon pipe riser. The vent pipe and  
siphon pipe are soft 3/8" copper. I didn't solder anything, it is all  
just  
press fit with a little crimping/flaring where necessary to make things  
snug.

>Also, what are the pro's and con's to a manifold type lauter tun.  
>

I don't know what you plan to lauter in, but I have had a minor problem  
with  
establishing and maintaining proper outflow rates. I do my lautering in  
my  
mash pot (doing a stove-top style step mash) which is a 6 gallon Vollrath  
pot. At mash-out time, I thin the mash a little more with a couple of  
quarts of sparge water, then I drop my lautering manifold in and start a  
siphon. I siphon off a quart or two, recirculate it and away I go.  
Again,  
the only problem has been establishing a siphon and maintaining a  
suitable  
flow rate. I think I am going to put a ball valve on my siphon hose and  
see  
if that helps any for the next batch.

I suspect that this is a side-effect of my setup, but I don't suck the  
grain  
bed dry anymore. I don't consider this good or bad, just different. I  
have  
been getting excellent yeilds with the manifold, the real test will be  
trying to sparge a big oatmeal stout.

>Any info would be greatly appreciated.  
>  
>Thanks,  
>

>Don Doyle

Hope this is helpful,

From: Paul Gibbs <paulrgb@gibbs.oit.unc.edu>  
Subject: plastics and forced carbonation

I've been seeing a lot of hype about plastics (food grade or not food grade? does it leach monomer in the presence of alcohol?). Recently a brewing buddy of mine has just converted his bottling system to 33 oz seltzer or gingerale plastic bottles(PETE #1 - recycling code on the bottom). These bottles have the following advantages: 20 bottles fit easily into 2 milk crates, so you can bleach and rinse all at once as a batch; 20 bottles holds a five gallon batch w/ less work - you can fill them directly after cleaning/sterilizing, and without removing from the milk crate to cap just screw the lid on snugly. They work like a charm! Also the way the bottle is shaped traps most of the sediment that starts to role down at the end of the pour - also if you don't want a 33 oz belt you can recap for later (half a bottle, or so, is still substantially carbonated the next day).

NOW THE BIG NASTY QUESTION - does it leach monomer? If so, is it a biohazard - brain/liver/genital toxic?

If anybody out there has a decent knowledge of polymers/monomers/plasticizers please write back in to help settle the plastic questions once and for all - it would be great to see a table of suitable plastics to use with beer.

Also, I've been thinking about investing in the 5 liter cans (from brew Ha Ha) - Which I was told are also internally lined with a polymer coating. Can these be force carbonated - if so what does it involve?

by the way this list serve is really well run - I thoroughly enjoy reading  
HBD.

From: Andy Phillips <PHILLIPSA@LARS.AFRC.AC.UK>  
Subject: Re: Electrim bin

There was a query last about boiling in Electrim bins. I have the same problem, namely that the thermostat cuts the power too frequently when boiling, so that the wort never quite reaches a rolling boil. I got around this by by-passing the thermostat. The element socket on my bin (I bought this 10 years ago, here in the UK - yours may be different) fits a standard kettle plug. I connected this to this mains. The only risk is that the element is not designed to take continuous power, and heat transfer from it may also be reduced by burnt-on sugars. However, I've only had one disaster so far - the element failed during a boil, and I had to boil the wort in 1 gallon batches on the stove. Moral: always carry a spare.

Hope this helps

From: chips@coleslaw.me.utexas.edu (Chris Pencis)  
Subject: attenuation and my \$.02

Ok fellow home brewers...(remember this phrase I'll get back to it), I have read Papazian in depth and been reading the HBD for about a month now and I have yet to get a definition of attenuation...something to do with the production from yeast? Please email me your responses on this question - if there's interest I'll post something to be entered into a HBD dictionary reference somewhere.

Ok back to the start..."fellow home brewers" - we are all here reading this digest (thanks go out to Rob Gardner) for one key reason...we enjoy home brewing. There may be other aspects to that: the many year experienced 'philanthropist' type spreading his or her experience through the net, the neophyte (like myself), or others who see an opportunity to generate interest in a product within their core market. Be that as it may, it is quite evident that this bulliten(sp?) is self-policing (I have yet to see evidence of non-self-censorship or people getting kicked off the net), some people do a very good job of letting letting others know that they've gone too far. Problem is, its all just somebody's opinion, so what are you going to do about it anyway.

Bottom Line: be thankful that we have the resource, some of us aren't as thick skinned as others - so take it easy \*please\* - thank you very much for your responses and your time.

Good luck and good beer,

Chris

Subject: Pumps, Farmers, Noble,

>From: Jonathan G Knight <KNIGHTJ@GRIN.EDU>

>For those of you who have chest-freezers with top-opening designs, how do  
get the full carboys in and out w/o breaking your backs?

I rigged up a rope and hook arrangement that didn't work very well and found  
that if I put the keg on a chair and then into the freezer, it was manageable. That is until I moved on to a ten gallon keg. This is going to  
take a few pulleys and a serious hoist.

However, I have a pump to move beer from fermenter to keg so the only reason  
to have to lift it would be to be able to shake it when carbonating. It only  
take a few days to carbonate it at 25 lbs so I have been doing it that way.

I think the pump was one of the best improvements I have made in my brewery  
and it cost nothing. I just removed the one from the sink in my little used  
motor home.  
.....

Just noticed you said carboy not keg. Good luck :)

>From: Gene Zimmerman <ezimmerm@hp.uwsuper.edu>

> It is said: Farmers make wine; Engineers make BEER! This is not simple sloppy work we are doing here....

What is often said, aint always so. Careless, uninformed people can no more  
make good wine than good beer. Being an engineer, I put everything I know  
into both and know for a fact that you only get out what you put in and considering the time invested in a good wine, the rewards can be far greater  
than from a good beer.

>From: korz@iepubj.att.com

>Styrian Goldings are neither noble nor are they Goldings, actually. The only three noble hops (this was confirmed from various sources in the Brewer's Forum) are Hallertauer, Tettnanger and Saaz.

I think a definition of "noble" would be appropriate. Doesn't sound like  
anything a botonist could get a hold of.

Just what does it mean?

Date: Mon, 5 Jul 93 10:52:09 -0700  
From: pascal@netcom.com (Richard Childers)  
Subject: do-it-yourself mash tuns - some pointers

"Date: Wed, 30 Jun 93 12:36:53 PDT  
From: Jurassic Engineer <fecich@csol.enet.dec.com>  
Subject: Homemade Bruheat/HB store in PGH/Advertising in HBD

"I'm looking for suggestions from anyone who has tried to make a home-made 'Bru-heat' type mash-tun. I've located the parts (cooler, 1KW element, thermostat), but I still have a few questions....

">Should the heating element be separated from the grain with screen?"

">I will place the thermostat near the element, but will there be a possibility of wide temperature variations in the grain?"

">Should I include some method of mixing/stirring the grain as I mash?"

--\*--

I see some major problems with a lot of mash tun designs I see posted.

Few of them, for instance, make use of any sort of insulator - choosing, instead, to put the heating element directly in the grain ... as well as failing to circulate the water through which the heat is transmitted ...

There seems to be room for a better design.

Tossing my hat into the ring, as it were, here's a proposal for a pretty good - but purely theoretical, as of this time - build-it-yourself mash tun ... I haven't built it yet, but I've been designing it in my head for a few months now.

(1) acquire two nested buckets

- one, sufficient to hold, say, six gallons
- one, sufficiently larger, that the first bucket can be placed within it, and be separated by at least 1" of air space from the second bucket

(2) assemble buckets, support structures, heating and sensing element(s), circulating element(s)

- cement plastic support structures to bottom of larger bucket ( to support weight of the bucket intended to sit within )
- cement heating element(s) to inside of larger bucket, on side(s), evenly spaced ( more, smaller heating elements, evenly distributed, gives a better overall control of temperature, as well as a degree of fail-safe behavior / redundancy )
- cement circulating pump(s) inside larger bucket, on side(s) - some sort of pump to circulate water

is absolutely necessary to guarantee that pockets of heat and cold do not develop, or that water does not become stratified by temperature.

- cement smaller bucket, atop supports cemented to inside bottom of larger bucket, well centered - note that heating and circulating components are placed such that they can be reached, and not beneath the ( now cemented ) bucket. (-: ( a 1" air space may not be sufficient, and a 2" air gap may prove more desirable. )
- optionally, cement braces along sides to hold the smaller bucket centered, against bumps and such, should it prove necessary to move the masher while it is full of water - be careful not to obstruct water circulation, or reorient circulation to keep this from becoming a problem.

(3) to operate,

- fill air space with water
- adjust thermostat to correct temperature
- turn on circulation pump, heater
- add water, grain to inside bucket, mash

The advantage of this design is a stable temperature - as a great deal of thermal mass, in the form of the water jacket surrounding the inner mash chamber, resists sudden changes in temperature.

Other advantages are the separation of the temperature module, from the mashing module ... and, with the addition of a two lids ( one to close off the mashing tun, and the other to cover the whole thing, and keep the water in the jacket from steaming off - despite this, water will need to be added periodically to offset evaporation ), and a wrapping of thick insulating material, you have a perfect mash tun. No flames, no hot spots, no problems at all.

I haven't solved the problem of circulating the mash yet, but some sort of mechanical oscillator - one suggestion has been a rotating shaft with eccentrically shaped washers on it, another has been piezoelectrical vibrators such as are found in pagers - would suffice, as this would create kinetic waves that would bounce through the solution and disturb any sorts of pockets or stratifications that might develop.

This chamber might also be used to cool the wort, also, by using the outer jacket to contain cold water ... and with the addition of an outlet valve, with a removable rolled-up screen, bent at one end, into a pipe that went through both inner bucket and outer bucket, you could sparge, as well as - after removing the screen and replacing the hot water with cold water

- pour the wort off of the hot break, all very nicely.

This also has room for added control electronics, so it could become half

of a BrewBot, if anyone wants to make an automated homebrew robot. ( Making  
the bottling automated, now there's a challenge ... :-)

**Subject: Keg Information Needed**

With all the talk on the HBD lately about CO2 pressure, I have grown interested in keggering.

I have located five 2.5 gallon kegs at a used restaurant supply house. Two of them have screw-on caps with tapered rubber washers, while three have clamp-type lids with smaller rubber gaskets/o-rings.

There is also a combination of fittings on the tanks themselves, with some having pins, and others having grooves for snap-rings.

I would appreciate hearing from any kegger out there on the relative merits of these various types.

The kegs are pretty crudded-up, but I think they will clean. Are there any fine points to be aware of before sinking money into these kegs?

TIA, and please reply to me with private e-mail, and I will post to the HBD if there is a consensus opinion. Please private e-mail to America On Line if possible.

From: rcristad@weber.ucsd.edu (Riccardo Cristadoro)  
Subject: Dangerous Zymurgy suggestion

I recently purchased a back issue of Zymurgy (Gadgets and Equipment). After reading an article on preserving and freezing yeast by Maribeth Raines Ph.D. I decided to give her suggestions a try.

I only wanted to store my yeast for a few weeks to a month so I followed her directions for storing the yeast in the fridge. I mixed yeast from the primary (British #1098) with an equal amount of a sucrose solution mixed at a ratio of 1 cup of water to 3/8 sucrose. I understand that the article was mostly about freezing yeasts, but she also suggests, "On the other hand, if you plan to use the same yeast within the next few months you can save the yeast from your primary fermenter and store it with an equal volume of sucrose (it's cheaper than glycerol) in the refrigerator. (Zymurgy Special 1992, p. 69)"

The new solution was placed in the fridge in a sanitized and closed glass jar. In a few hours I noticed that the solution was fermenting away. So, over the last few days I have been venting the jar to keep it from exploding. This situation seems quite dangerous. Most of all, I was surprised to see an ale yeast ferment at 38 degrees. Should I take that to mean that I have a wild yeast fermenting away beside the British yeast strain.

Any suggestions are appreciated. Am I doing something wrong? Any suggestions or amendments to the article.

From: Jeff Benjamin <benji@hpfclub.fc.hp.com>  
Subject: Besieged by baleful bacteria

Fat Wanda's Brewery & Recording (my basement) is under attack by vicious bacteria. I've had a recurring house infection that I can't seem to get rid of, in spite of the scourings and bleach treatments. Now it's gotten to the point I can't even get an uninfected starter!

To the best of my meager knowledge, it's some kind of lactobacillus or possibly pediococcus infection. Symptoms are cloudiness, a slight acidic flavor and aroma, and a tan slime on top of the krausen. These all match the symptoms described in Noonan (p. 81).

My starter had been prepared normally, with dry malt and some hops, boiled, put in clean jars, given a water-bath canning procedure, then put in the fridge for a few weeks. I popped a package of WYeast 1056 on Saturday, let it swell for a few hours, then pitched it into a quart starter and capped with an airlock. By Monday, the infection was obvious.

I can't imagine how the infection entered the starter. The airlock stopper? The airlock itself? Are there any beer-loving strains of lacto or pedio that can survive canning? Is there any easy way to ID the exact beasties that are giving me problems, and if I do will it help?

This is really getting frustrating. I now have a batch of porter that will have to sit overnight until the brew store opens tomorrow and I can get some fresh yeast.

From: Kern <IZSJ@CORNELLA.cit.cornell.edu>  
Subject: Wedding brews

While I am here in Ithaca NY trying to get a thesis written by the end of the year, I am also in the process of planning an Oregon wedding for next Spring.

(I fell in love with the place (after working a summer in Portland --it will be

"home" just as soon as I wrap things up here in New York!) We are getting

married at Timberline Lodge (Mt. Hood) probably around the early part of June

or late May '94. The reason I am writing to you all is for some advice. I am

a homebrewer (since my days in Portland) and my fiance and I are avid appreciators of fine brew. Thus, we would like to plan our wedding reception

around beer. Say, for instance, a Duvel-like toast, IPA or an amber during the

meal, followed by something along the lines of a barley wine or Grant's Imperial Stout. I am hoping to work something out with one of the micro-breweries in the area (Widmer, Hood River, Mt. Hood, or even Weinhard?) for

contract batches of both barrels and some custom bottled brews for souvenirs.

(I'm sure it would taste better on the first anniversary than that frozen wedding cake!)

I am pretty sure this is "do-able", but the most difficult part is trying

to coordinate everything from 2,000+ miles away! If any HBDers (esp. you in the Pacific NW) have any clues, advice, hints, suggestions, (ETC..!) I would REALLY appreciate it! Thanks.

From: ron\_hall%80@hp6400.desk.hp.com  
Subject: KQED San Francisco Beer Festival

I am surprised that there have been no posts yet about the KQED San Francisco Beer Festival. Perhaps it is the format of the thing that makes it not get the kind of recognition that the GABF or the Oregon Brewers Festival get, as it may not appeal to some homebrewers.

Let me describe it this way:

Have you wandered into your local import beer shop and said to yourself, "boy, I sure wish I could taste ALL of these beers." Well, you almost can. The format of the KQED Beer Fest is that you pay about \$30 for a ticket, then you get to taste all the beer you can in 3 hours. About 250 beers are represented, mostly imports and microbrews. I can't remember all of them, but Samuel Smith, Paulaner, Bass, Guinness, Anchor, Sierra Nevada, and many others serve their full assortment of brews in

1-2 oz tastes, usually poured from bottles. There are also many free food samples such as french bread, salmon pate, etc., to soak up some of the brew.

I have to admit that I like the format of the Oregon Brewer's Fest better, as it is more relaxed and its outdoors. But I know of no other festival where you can taste the variety of import beers as the KQED. Also, the servers are often volunteers who know nothing about the beer, and the palate tends to become a bit muddled after tasting several hundred different beers :). Nevertheless, I always manage to have a great time.

The KQED Beer Fest is on July 10 in San Francisco, I believe at the Armory, south of Market Street near I-80. Disclaimer: I have nothing to do with this Festival, just thought you should know. Also FYI, KQED is the local public television station.

Bay Area Locals: Please post corrections or more specific info if you know more than this.

From: ek@chem.UCSd.EDU (Ed Kesicki)  
Subject: High Gravity//South Carolina HB

Here's a data point on high gravity beermaking. I did this once inadvertently on my 2nd all grain batch. I managed to make a wort with an orig. grav of around 75-80. I fermented it as such, using Sierra Nevada Yeast.

Came time to bottle, and I got three gallons bottled (out of five total). Then I decided to bring the last two gallons up to three using tap water, added an appropriate amount of additional priming sugar, then bottled.

These beers came out totally different. The undiluted one was very strong and had that winey flavor (similar to bigfoot barleywine). The diluted one turned out to be a reasonably good pale ale. Very interesting. I'd be interested in hearing from someone else who could go through this same simple process and see if my data point is valid. Another good point is that you get an extra gallon without much extra work and without obtaining any larger equipment--and you get two different beers, to boot.

Also, another thing to consider is hop rate. My original wort was well hopped. 11 or 12 AAU's, so the diluted one ended up with a decent bitterness.

Second Thing: I am moving to Columbia, South Carolina in about a month. Anyone have any advice or info on where to get HB stuff around there, either in town or by mail order. I am doing this now in case I don't have internet access there. Thanks.

From: Martin Wilde <martin@gamma.intel.com>  
Subject: Low gravity all grains

This past weekend I brewed an all grain English Bitter (I know English Ale on the 4th of July... flame off...). The target gravity was 1037. I used 1 qt of water per pound and grain. Usually I am fairly good at hitting my target gravities. Most of my batches are OG of 1045 - 1080.

For a 5 gallon batch I collect 6.5 gallons of extract (stopping when gravity reaches 1010). However this time I was only able to collect 5 gallons of extract. I had to add 2 gallons to the fermenter to get the gravity down from 1056 to 1039. What gives? Is this just the results of brewing low gravities and having to top off the boiler with water?

thanks

From: LLAPV@utxdp.dp.utexas.edu  
Subject: orange peels/ranting

Howdy,

In HBD 1175, Phillip Seitz writes about orange peel in Belgian beers. As a point of reference, Celis White is brewed with Curacao peels. They grind it with coriander in a small grain mill. If that's the flavor you're shooting for, that's the orange to use. I have no idea where Pierre Celis gets it from, though.

Speaking of Celis, he sold his small brewery in Hoegaarden, Belgium, a few years back to Interbrew, a huge brewing conglomerate. With the millions he made he was able to set up shop here in the states. If Jim Koch did the same with A-B, maybe it will allow him to do other things in the world of brewing. It certainly will give him a lot of fast capital to work with. And who cares if A-B is brewing Sam Adams? If they stay faithful to the quality (believe it or not, Auggie Busch is big on quality), does it make any difference if Koch or Busch is in charge?

Happy brewing,

>>Should I use a hop bag for the pellets?  
>  
>I do, but then I also add 10% to Ragers numbers because of it. I add  
another  
>10% if I use pellets or plugs.  
^^^^^^^^^^^^^^^^^^^^

This should have read WHOLE hops or plugs. I add 10% for the hop bag  
because  
I contend (and have verified empirically) that the decreased agitation of  
the hops and decreased circulation of wort through the hops when using a  
hop bag require an increase in the amount of hops you use. I increase  
another  
10% when I use whole hops or plugs because I theorize that the  
pelletization  
process exposes a lot more lupulin than is available in whole or plug  
forms  
of hops. Again, I have settled on 10% because my experience, with  
perhaps  
75 batches since I started to make these compensations mathematically  
(instead  
of just targeting for a higher IBU in the formulas), has shown that they  
are  
pretty close -- within the tolerances of my tastebuds. I'd like to  
verify  
these numbers with actual tests, but the cost of these types of tests are  
a  
bit too expensive for me at this time. Perhaps some day.

From: mdcsc!gdh@uunet.UU.NET (Garrett Hildebrand)  
Subject: Re: HBD soul-searching and hops

Regarding Jonathan Knight's HBD 1174 posting on advertisements and technical posts: right on! Well said.

Regarding my Southern California hop garden, the hop cones have just started appearing in the last week. These are Cascade. I recall someone mentioning a while back not to grow hops near roses because the bugs on roses are bugs for hops, too. Well, I have no choice; the only spot in my yard which is good for hops is right next to the roses.

I also have had no problem. I have enough praying mantis, ladybugs and green lacewings running around my yard that little in the way of spray-on chemicals has been required. But there is a reason why one would not want to grow hops near roses which has been brought to my attention, and which I'll share.

If your roses -- or any other plant near the hops -- are being treated with any type of systemic insecticide, then beware, because the systemic in the soil can be absorbed by the hops!

Subject: Re: lautering manifold with siphon

In HBD 1175, Lynn Kerby discusses a lautering manifold in a pot,

>I don't know what you plan to lauter in, but I have had a minor  
problem  
>with establishing and maintaining proper outflow rates. I do my  
>lautering in my mash pot (doing a stove-top style step mash) which is  
a  
>6 gallon Vollrath pot. At mash-out time, I thin the mash a little  
more  
>with a couple of quarts of sparge water, then I drop my lautering  
>manifold in and start a siphon. I siphon off a quart or two,  
>recirculate it and away I go. Again, the only problem has been  
>establishing a siphon and maintaining a suitable flow rate. I think I  
>am going to put a ball valve on my siphon hose and see if that helps  
>any for the next batch.

I, too, have a six-gallon Vollrath. I have been thinking about  
modifying  
it with a valve on the bottom, as has been mentioned by others, and of  
trying out the "easysparge" type of system discribed by js and others,  
but I haven't found anybody to do the welding, and I also don't know  
where to get a suitable stainless valve.

After reading your comments about your lautering manifold and the use  
of  
a syphon, it sounds like you have gotten around the problem of needing  
a  
valve on the pot.

How about a little more detail on how this manifold is set up?

Date: Tue, 6 Jul 93 16:41 CDT  
From: korz@iepubj.att.com  
Subject: Hop bags/mash pH

Mark writes (in reference to not using hop bags for boiling hops):  
>Also, there are many  
>benefits to be had to the wort by having the hop particles (whole or  
pellet)  
>thrashing around in the wort during the boil (help with protein  
coagulation  
> - aka the hot break) is the main one.

Indeed hop particles will help with protein coagulation, but I feel that  
you  
should wait till after the hot break to add the hops in the first place.  
The last time I recall reading about this is in a post from Stuart  
somewhere  
around HBD 1150. My contention, as that mentioned by Stuart, is that the  
hops will do too-good a job coagulating proteins \*AROUND THEMSELVES\*  
thereby  
reducing the utilization. Now, if you wait till after the hot break, I  
suggest that there will still be some coagulation of proteins around the  
hops, but not nearly as much as if the hops were added before the hot  
break.

Why does this matter? Well, the theory is that the protein coagulated  
around the hops will reduce utilization. I have not done side-by-side  
tests of this, but I do recall a significant increase in hop utilization  
when I began to wait for the hot break before adding the hops. I did not  
put the two together till someone on the HBD mentioned it.

>Anyway, I recommend you do use a secondary and rack carefully. The two  
step  
>racking process should leave all of the pellet particles in the trub  
layer on  
>the bottom. This is instead of the hop bag. The hop bags are great for  
dry  
>hopping, but I don't like them for the boil.

I disagree. I do just the opposite. I use a hop bag for boiling  
primarily  
to avoid the problems of having to remove the hops from the wort later,  
either as you pour the wort into the fermenter (my screen kept clogging  
and that made it a real pain!) or when racking. I just compensate by  
adding 10% more hops. I don't use a hop bag for dryhopping but only use  
whole or plug hops because they float. I've never had any problems  
siphoning the beer out from under the whole hops.

>Also, your racking techniques  
>will improve with time. The key is to have a reliable way to suspend  
the  
>end of the racking tube just above the trub layer. I use a rubber  
stopper  
>that fits in my carboy with two holes in it: One for the racking tube  
and  
>the other I use to force CO2 into the carboy (at \*low\* pressures) to  
push the  
>beer into the secondary (I use a soda keg for the secondary).

then later:  
>BTW, I have found

>the "orange racking tip" thingy to be essentially worthless. Ditto  
>Fermtech's \$2 racking tube clothespin.

Interesting, but I've had no trouble with the orange tip on the end of my racking cane -- I tip the carboy with a stack of coasters or a block of wood and then gently lower the cane into the lowest part of the carboy. I then use masking tape or a rubber band to make sure the cane doesn't move. I discard the first two cups or so and the beer runs clear from there on. Perhaps you are not getting a good cold break and your trub layer is very deep. Then again, you've got hops in your trub and I don't.

On a typical 5 gallon batch, my trub layer is about 1 inch thick, say between 0.75 and 1.5 inches. Just for the record, I have not tried Fermtech's racking tube holder.

In another post, Mark writes:

>I have always gotten decent extractions (except my first batch because I  
>didn't grind the grain fine enough). My latest pale ale got around  
>32 pts/lb/gal. I just did another batch, but decided to leave out any  
>mineral additions to see if it would make any difference to the taste of  
the  
>beer. Things proceeded fine but my extraction was down around 28.5 pts.  
>Could the higher pH of the water (because I didn't add any gypsum) make  
that  
>big a difference, or was I just lucky before?

The pH does make a big difference and the luck is that you still got 28.5 points without adjusting the pH. Those enzymes are pretty picky about their environment and you could have gotten much worse than 28.5.

From: RBSWEENEY@msuvx2.memst.edu  
Subject: Yield calculator (tm)

As part of my neverending work to improve the spreadsheet program I use to keep track of my brewing I decided to include an Extraction Rate Calculator (tm) to automatically compute an extraction yield based on the o.g., total weight of grains used, gallons of beer produced (pts/lb/gal). I then decided to go that one better and include a calculation for the maximum extraction rate based on some yields found in Dave Miller's book-Brewing the World's Great Beers (p. 129). These yields in alpha order are:

| Type of malt         | Yield |
|----------------------|-------|
| Black                | 24    |
| British crystal      | 26    |
| British mild         | 33    |
| British pale         | 36    |
| Brown sugar          | 45    |
| Cara-pils            | 30    |
| Chocolate            | 24    |
| Crystal              | 24    |
| Flaked barley        | 30    |
| Flaked maize         | 40    |
| Malt extract (dry)   | 45    |
| Malt extract (syrub) | 35    |
| Munich               | 28    |
| Pale 2-row           | 35    |
| Pale 6-row           | 33    |
| Roasted barley       | 24    |
| Vienna               | 32    |

I can now find the maximum yield for a batch by typing in the type of grain and the pounds used, then use a lookup table to access the above yields in my maximum extraction rate formula. I have also included a formula for the percentage of maximum yield to give me an idea of the efficiency of my mashing/sparging operations. When I plugged some of Miller's recipes from BTWGBs I computed efficiency ratings of between 81-91% of maximum, which is what I got on my last couple of batches. However, since Miller did not include any source for these yields I was wondering if they look reasonable to the informed readers of the HBD. Also he did not include yields for a couple of grains I have used in the past, such as Wheat malt and Flaked Oats and I was hoping someone else could supply them.

In the for what its worth department, on my last batch I used an all-at-once sparging method (you pour in the all the sparge water, mix for 10 minutes, let

it settle and after recirculating until clear, drain the wort into the brewpot) which was described in the FAQ on grain brewing in the archives (sorry, I can't remember by who to give proper credit) and got an 85% yield efficiency. If I can get this high a percentage with this extremely simple approach I don't think I will ever go back to the old way.

I will merrily post any interesting reply results received relative to grain yields. As always, your constructive comments are greatly appreciated.

P.S. Invoking the principle of one CPU, one vote, I would like to see the HBD include less technical ramblings and more investigative reporting (do we have someone watching Koch(tm) full time now?), argumentativeness and flaming characteristic of Phil, Montel, Opera, Hard Copy, Current Affair, etc. Lets quit this polite and informed, but incessant bickering and really spice it up so we can have a forum to be proud of. :)

From: korz@iepubj.att.com  
Subject: Specialty Products Intl. part 3 of 4

This is part 3 of my review of "Home Beermakers Guide" by Leigh P. Beadle.

Pg8:

"PROCEDURE Fill your fermenter with 4 gallons of cold water."

No mention of boiling and cooling, so I'm assuming that plain, chlorinated or bacteria-laden tapwater is recommended. Chlorinated water, if unboiled to drive off the chlorine, can result in chlorophenols in your beer which are detectable to taste at the parts-per-billion level. Bacteria, well, we all know what that will do to your beer.

"Add 1/4 teaspoon of gelatin to the water in the saucepan without stirring, bring to a boil, and turn off the heat. Add a can of Superbrau Ingredient Mix and a level teaspoon of salt to the saucepan and stir until completely dissolved."

Hmm? Gelatin? Salt? My ingredient count is up to 8, how about yours? Gelatin can reduce chill haze if used correctly, but it should be used at bottling time and not boiled -- just raised to 140F to sanitize. Boiling it would render it quite useless for fining-out the tannins that the author is presumably trying to remove. It's true that a little salt can improve flavor (Chlorine ions), but I'd say that this recipe is already beyond help.

"Add 2 pounds of cane sugar (4 cups), and stir until dissolved. Reheat the mix to a boil for 2 minutes, then pour it into the cold water in the fermenter. Stir thoroughly or the hot mix will sink to the bottom. Next, pour a pack of Superbrau yeast into the beer and after 10 minutes, stir thoroughly."

No mention of aeration. To me, "stir thoroughly" is different from aeration.

Even though this is dry yeast that was "imported from overseas," it still requires that the wort be aerated. Again this 2 minute boiling time is a laugh and a half. By the way, cane and corn sugar will, indeed, create the same cidery flavors, but they are not actually the same. Corn sugar is dextrose (glucose) and cane sugar is mostly sucrose. Yeast can absorb glucose directly, but sucrose is a glucose molecule bonded to a fructose molecule and thus must be split outside the yeast cell by an enzyme that yeast release (whose name escapes me at the moment) before being absorbed by the yeast.

Pg9:

"To carbonate, add on-half teaspoon of white household sugar to each of your clean 12 ounce bottles. You will need 48 bottles. Use a small funnel and 1/2 measuring teaspoon."

No mention of sanitizing the bottles, spoon, funnel or the sugar.  
Bacteria  
and wild yeast can and do exist on clean glass, spoons, funnels and in  
sugar. Besides being unsanitary, inconsistent carbonation can be the  
result of this procedure, not only from inconsistent amounts of sugar,  
but  
also from incomplete dissolution of the granular sugar. No, a much  
better  
way of priming is to siphon into another food-grade vessel and add a  
measured  
amount, 1/2 to 3/4 cup dextrose boiled in a cup or two of water.

To be continued...

Al.

From: pohl@unixg.ubc.ca (Derrick Pohl)  
Subject: Hops: Growin' & Dry

Two points re hops - one a question, the other a report:

1) Growin' Hops

I planted two rhizomes about six or seven weeks ago, received from a mail order company. One was Nugget, the other Centennial. Nugget sprouted and is doing well, but no sign yet of Centennial. I followed the accompanying directions, i.e. planted upright with the top of the rhizome about two inches underground. I'm sure neither was planted upside down. Both had small traces of some sort of mold growing here and there on the skin of the rhizome (they were shipped wrapped in plastic bags). They've had plenty of water and are in a sunny spot, but the soil is not great. Realizing the soil was indeed substandard, I fertilized nine days ago and the Nugget, which had sprouted but was small, responded vigourously. But still, no Centennial.

My question is: is there hope for the Centennial? How long can a rhizome conceivably sit underground without sprouting? Might it appear next year? Or is it now no more than a decomposing stick?

2) Dryhoppin'

Just wanted to report with considerable glee that my first attempt at dry-hopping has resulted in a phenomenally hoppy and delightful pale ale! I think it's the only way to get that bright, in-your-face, almost citrus-like, aggressive hoppiness characteristic of the finest North American microbrew. I threw an ounce of loose Cascade hops into the secondary and bottled nine days later. The hops pretty much just floated on top, even though I tried to push them down a couple times with a sanitized slotted spoon, and I was worried that not enough hop flavour would get into the brew, but my fears were groundless. God knows what the hop utilization figures might be (though judging from the recent thread on the issue, even s/he is probably not sure), but the result was exactly the delicious mega-hoppiness I sought. And as has been suggested here, one does obtain a major aroma boost with little additional bitterness. I also had no clogging problems with the racking tube. The hops just floated at the top, and I siphoned the beer out underneath them. I look forward to trying it with my lagers next winter.

So if you haven't tried dry-hopping yet, do it, do it, do it!

**Subject: Oxygenation during secondary rack**

In planning my next batch of beer, the question came up as to the extent of oxygenation when racking to the secondary. Anybody want to estimate the effects? Other than to be as gentle as possible any suggestions to minimize the oxygenation? How about throwing a small piece of dry ice into the secondary, and letting it evaporate. CO<sub>2</sub> is heavier than air and as the dry ice sublimates it should force out all the air. Should I bother?

Subject: Beer in Chicago, Beer at the ballpark (Philadelphia)

From: Matthew Mitchell  
Sorry if this rains on anyone's parade, but I was quite disappointed by Goose Island when I visited Chicago a couple of weeks ago. Granted I didn't get to try the Hopscotch Ale which I was looking forward to (it's my kind of style) but there wasn't anything there that I liked as much as its counter-part which I had had at Dock Street (Philadelphia) the night before. Best example was the weissbier: I actually finished the sampler size at Dock Street the first weissbier I remember finishing|  
Generally, the Goose Island seemed less flavorful.

To change the subject: someone pointed out the micro-brew available at the Stick. Veterans Stadium now has a stand on the 200-level which is exclusively imported beer (and some from Pottsville 8^) Price is \$4.75 a bottle with a couple of exceptions like Sam Smiths. Now I didn't check to see if they actually had everything offered: I'd much rather bring a half-gallon of lemonade (99c) and maybe a flask if I have to have something alcoholic.

Do we need to compile a Ballpark beer guide???  
My recommendation: Blue Hen beer at Wilmington, Del.  
(As I've said before: Lion in Wilkes-Barre is #1 for contract-made beer both the late, lamented Trupert BTW: anyone ever try to match that or get the recipe from Joe Ortlieb? and Blue Hen. Apologies to West End, a close #2, if only because the Saranac they sell themselves)

From: jim@n5ial.mythical.com (Jim Graham)  
Subject: Problems with recent batches---cidery taste

My apologies if this appears twice---it shouldn't. It seems that my first attempt at routing this via a faster UUCP path didn't quite work. :-)

First, some background:

I'm more or less a beginner.... I still brew from kits (or at least, from malt extracts+hops), and can't afford the equipment to go beyond this yet. I've made a fair number of batches, and all (except the most recent two) came out fantastic.

Now, the problem:

My most recent two batches have a cidery sort of taste to them. It's not really what I would call sour, as such, but it is pretty bad. The owner of the local homebrew supply shop tells me that sometimes, you'll get a batch that takes a \*LOT\* longer to age (he said sometimes even 5 weeks---the first of these has now been in bottles for roughly 3.5 weeks), and based solely on my description, he thinks these batches might just need to continue to age.

Btw, both batches have good carbonation, and at the bottling stage, everything seemed perfectly normal (from what little I know, at least).

Does this sound like anything people have seen before? Could these batches have gone bad on me? Does this have anything to do with the fact that the outside temps are no longer just in the 80s and low 90s, but more like 90s, with heat index readings at/near 110 deg. F? I do have central air, and keep the temperature inside at/near 78 deg., but I gather that there's more to it than just this?

Any idea if these batches will recover? What about the batch in the fermenter now? Is it likely to suffer the same fate?

From: waltman@BIX.com  
Subject: Techincal postings, Continuous brewing

As a new homebrewer (8th batch in primary) and a very new HBD reader (1 week, but have been reading archives) I thought I'd add to the discussion of the technicality of some postings. Even though there are many discussions I do not follow AT PRESENT -- as my knowledge of the chemistry and biology of brewing increases I hope to go back and understand them better at a later date. Similarly, I do not now do any kegging of my beer, so I do a quick scan of the posts on that subject, but when I do have decide to take the plunge it will be nice to have this information available. In the mean time, that is why the PageDown key was invented. So keep the technical posts coming and help me changed from a receipe follower to a brewing engineer and scientist.

As for advertising, I do think a policy is required. Some of the posts remind me of the benchmark wars I've seen in other forums. As Mark Twain has been paraphrased "There are lies, damned lies and benchmarks." Announcements of new products by their distributors are great. So are third parties comments of "I used X and it was great" or "I tried Y and it was lousy." Distributors of products should not make negative comments about competing products and personal remarks should be avoided.

On another note, does anyone have any references or information on continous brewing? My father is a mathematician and one class of problems he studies is the theory of chemostats -- which is essentially a continuous fermentor. Private e-mail is fine.

Lastly, thank you to all who responded with advice on my question regarding importing homebew into Canada. I will let you all know how things turned out after the family re-union/

From: hmcook@boe00.minc.umd.edu (Hardy M. Cook)  
Subject: Weissbeir Yeast Cultures

Concerning Dennis Lewis's question about Weissbeir yeasts:

You might try Brewer's Resource at 1-800-8-brewtek for slants of wheat yeasts.

- CL-90 Belgian Wheat -- A top fermenting yeast which produces a soft, bread like flavor and leaves a sweet, mildly estery finish.
- CL-92 German Wheat -- A true, top fermenting Weizenbier yeast, Spicy, clovy and estery. High attenuative.
- CL-94 American Wheat - Offers a smooth, slightly sweet wheat beer, with a full, clean, underattenuated malt flavor.

I have purchased the German and the American but have not had a chance to use these two cultures yet. The other cultures I purchased from BrewTek have worked great.

Hope this helps.

- --Hardy M. Cook  
HMCook@boe00.minc.umd.edu

PS: the German Wheat is a single strain culture unlike the Wyeast variety.

From: WEIX@swmed.edu

Subject: Yeast info, steam beer recipe request, and a chest off-getting.

Thanks to all who responded to my recent request for info on yeast strain variance. Unfortunately the compiled information is greater than 8k which precludes posting it on the HBD whole; however, I found this information to be

of great interest Given the certainty of this topic's reemergence, I was wondering if anyone else would like to see a Yeast FAQ for storage on the archive. I could and would submit the strain variances, proper rehydrating

techniques, and culture methods as a FAQ resource. Can someone tell me how to

go about this or who to contact? If there is no interest in an archive submission, I will chop the info up into 4 sections (Dry, Liquid Ale, Liquid

Lager, and Misc/Wine/Funky\_Belgian\_Fungi/etc) and force it on the digest readership as a whole.

One more request:I wanna make a Steam(tm) beer! I have looked at the recipe in

Papazian's New Testament for The Sun Has Left Us on Time Lager, but am unsure

of the fermentation times. Does one lager a steam beer? How cool does room

temperature have to be? Please deluge me with your favorite award winning recipes! Thanks!

Patrick Weix

UT Southwestern at Dallas

weix@swmed.edu

P.S. Not to start a flame war or anything but why do people submit recipes that they have not tried? I hate to read an interesting recipe only

to see "I'll let you know if this works" or some variant of same at the end.

Show some restraint and tell us if it works after you've had a glass or three!

Glad to get that off my chest!

P.P.S. The above does not of course reply to harebrained ideas about papershredder/maltermills etc. That sort of free exchange of ideas and brainstorming makes the HBD great! (I use harebrained in the best intentioned

way of course >(:p <--rabbit sticking out tounge?!?!).

Subject: Oxidation

Greetings.

There has been a lot of talk about oxidation lately. Would someone be so kind as to give me an explanation of what exactly it is. I realize it has something to do with having hot wort exposed to oxygen (aerated).

Is cooling the hot wort (before adding it to the cold water in the fermenter) the best way to prevent this problem?

Fill me in!  
Thanks

Alex Ramos

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Re: Cask Question

Keith asks about wooden casks. I don't use one myself, but obviously they are not going to hold a great deal of pressure in the first place and, secondly, are likely to lose pressure with time. So you need a strategy in which (a) you are prepared to drink the brew quickly and young and (b) you encourage a prolonged secondary ferment in the cask. My advice would be to use finings both to hasten drinkability, but more importantly, to slow the primary fermentation down before it has gone quite to completion. This seems to result in earlier condition than that which is achieved simply by priming the cask. Lastly, (heresy button on) an attenuative dried yeast could be used to ensure prolonged fermentation.

From: Dave Justice <DD24005@UAFSYSB.UARK.EDU>  
Subject: starters,pH adjustment

Hi all,

I've been reading HBD for a few months now and my brewing has improved as a result. This is a fantastic forum and I wouldn't change a thing. For this, my first post, I have one datapoint and one question.

Datapoint: I've been getting much quicker and visibly impressive yeast starters going by using boiled or canned wort saved from previous (all-grain) batches. I usually pitch the starter before retiring at night and with this method, I'm seeing a good 1/2" to 3/4" krausen in the starter the next morning. No combination of DME and yeast nutrients ever worked this well for me, I was lucky to see any decent krausen after 1.5 days or so.

Question: Lately I've taken to adjusting the pH of my sparge water using acid blend. Exactly what is that stuff? It takes about 3/8 tsp. per 5 gallons to get the pH of my tap water into the 5.5 to 5.8 range. My beers are turning out just fine, but it hasn't seemed to improve my extraction. I think there are other more significant factors at work there.

Comments?

From: gmeier@ncsa.uiuc.edu  
Subject: use of oxygen regulators with CO2 (DON'T).

David Skelton writes:

>"I'm currently setting up a keggung system for my beer and I was wondering if  
>there was any reason why I can't use my O2 regulator from my oxy/acetylene  
>setup. If threads are the only problem then I could come up with an adapter  
>but I don't know if there is any difference in the regulator itself."

I wouldn't do it. I don't know if there is any difference in the regulator itself, but regulators for oxygen service should never be allowed to be contaminated with anything potentially flammable (oil or other hydrocarbons are the most common problem). A contaminated regulator, when put back into service with high pressure oxygen, presents an explosion hazard. Regulators are so expensive that I assume somebody somewhere will hook up your oxygen regulator to an oxygen tank again. In the same issue of HBD, Al wrote:

>"Regarding force carbonation, you can begin at a higher pressure, but in  
>eventually, you will need to use the tables to determine what pressure  
>you need to use for the temperature you've chosen. Be careful when  
>you lower the pressure at the gauge (release the pressure in the keg  
>first) or you will get a lot of foam and some may travel back up your  
>CO2 line towards the regulator."

So it looks like contamination of the regulator is a real risk.

In HOMEBREW Digest #1164, Thu 17 June 1993, we find:

>From: STROUD%GAIA@leia.polaroid.com  
>Subject: brewing capitol of the world  
>

>It is very easy in the current renaissance-in-brewing atmosphere in the US to  
>get wrapped up in our own little corner of the world and think that we sit on  
>top of the best beer. But the truth is that we're not even close. There is  
>high quality brew in this country, but there is also a \*lot\* more mediocre beer  
>being made, whether you're talking the East Coast, the West Coast, or  
>somewhere in between.

Partly true. Microbrews hold a fraction of the market, and the big three or four lager brewers hold a huge share of the market among them. However, in the last 12 years, we've gone from 50 operating breweries in the USA to over 350 - and about 300 of these are putting out some quality products. In terms of volume, the USA is the brewing giant of the world - we 'Merkins brew more in quantity than any other country, although we don't consume more per capita (viz. Germany, Belgium, Czech Republic). In terms of quality, though, we're still re-learning lessons forgotten long ago, a result of Prohibition.

The current wave of American beer-bragging is due to a recent phenomenon - we finally have beer to brag about! For years, Europeans could visit us here, and while we Americans could crow over their material life-style, they could justifiably sneer at the mediocre, flavourless American beers. Now we have good brews again (although some of the praise is not fully justified), and we've come a long way. As local people become accustomed, I hope they'll be able to relax and enjoy the good things being made with a quiet sense of pride. Some of our recent converts to Good Beer still have a bit to learn about the Rest Of The World; just give 'em some time.

>Beer Heaven (and the Brewing Capitol of the World) in undoubtedly located in  
>Europe. I'd nominate Belgium for Heaven, Bavaria for the Capitol, with the  
>British Isles and the rest of Germany as close also-rans.  
>The USA is hardly in the race.

Much has been said about the "beer-belt" of brewing that stretches from the UK across much of north-central Europe. The origins of most of our well-known beer-styles are in these lands. It's kind of ironic to brag about "locally-produced" pale ale, stout, or pilsener, knowing the origins of these styles. We might be able to make a case for Anchor Steam, it being a style all its

own, but most of our beer is derived from some style imported from across the Atlantic. Lager from Germany and Austria, pilsner from Bohemia, bitter

ale from the UK; even our basic barley and hops were originally imports, transplanted here. What was that about "our victuals and especially our ale being spent", entered in the log of a little boat called the "Mayflower". ..?

Hey, we've even imported actual brewers! Does "Celis" ring a bell?

>If you've been to Europe, you know what I mean. If you haven't been there,  
>what are you waiting for?

For a lot of folks, it's a matter of priorities. Raising a family, paying the rent or mortgage, or even a touch of good old xenophobia: all may contribute to settling for what's available in "my own back yard". In some cases, this has eventually hardened into an attitude that it's just plain "disloyal" to consume foreign products, because if it was American-made, it was good enough. Well, it often wasn't "good enough", as GM and Ford discovered in the 70s and 80s, and the big brewers are discovering as they fight for stagnating or declining market share, while the micros keep on growing, and the homebrewers keep on making their own. For those who go abroad, though, visit the old centers of brewing - and take one or two bottles of good New American micro-brew with you, to show the natives that maybe we are catching on, finally. I've done it once or twice.

BTW, beer chauvinism is alive and well in Germany. They don't much care for beers from outside of Germany, with the very occasional exception. Of course, they may just be a teensy little bit justified, at least on occasion, in thinking that their country, especially the southern part, is some sort of center of brewing.

Actually, I keep thinking that my brew-cellar is the brewing capitol of my own immediate neck of the universe (Maritime Pacific and Redhook notwithstanding). Don't all homebrewers regard their cellars this way ... ? ;- )

One of the Boston NPR stations, WBUR (Boston University Radio?) has been running essentially the same event for a few years, calling it "A Brewer's Offering". Part of the price is tax deductible, and you get a free Pilsner glass (at least you did two years ago.)

If you are in the Boston area, 90.9 FM is where you can get details. The event is more conducive to getting mildly trashed on quality brew than it is to actually doing some judging. Noise, banners, munchies, bands playing, CROWDS, more noise, too much to choose from, no space for taking notes. That said, though, it's a fun time for what it is.

I, for one, am heading to Portland this year. See y'all at Tom McCall park...

Dave

Subject: Bruheat etc.

Hey now --

In HBD 1176 Richard Childers described his ideas for building a mash/brew kettle. While this was quite detailed it seemed overly complicated

(maybe a case of overanalysing a simple problem :- ) ).

The final product described in Richard's post sounds suspiciously like a commercial steam jacketed kettle as used by almost every restaurant in the world. These kettles are a double walled stainless steel vessel which circulates live steam through the gap between the walls and are available in sizes from 3 gallon all the way up to 100+ gallons.

I have been thinking that it would make an ideal mash/boil vessel and have been actively searching the used restaurant equipment dealers in the area for one. I have found many in a variety of sizes but they are all a little too expensive right now. In addition, I need one with a built in boiler (not many people have steam boilers in their houses)

this adds to the price considerably. Used kettles in the 5 -10 gallon range

that fit my requirements are available for around \$300-500. I would like to find one for around 100 -150 in fair condition that can be cleaned up.

The principle advantages of using steam to heat your wort are

1. Speed. Since steam has about 6 times more latent heat than water at the same temperature, it will bring 10 gallons of liquid to a boil in a few minutes.

2. Ability to maintain a rolling boil without having to worry about scorching. Since there is a maximum temperature that steam can maintain it is much more difficult to scorch and/or caramelize sugars in the process.

I do see some potential difficulties in trying to mash in this type of vessel though. Since steam is generally much higher in temperature than the target temps of the mash and the heat generated in the kettle is evenly distributed throughout the interior spaces it would be a little difficult to maintain targeted temperatures. Constant monitoring and adjustment would be necessary to avoid overshooting.

i still think that a steam kettle would be worth investigating. Anyone out there with any experience using one is welcome to respond.

Subject: RE: Copper question

Jim Grady writes:

> Well, I have finally started to build a copper manifold and have a  
> question. I see two types of copper pipe in the hardware store; M type  
> and L type. What kind do I want? Do I care?

Well I don't know what the M and L stand for, but last weekend when I was constructing my copper manifold, I discovered the hard way what the differences are between the two types of flexible copper pipe available to me. (deep breath, don't you love run on sentences)

To make a long story short, the two types of copper pipe that I found are both the same O.D. (5/8ths I think), but one has much thicker walls and is, (with my limited skills) impossible to bend smoothly and in has some sort of greasy film on the inside. The other pipe has much thinner walls and is bright and clean on the inside. The thinner walled pipe can be easily bent into just about any configuration that you need.

So, to sum it all up, get the thinner walled pipe, your life will be much more fulfilling, and your neighbors won't cover their children's ears when they walk past your garage.

Hope this helps.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Little Hole

>From: mdcsc!gdh@uunet.UU.NET (Garrett Hildebrand)

>I, too, have a six-gallon Vollrath. I have been thinking about  
modifying it with a valve on the bottom, as has been mentioned by  
others, and  
of trying out the "easysparge" type of system discribed by js and  
others,  
but I haven't found anybody to do the welding, and I also don't know  
where to get a suitable stainless valve.

Two points here. If you use the easymash concept, no welding is  
required and  
you can get by just fine with brass fittings available at any hardware  
store.

>After reading your comments about your lautering manifold and the use  
of a syphon, it sounds like you have gotten around the problem of  
needing  
a valve on the pot.

It has been pointed out by several that the easymash screen can just as  
well  
be put on the end of a long piece of copper tubing that rises up out of  
the  
kettle and connects to a hose. It produces a siphon and the screen is  
far  
easier to make than the tubing manifold.

Having said that, a spigot on the bottom of a kettle just seems to add a  
touch of class and convenience that I could not live without. I will  
never  
understand the reluctance of some people to drill a hole in a kettle  
that  
they bought specifically for the purpose of brewing, when that little  
hole  
will make the kettle a "real" brew kettle.

>hops, but not nearly as much as if the hops were added before the hot break.  
>  
>Why does this matter? Well, the theory is that the protein coagulated  
>around the hops will reduce utilization.

I always wait until after the hot break to add hops for this reason. However, I also always find myself wanting very badly to add the hops to avoid a boil over. Does anyone else have an opinion on this? Has anyone done a side by side analysis of this? I have observed that even waiting until after the hot break to add hops, they still get coated with protein.

From: Drew Lynch <drew@chronologic.com>  
Subject: Re: Besieged by baleful bacteria / infection survey / adverts

Jeff Benjamins bacteria problem:  
Acck!

I just got rid of a nasty infection which ruined 6 5 gallon batches. It's almost enough to send you back to the liquor store for commercial beer. I think that our problems differ in source, but not in result. My contamination was occurring due to a contaminated primary fermenter, and a desire to dump less bleach into the environment.

Anyway, I think my solution may work for you as well. I became a serious anal retentive when it comes to sanitization. I bleach the shit out of everything(1 cup/[3-5] gallons). I use long contact times on everything, at least 15 minutes, including the fermentation locks, rubber stoppers, my rubber gloves, everything. I rinse with \*chlorinated\* tap water.

Three points with you method: 1) Try reboiling your canned starter wort just prior to use. You may have bacteria collecting around the lid of the jar, creating an infection upon opening. Put the lid on the boiling pot prior to turning off the heat, so even the lid is steam sterilized. 2) Put a drop of bleach in each fermentation lock used, so bacteria will not be able to "swim" through it.. 3) Let the yeast package swell until you are sure it will burst, then a little more. Get that population as high as possible before exposing it to your environment.

=====  
Infections in general:

About 6 months ago I posted a request for people's infection rates and sanitization methods. I did this because I had heard so much about other folks problems, and had had none myself, and was curious about my good fortune. Well, I guess I forgot to "knock on wood" before posting "I've never had a contaminated batch" :-( Anyway, I got 30 responses but was unable to find a reasonable thread of cause/effect. I will mail out a compressed, uuencoded tarfile of the responses if anyone is interested.

=====  
Advertising:

How about this: Once a month, each person who sells a product may post a "I sell this product" message. No claims, no hype, no prices, no details, just a clear statement of intent to sell. Interested parties may then send them private email requesting info on their product. These people should then refrain from taking part in discussions on their or competing products. People with personal or financial interest (close friends of sellers, etc) should show similar restraint. Recommendations from satisfied customers in responses to queries from other list members would always be welcome.

From: korz@iepubj.att.com  
Subject: Specialty Products Intl. part 4 of 4

This is part 4 of my review of "Home Beermakers Guide" by Leigh P. Beadle.

Pg10:

"To establish a siphon you must suck on the end of the siphon hose while it is lower than the opposite end."

Actually, the author is not only showing that they know nothing about microbiology, but also that they know nothing about physics. For a siphon to work, the position of the inlet does not matter as long as it is under the level of the liquid. The level of the siphon outlet must be below the level of the top of the liquid and is NOT AT ALL DEPENDENT ON THE LEVEL OF THE INLET! Back to microbiology. Besides the zillions of bacteria on your hands, there are hundreds of zillions of bacteria in your mouth. Sucking on a siphon hose with your mouth is probably one of the best ways to infect your beer with lactobacillus which is everpresent in the human mouth. Lactobacillus will eat sugars that the yeast have left behind and cause your beer to gush about four to six weeks after bottling.

"Unlike commercial beers, which start deteriorating as soon as they are bottled, your home-made beer has an unlimited shelf life. This is because of the natural preservative quality of the yeast."

No, the author's beer has an unlimited shelf life because the author has infected their beer by using an unsanitized fermenter and by sucking on unsanitized siphon hoses and there is nothing left in the beer to spoil. Also, the bacteria and wild yeast have produced so many off-flavors, combined with the chlorophenols from the tapwater, that any further spoilage would not be noticeable. Please also note that there are commercial beers such as Sierra Nevada and Bell's that do have yeast in them. It is unfair (besides being wrong) to include these fine beers when criticizing the industrial megabrewers.

Pg13:

"Types of Beer... CANADIAN LAGER Throughout the world pilsner beers represent the highest class of beer. This recipe will produce a refreshing, non-filling beer with rich European flavor and aroma."

I will not debate the highest class of beer, although I, personally, prefer Belgian and English ales over pilsners. Given that the author says: "Do not ferment your beer in rooms that are less than 60 degrees..." none of these kits are for making lagers. They are for making (to use the expression very loosely) ales. Also, if it has a "rich European flavor and aroma," then why call it "CANADIAN LAGER?"

"AMBER This beer is traditionally brewed during the Oktoberfest season in Germany and is made using lightly roasted malt. It has an amber color and heavier malt flavor than most beers."

I think the author incorrectly believes that this is an Oktoberfest recipe. Oktoberfest is a lager and is traditionally brewed FOR Oktoberfest not DURING. It has traditionally been brewed in March for consumption in October. Nonetheless, at fermentation temperatures above 60F, what will probably be made is a very watery and cidery scottish ale.

Pg15:

"For a European-style beer, simply increase the boiling time for the Ingredient Mix. For a Heineken or Becks style beer, give the mix a high boil for 10 minutes... A fifteen minute boil produces a strong British ale, and a 20 to 40 minute boil with the Dark Mix makes a moderate or strong stout. for a richer stout, leave out a gallon of the cold water..."

The magic of brewing, eh? Gosh, I never new it was so simple.

Beginners: please just forget you ever read the above quote -- it is so wrong, I can't even begin to correct it.

Pg21:

"SOME FINAL THOUGHTS The unique feature of our Ingredient Mixes is that they contain 1/2 ounce of fresh, uncooked hops. (These are the lumps you see in the syrup when you pour it out.) This gives you an infinite variety of beer flavor which you tailor to your own taste simply by extending the normal 2 minute boil."

"The beer should be consumed within a month after bottling..."

Hey, what happened to unlimited shelf life???

"...This is because the yeast may slowly convert some of the remaining sugars in the beer and cause it to become thinner flavored and may over-carbonate it. If the carbonation remains normal after 3 weeks in the bottle, no problem."

No, it means that you have been lucky and did not infect your beer too bad. Of course it's not the yeast that continues to eat the sugars, it's the bacteria, but I don't think Leigh P. Beadle has ever bothered to learn about bacteria, despite the fact that he is the author of some "best selling" books on brewing. Yeah, right.

This is a comedic brochure, right? This company doesn't really exist, does it? Did Chris Campanelli write this for laughs? No, I'm afraid this is a real company and they are really misguiding beginners into brewing a "beer" that tastes worse than the industrial megabrews. The prices are reasonable, but are not the best available through mailorder. They do have a Pure Malt Extract (without lumps, and allegedly without corn syrup) for the same price as the mercifully named "Complete Ingredient Mixes" but you must buy it by the case and the price is still higher per pound than Northwestern (100% malt) Malt Extracts.

## Subject: attenuation definitions

There's "apparent attenuation" and "real attenuation". The difference comes about because alcohol has a specific gravity less than 1 (about .8). Real attenuation is the percent of sugars converted to alcohol. So, if you had a 10% (by weight) sugar solution (about 1.040), and got 100% real attenuation, the resulting specific gravity would be about 0.991 (corresponding to about 5% alcohol by weight). The apparent attenuation of this brew would be 122% !

George Fix published a set of equations relating apparent and real attenuation and alcohol content last year. To wit:

```
>A = alcohol content of finished beer in % by wt.
>RE = real extract of finished beer in deg. Plato
>
> Since A and RE are generally not known to us, additional approximations
> are needed. The following are due to Balling, and have proven to be
> reasonable. Let OE and be defined as follows:
>
>OE = original extract (i.e., extract of finished wort in deg. Plato)
>AE = apparent extract (i.e., measured deg. Plato of finished beer).
>
> Then
>
>RE = .1808*OE + .8192*AE,
>
> and
>
>A = (OE-RE)/(2.0665-.010665*OE).
>
```

The "tricky part" here is the expression of the sugar content in degrees Plato. This is a fancy term for % sugar by weight, and corresponds roughly to "degrees gravity" divided by 4. That is, a 1.040 wort has an extract of 10 degrees Plato.

He goes on to calculate an example:

```
> To take Walter's specific case, first note that from Plato tables an OG
of
> 1.045 is equivalent to
>
>OE = 11.25 deg. Plato,
>
> while a FG of 1.010 is equivalent to
>
>AE = 2.5 deg. Plato.
>
> Therefore,
>
> RE = .1808*11.25 + .8192*2.5 = 4.08 deg. Plato,
>
> and
>
> A = (11.25 - 4.08)/(2.0665 - .010665*11.25) = 3.68 % wt.
```

The apparent attenuation is 75% (from 1.040 to 1.010), the real attenuation is  $(11.25 - 4.08)/11.25 = 64\%$ .

=S

From: "Bret D. Wortman" <wortman@centurylub.com>  
Subject: Low SG -- what might the cause(s) be?

Greetings, all. I'm a novice who has just started my second batch (a  
5 gallon batch that has managed to foam over the fermentation lock on  
a  
6 1/2 gallon carboy, but I digress).

Both of my first two batches used kits -- syrup -- and no sugar. The  
first used a 3.3lb Munton & Fison Pilsner kit with 1.4 lb Light Amber  
Malt kicker. The second used 1.8kg Muntons IPA Bitters with 1.4 lb  
Lilght Amber Malt kicker.

In each case, the SG after sparging and after getting the total  
volume  
of liquid to ~5 gallons was around 1.015. This seems awfully low to  
me, as it'll result in beer that has (at most) around 1.5% alcohol  
content.

What might I be doing wrong, or what should I be looking for? I  
carefully noted the 5 gallon mark on my carboy so I'm sure I'm not  
making more than I think I am....

From: korz@iepubj.att.com  
Subject: attenuation/hop nobility/2.5 gal kegs/cask priming/infection

Chris asks about attenuation and then posts that he's got it figured out.

I just want to mention that this is APPARENT ATTENUATION -- that is, the percentage difference between the original gravity and the final gravity. The reason that it is only the APPARENT attenuation is because the yeast is making alcohol which is lower specific gravity than water. Therefore, to determine the actual attenuation (which can be quite a bit less than the apparent), you must distill-off the alcohol and replace it with an equivalent amount of distilled water. Don't bother though, because virtually all attenuation values and final gravities you see in homebrewing books, here and in magazines are apparent ones.

> anything a botanist could get a hold of.

>

> Just what does it mean?

It's not a botanical term, rather a brewing term simply made-up by (I believe)

German brewers. Hallertauer, Tettnanger and Saazer appear to have simply been grouped together quite a while ago and labeled "noble hops."

\*\*\*\*\*

Robert writes:

>I have located five 2.5 gallon kegs at a used restaurant supply house.

>Two of them have screw-on caps with tapered rubber washers, while three have

>clamp-type lids with smaller rubber gaskets/o-rings.

Grab them. They are very rare -- you can always replace the fittings you don't like with ones you like (i.e. you can switch them all to ball-lock).

>There is also a combination of fittings on the tanks themselves, with some

>having pins, and others having grooves for snap-rings.

I suspect that the grooved ones are actually ball-lock. The pin ones are pin-lock. Coke uses pin-lock and Pepsi uses ball-lock. I personally like

the ball-lock ones because they are easier to recondition (you can simply use a 12-point socket for the fittings, whereas for the pin-lock you need to buy (\$40) or build yourself a tool to remove the fittings.

>The kegs are pretty crudded-up, but I think they will clean. Are there any

>fine points to be aware of before sinking money into these kegs?

Check the seams inside and out -- be careful to release all the pressure before removing the lid -- you could injure yourself quite seriously if you don't. If the seams are all pitted and cracked, you may have to pay more to have them re-sanitary-welded than to buy new ones. You really should replace all the rubber. If the lids don't have overpressure release valves, you should get some. There were some posts about two or three years ago that said that the Cornelius company will exchange lids without valves for new lids. All my lids had valves, so I didn't keep the post.

There are many hidden rubber gaskets that you should replace. There are eight including the gasket on the overpressure valve. The issue is not one of sanitation, but more so of soda (root beer, grape) smells that would enter your beer. Some have suggested boiling, but I've tried it and I could still smell root beer in the rubber. To completely recondition a keg with new rubber (including a new overpressure valve -- the rubber does not come separately) will run you about \$10, but I feel it's worth it. See a recent HBD for a post I authored which explained where the gaskets were.

>gotten to the point I can't even get an uninfected starter!

I suspect it is in the air. You could try to get an air cleaner and keep all the doors closed and the air conditioning off while you brew (give the dust some time to settle and the air cleaner to do it's stuff). Alternatively, you could wait till fall, when your air will go back to being less microbiologically active.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hops vs. Protein and Hop Storage

Al writes in response to my post:

:Mark writes (in reference to not using hop bags for boiling hops):  
:>Also, there are many  
:>benefits to be had to the wort by having the hop particles (whole or  
:pellet)  
:>thrashing around in the wort during the boil (help with protein  
:coagulation  
:> - aka the hot break) is the main one.  
:  
:Indeed hop particles will help with protein coagulation, but I feel that  
:you  
:should wait till after the hot break to add the hops in the first place.  
:The last time I recall reading about this is in a post from Stuart  
:somewhere  
:around HBD 1150. My contention, as that mentioned by Stuart, is that  
:the  
:hops will do too-good a job coagulating proteins \*AROUND THEMSELVES\*  
:thereby  
:reducing the utilization. Now, if you wait till after the hot break, I  
:suggest that there will still be some coagulation of proteins around the  
:hops, but not nearly as much as if the hops were added before the hot  
:break.  
:  
:Why does this matter? Well, the theory is that the protein coagulated  
:around the hops will reduce utilization. I have not done side-by-side  
:tests of this, but I do recall a significant increase in hop utilization  
:when I began to wait for the hot break before adding the hops. I did  
:not  
:put the two together till someone on the HBD mentioned it.

I don't buy this. Number one, if it really did boost utilization, you  
:can  
:bet the big breweries would be using it. I've never seen any reference  
:to  
:it. Number two, I've never noticed any protein coating the hop petals  
:or particles and even if it did, it wouldn't matter cause there isn't  
:any-  
:thing of value in there anyway. Now if we're talking microscopically  
:around the resins, maybe there's a possibility. But the biggest problem  
:I  
:have with it is waiting for the hot break. Besides the fact that a lot  
:of newbies don't even know what it is or what it looks like, I don't want  
:to keep sampling my wort to see the break so I know when to add hops.  
:Then I'd have to figure out how many boil minutes remained and adjust my  
:hopping rate accordingly in real time. What if I didn't get a break  
:until  
:30 minutes into 1 hour boil? I'd be getting a \*lot\* less utilization  
:from  
:the shorter boil time than any better utilization advantage I might have  
:got  
:by waiting.

:  
:>Anyway, I recommend you do use a secondary and rack carefully. The two  
:step

:>racking process should leave all of the pellet particles in the trub layer on  
:>the bottom. This is instead of the hop bag. The hop bags are great for dry  
:>hopping, but I don't like them for the boil.  
:  
:I disagree. I do just the opposite. I use a hop bag for boiling primarily  
:to avoid the problems of having to remove the hops from the wort later,  
:either as you pour the wort into the fermenter (my screen kept clogging  
:and that made it a real pain!) or when racking. I just compensate by  
:adding 10% more hops. I don't use a hop bag for dryhopping but only use  
:whole or plug hops because they float. I've never had any problems  
:siphoning the beer out from under the whole hops.

Floating hops does not make for good oil utilization. The best method is to keep the hops suspended in the middle of the beer using a bag and weight system (tie the weight to the drawstring instead of putting it in the bag).

This is what Anchor does and I have found it works well for me and other brewers I know. I don't know of any commercial brewers that boil their hops in a bag, but they do use them for dry hopping. But what works for you works for you.

:  
:>Also, your racking techniques  
:>will improve with time. The key is to have a reliable way to suspend the  
:>end of the racking tube just above the trub layer. I use a rubber stopper  
:>that fits in my carboy with two holes in it: One for the racking tube and  
:>the other I use to force CO2 into the carboy (at \*low\* pressures) to push the  
:>beer into the secondary (I use a soda keg for the secondary).  
:  
:then later:  
:>BTW, I have found  
:>the "orange racking tip" thingy to be essentially worthless. Ditto  
:>Fermtech's \$2 racking tube clothespin.  
:  
:Interesting, but I've had no trouble with the orange tip on the end of my  
:racking cane -- I tip the carboy with a stack of coasters or a block of wood and then gently lower the cane into the lowest part of the carboy.  
:I then use masking tape or a rubber band to make sure the cane doesn't  
:move. I discard the first two cups or so and the beer runs clear from  
:there on. Perhaps you are not getting a good cold break and your trub  
:layer is very deep. Then again, you've got hops in your trub and I don't.  
:On a typical 5 gallon batch, my trub layer is about 1 inch thick, say  
:between 0.75 and 1.5 inches. Just for the record, I have not tried  
:Fermtech's racking tube holder.

So you get a couple of cups of trub? Isn't this exactly what the orange racking tube tip is supposed to prevent? I guess it doesn't work for you either! :-) I suggest you try leaving it off once and I'll bet your results will be identical. My trub layer isn't any deeper than yours, and  
I don't have hops in it. My strainer works fine. I also use a "settling tank" between the kettle and the primary. I use my old plastic fermenter with the spigot in the bottom. I cool the wort, pour through the strainer

into the bucket, put the top on and let the cold break settle out. Then I attach a hose to the spigot and run the wort into my carboy through a homemade "wort squirter" to help aerate it. I usually only have .5" of trub at the end of the primary. And for the record, the problems I found with Fermtech's tube holder were that 1) The tube tended to come out of molded holder clip and 2) The spring didn't hold the clip to the carboy steady enough with the weight of the racking hose (works fine with just the racking tube, but that isn't very practical). I rubber banded the heck out of it to get it to work and ended up in the same place as my clothespin, but wasted \$2 in the meantime.

Jonathan Knight asked about hop storage:

I was the one that recommended an "investment" in a home vacuum sealer, and, BTW, also recommended CO2 or nitrogen purged mason jars as an alternative. The reason I recommended a home sealer is that they not only are nice for storing hops, but are also useful for sealing other things like DME, grains and minerals. Anyway, what's more important in Jon's post is the whole issue of hop storage. I'm working on a longer post that will address this issue and will post it in a few days.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: sugar in beer

Sugar added to certain beers (british ales and belgian ales) have been discussed here before. Was there a consensus as to the best thing to use that is available in the states? Brown sugar? What is best for a brown ale versus a belgian double or triple? In the belgian ale book the author says the brown color of the double is from the sugar, so I'm not sure what the homebrewer is to do.

Is rock candy anything more than just sucrose? If so, would it dissolve in the boil?

Thanks.

Although I picked JC's post (sorry JC), there are a number of posters who seem to be confused by this "high-gravity" brew thread. There's a big difference between partial boil (which could also be called high-gravity boil) and high-gravity ferment. I believe that the original post that started this thread asked about what kind of compensation had to be made for a high-gravity ferment. Well, a number of brewers have posted that a higher gravity ferment will result in a beer with more esters. I have found this to be true, but have not tried diluting the resulting beer into a medium-gravity beer. I think what JC is asking about (as well as a couple of others) is a partial-boil recipe. One in which, say, 3-

gallons of wort are boiled and then this is diluted into a 5-gallon batch in the fermenter. You see, there's a big difference between diluting before fermentation and diluting after fermentation. In either case you need to use some math to figure out how much hops to add to achieve the bitterness

you want in the final beer. I suggest (although they are being disputed by some) that Jackie Rager's numbers in the Hops Special Issue of Zymurgy are still very good if you compensate, as I do, for hop bags and whole hops (adding 10% more if you use a hop bag and 10% more again if you use whole or plug hops in stead of pellets).

In both cases (partial boil and high-gravity ferment) you need to pick the IBUs you want and then use 5-gallons for the volume in the formula. When it comes to figuring the boil gravity, calculate it for the boil volume. For example: 6 lbs of Northwestern in 3 gallons of water will give you about a 1080 gravity boil. Use that for the gravity adjustment. Dr. Bob Technical's Amazing Wheel of Beer is great for approximating the contribution of a large variety of grains (beware that some extracts contribute a bit more points some less).

There is another issue at stake here. These protein molecules are contributors to haze. We all like our beers to clear without filtering, so we want to use all of the tools we have to coagulate these proteins. If you place your hops in the wort before the boil and the hot break occurs you will not get the full benefit of the hot break. The hard resins from the hops will bind with protein molecules that would have otherwise coagulated without their aid.

For me the extra coagulation power is secondary to any added efficiency in utilization. I am also an avowed user of pelletized hops. I do not put my hops or my dates in bags.

Cheers, Rick

Subject: Keeping Soda Kegs Cool

For keeping kegs cool , there is a simple, low cost alternative to a bucket of ice- insulate! All you need is a larger version of the foam plastic single-can insulators that are popular among the canned beer crowd. The insulator I use is made from a polyethylene foam sleeping pad, of the type used by backpackers. These can be purchased at sporting goods stores for about ten dollars, and are big enough to make a couple of insulators, if you get one longer than about 55 inches. Use contact cement to join the ends of a piece of the pad, which has been cut to the proper width (the height of the keg) , and length (about 3/16" shy of having the ends meet when it's wrapped around the keg). To use the insulator, just slip it down over the top of the keg when you remove it from cold storage.

Subject: Re: KQED Festival

I have one very serious objection to the way this festival is being run. That is the fact that it only runs for three hours. Who came up with that brilliant idea?

I have always found that the best brew/food festivals are the ones that allow you plenty of time to relax and enjoy the offerings. To charge \$30.00 for what is billed as the largest event of its kind, then to allow barely enough time to get started, is pretty bad.

Personally, I'll save my money for the smaller festivals that give you for fun and enjoyment.

Subject: Home Brew U BBS: CHANGES!!

Announcing a new "campus" of the popular BBS dedicated exclusively to Home Brewing and Beer Appreciation:

HOME BREW U. - MIDWEST  
(708)705-7263, N,8,1  
1200-14400 bps, V.42bis

I plan to run the new campus in much the same manner as the old one. The focus is on BEER (making it, buying it, drinking it, and ENJOYING it! )

While a large library of beer-related files is available, the REAL strength of this BBS is in the quality of brewing knowledge contained in the message base. So please remember to take a look at the messages, and feel free to ask questions. Many novice brewers have gotten prompt help and advice from the HBU message base.

Beer lovers in the Southern USA should note that the original Home Brew U. continues to operate in Houston, Texas, with a new Sysop and a new phone number: (713)923-6418. Its name has been changed to 'Home Brew U - Southwestern Campus'.

A lot of it has to do with your water, and how it affects hop  
utilization. Boil Time / AAU tables are a start, but don't  
take water quality into account.

found  
>the "orange racking tip" thingy to be essentially worthless.

gotta disagree with this one. the orange racking tip thingy gets  
me at least 1/2" more clean wort out of a 5 gal carboy before it  
starts picking up trub (out of the post-boil pre-ferment wort,  
which doesn't cake down).

- - - - -

>I think the concensus is that brewing Belgian-style beers is tough to  
do,  
>and I'm sure that anyone who's seriously worked on this has had more  
than  
>their share of disappointments.

I can't seem to brew high-gravity ale that doesn't turn out belgian-  
like.  
High ferment temp is the big thing. Put an electric blanket around  
your fermenter for the first day or two. Add a pound of sugar or  
two, any type (but different tastes). If you add finish/dry hops, saaz  
works best. It's a lot easier to enjoy the irreproducible results than  
it is to worry about consistency. Relax and don't worry, because  
belgian ales are not well-defined and you can get away with a lot in  
a competition.

prosit!

Subject: Copper Manifold System

Jeff,  
Since the HBD has been filled with the copper manifold/easy masher/zapap thread I thought I'd send you a note thanking you for your help. I have been using a copper manifold system for my two last batches (it works very well :-)) that is based on your design. I only changed one thing, instead of soldering a copper 1/2" to 3/8" reducer I purchased a larger (I can't recall the size) vinyl tube that fits over the 1/2" pipe. The vinyl tube needs to be heated in hot water in order to fit it on the copper pipe but creates an airtight fit. Using a large plastic hose clamp, with adjustable click stops, on the tightest setting that allows liquid to flow lauters six gallons in 45 minutes. The only drawback is that you need to brace the tubing where it comes out of the standpipe or it bends over. I used some copper wire and it worked OK but I am trying to come up with a better solution. I thought you might be interested in any modifications of your system. Thanks.

Subject: Siphoning

Message Creation Date was at 8-JUL-1993 08:44:00

Greetings,  
I recently brewed a relatively light batch which is still sitting in the primary fermenter. I plan to run an experiment on this beer. I will split the beer into two separate carboys for secondary fermentation. I will have a bed of raspberries in one of the carboys in the attempt to create a fruit beer without loosing the fruit aroma. In the other secondary carboy the beer will ferment w/o any fruit. This way I can compare and determine the exact contribution of the raspberries.

Now the questions:

1. Is 2 lb raspberries/gallon of beer a reasonable amount?
2. Should I use a Campden tablet overnight in the raspberries to prevent introducing any new bacteria in the secondary fermenter?
3. Siphoning: If I siphon first into one carboy and then into the second, I'm afraid I may end up with differing beers. I would think the first carboy would get the lighter beer and the second a heavier beer (and more trub remnants). I was thinking of a "Y" siphoning connector. The beer being siphoned would hit the "Y" connector and then branch out down two paths into the two carboys. I would end up using 3 lengths of 3/8 " tubing along with the "Y" connector to accomplish the siphon.  
Does anyone know if this would work, or is it doomed to abject failure?  
If it would work, does anyone know where I could procure a "Y" connector?

TIA

Andy A

From: John Brooks <jbrooks@u.washington.edu>  
Subject: Duval, Fuller's ESB and Full Sail Ales

In reply to the HBD inquiries of Domenick Venezia (6/30/93) and Tim Born (7/1/93) about recipes, I offer the following:

Duvel - Ingredients: pale malt; Saaz and Styrian hops (30 B.U.); top fermenting yeast; brewing sugar for bottle fermentation; O.G. 1.070, degrees Plato 17.5; 8.5% alcohol by volume; unpasteurized.

Fuller's E.S.B. (export) - Ingredients: pale ale and crystal malt; flaked maize; caramel and brewing sugar; Challenger, Northdown and Target bittering hops, Goldings aromatic hops; O.G. 1.060, degrees Plato 14.8 (ale that is kegged/casked for domestic consumption is O.G. 1.054); alcohol by volume 6.0%.

Redhook's E.S.B. is reputed to be a take-off on Fuller's (and at 50,000 barrels this year, successfully so) - Ingredients: 2-row Klages malt, caramel malt (60L); Willamette and Tettnanger hops; O.G. 1.054; 4.3% alcohol by weight; no pasteurization; another interesting point about all of Redhook's products is that carbonation comes from their primary fermentation in airtight vessels (no secondary fermentation, bottle fermentation or CO2 injection).

Full Sail Golden Ale - Ingredients: Oregon 2-row Klages malt, caramel and Cara-pils malt; Oregon Tettnanger and Halletauer hops.

Full Sail Amber Ale - Ingredients: 2-row pale malt, caramel and chocolate malts; Kent Goldings and Willamette hops.

The source for the info on Duvel and Fuller's is "The European Beer Almanac" by Roger Protz, 1991, Lochnar Publishing, Scotland. The sources for Redhook and Full Sail are those companies published product sheets.

I would be interested any more detailed info anyone may have on Full Sail Amber (O.G.'s, B.U.'s, etc.). When I downloaded Cat's Meow, I found a reference to Full Sail Amber in the index, but not in the text. Please post or reply to private e-mail.

From: sag5004@yak.ca.boeing.com (Ford Prefect)  
Subject: Summary of a large scale home system

I guess that I have waited long enough for the replies to trickle in... The executive summary was lots of "me too" replies :-)

Basically when you scale up in size you need to think long and hard about the following:

Anything >1bbl will you will probably need pumps (or a very tall gravity system :-) And need to make sure you can move around large quantities of hot fluids in a timely maner.

How to handle large amounts of grain, floorspace and other bits. e.g. How do you crush and handle and dispose of a the huge amount of grain you will be using.

I was warned to not forget about losses (of product) in the transfer and handling process.

One person wrote that he would write up his experiences in brewing in a 2bbl brewhouse when he get a spare moment. Look for it in an upcoming issue of the HBD... (sorry, I don't know when)

"It is not as easy as one might think to design a plug and play system of this size." I know that the system that I use now has sort of evolved to what it is now, and the problem with doing this in a large scale is that it gets expensive fast.

- - - - -  
A couple of people replied with stuff that they have for sale. All has been posted in the HBD

A guy in Ohio has a 112 SS vessel, and another guy Arizona has a few leftover pieces (kegs, boiler and vessel, and a fermenter) [Sorry I am not posting their names because I didn't ask permission too]

- - - - -  
It appears that boiler geometry is use whatever is convenient to fabricate or buy. You should stick to using standard sizes of stainless sheets ( basically 4x 6,8,or 10 feet) because this stuff is \$\$\$ and you don't want to waste any.

I was warned against getting the lauter geometry 'too vertical' and was given a rough number of 1-3 feet is a good depth for a grain bed.

Sorry, about the disjointed ramblings, but this is what I know at this time.  
I was really hoping that there would be a journal article I could read, but  
no such luck :- ( I will report back periodically if I learn anything new.

>>Charlie Papazian in TCJOH refers to the dumping of the wort through a  
strainer  
>>into the fermenter to remove the hops and any other particulates as  
sparging.

>And I disagree with the esteemed CP on this. While I'm not one who  
>thinks you need to rack off the cold break before fermentation begins,  
>I do believe you need to get as clear a runoff as possible off the hot  
>break when going to the fermenter.

I was merely trying to point out that CP called this sparging which is  
probably what the original poster meant when he used the term.

By the way, it seems to me that you agree with CP on this. The  
"sparging" of  
the wort into the primary seems to remove most of the hotbreak material  
along  
with the hops.

>>This might be the source of the confusion. He also recommends scooping  
out  
>>the specialty grains just prior to the wort coming to a boil.

>Hmm... The conventional wisdom here is to remove the grains at 170  
>degrees to avoid leaching tannins into the wort. Waiting until just  
>before the boil is too long.

This sounds like a momily to me. I haven't noticed an astrigency problem  
with  
beers I've made to date using this method and I know of several other  
brewers  
who use this method with success.

> Is it ? Do I need to buy a larger soaking vessel ?

I simply fill the primary up to capacity and snap on the lid and let it soak.  
Just before I'm ready to go, I wipe down the lid with a sponge that has been soaking in the sanitizing solution. Seems to work OK so far. Wiping stuff down was recommended by a local supply shop. I think the physical action of the wipe would offset the minimal contact time.

I hadn't heard that. I've used American Eagle for a few batches and noticed no characteristic cidery taste. It also claims to be all malt. The use of corn sugar might explain the low price, though.

From: Rich Ryan <ryancr@install4.swin.oasis.gtegs.com>  
Subject: flat beer

Let me start by saying I'm a neophyte in the homebrew field. I just bottled my first batch three weeks ago. The beer tastes fine other than being somewhat flat.

Papazian's troubleshooting section came to two conclusions:  
1) I left an excessive amount of sterilant in the bottles or  
2) I'm storing the beer at excessively cool temperatures.

I used B-brite to sanitize the bottles and equipment and was very diligent to make sure I washed it all off. As far as storing the beer goes, it hasn't gone below 70 since it was bottled. Can anyone suggest any other possible reasons for the lack of carbonation?

I also read somewhere else in Papazian's book that you should leave about an inch of air space in each bottle. I noticed that I have more like two inches of air space in each bottle. Could this have some effect on the carbonation. It would seem that as I increase the air space in each bottle the carbonation should increase as well.

From: rush@xanadu.llnl.gov (Alan Edwards)  
Subject: A Handy Table for Keg Pressure

Hello fellow brewmeisters,

While we're on the subject of kegging and pressure, I've come up with a formula and a table for determining what pressure to apply to achieve a certain carbonation level. I believe that this table is more useful compared to the other table that has appeared on the HBD and elsewhere. It's smaller (fits easily in an 80 column window), but contains all the needed information in a more obvious arrangement. (It makes more sense to me to ask "what pressure do I need" rather than "what do I get if I use this pressure"). Besides, it can do any temperature.

You can print the table out and stick it in your brewing logbook or on the side of your kegs.

#### TABLE

Look at the row that corresponds to your keg temperature, and read the number at the column corresponding to the desired carbonation level. That number is the pressure to apply to the beer, in PSI.

#### PRESSURE REQUIRED FOR DESIRED CARBONATION

| Volumes of CO2 desired |      |      |      |      |      |      |      |      |      |      |      |

#### REFERENCE

Volumes of CO2:

British style beers = 2.00 - 2.40

Most other beers = 2.40 - 2.85

High-carbonation beers = 2.85 - 2.95

#### FORMULA

If you use a spreadsheet or a programmable calculator for your brewing endeavors, this formula works very well (it was used to create the table):

Pressure = F(Temperature, Volume)

$$P = -16.6999 - 0.0101059 T + 0.00116512 T^2 + 0.173354 T V + 4.24267 V - 0.0684226 V^2$$

#### C-SHELL

For you Unix users, here's the above formula converted to a C-shell script called "pressure":

```

-----CUT-HERE-----
-----
#!/bin/csh -f

if ($#argv != 2) then
    echo "pressure: calculate pressure needed to acheive a certain volume"
    echo " of CO2 in solution."
    echo "Usage: pressure volume temperature (F)"
    exit 1

```

```
endif

set vol = $1
set temp = $2

set eqn1 = "scale=2;(-16.6999-0.0101059*$temp+0.00116512*$temp*$temp+0.
173354"
set eqn2 = "*$temp*$vol+4.24267*$vol-0.0684226*$vol*$vol+.005)/1"
set pressure = `echo "$eqn1$eqn2" | bc`

echo "To get $vol volumes of CO2 into solution at $temp degrees F, you
need:"
echo "$pressure PSI"
-----CUT-HERE-----
-----

Have fun,
-Alan

Subject: yeast FAQ/filters/temps

I certainly would like a yeast FAQ. I think that would be a tremendous help for new/intermediate brewers and for those like me who simply want to learn more. FAQs make a great place to learn enough to ask intelligent questions.

I have a question about filtering beer. Out of curiosity, I just made some quasi-czech pilsner at a U-Brew-It-Here place, and they of course filter their beer to get that commercial look. Why should I filter, or not filter my homebrew? What would it do for my beer? (by the way, I have chosen not to patronize those brew-places again, they charge exhorbitant rates).

Finally, I would like some information on warm temp brewing. If brewing ales, what are the consequences of fermenting between 18-24 degrees C? My apartment is not air-con. nor do I have a basement (!). Is bacterial contam. my main worry, or will I develop some interesting, but perhaps 'out of style' flavours?

geoff.

From: cjohnm@ccit.arizona.edu (John Mare)  
Subject: India Pale Ale's

In a recent discussion on India Pale Ales (IPA's) the assertion was made that these are all high gravity ales. Conventional wisdom tells us that these ales were brewed at high gravity to allow them to travel well (ie. by ship to India), and our US beer competitions persist in defining IPA's as medium to high gravity (OG 1050 to 1065). It is interesting to observe, however, that in their land of origin IPA's are not in fact high gravity ales. Some of the truly outstanding examples of this type which I tasted on a recent beer tour of The British Isles include "Palmer's IPA" (Dorset, OG 1039, ABV 4.3%), "Robinwood IPA" (Yorkshire, OG 1040, ABV 4.2%), "Younger IPA" (Edinburgh, OG 1043, ABV 4.5%), "R&D Deucher's IPA" (Edinburgh, OG 1048, ABV 3.9%), and "Thompson's IPA" (Devon, OG 1045, ABV 4.6%). The Palmer's IPA has won the "Beer of th Show Award" at a British Guild of Beer Writer's beertasting, attesting to the fact that in Great Britain an ale with an OG of 1039 can both qualify as an IPA, and win awards. Perhaps we should focus less on categories and their physical parameters, and more on the sheer joy of producing fine ales fitting the broad spectrum of taste and aroma nuances found in the "real ales" of Britain.

Subject: Steam Kettle

>From: steve@Pentagon-EMH6.army.mil (Steve Lichtenberg x79300)

>The principle advantages of using steam to heat your wort are  
1. Speed. Since steam has about 6 times more latent heat than water at  
the same temperature, it will bring 10 gallons of liquid to a boil in a  
few  
minutes.

That presumes you have an infinite supply of steam. If you use the same  
burner to create the steam that you would have used to just heat the  
wort,  
you gain nothing.

If you have a burner that produces enough steam to bring ten gallons of  
liquid to a boil in a few minutes, you might just as well put the kettle  
on  
it.

> 2. Ability to maintain a rolling boil without having to worry about  
scorching.

Scorching is only a problem in mashing as a rolling boil by itself  
precludes  
it. You may be referring to caramelizing in the boil but that is easily  
controlled by the amount of heat applied.

Sorry but the steam jacketed brew kettle for the homebrewer sounds like  
a  
very complicated and expensive solution to a problem that does not  
exist.

That is not to say however, that if it turns you on, go for it. After  
all,  
there are the RIMS fundamentalists out there so why not steam boilers in  
the  
kitchen?

From: Gene Zimmerman <ezimmerm@hp.uwsuper.edu>  
Subject: Farmer/Engineer etc.

Salutations!

When I made that comment about Farmers making wine and Engineers making beer, I was just saying that the creation of beer is more intricate than the production of wine. The fermentables are already present in wine, as Brewers, we must coax sugars out of the grains. Granted, winemaking doesn't seem easy, but I think brewing has the capacity for more complexity.

I also have a comment for the fellow who has the most unfortunate infection problem. I noticed you mentioned sanitizing everything you use, but didn't say you do anything to the yeast packet itself. I dunk mine in bleach water for a while before opening. I cut the packet with a recently bleached pair of scissors. Just a comment. I hope you work it out.

How many people brew in their basements? Unless it's an enclosed room, I can't see as it would be very sanitary at all. Most of them are a little damp, dark, and although not warm, a constant temp. I think someday I'll have a brew set up in a basement, but I've always thought of sheet rocking off a room and putting ceramic tile on the floor and waist coat.

Gene in Duluth (Soon moving to Laramie, WY (I don't know why...) :)

Subject: AdvertisingWyeast

Among other thing yesterday, Drew Lewis said:

>..... 3) Let the  
>Wyeast package swell until you are sure it will burst, then a little  
>more. Get that population as high as possible before exposing it to  
>your environment.

My exeperience with letting the Wyeast go the extent of bursting has been poor. My original orientation was to treat the directions of letting the package swell to 1" as a minimum and anything greater than that was so much the better. I found that once the package is about to burst the yeast do not respond well in a starter environment. Has anybody else found that to be true?

Again Drew says:

> How about this: Once a month, each person who sells a product may  
>post a "I sell this product" message. No claims, no hype, no prices,  
>no details, just a clear statement of intent to sell. Interested  
>parties may then send them private email requesting info on their  
>product. These people should then refrain from taking part in  
>discussions on their or competing products. People with personal or  
>financial interest (close friends of sellers, etc) should show similar  
>restraint. Recomendations from satisfied customers in responses to  
>queries from other list members would always be welcome.

I agree wholeheartedly with this recommendation. This would perform many services to us in this forum. It would allow the commercialists (me being one) to do their thing in a confined marketplace, would restrict commercial behaviour to what would be strictly proper and improper, provide product information to customers, and allow the real artists and scientists here their needed airtime to talk about their hobby/pastime/professions. I have truly restrained myself in all the highly shrouded pursuits of customers on the HBD and I feel good about that. I want others to do the same, however I see some of us want commercials and some do not. Drew's recommendation is an excellent one. There was also one just like it by someone else last week (sorry that I cannot give you credit as well but I cannot remember your name).

Dear Moderator,

I hereby propose the implementation of the above recommendation. How do we proceed? Shall I contact you directly?

Frank

About the review of "Home Beermakers Guide" by Leigh P. Beadle

Sad but true:

When I first tried my hand at brewing over 10 years ago I bought an equipment kit which included Superbrau and L.P. Beadle's ~guide~. Looking back, I am amazed that I didn't get any truly BAD beers from following his advice. It took some time (and much better books on homebrewing) to rid myself of bad brewing techniques I gotten from that book.

I wish that ~guide~ had been a joke, but no laughs, it just makes me angry thinking about it.

Subject: Not enough body & Brewpubs

I recently got into homebrewing (plan on doing my fifth batch this evening). I have two questions. The first has to do with body. I like my beer "chewy" (or so my wife claims). None of my beers have been as full-bodied as I would like. How do I increase the body of the beer without necessarily increasing the alcohol content? Can I use dextrine malt without mashing it? What about Lactose?

The second question may be due to a related problem. None of my Original Specific Gravities have been as high as I'd expected (given similar recipes I've seen). For example, my last batch was a stout (6 lbs. of dark liquid extract, 1 lbs. of dark dried extract, and .75 lbs. each of crystal malt (L50), black barley, and roasted barley; along with about a couple of ounces of Northern Brewer's hops). I estimated the Original Specific Gravity to be around 1.042 which was lower than I'd expected. What could be causing this? I may be putting too much water in the fermenter. I start my boil with 3.5 gallons, and I typically fill up the 5 gallon carboy with water and the boiled wort (thus compensating for the amount that evaporated during the boil). Could it be due to the type of extract I'm using? Could it be my water? (I have a Culligan water softener.) Could it be due to my estimation method? (I add a little to the SG reading for each degree over 60F according to the error estimates Charlie P. gives in his book. I think it is somewhere around 0.003 for each degree. I can't remember because I've got the formula in a database cell somewhere.)

Finally, I am taking two trips soon and would like some information on brewpubs. Can anybody suggest brewpubs worth visiting in Louisville, KY or in San Francisco, CA?

In HBD 1177 Drew Lynch talks about preventing infections...

>Let the Wyeast package swell until you are sure it will burst,  
>then a little more. Get that population as high as possible  
>before exposing it to your environment.

The guy who runs our local homebrew shop talked about Wyeast at our last club meeting. He said that your best bet is not to pop the nutrient pouch inside the Wyeast package. He suggests that you just cut open the outer package, and pour the yeast into a sterile starter.

He does this because the Wyeast nutrient appears to be infected. Maybe they can't sterilize the nutrient without destroying it. He claims that if you leave the nutrient pouch sitting on a warm kitchen counter, it will swell up on its own -- and not with yeast!

Date: Wed, 7 Jul 93 17:35:13 -0400  
From: rxh6@po.CWRU.Edu (Randall Holt)  
Subject: Sparge Manifold/100% Wheat Beer/Balling vs. SG

I don't contribute often to this newsletter, but I have a few things of interest:

#### Sparge Manifold

I, also, have built and used the sparge manifold suggested by Jeff Benjamin back in the 3/16/93 HBD and discussed in recent issues. One difference in construction, he suggests half-slots every 2 cm, I made half slots every 0.5 cm. The outflow rate was way too high, but can be restricted with a screw clamp at the tygon-tube siphon. I felt that adding more slots would create more evenly distributed flow throughout the grain, and improve the sparged leeching of maltose sugars from the grain. With only two all-grain batches under my belt, and as both used the sparge-manifold system, I wouldn't call myself an expert, but I'm happy. I am planning to install a drain spigot in my mash vessel, as siphon starting 158F liquor can really scorch the lips.

#### 100% Wheat Beer

Last winter I asked about 100% wheat malt, for use in an experimental brew, specifically to benefit a poor afflicted friend who is allergic to barley. Many responded that Ireks sells such, but I was worried that some barley was used in the mashing to provide a-amylase enzyme. So, I made the jump to full-grain (see above) in order to be certain that no barley contaminants would be included. But, based on helpful hints from HBDers, the a-amylase content of malted wheat is low, and so I used a bit of fungal-extract a-amylase enzyme (at your local brew-shop/mail outlet) which I think is used in sake fermentation (?). Well, the extract rate came to 29 points ( a tad low, possibly the enzyme), the wort fermented in the primary for 4 days and 2 weeks in the secondary, bottled up at about 4.5% EtOH. Taste? Well, it tastes like a tangy whole-wheat bread, with a little alcohol. I fed some to my barley-allergic friend, who smacked his lips, drank another sip and set the bottle down. He did not go into anaphylaxis, but did leave the other 35 bottles of wheat-beer behind. Personally, I couldn't blame him, but I like the flavor of barley. Not to let it go to waste, I tried mixing an older porter with two wheats - dynamite dark wheat. So, it wasn't a total loss, but I wouldn't suggest anyone bother with the 100 % wheat recipe - maybe some maple or honey might give a different flavor, but I'd guess that it just transforms the Wonder Bread flavor into Pancakes with maple syrup flavor.

#### Balling (brix)/Specific Gravity Conversions

A couple of weeks ago Pfr. Fix requested the conversion of Balling sugar density units to specific gravity units. He had a second order fit, something like  $P = -205.347 \cdot (SG-1) \cdot (SG-2.25)$  (my factoring), which he inverted via Newtons approximation to get a  $SG=f(P)$  function. The question Dr. Fix had, was (paraphrased) 'Was there a reason for this function, and did it have some historical significance?'

I think that the significance is evident in the definition of;  
" Balling Saccharometer shows directly the per cent of sugar  
(sucrose) by weight at the temperature indicated on the instrument,  
usually  
17.5 degrees." from CRC HBDK on Chem/Phys. under Hydrometers and  
Density  
Units.

An table of %Wt vs. Specific Gravity vs. grams solute/liter  
solution is given in CRC under Specific Gravity of Aqueous Invert  
Solutions, where the %Wt (== Balling points) vs. specific gravity  
fits very closely to Dr. Fix's noted 2nd order fit. I believe, then,  
(and this is purely a guess) that the historical reasons for the  
Balling/SG curve are largely phenomenological, i.e. add sugar up to  
percentage of sugar byweight, then measure specific gravity.  
Although SG can be determined from partial fractions and pure SG's  
at varying temps (and will eventually lead to an approximation of  
the above 2nd order fits - an exercise which I leave to the reader),  
SG's vary; the most accurate method depends on laboratory readings.

Again, this last bit is pure conjecture, based on extrapolated  
speculation.

My 0.02 on NetAdverts vs. NetComplaints

Frankly, I'd rather ignore a couple of blatant capitalists than suffer  
through megabytes of pissing and moaning about abusing the nets.  
If you are pissed off at someone for NetAbuse, then flame them,  
not the rest of us on the HDB.

From: Leo Reilly <zanadu@well.sf.ca.us>  
Subject: Guinness

I am sure that this has already been answered but I have been unable to find an explanation in previous postings.

1. Does the NO2 cartridge in the canned Guinness affect more than just the head of the brew? It seems to me that the canned Guinness is alot smoother and less bitter than the traditional bottled stuff.
2. What does the nitrous oxide actually do to the beer? I.e. how does it interact with the brew to give the creamy head and the smoother taste.
3. Is any other brewer using the NO2 cartridge? If so, who?
4. Would it make sense to use the NO2 cartridge in any other brew (lambic? porter? scottish ale?)
5. Are any home brewers using the NO2 cartridge for their homebrew, or contemplating trying it?

I apologize if I am covering old ground, but "enquiring minds want to know"!

Subject: hops storage, victory malt

I have been asking a lot of questions lately, and I have been getting lots of great replies both on and off line -- thanks to all! The generosity shown by the experienced brewers toward those less experienced is one of the great strengths of this forum.

Here is one question that didn't get answered, though: if I buy a bunch of whole hops and use part of the bag, how long can I expect the remainder to stay fresh in the freezer? I do not have a CO2 dispenser nor a vacuum sealer, so I would not be able to purge the container of O2.

And someone else asked this eons ago, but I don't remember seeing an answer posted to the digest. What is "Victory malt"?? Does it have to be mashed, or can it be steeped like specialty malts? What characteristics does it impart to the beer?

From: mtavis@gemini.hyperdesk.com (Mike Tavis)  
Subject: Pike's Place yeast

Alright all you Seattle-ites, here's a question for you.

A few months ago a friend of mine brought me a bottle of Pike's Place back from Seattle. I tried it and absolutely loved the fruitiness (esters?) of this ale. I assumed that it was due to the yeast used in making the beer, so when another friend went to Seattle I made sure he brought me back another bottle so I could try and culture the yeast out of it.

Well last night after several starter solutions and some offerings to the gods of beer I have what looks like a healthy Pike's Place sample. My only questions is: Is the yeast I cultured the same yeast used in fermentation or is a yeast used for bottle conditioning?

Thanks in advance for your help.

Subject: Fermenting in 100 degree weather

Message Creation Date was at 9-JUL-1993 08:41:00

Greetings,  
This is just a data-point for those looking for information on how to cool their carboys on hot days:

It's been 100 degrees F in Washington, DC for the last few days as well as for the next few days to come. I had not brewed a batch in 2 months due to extensive home repairs and had grown desparate (i.e. withdrawl symptoms) to brew again. I didn't realize it would be so hot, and I don't have central A/C. I have window units which I turn off when I go to work. What to do?

I have a basement, but it's only 6 ft below ground level - but that's better than nothing. I placed the carboy in a large plastic bucket on the basement floor. I filled the bucket with about 8 inches of water and then covered the carboy with a towel. Then I put a fan right beside the carboy blowing constantly. I attached one of those strip thermometers which tells the temperature inside the carboy as opposed to the ambient air temperature. In the mornings after the night "lows" were 80 degrees, the thermometer would read 70 degrees. When I would read the thermometer at 4 PM, it would only rise to 75 degrees. Acceptable for ales.

I still prefer brewing in winter, but at least it is possible to cool a carboy during a summer week-from-hell.

Cheers,

Andy A

Well, I don't know if this is good or bad.

Basically, yeast starters are designed with only one purpose in mind:

to increase the yeast population you pitch into your wort

It has been my impression that there are two basic approaches:

- 1) Catch the yeast while they are already reproducing, \*before\* they have begun fermentation, and pitch them then.
- 2) Wait until they have all settled down for a long winter's nap and concentrate on pitching the yeast sediment in the starter.

I would personally \*worry\* if I saw appreciable krausen. Is this silly?

From: wegeng.henr801c@xerox.com

Subject: Re: Cheap carboys

It sounds like the seven gallon carboys that St. Pat's of Texas is selling are "used" from the chemical industry (where they are used for shipping acid). Homebrewers in many areas of the country will be able to buy similar carboys from industrial chemical supply companies, probably at a lower cost since they don't have to be shipped. Apparently these carboys cannot be reused for their original purpose (I dunno why). Look in the yellow pages under Chemicals, and then make some phone inquiries. Note that since these carboys contained acid they should be handled with caution until you clean them (with baking soda).

Homebrewers in the Rochester, NY area can buy used carboys from Jones Chemical in Caledonia. The people at Jones are used to dealing with home wine and beer makers.

Subject: Content and Siphons

As others have basically said already, there are lots of articles I skip over, like all the ones on kegging. But I might want to read it later, and don't want to keep others who need the info from getting it.

Plus, if I really want info on, say, wort chillers, a well-designed posting containing a stupid theory works wonders <grin>.

>From: korz@iepubj.att.com

>Back to microbiology. Besides the zillions of bacteria on your hands, >there are hundreds of zillions of bacteria in your mouth. Sucking on a >siphon hose with your mouth is probably one of the best ways to infect >your beer with lactobacillus which is everpresent in the human mouth. >Lactobacillus will eat sugars that the yeast have left behind and cause >your beer to gush about four to six weeks after bottling.

Well, Al, I appreciate your posting of seriously stupid advice, but the "start siphon with mouth" issue comes up all the time and many (including myself) have no problems with this approach. I always \*start\* my siphoning with boiled water in the tube, but whenever it stops for some reason, I end up using my mouth. In four years, my only infection has been because I used an infected starter. I can just see the testimonials pouring in again.

>a couple of others) is a partial-boil recipe. One in which, say, 3-  
gallons  
>of wort are boiled and then this is diluted into a 5-gallon batch in the  
>fermenter.

You are correct here. A partial-boil is what I want to do, or, perhaps  
it is better worded at a partial-high-gravity-boil, which is diluted in  
the primary fermenter.

I'm still looking for all-grain recipes that'll allow me to do this. I've  
done some partial mashes, hence I'm familiar w/ the process to some  
degree.

Does one just cut the amount of H2O used during the mash process in half  
to  
get a high-gravity wort? I could probably handle mashing with a full  
grain bill and H2O (1 qt/lb), but my pot would be insufficient to handle  
the  
grain sparge through my lauter-tun...

> content.

In my experience, 9 times out of 10, this happens because people mix the water and wort in the fermenter, but don't do it well enough. The result is that there is layering, and samples are likely to have really low readings.

What \*I\* do nowadays when I have to add some water to top things off is to draw my sample from the wort first. Then I had the same proportionate amount of water to my sample as to the wort.

So if I end up with 4 gallons of wort and have to add 1 gallon of water, I siphon off maybe 4 ounces of wort in the sample tube and then add 1 ounce of water to it. It may sound hard but is really very easy if your fermenter has every gallon marked off and if your sample tube is graduated as well.

From: "John DeCarlo" <jad@pegasus.mitre.org>  
Subject: Hot Break and Hops

Well, the question again arises of when to add hops and what is the hot break, etc.

I used to add hops right away as boiling started and had to be very careful about boil-overs.

I now wait until a film or scum forms on top of the boiling wort (it doesn't take very long, maybe 10 minutes into the boil). With a strainer, I then remove as much of this is feasible. Within a few minutes you will see vigorous boiling with no film/scum on top and you no longer have to worry about boilovers. At that point you can add your hops (it gets hard to strain the film off with hops in your way).

P.S. I didn't define hot break or anything here, except by accident.

Subject: What's wrong with my wheat beer?

Howdy -- and here's hoping that someone can help. I've brewed two batches now using two cans of M&F's "wheat" syrup, in attempts to make a nice, light wheat like I'd get at my corner micro (were there one). However, both of these batches have turned out *\*quite\** dark -- and I can't explain to myself quite why that's true. Could it be that my hour-long boils have darkened the otherwise light malt (which would shock me)? Is M&F Wheat always so very dark (and if so, why)? And what kind of extract can I use next time (I really don't have the time, energy, or space to go all-grain) to get the light color I'm looking for? I'm pleased with the taste of the stuff I've been getting, but the darkness has got me weirded out. Anyone with info that'll make it clear to me?

TIA -- d8^) Johann

From: Spencer.W.Thomas@med.umich.edu  
Subject: sugar in beer

I was recently re-reading Rajotte's book, thinking about trying for a "Grand Cru" style, with Celis's yeast (assuming, as has been claimed here, that the White and Grand Cru use the same yeast). He seems to contradict himself on the topic of the exact composition of "candi" sugar. On one page, referring to the "rock" kind, he says it's 99% sucrose. On the next page, referring to the liquid kind, he says it's a mixture of sucrose and invert sugar. Elsewhere in the "Sugar" section, he says that brewers prefer invert sugar because it's easier for the yeast to "eat" (they don't have to break it down first).

Does anyone know whether the inconsistency is because that's the way it really is, or are one or more of the above statements incorrect?

Does anyone know of a good source for invert sugar? I assume I can color it by caramelizing some of it.

Now that I have fallen in love with my Airstat controlled "lagering room", I want to put one on a window air conditioner, which just happens to be what they were developed for.

I was informed by Hunter that they no longer make the 220V version and I seem to be out of luck unless someone got one buy mistake or still has one in stock. If anyone has or is aware of either situation, please let me know.

For whoever it was looking for a local source, you can call (901) 745 9222 and they will give you a list by Zip Code. Not a single source in Chicago but what would one expect for such a small town?

Builder's Square carries them, but not in the city.

>of liquid to ~5 gallons was around 1.015. This seems awfully low to  
>me, as it'll result in beer that has (at most) around 1.5% alcohol  
>content.

>

>What might I be doing wrong, or what should I be looking for? I  
>carefully noted the 5 gallon mark on my carboy so I'm sure I'm not  
>making more than I think I am....

>

>

Bret, your problem is easily resolved: use more malt!!!!!! Instead of  
using a 1.4# kicker, use two (2) 3.3# cans of malt. Your SG will then  
fall into the normal range. Really.

From: gummitch@techbook.com (Jeff Frane)  
Subject: Irish Moss

I'm interested in hearing about people's experience using Irish Moss as a kettle fining agent. I had been using it off and on for years, without being able to notice any difference when I remembered to add it. Eventually, I stop bothering all together, and since I was using 1056 yeast almost exclusively, I hadn't any problems with clarity.

Recently, however, I returned to using an old friend, a culture from a local microbrewery, and discovered that my beer was no longer as clear as it should be (thanks to Dr. Fix for pointing this out rather definitely). A local brewer mentioned to me that they were switching back to flaked Irish Moss from the powder and was appalled to learn I wasn't using it at all. The ever-helpful Dr. Fix not only sent me some IM (enough to brew many hectoliters) but a copy of a paper he'd done analyzing the use of Irish Moss and its effect on hot break, head retention and body. Very interesting.

So I used Irish Moss in my most recent brew, and the results were pretty amazing -- a very dramatic hot break, quite different from what I'm used to, some strange behavior early in the fermentation (the yeast clumped into weird shapes near the surface of the wort -- George says this is normal), and what appears to be extremely good flocculation (earlier than would be expected, and more thorough).

So, what's different from the past? Well, for one thing, the "standard" homebrew texts (e.g., Miller & Papazian) suggest adding 1/4-1/2 tsp for a five-gallon batch. Miller pretty much says it's a waste of time, although it might be useful in British infusion style mashes. He says he hasn't observed any changes in other batches.

Well, I'm not surprised. According to the data George offers, and the recommendations from Siebel, the optimal addition is 1/8 gm/liter (I hate those figures, but wotthell), which turns out to be about 5 gms/10 gallons or 2.5 gms/5 gallons. Five grams of dried, flaked Irish Moss is almost exactly one TABLESPOON -- for those who are kitchen-illiterate, a Tablespoon = 3 Teaspoons. So the correct addition of Irish Moss for 5 gallons of beer = 1/2 Tablespoon, three times the amount suggested by Miller & Papazian.

Quite a difference.

Another recommendation was given me by the local brewer, and followed, which was to rehydrate the Irish Moss before adding it to the kettle. In fact, he suggested rehydrating it a day in advance, but the five grams turned back into seaweed in 1/2 hour or so; this presumably reduced the time necessary for it to go to work in the kettle. It also meant that the volume was considerably more than a Tablespoon when it was added.

Frankly, I'm convinced already but will reserve final, passionate adoration of Irish Moss until the beer is in a glass.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: In defense of Jim Koch, pt 2

Since I posted a bit last week on Jim Koch's brewery in Jamaica Plains I received some email disputing the assertion that this place could possibly be producing quality beers, much less "world class" ones. As I noted in my earlier post, I was not personally at the brewery so I was passing on second mouth information. Since then I have been able to learn some more details about the facility that Jim has installed at Jamaica Plains (near Boston).

The brewery is a 15 BBl system manufactured by The Pub Brewing Co. It consists of twin copper jacketed fired kettles, one being the usual mash tun/kettle, the other being a full sized decoction kettle. This in itself is unusual in that a brewer would spend money on a full sized decoction kettle since one usually only needs to decoct about 1/3 to 1/2 of a mash volume. There is a dedicated lauter tun and I believe a dedicated whirlpool. One of the "showpiece" aspects of this system is that Pub has engineered a bottom driven motor, as opposed to the normal top mounted drive system seen in many breweries throughout the world. Pub is apparently quite proud of this development, and probably justifiably so. The report I received indicated that some of the Unitanks are new and some are old. The system was installed in March, 1993.

The "triple bock" that I previously noted is made from an OG of 40 Plato! I believe triple is an understatement here (the first ever from Jim & Co!). It is indeed aged in old Jack Daniels whisky barrels.

Word is that the brewing staff is knowledgable and enthusiastic about the beers being produced. This is certainly not the same Ringwood system that was in this facility prior to the Pub system and as such I would say to those in the Boston area, go try it out and let us know what you think. (one of these days I have to get to Boston....)

Now I realize some of you could care less if Jim Koch brews beer in gold lined satin covered vessals, you wouldnt touch it with a ten foot sample glass and thats OK, its your consumer rights. I am no fan of Jim Koch's bastardization of the Lambic name, nor of his blatent misrepresentation of his achievements at the GABF, but I am merely pointing out that in this brewery we have someone who has gone the extra step of putting in a serious system and producing some seriously different and interesting beers and that is good for craft brewing.

Good brewing,  
Jim Busch

From: WESTEMEIER@delphi.com  
Subject: BEER & SWEAT #5: 8/21/93

\*\*\*\*\*  
\* BEER & SWEAT #5 \*  
\*\*\*\*\*

WHAT:

The 5th Annual Beer & Sweat is a huge summer party of, by, and for homebrewers. Sponsored by a consortium of homebrew clubs, it is one of the largest gatherings of homebrewers on the planet, and it is of interest to all who live in the midwestern USA. Please come if you are within driving distance of Cincinnati, and bring a keg or two of your best homebrew to share. Beer & Sweat is absolutely free. There is no admission fee of any kind, except for a \$5 fee if you wish to enter a keg in the competition.

WHEN:

Saturday, August 21, 1993. Setup will be between 3:00 and 5:00 pm.

WHERE: At the Drawbridge Estate (home of the Oldenberg microbrewery). About five miles south of downtown Cincinnati, in Ft Mitchell, Kentucky. Take the Buttermilk Pike exit from Interstate 71/75 and go east one block.

Room rate at the Drawbridge is \$70 a night, for up to four persons. Call 606-341-2800 for reservations, and mention Beer & Sweat to get this special rate and one of the block of rooms set aside for us.

WHY:

Beer & Sweat is unique in that it is 100% homebrew oriented. Unlike the usual gathering of brewers, where everyone keeps opening their cooler and pulling out another example of a favorite commercial beer, we stress the homebrewer's craft exclusively.

Beer & Sweat is also almost entirely devoted to DRAFT homebrew. For example, last year we had almost 30 kegs of top quality homebrew on hand, almost all containing 5 gallons each. There were also a few 10 gallon kegs and a few smaller kegs, but with over 150 homebrewers in attendance, we still had a quantity of beer sufficient to produce the expected quantity of sweat.

NEW LOCATION THIS YEAR:

Beer & Sweat has grown to the point where we can no longer feel comfortable mingling with the general public. Based on a number of suggestions, we have secured practically the exclusive use of the Garrison facilities. Slightly separated from the main Drawbridge complex, Garrison has an outdoor pool, tennis courts, and recreation area. There are also plenty of ice machines and soft drink vending machines. Next door to the Oldenberg brewery itself, and close to the area's biggest and best brewpub, J.D. Brews, this is the perfect spot. The Drawbridge will have food booths set up (of course you can bring your own), and we plan to set up a large tent for an outdoor eating and drinking area.

COMPETITION:

We encourage entries to the B&S Open Draft Homebrew Competition. We are considering making this an AHA sanctioned competition next

year, so this is kind of a "wet run" to see how well it goes. For a \$5.00 entry fee, you can enter a keg (no bottles) of ANY style beer. Get it set up (bring your own CO2 etc.) between 3 and 5 pm, pay the registration fee, and judging will take place at 5:00 pm. Any BJCP judge who would like to participate should contact Ed Westemeier in advance via e-mail at: westemeier@delphi.com (or by phone at 513-321-2023). No points, just great draft beer. Next year we probably WILL have points available.

First prize in this competition will be a PhilMill donated by the Listermann Mfg. Co. and second prize will be a Phil's Lautering System from the same source. Third prize is a pound of hops. A prize will also be awarded to the club with the highest average point total. After the formal judging of registered entries, ALL kegs present will be eligible for the popular vote competition, and a prize will also be awarded for that.

**BJCP EXAM:**

The BJCP Exam will be conducted at 10:00 am SHARP. Anyone wishing to join the ranks of the "official" beer judges should register no later than July 31. Test fee for first time exam takers is \$40, and \$30 if you have taken it before and want to raise your score. Contact Keith Wilbourn by phone at 502-422-6954 or fax him at 502-422-6955.

**MORE INFORMATION:**

General questions should be directed as follows:  
e-mail: westemeier@delphi.com  
phone: Allan Moellmann at 513-232-9182 anytime during July  
phone: Chuck Boyce at 513-531-8076 after 5 pm weekdays

From: sc@vcc.com (Steve Casselman)  
Subject: Yeast Storage

This question was recently presented.

>I recently purchased a back issue of Zymurgy (Gadgets and  
>Equipment). After reading an article on preserving and freezing  
>yeast by Maribeth Raines Ph.D. I decided to give her suggestions  
>a try.  
>I only wanted to store my yeast for a few weeks to a month  
>so I followed her directions for storing the yeast in the fridge.  
>I mixed yeast from the primary (British #1098) with an equal  
>amount of a sucrose solution mixed at a ratio of 1 cup of water  
>to 3/8 sucrose. I understand that the article was mostly about  
>freezing yeasts, but she also suggests, "On the other hand, if you  
>plan to use the same yeast within the next few months you can  
>save the yeast from your primary fermenter and store it with an  
>equal volume of sucrose (it's cheaper than glycerol) in the  
>refrigerator.(Zymurgy Special 1992, p. 69)"  
>The new solution was placed in the fridge in a sanitized and  
>closed glass jar. In a few hours I noticed that the solution  
>was fermenting away. So, over the last few days I have been  
>venting the jar to keep it from exploding. This situation seems  
>quite dangerous. Most of all, I was surprised to see an ale  
>yeast ferment at 38 degrees. Should I take that to mean that I  
>have a wild yeast fermenting away beside the British yeast  
>strain.  
>  
>Any suggestions are appreciated. Am I doing something  
>  
>wrong? Any suggestions or amendments to the article.  
>  
>STEVE

The well documented procedure will allow yeast to be stored  
for as long as two years. The principle behind it is at 4  
degrees C invertase becomes inactive. This means there is  
no way for the yeast to metabolize the sucrose. If you are  
getting fermentation there are a few things you might not  
have made sure of: 1) you can have no other sugars but sucrose,  
common errors might include; taking the yeast from the  
primary before it is completely fermented, using a low  
purity sucrose (it might have glucose in it for example),  
and 2) the solution must stay under 4 C at all times.

In your current position I would put your jar in the  
refrigerator with the lid on loosely to allow any sugars  
other than sucrose to ferment out then close the lid. If  
this does not work than your refrigerator may not be keeping  
a constant cold temp.

Your problem, of course, could also stem from the introduction  
of some wild yeast - in which case I would not recommend  
repitching the yeast.

I hope this helps.

Steve Casselman

> content.

> What might I be doing wrong, or what should I be looking for? I  
> carefully noted the 5 gallon mark on my carboy so I'm sure I'm not  
> making more than I think I am....

There are several possibilities.

- 1 Are you taking your gravity readings when the wort is 60 deg. F?  
Taking readings at higher temperatures will give lower than  
expected readings. For example, if your reading of 1.015 was  
measured at 110 deg. F your actual SG is 1.023. If the temperature  
of the wort was 140 deg. F your actual SG would be about 1.027.
- 2 Your hydrometer is bad. A simple check is to measure the SG  
of water at 60 degrees F. It should measure 1.000 (or very close).
- 3 Assuming that by "sparging" you really mean pouring and straining  
the wort into your carboy, do you vigourously shake the carboy  
to get a homogeneous mix. (I'm assuming that since your just  
beginning, your not boiling all 5 gallons at once and are mixing  
your boiled wort with cold water in the carboy.) If so, it is  
conceivable that the higher density wort has settled to the bottom  
and you are measuring the gravity of the lower density stuff  
which has stratified on top.

By the way you should have gotten gravities of about  
1.034 for 3.3 lbs Canned Malt Extract + 1.4 lbs DME  
and  
1.038 for 1.8 kg (3.97 lbs) Malt extract + 1.4 lbs DME.  
for your 2 batches.  
Here, I've used the empirical formula

$SG = 1.000 + (\text{lbs of DME} + 0.8 * \text{lbs of Malt Extract Syrup}) * .0084$

for a 5 gallon batch. This assumes 42 points for DME and 20% less  
for syrup.

From: "Rex K. Perkins" <70651.1611@CompuServe.COM>  
Subject: 6oz bottles / Mail order Belgium imports

To: >Internet homebrew@hpfcmi.fc.hp.com

I am about to start my first mead and was recently pondering the problem of bottling the stuff. As it is going to be mighty strong, I won't really want to drink it 12oz at a time. It will also be sparkling, so re-sealable screw caps won't help either. So, the natural solution would be for smaller bottles.

I was once given a case of European lager in small bottles. I think these were 225ml (8oz), but I'm not sure, so I know they exist. I'm sure I have seen smaller bottles (6oz?), but I can't think where.

My question is: Where can I get 6-8oz bottles from? I see many home-brew suppliers carry 12 and 22oz sizes, but no mention of anything smaller. Does anyone know of a source of such bottles? I guess I'd be looking for 2-4 cases.

\*\*\*\*\*

Reading the current issue of CAMRA's What's Brewing I see several UK companies offering Belgium beers by mail order. Are there such companies in the US? The selection of such beers available locally (central MA) is very limited and I would like to expand my knowledge of these beers. I could ask the UK companies if they would send to the US, but I expect I would get hit on both UK and US taxes that way.

Cheers,

Rex K. Perkins

>  
>1. Does the NO2 cartridge in the canned Guinness affect more than just the  
>head of the brew? It seems to me that the canned Guinness is alot  
>smoother  
>and less bitter than the traditional bottled stuff.

Guinness does not use NO2; it uses N2, nitrogen. The canned stuff is all together different then the stout in the bottles. IMO, the canned stuff is light and the bottled stuff is heavy. Guinness names the can stuff "Draught" and the bottled stuff "stout."

>2. What does the nitrous oxide actually do to the beer? I.e. how does it  
>interact with the brew to give the creamy head and the smoother taste.

again, N2; my understanding is that the N2 facilitates much smaller bubbles, hence making that creamy head.

>3. Is any other brewer using the NO2 cartridge? If so, who?

Murphey's stout; same design as guinness. not sure if this is available in the US yet; I've brought some back from Ireland w/ me in the past.

>5. Are any home brewers using the NO2 cartridge for their homebrew, or  
>contemplating trying it?

No, but i have thought about buying a second CO2 cylinder and having it filled with 40% N2 and 60% CO2 for some winter stouts out of my keg. Has anyone done this with success (ie: brewed a stout and dispensed it w/ a nice creamy head ala guinness?).

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Re: IPAs & Basements

John Mare makes some excellent points regarding English IPAs:

<From: cjohnm@ccit.arizona.edu (John Mare)  
<Subject: India Pale Ale's

<In a recent discussion on India Pale Ales (IPA's) the assertion was made  
<that these are all high gravity ales. Conventional wisdom tells us  
<that these ales were brewed at high gravity to allow them to travel well  
<(ie. by ship to India), and our US beer competitions persist in defining  
<IPA's as medium to high gravity (OG 1050 to 1065). It is interesting to  
<observe, however, that in their land of origin IPA's are not in fact  
high  
<gravity ales. Some of the truly outstanding examples of this type which  
I  
<tasted on a recent beer tour of The British Isles include "Palmer's IPA"  
(Dorset, OG 1039, ABV 4.3%), "Robinwood IPA" (Yorkshire, OG 1040, ABV 4.  
2%),  
<"Younger IPA" (Edinburgh, OG 1043, ABV 4.5%), "R&D Deucher's IPA"  
<(Edinburgh, OG 1048, ABV 3.9%), and "Thompson's IPA" (Devon, OG 1045,  
ABV  
<4.6%).

This is absolutely true. In fact I had troubles locating a IPA as high  
as 1.046 OG. Even "strong ales" tend to be around 1.052 and are regarded  
with fear from many pub goers. It is really sad to find this attitude,  
since as a result these beers tend to be some of the oldest and less  
crisp  
cask ales to be found. Of course, the higher gravity gives them a slight  
edge on shelf life. Note how much residual sugar is in the R&D Deucher  
IPA at only 3.9 ABV with an OG of 1.048. This can be true of the  
ordinary  
bitters too.

Gene asks about basement ferments & sanitary conditions:

<From: Gene Zimmerman <ezimmerm@hp.uwsuper.edu>  
Subject: Farmer/Engineer etc

<How many people brew in their basements? Unless it's an enclosed room,  
<I can't see as it would be very sanitary at all. Most of them are a  
\_little\_  
<damp, dark, and although not warm, a constant temp. I think someday I'll  
<have a brew set up in a basement, but I've always thought of sheet  
rocking  
<off a room and putting ceramic tile on the floor and waist coat

Well, I ferment in my basement, in an open SS vessal. I do leave the  
heavy  
lid ontop, and remove it to skim yeast. I still have numerous cobwebs  
over-  
head and it could be much cleaner but it works fine. Sure, Id love to  
have  
sheetrock and tile too, but Im too busy spending money on SS vessals to  
do  
the tile work. The key is always lots of clean healthy pitching yeast.  
You  
would not believe how dirty some english and belgium breweries are.

Good brewing,  
Jim Busch

Subject: 2 holes

In a recent post to Mark at Hoptech in response to a query as to where one might obtain a two hole stopper for carboys, Mark was kind enough to tell me of how he ended up drilling a second hole himself. He said he used a regular drill, but it chewed up the rubber. Not having a suitable drill bit, I tried an alternative, a 1/4 inch piece of brass tubing lying about, which I filed to an edge on one end and chucked up in a hand drill on the other. I lubricated the tube with a drop of water. The thing worked beyond my wildest hopes and made a hole cleaner than the original. Altho the tube was 1/4 inch, the hole it made was smaller such that a piece of 1/4 inch copper tubing fits perfectly. The tube also just fits the inside of my keg system CO2 line so I now have a way of starting the syphon system on carboys for transfer to kegs. Lab types I know have stoppers available, but none of the local homebrew suppliers do :-).

Subject: it's in the air

For those of you with possible airborne infection problems, one way to clean the air is to allow steam from boiling sparge water or wort to fill the brewroom. As the steam settles out, it will take airborne particles down with it, much as rain clears out smog. The heat of the steam may also help in sanitizing.

smoother

>and less bitter than the traditional bottled stuff.

I believe Guinness draught and Guinness Extra Stout are two different recipes, the draught recipe being smoother, the Extra Stout containing a small portion of soured beer.

>2. What does the nitrous oxide actually do to the beer? I.e. how does it

>interact with the brew to give the creamy head and the smoother taste.

N2, not NO2. It doesn't dissolve (well, not well). The thick body and tiny bubbles make for the creamy head.

>3. Is any other brewer using the NO2 cartridge? If so, who?

There are a few british ales using the N2 cartridge (called, I believe, a "bobo")

>4. Would it make sense to use the NO2 cartridge in any other brew (lambic?

>porter? scottish ale?)

A scottish ale perhaps, definitely NOT a lambic. Any beer which is cask conditioned and served by hand pump rather than by pressure (ie "Flat" beers) could be served with this method.

>5. Are any home brewers using the NO2 cartridge for their homebrew, or  
>contemplating trying it?

Not unless they have a way of canning their beer under N2 pressure. Most homebrewers use bottle conditioning for carbonation. Some may have used a CO2/N2 mix for dispensing Kegs, though.

Invert sugar is split sucrose. Same components, easier for yeasties to digest, and perhaps the invert sugar is easier to make into a syrup (higher solubility rate?).

>Does anyone know whether the inconsistency because that's the way it really is, or are one or more of the above statements incorrect?

>Does anyone know of a good source for invert sugar? I assume I can color it by carmelizing some of it.

Might be able to find invert sugar at the grocery store near the cakes and frosting mixes. If not, try food distributors, or your local mega bakery. What I did was to dissolve sucrose in a bit of wort, and I added just a touch of honey and corn syrup. Then I boiled the s\$#@ out of it to caramelize it. As the water evaporates it will all froth up and make a mess, so keep your eyes on it. To get the caramelized sugars out of the pan, keep the heat on and add more wort, stir to dissolve.

The belgian ale I did this way came out tasting right, anyway.

I use a propane torch. Overkill, maybe, but it certainly does the job.  
I originally bought it for constructing a counterflow wort chiller, and  
wouldn't be using it much any more if not for yeast culturing.

A bottle of propane cost about \$8 at the hardware store, if memory  
serves.  
The head (valve/nozzle assembly) can be had for about the same, or you  
can spend a little more if you want one with a built-in igniter.

> content.

It has already been mentioned that perhaps the water that you sparged  
with  
had not mixed very well with the wort at the bottom of the fermenter.  
This  
is most likely the problem. However, you should also remember to  
compensate  
for temperature. Check your hydrometer -- most are calibrated for 60F,  
but  
some are calibrated for 70F. Once you know what it's calibrated at, you  
need to compensate for the temperature of the wort you're measuring. All  
I  
have handy right now is a sheet that came with one of my very first  
hydrometers. It was calibrated to 60F and here's the temp. compensation  
chart:

50F -0.0005  
60F 0.0  
70F +0.001  
77F +0.002  
84F +0.003  
95F +0.005  
105F +0.007

Check back issues of HBD for at least three more charts/formulas for  
SG temperature compensation.

can  
>bet the big breweries would be using it. I've never seen any reference  
to  
>it.

Researchers research & publish, whereas brewers brew & usually don't publish.  
A problem with articles written by researchers is that much of the information is not bound to practical applications. I called the Siebel Institute and they confirmed that except for hop extracts, the hops are generally not added at the very beginning of the boil for several reasons including the one I mentioned.

>Number two, I've never noticed any protein coating the hop petals  
>or particles and even if it did, it wouldn't matter cause there isn't any-

until  
>30 minutes into 1 hour boil? I'd be getting a \*lot\* less utilization  
from  
>the shorter boil time than any better utilization advantage I might have  
got  
>by waiting.

Mark, you might as well admit you are one of those newbies. For you and the others, that don't know what hot break looks like, it looks kind of like egg drop soup. No need to sample your wort unless you are boiling in a keg with a small hole cut in the top of it. You just look in the pot and see the flakes churning about. It begins usually within the first 5 minutes of the boil as little flakes of off-white globs. I'm not saying wait 30 minutes (although some brewers do) for your first hop addition -- I usually wait 10 or 15 minutes and then add my hops. So my logbook reads:

```
boil: 70 min
60min -- 1oz Nugget Pellets 12.8% AA.
15min -- 1/2oz East Kent Goldings Plugs 4.7%AA.
dryhop -- 1oz East Kent Goldings Plugs 4.7%AA.
```

>:>the bottom. This is instead of the hop bag. The hop bags are great for dry  
>:>hopping, but I don't like them for the boil.  
>:  
>:I disagree. I do just the opposite. I use a hop bag for boiling primarily  
>:to avoid the problems of having to remove the hops from the wort later,  
>:either as you pour the wort into the fermenter (my screen kept clogging  
>:and that made it a real pain!) or when racking. I just compensate by  
>:adding 10% more hops. I don't use a hop bag for dryhopping but only use  
>:whole or plug hops because they float. I've never had any problems  
>:siphoning the beer out from under the whole hops.  
>  
>Floating hops does not make for good oil utilization. The best method is

>to keep the hops suspended in the middle of the beer using a bag and weight  
>system (tie the weight to the drawstring instead of putting it in the bag).  
>This is what Anchor does and I have found it works well for me and other  
>brewers I know. I don't know of any commercial brewers that boil their  
>hops in a bag, but they do use them for dry hopping. But what works for  
>you works for you.

I contend that it is more difficult to get the hop bag into a carboy than loose hops, more difficult to remove the hop bag than loose hops from a carboy (not an issue for Anchor, with their open fermenters), sanitation of the hop bag is not particularly easy (I just sanitize a funnel and a 1 foot length of plastic HDPE hose and stuff the hops through it into the carboy) and the total surface area contact of loose hops is probably greater than that of hops in a hop bag despite the fact that the very top layer of hops is not immersed in the beer (I'm just basing my assertion on my observations -- not on any experiments that I've done)

>:>BTW, I have found  
>:>the "orange racking tip" thingy to be essentially worthless. Ditto

>:Interesting, but I've had no trouble with the orange tip on the end of my  
>:racking cane -- I tip the carboy with a stack of coasters or a block of wood and then gently lower the cane into the lowest part of the carboy.  
>:I then use masking tape or a rubber band to make sure the cane doesn't  
>:move. I discard the first two cups or so and the beer runs clear from  
>:there on. Perhaps you are not getting a good cold break and your trub  
>:layer is very deep. Then again, you've got hops in your trub and I don't.

>So you get a couple of cups of trub? Isn't this exactly what the orange  
>racking tube tip is supposed to prevent? I guess it doesn't work for  
>you either! :-)) I suggest you try leaving it off once and I'll bet  
>your  
>results will be identical. My trub layer isn't any deeper than yours,  
>and

I don't think you understand the principle. When I insert the racking tube with the orange tip into the fermenter, I'm careful to avoid disturbing the trub. The tip sinks partly into the trub and the first two cups of beer through the racking tube draws the nearby trub in -- subsequent beer is virtually crystal clear.

>I don't have hops in it. My strainer works fine. I also use a "settling  
>tank" between the kettle and the primary. I use my old plastic fermenter  
>with the spigot in the bottom. I cool the wort, pour through the strainer  
>into the bucket, put the top on and let the cold break settle out. Then

That must be some mongo strainer or you must have to dump it after every gallon of wort -- I stand corrected -- I had theorized that perhaps the reason for your dissatisfaction with the orange tip racking tube was a very deep trub layer in the primary. I try to avoid transfer of beer when I can, since every additional transfer is one more container to sanitize

(plastic fermenters being even harder to sanitize than stainless or glass)  
and an additional invitation for infection.

From: korz@iepubj.att.com  
Subject: fruit/hot break

Andy writes:

>1. Is 2 lb raspberries/gallon of beer a reasonable amount?

It may be too intense. I used 5 lbs of raspberries and 5 lbs of cherries in a 5 gallon fermenter and then added about 3.5 gallons of beer on top of them. One judges comment (from our very own Roger Deschner) was that the beer didn't have enough "beer flavor" and that the fruit completely overpowered the malt. By the way, I presumed that some of the fruit flavor would subside after a while and the same beer entered in a competition

two months later took first in fruit beers. Note that raspberries have a much more dominant flavor/aroma than cherries and this is why I'm speculating

that 2#/gal would be too intense. If I were to try a balanced raspberry/cherry beer, I would probably use 2:1 for the cherry/raspberry ratio.

>2. Should I use a Campden tablet overnight in the  
>raspberries to prevent introducing any new bacteria in the  
>secondary fermenter?

Can't help you there -- I froze and blanched my fruit for sanitation, but you are correct in assuming that you'll introduce some microbeasties with the fruit and you need to deal with them somehow. I just don't have any experience with Campden tablets.

>

>3. Siphoning: If I siphon first into one carboy and then  
>into the second, I'm afraid I may end up with differing  
>beers. I would think the first carboy would get the lighter  
>beer and the second a heavier beer (and more trub remnants).  
>I was thinking of a "Y" siphoning connector. The beer  
>being siphoned would hit the "Y" connector and then branch  
>out down two paths into the two carboys. I would end up  
>using 3 lengths of 3/8 " tubing along with the "Y" connector  
>to accomplish the siphon.

>Does anyone know if this would work, or is it doomed to  
>abject failure?

>If it would work, does anyone know where I could  
>procure a "Y" connector?

The "Y" would work and you can probably get it from a place that stocks parts for Recreational Vehicles. Note that a problem with your experiment

that you haven't mentioned is that the geometries of your fermenters will be different, no? You have to account for the space taken up by the fruit.

\*\*\*\*\*

Bill writes:

>1) from the FAQ file, what and when is hot break?

Hot break is coagulated protein. It is basically cooked protein, but is formed partly due to the proteins in the wort reacting with tannins from the grains and (later, for those who do wait for the hot break) hops.

>2) do you wait for hot break before adding bittering hops (the  
>hops usually added at the beginning of the boil). Or are we

>talking aromatic hop addition here?

Personally, I do wait, even for the boiling hops.

\*\*\*\*\*

Dave writes:

>I've just recently started lagering, and I found it impossible to find  
>a Hunter Airstat anywhere in the Milwaukee, Wisconsin area. Everyone I  
talk  
>to at home supply type stores (Menards, etc) give me that look of "Yeah,  
right,  
>temperature controller...uh huh....sure....that's OK" You know, that  
look.

You might try asking for a thermostat for a window airconditioner. I  
have  
the Hunter sales brochure and they make something like eight thermostats.  
One of them is most definately the Hunter Airstat. If your retailer  
carries Hunter thermostats, they should be able to get the Airstat. You  
could also call the number Jack posted -- sometimes I think homebrew  
makes  
you psychic.

Subject: U-brew-it-here-place

On Thu, 8 Jul 93 10:16:59 PDT, Geoff (ghultin@sfu.ca) said in the course of

a discussion that was really about: Subject: yeast FAQ/filters/temps:

->I just made some quasi-czech pilsner at a U-Brew-It-Here place

Geoff,

This is the first I have ever heard about a place of this nature. My husband and I are about to move, and it now occurs to me that this might be

a good little sideline to get into in our new location. How do they get around the laws concerning selling homebrew, the gallons per year rules, and all the other regulations that exist to prevent us from all realizing our dreams and opening brew pubs in our basements? What state are they in, and if possible, could you tell me the name of the store and their address? Do they let the batch ferment there, bottle or keg it and baby-sit

it for you? Take gravity readings, etc.? Is your batch guaranteed, or if

there is an infection or the batch tastes like something awful, do you eat

the cost of the brew? And do they have a standard selection of brews you can

do, or do they let you use your imagination? There are plenty of homebrew

supply shops where we are going, but this idea could really be a winner!

Bettina B, dreaming in CT...about doing something like this in NY

Date: Mon, 12 Jul 1993 19:05:22 EDT  
From: CKXB66B@prodigy.com (MRS BETTINA A BARBIER)  
Subject: Flat Beer

On Thu, 8 Jul 93, Rich Ryan <ryancr@install4.swin.oasis.gtegs.com> said about: Subject: flat beer:  
>The beer tastes fine other than being somewhat flat. Papazian's  
>troubleshooting section came to two conclusions: 1) I left an excessive  
>amount of sterilant in the bottles or 2) I'm storing the beer at  
>excessively cool temperatures. I used B-brite to sanitize the bottles  
>and equipment and was very diligent to make sure I washed it all off.  
As  
>far as storing the beer goes, it hasn't gone below 70 since it was  
bottled.

Rich, how did you prime the beer at bottling time? If you rinsed the bottles well and are keeping them at 70 degrees, either you didn't prime the beer right or you have a brew that attained so high a level of alcohol that it killed all your yeast-critters. Why don't you give us a little more info...Style brewed, ingredients, OG, FG, type of yeast used and how long the fermentation took.

>I noticed that I have more like two inches of air space in each bottle.

I would think that with over 2 inches of headspace you would have little beer bombs ready to explode. I usually go for less air space rather than more, based on no real theory but just on our own good results and the hope that by eliminating one little 1/2 inch of space in each bottle we might reduce the amount of bottles to fill and cap (and wash) per batch. I think that if this situation continues, you may want to re-bottle the beer, perhaps by making up a rather large starter, uncapping all the bottles, putting the beer into a well-sanitized bucket, adding the starter at high krausen and re-bottling in a new batch of (already waiting) sanitized bottles. I would not use the same bottles again. Do you have a jet washer?. Or you could keg it and force-carbonate it.  
Good luck with it...Bettina

From: CKXB66B@prodigy.com (MRS BETTINA A BARBIER)  
Subject:

On Thu, 8 Jul 93 13:18 CDT, Frank (fjdobner@ihlpb.att.com) quoted Drew in:

Subject: AdvertisingWyeast

>>Again Drew says:

>> How about this: Once a month, each person who sells a product may  
>>post a "I sell this product" message. No claims, no hype, no prices,  
>>no details, just a clear statement of intent to sell. Interested  
>>parties may then send them private email requesting info on their  
>>product. These people should then refrain from taking part in  
>>discussions on their or competing products. People with personal or  
>>financial interest (close friends of sellers, etc) should show similar  
>>restraint. Recommendations from satisfied customers in responses to  
>>queries from other list members would always be welcome.

Frank then says:>I agree wholeheartedly with this recommendation.

>This would perform many>services to us in this forum.

>It would allow the commercialists (me being one)

>to do their thing in a confined marketplace, would restrict commercial  
>behaviour to what would be strictly proper and improper, provide product  
>information to customers, and allow the real artists and scientists  
>here their needed airtime to talk about their hobby/pastime/  
professions.

Bettina chimes in with her non-commercial 2 cents:

I agree, as a newcomer here but a regular on another service (am I  
allowed

to mention other services I am on?) that the problem of crass  
commercialism

would be well addressed by this approach. I have no problem with people  
who sell things saying so...who knows, I might just want to buy one! I  
think the caveat should be that the description should fit into a  
proscribed amount of space, with details limited to descriptions of  
technology used or actual physical characteristics rather than long  
laudatory sales pitches about the item, i.e. "Fresh Belgian Yeast  
straight

from a Trappist brewery and flown in every week on the Concorde, in  
special

containers of x composition and gathered using y methods, including a  
hermetically sealed container of air from near the roof tiles of the  
brewery" might be acceptable...but NOT GUARANTEED TO MAKE TRAPPIST ALES  
BETTER THAN THE MONKS DO!!!!!!...I am always interested in reading about  
new things, and especially in how things work or how they are done, but  
NOT

in hearing about how great the inventor, seller or best friend of the  
above

think the whateveritis is.

From: Domenick Venezia <venezia@zgi.com>  
Subject: Pike Place Yeast

In HBD #1179 Michael Tavis asks,  
> My only questions is: Is the yeast I cultured the same yeast used in  
> fermentation or is a yeast used for bottle conditioning?

I called the Pike Place Brewery, and the gentleman that answered (did not get his name) was very helpfull. At the tail end of the fermentation (primary or secondary?) the fermenter is sealed and allowed to pressurize. It is then cooled to help dissolve more CO2, and flocculate the yeast, then they bottle using a counter flow pressure system. So, the yeast Michael cultured is what they use to ferment.

Subject: Re: J Klaassen's wheat beer

I think you provided the answer - the boil is too. Try your next batch at twenty five minutes. I have successfully used the M&F Wheat (two cans with 1 pound of malted wheat mashed in 3 cups of 150F water and sparged to add to wort to make 5 gallons) with 1 1/2 Hallertau plug hops to make a very satisfying, pale wheat ale. The last batch I added a hop tea of Hallertau to add to the aroma and liked the results.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)  
Subject: electric surface heating elements

I would like to find an electric surface heating element which could be used for a 6 - 8 gallon boil. Right now I do a 2.5 gallon boil using the 1 kW element on my kitchen stove, which takes about 30 to 45 minutes. All else being equal, seems I could use a 2 - 3 kW element.

Note that I don't intend to replace the stovetop element. I want to make a stand-alone unit that I could use in the garage or outside with a 10 gallon stainless pot.

Thanks in advance.

Mike, yes you have the fermentation strain. Pike Place is a single  
strain  
yeast.

Since they Irish Moss their beer I am suprised you obtained any yeast  
from the bottle. I was told by the brewery - Good luck... Then I took  
them a quart jar and they gave me some yeast...

This strain is a good strong fermenter. Not much esters and other  
flavors.

Subject: Extract darkening with boil

In HBD #1179, Johann Klaassen writes:

>Could it be that my hour-long boils have darkened  
>the otherwise light malt (which would shock me)?

Funny you should mention this, because this very weekend I was at my local brew store talking to the guy there about brewing with extract. I usually brew all-grain, but due to time constraints I'm doing an extract batch next, and so I was getting some advice on it. He said that boiling does indeed darken malt - he thinks it's actually an oxidation process and that splashing the wort around a lot when hot darkens it even more. His solution: do a mini-mash of your specialty grains first (crystal, chocolate, etc.), strain the grain out, then boil the hops in that water, and only add the extract for the last twenty minutes of the boil, thus minimizing the time the extract is boiling, but still giving you the full time for the hop boil.

How does this technique sound to the more experienced extract brewers out there?

Subject: Not enough body/SF area brewpubs

Response to Ed Wolfe

Beer Body

I use at least 1/2 to 1 lb Dextrin malt in my mash for an acceptable level of body. This malt must be crushed and mashed with your 2-row. You can use dextrin powder and add directly to your boil but I have never experimented with it as I went to all-grain before I had the chance.

SF area brewpubs

If you can, check out the Anchor Brewing Co. on Potrero Hill in the South part of the city just off of Hwy 101. The fresh beer is outstanding, not like your bottled stuff! Try a 50-50 mix of Liberty Ale and Old Foghorn Barley Wine, you'll never be the same. Pick up a Celebrator magazine when you get there and you will have an instant guide to the local micros. Call Anchor Brewing or SF Brewing Co. on where to get a copy. For the Jurassic Park of micro brewing you MUST visit Buffalo Bill's in Hayward, enough said.

Subject: Fruit quantities in beer

I am interested in trying my hand at a couple of fruit beers. I was wondering if anyone has put together a chart that shows how much fruit to add for five gallon batch. Also, whether to add to the wort, primary, secondary, or bottle. Also weather to cut, blanch, or whatever. It would look something like this.

| Fruit     | WGT. | Conditioning | Wort | Primary | Secondary | Bottle |
|-----------|------|--------------|------|---------|-----------|--------|
| Blueberry | 10#  | Blanched     | X    |         |           |        |
| Orange    | 10#  | Cooked       | X    | last    | 5m        |        |

|        |     |          |   |      |    |   |
|--------|-----|----------|---|------|----|---|
| Orange | 10# | Cooked   | X | last | 5m |   |
| Prunes | 5#  | Blanched |   |      |    | X |

Of course, the above are fictional, but maybe someone who knows these things can fill in the blanks. TIA, Ed

From: scott.powell@amail.amdahl.com  
Subject: Beer in the White House

I was digging through some of my old books and I found one I had forgotten about. It's titled The White House Cook Book. A Comprehensive Cyclopedia of Information for the Home. It was first written in 1887 (though I have a second printing from 1907) by Hugo Ziemann (Steward of the White House) and Mrs. F.L. Gillette. Here are the beer recipes I found.

#### Hop Beer

Take five quarts of water, six ounces of hops, boil it three hours; then strain the liquor, add to it five quarts of water, four ounces of bruised ginger root; boil this again twenty minutes, strain and add four pounds of sugar. When lukewarm put in a pint of yeast. Let it ferment twenty-four hours it will be ready for bottling.

#### Ginger Beer

Put into a kettle two ounces of powdered ginger root (or more if it not very strong), half an ounce of cream of tartar, two large lemons, cut into slices, two pounds of broken loaf sugar and two gallons of soft boiling water. Simmer them over a slow fire for half an hour. When the liquor is nearly cold, stir into it a large tablespoon of the best yeast. After it has fermented, which will be in about twenty-four hours, bottle for use.

#### Spruce Beer

Allow an ounce of hops and a spoonful of ginger to a gallon of water. When well boiled, strain it and put in a pint of molasses, or a pound of brown sugar, and a half an ounce or less of the essence of spruce; when cool add a teacupful of yeast and put into a clean tight cask, and let it ferment for a day or two, then bottle it for use. You can boil sprigs of spruce fir in place of the essence.

#### Egg Flip, or Mulled Ale

Boil one quart of good ale with some nutmeg; beat up six eggs and mix them with a little cold ale; then pour the hot ale into it, and pour it back and forth several times to prevent its curdling; warm and stir it till sufficiently thick; add a piece of butter or a glass of brandy and serve it with dry toast. (I'm going to try this at a Homebrew party in August)

>From what I gathered about this book it is a compilation of information  
from  
the recipes and experiences of the White House staff since the time it  
was  
first occupied (circa ????) till 1887.

Subject: re-using yeast slurry

>When fermenting with liquid yeasts, is there a simple way to use the  
>slurry on the bottom of the secondary for pitching into a new batch?  
>Any comments on the amount to use would be helpful. Also, is there  
>a method for storing such a slurry for later use?

I have been re-using yeast slurry for several years. My method is to add a cup or so of cool water to the slurry after I've racked off of it and swirl it around, mixing the slurry really good with the water, then pouring it into a sterilized glass quart jar. I let this sit at room temp for several hours until there is noticable seperation, then pour the top liquid layer off. I again add about a cup of cool water to the yeast, mix it up good, cover and let sit at room temp for several hours. Pour off top layer, pour the resulting yeast cake into a sterile canning jar, cap and store in the refridgerator until you're ready to brew again. This is better know as washing yeast and the method can be used with either dry or liquid yeasts. I have been usually re-use a package of yeast anywhere from 7 to 10 brewing sessions before it starts to appear suspicious.

Cheers,  
Jami

again.

I probably shouldn't get involved here, but I'm a bit confused.

Are you saying it's impossible to get an infection using your mouth when  
starting a siphon? Because if it is possible, then why is Al's advice  
"seriously stupid"? The fact that you have not gotten any infections  
using a siphon by mouth seems analogous to not getting lung cancer  
after smoking for 30 years, or not getting killed while driving  
without a seat belt, or not getting an infection while having sex  
without a condom. All these are likely outcomes but since they  
are all possible any advice on not smoking, or on wearing seat belts,  
or a condom aren't "seriously stupid". If you believe the chances  
of infection are so remote that one shouldn't worry about it,  
then why not use your mouth all the time instead of using boiled water?

It is my understanding that you will need a different type of tap to  
completely duplicate the creamy head. The taps used for Guinness  
must add some turbulence or some other effect whereas the standard beer  
taps go for smooth flow so as not to knock the CO2 out of solution. I  
have not found a bar owner who would let me take their Guinness tap apart  
to find out but I do keep trying.

From: Jim Griggers <brew@devine.ColumbiaSC.NCR.COM>  
Subject: Parking in Portland

I will be attending the AHA's Brewing Frontiers in Portland, Oregon. When I picked up my airline ticket yesterday, I discovered yet another cost for this trip.

I will be flying into Seattle and driving a rental car to Portland. One big shock came when my travel agent informed me that the parking charge at the Marriott is \$14 a day. Parking the car for a week will cost almost as much as the car rental. I don't plan on using the car very much during the conference, but I do want to have a car for a couple of days to sight-see after the conference and Brewers Festival.

Does anyone have a suggestion on where to park? Renting the car "by the day" is out because they have a \$75 drop-off charge. Maybe some other combination of travel would work (air, bus, rail, boat, ???).

Subject: Irish Moss

Jeff Frane asks:

I'm interested in hearing about people's experience using Irish Moss as a kettle fining agent. I had been using it off and on for years, without being able to notice any difference when I remembered to add it. Eventually, I stop bothering all together, and since I was using 1056 yeast almost exclusively, I hadn't any problems with clarity.

I recently made a steam beer using Papazian's all grain recipe. The recipe called for Irish moss but I decided to omit it. After a month in secondary the brew had a permanent haze that just wouldn't go away. On a hunch, I boiled 1/2 tsp irish moss in a quart of water for 10 munutes and after cooling added to the secondary and mixed well. Within minutes globs of solids formed (I love technical terms :- ) and settled to the bottom. Within 24 hours the brew was crystal clear - I mean CLEAR!

The beer is currently on tap and is great.

- --Tony Verhulst

P.S. I had done a protein rest (122F for 30 min) and the iodine test was negative for starch.

From: fjdobner@ihlpb.att.com  
Subject: Duvel

The recent post on Duvel got me thinking about something I read in Jackson's Belgian beers book. On page 216 paragraph 3, it states "A proportion of dextrose is added before primary fermentation, to boost alcohol and further attenuation." Well, my understanding of dextrose is that it is not largely fermentable (by commonly used yeast). How could the dextrose boost alcohol and further attenuation. Perhaps its in the type of yeast used. Jean De Clerck at it again. A further reference to dextrose being used in priming after cold maturation and yeast compaction (see last paragraph same page).

It is also interesting to note that the maturation for this top-fermented product is so low: 30.2F or -2C. After maturation they drop the temperature to 26.6F (-3C) for compaction and precipitation of the yeast bed. All this happens prior to conditioning. During which the temperature is boosted to 71.6F (22C). My experience with yeast is after it has sedimented and been treated in such a cold manner that it doesn't take to a quick revival. Must be a truly remarkable yeast.

From: Jeff Benjamin <benji@hpfcbug.fc.hp.com>  
Subject: Re: 6oz bottles

> My question is: Where can I get 6-8oz bottles from?

Coca-Cola has recently started selling Coke in 6-packs of 8oz bottles (at least here in Colorado). The bottles are nice heavy glass and take normal crown caps, not screw-ons. I've used them quite successfully to bottle strong ales and such. Check out your local grocery stores. Donate the bottle contents to your friends if you're not fond of Coke or if you'd rather try to win a syringe :-/.

The disadvantages are that the glass is clear, so you need a dark case to store them, and you have to live with the screened "Coke" label.

From: gbaldw@zaphodusin.com (Gordon Baldwin)  
Subject: Irish Moss

In #1079 Jeff Fane asks about others experience with Irish Moss and recommends using 1 Tablespoon per 5 gallon batch. I have been having similar problems with Irish Moss. I use 1/2 to 1 teaspoon per 5 gallons, and it doesn't seem to make any difference if I add it or not. My beers are mostly clear with a slight chill haze. Some have a fairly high amount of chill haze.

When should the irish moss be added to the boil. I think Papazian suggests 5 minutes from the end of the boil, and the instructions on the packet of irish moss I got from the homebrew store say 30 minutes. (It could be the other way around) From what Jeff is saying it looks like it should be added as the wort is heating up before the boil. So when is the best time to add it?

> IPA at only 3.9 ABV with an OG of 1.048. This can be true of the  
ordinary  
> bitters too.  
>

Actually, what's amazing to me is not British "fear" of stronger ales,  
but the fact that British brewers can produce such flavorful beers at  
such low gravities. But Jim is right: a British relative went on at  
great length about how my 1.050 beer tasted like a barleywine. You  
should have seen his eyes bug when I served him a real strong ale!

I suspect part of the "fear", however, stems from the British propensity  
for session drinking. Beers in the 1.030-1.035 range certainly lend  
themselves to spending the whole evening in the pub and still being able  
to find one's way home. (Of course, as Andy Capp has it: "You know  
where I live, Chalky knows where I live. We don't \_all\_ need to know.")

Subject: Irish moss/hot break?

Subject: Time:11:54 AM  
OFFICE MEMOIrish moss/hot break? Date:7/13/93

Jeff asks about Irish moss users. I also used to use it (powdered) when I remembered (about half the time) and could notice no significant difference in clarity. 1 full teaspoon/5 gal. for the last 10 or so minutes of boiling. When I ran out I did not buy more. My kegs would condition for about 2 months in the cool cellar. Recently I have been supplying my father on a regular basis and the beer now seems disappear twice as fast (at least!). In the shortened conditioning phase I had noticed a clarity problem which I attributed to process changes that I made when I increased my brew length. Then I happened to notice the Irish moss FLAKES at my local supplier. Since I'm a sucker for anything new/different I tried them. Suddenly the clarity problem is GONE. Imagine that. I am convinced.

But I am confused about one statement

>So I used Irish Moss in my most recent brew, and the results were pretty >amazing -- a very dramatic hot break...

Hot break? You make no mention about time of addition. I always thought IM was to be added very late in the boil, well after the hot break had formed.

From: cjohnm@ccit.arizona.edu (John Mare)  
Subject: RE:Homebrew Digest #1180 (July 13, 1993)

I heartily agree with Jim Busch's assertion that Jim Koch's efforts in assembling a fine brewery at Jamaica Plains, and taking the trouble to experiment with a variety of unusual (for the USA) beers is good for craft brewing. I have visited the brewery, and was very impressed with the knowledge of our guide, and with the beers we tasted. We don't have to like the guy to acknowledge that he has helped shift the focus of the common beer drinkers to something better.

Subject: Publist at sierra

Yesterday I uploaded the publist from sierra.stanford.edu and noticed that  
1) it had out-of-date info. on it - the old Sieben's brewery, more recently used by Berghoff, in Chicago is now closed. 2) It did not have the info. I was looking for - I've heard that there is a brewpub in the Evansville, IN area that brews a chili pepper beer, and I wanted to find it. So - I'd like to find out how this list is being updated. Please, please, don't get me wrong - it was obviously a great chore just to put out such a list, keeping it current must be impossible. I'd just like an email address to send info to - like the Berghoff closing in Chicago, and this Evansville brewery, if I ever find it.

thanks,  
andrius

From: Chuck Coronella <CORONELLRJDS@CHE.UTAH.EDU>  
Subject: Irish Moss

Jeff Frane brings up the subject of Irish Moss. I've always used it, but since my beers are never light colored, it doesn't make a helluva difference.  
That I've noticed.

But I'm curious about one thing. Papazian et al say to add IM 10 - 15 minutes before the end of the boil. This seems to contradict what Jeff (Dr. Fix?) says about helping the hot break. Doesn't the hot break happen near the beginning of the boil?

On other thing. A while ago, I experimented with with larger amounts (like what Jeff suggests) and I remember having some problem, (Maybe low SG?). I'll have to check my notes at home.

Brew hard,  
Chuck

Subject: Nitrogen

>From: 12-Jul-1993 0931 -0400 <ferguson@zendia.enet.dec.com>

>5. Are any home brewers using the NO2 cartridge for their homebrew, or  
>contemplating trying it?

<No, but i have thought about buying a second CO2 cylinder and having it  
filled with 40% N2 and 60% CO2 for some winter stouts out of my keg. Has  
anyone done this with success (ie: brewed a stout and dispensed it w/ a  
nice  
creamy head ala guinness?).

It is difficult or impossible to mix at home and keep it mixed. You can  
buy  
it already mixed in a product called Alagal. They roll it for hours to  
mix  
it properly. I tried it, it's cute but not much can be said beyond  
that.  
The head seems to form a little strangely but I could detect no  
particular  
difference in the feel of the carbonation or in the lingering head.

Contrary to popular notions, the product was developed to make more  
money not  
better head. The fact that it does not dissolve into the beer means that  
high  
pressures can be used at the source for rapid dispensing at remote taps.  
Football stadiums and ball parks are the best customers so that should  
give  
you a clue as to the objective.

It is impossible to force carbonate beer with this stuff so you  
definitely  
need two separate tanks. The method I used was to pressure up the keg  
at 50  
psi with the mix and shake it for a few minutes. No matter how long you  
do  
this, there is no noticeable drop in pressure or other indication that  
anything is happening but some nitrogen is dissolved. I then purge the  
tank  
and carbonate in the usual manner with CO2, then purge again and rest it  
over  
night with the mix at 30 psi, then reduce to normal dispensing pressure.

I rented the mix just to experiment with and returned it a few weeks ago  
as  
another idea of little value to homebrewers.

>This sounds like a momily to me. I haven't noticed an astringency  
problem with  
>beers I've made to date using this method and I know of several other  
brewers  
>who use this method with success.

I thought so too on my first few batches, but then a more experienced  
brewer pointed out the astringency in my beer. Upon questioning, it  
was traced to my removing the grains when the water came to a boil.  
Heck, for my first batch, I boiled them for 60 minutes. I recall I still  
loved the beer, but today, now that my palate is more sensitive I'll bet  
I wouldn't enjoy it.

>Papazian's troubleshooting section came to two conclusions:  
>1) I left an excessive amount of sterilant in the bottles or  
>2) I'm storing the beer at excessively cool temperatures.

You may also have:

1. not stirred the priming sugar well and some of your bottles may be overcarbonated (did you first dissolve the sugar in a few cups of water and boil it to sanitize and dissolve the sugar?), or
2. you may not have used enough priming sugar (1/2 to 3/4 cup corn sugar for a 5 gallon batch -- or use 3/4 to 1.25 cups of DME),
3. or, you may have brewed such a high-alcohol beer that the yeast is pooped-out (I once brewed an Imperial Stout with an OG of 1120 -- it never really carbonated at all -- in retrospect, I should have pitched a more attenuative yeast once the Wyeast #1028 pooped out at 1050).

>I also read somewhere else in Papazian's book that you should  
>leave about an inch of air space in each bottle. I noticed that  
>I have more like two inches of air space in each bottle. Could  
>this have some effect on the carbonation. It would seem that

>should increase as well.

Yes, too much headspace will give you more carbonation not less.

>for my beer? (by the way, I have chosen not to patronize those  
>brew-places again, they charge exhorbitant rates).

The look will change, but the flavor will change also. A pair of brewers who have won gobs of awards for their beers (including the Ninkasi Award in 1992), Steve and Christina Daniel, are strong proponents for filtering. When you filter, you must be aware that you can filter too much -- try Miller Brewing Company's Amber Ale -- not bad in flavor, but all the body has been filtered out of it!

>Finally, I would like some information on warm temp brewing. If  
>brewing ales, what are the consequences of fermenting between 18-24  
>degrees C ? My apartment is not air-con. nor do I have a basement (!).  
>Is bacterial contam. my main worry, or will I develop some  
>interesting, but perhaps 'out of style' flavours?

Bacterial contamination as well as wild yeast and mold (however mold should not be a problem (unless you've got tons of it in your air) if you watch aeration (molds are aerobes)) can be problems so watch your sanitation. Higher temperatures will increase the yeast's production of all kinds of by-products from esters (fruity flavors and aromas) to phenols to higher alcohols. If you use a good, clean yeast, you should not have problems with phenols and higher alcohols too much. Some yeasts produce more than others. I feel that Wyeast #1056 and #1028 are quite clean. I believe that diacetyl production is increased at higher temperatures also, so you may want to avoid high-diacetyl producers like Wyeast #1084 when you brew at higher temperatures.

John writes:

>In a recent discussion on India Pale Ales (IPA's) the assertion was made  
>that these are all high gravity ales. Conventional wisdom tells us  
>that these ales were brewed at high gravity to allow them to travel well  
>(ie. by ship to India), and our US beer competitions persist in defining  
>IPA's as medium to high gravity (OG 1050 to 1065). It is interesting to  
>observe, however, that in their land of origin IPA's are not in fact  
high  
>gravity ales. Some of the truly outstanding examples of this type which  
I  
>tasted on a recent beer tour of The British Isles include "Palmer's IPA"  
>(Dorset, OG 1039, ABV 4.3%), "Robinwood IPA" (Yorkshire, OG 1040, ABV 4.  
2%),  
>"Younger IPA" (Edinburgh, OG 1043, ABV 4.5%)...

I believe that the use of the title India Pale Ale has been misused in Britain as well as in the US. I feel that the AHA's definition is closer to the mark on this particular style than are the commercial examples, but this is just my opinion.

> have been as full-bodied as I would like. How do I increase the body  
> of the beer without necessarily increasing the alcohol content? Can  
> I use dextrine malt without mashing it? What about Lactose?

I've used dextrine malt without mashing it and yes, it will increase  
body.

Lactose will not do much for body (I feel) but will increase residual  
sweetness which can be interpreted as increased body. Malto-dextrin  
powder is available and can increase body and mouthfeel, but I haven't  
tried using it yet. Some extracts will give you a higher final gravity  
which will give you that "chewyness" that you seek. The best extract for  
this is Laaglander Dried Malt extract. Northwestern Malt extract also  
tends to finish a bit higher, but not nearly as much as Laaglander.

>The second question may be due to a related problem. None of my  
> Original Specific Gravities have been as high as I'd expected (given  
> similar recipes I've seen)....

> ....Could it be due to the type of extract I'm using?

> gives in his book. I think it is somewhere around 0.003 for each  
> degree. I can't remember because I've got the formula in a  
> database cell somewhere.)

It could be that you are not stirring well enough when you top your wort  
up  
with water (see a recent HBD). Another point I'd like to make is that  
you  
should not use softened water for your brewing. Water softeners work by  
adding salts to the water. If you have bicarbonate hardness, you can  
reduce  
it by boiling and then pouring off the sediment that forms. A little  
more  
trouble, yes, but I think your beer will taste better. Note that a high  
carbonate water is perfect for brewing stouts like Guinness!

Leo writes:

>I am sure that this has already been answered but I have been unable to  
find  
>an explanation in previous postings.

Search further back -- about two years ago there was much discussion on  
this  
topic.

>1. Does the NO2 cartridge in the canned Guinness affect more than just  
the  
>head of the brew? It seems to me that the canned Guinness is alot  
smoother  
>and less bitter than the traditional bottled stuff.

It's not NO2 and I don't believe there's any nitrogen at all in the cans. The recipe is different for draft Guinness compared to the bottled version.

Jackson gives the bottled version four stars, but I believe only three for the draft. The cans are the draft recipe. To make a long story short, the cans work because the plastic bubble squirts beer into the can through a small opening and makes the beer foam. Please see late 1991 to early 1992 HBDs for more details.

\*\*\*\*\*

Jonathan writes:

>And someone else asked this eons ago, but I don't remember seeing an answer  
>posted to the digest. What is "Victory malt"?? Does it have to be mashed,  
>or can it be steeped like specialty malts? What characteristics does it  
>impart to the beer?

It is somewhere in color and flavor between Munich and Vienna Malts (at least that's where Briess Malting puts it on their price sheets) and yes, it must be mashed.

>for boiling the wort?

Some say it can, others say it doesn't, but you need to describe the funny taste more for us to help you -- is it metallic? can you relate it to some kind of food? do you have hard water? do you use well water? what kind of yeast did you use? is it sour? Post more details and I'm sure someone will be able to help you find the source of this flavor.

\*\*\*\*\*

JC writes (quoting me):

>  
>I'm still looking for all-grain recipes that'll allow me to do this.  
I've  
>done some partial mashes, hence I'm familiar w/ the process to some  
degree.  
>Does one just cut the amount of H2O used during the mash process in half  
to  
>get a high-gravity wort? I could probably handle mashing with a full  
>grain bill and H2O (1 qt/lb), but my pot would be insufficient to handle  
the  
>grain sparge through my lauter-tun...

Hmmm... I seem to have gotten it all wrong. It's not a partial boil that  
you  
want. What you really want to do is to sparge into your kettle till it's  
about 3/4 full, then boil that down to where you can add more runoff.  
Once  
you're done sparging boil this down to about 6 gallons and then add the  
boiling hops. If your pot is too small to handle 6 gallons comfortably,  
you  
can do the boil in two parts, splitting your hops in half. Many  
breweries  
do this when their fermenters are twice the size of their boilers. You  
don't get a high-gravity wort simply by reducing your mash water in half.  
..  
you get one by either just taking the first runnings and making a 1  
gallon  
or 2 gallon batch (then using the second and third runnings for a smaller  
beer) or by taking all the runnings from, say 12 or 15 lbs of malt and  
then  
boiling this all down to 4 or 5 gallons. A partial boil is an extract  
procedure where you boil your extracts with only part of your total water  
(compensating for the low hop utilization) and then adding water after  
the  
boil in the fermenter.

**Subject: BruHeat Insulation**

BruHeat Users/Potential Users:

My first attempt to heat 5 gal. of water in a BruHeat took >1 hr to reach  
a  
boil

I purchased a sheet of 1.5" very dense foam, cut holes for the gauges and  
spigot and duct-taped it around the BruHeat.

Next batch took ~30 min to boil.

Also, I'm extract brewing only, but I bet mashing temperatures could be  
much  
more easily maintained and more quickly increased with the insulation.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: more on sugar in beer

I'm trying to find out the constituents or chemistry of different sugars added to British or Belgian beers. What I think I need to determine first, however, is what is the purpose of adding the sugar? What are we trying to accomplish?

What is taken as truth about sugar (I think):

- \* Glucose is 100% fermentable and thus adds alcohol and no flavor
- \* Table sugar is sucrose and is mostly fermentable but can add a cidery taste if the amount is too much
- \* Brown sugar is sucrose with a little molasses still in it
- \* Turbinado sugar is similar to brown sugar; it is table sugar that has not been completely refined.

What is invert sugar? I thought it was an optical isomer of sucrose, but sucrose is a disaccharide of glucose and fructose.

Back to the original point. If the idea behind adding sugar is to lessen the body of high gravity beers (doubbel, trippel), then it would seem that glucose is the best bet. Rajotte's book implies that invert sugar is more fermentable (than sucrose), but it shouldn't be more fermentable than glucose.

If the idea is to add some additional flavor, then brown, turbinado, or candi sugar would be a better bet. Glucose leaves no flavor and sucrose leaves an undesirable (usually) flavor.

Where do candi sugar and turbinado come in? That is, what do they add that the other sugars don't?

So what did I get wrong? Sugar is usually a taboo subject with homebrewers, so I'm not suprised that there is no primer or anything. Fire away...

- Bryan

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: The Tumbleweed Report (part 1)

What happened to all that free time I was supposed to have this summer?

I promised to summarize some of my experiences at the Tumbleweed Grille for the forum. I received dozens of requests to do so, so here goes... Sorry it's taken so long. I apologize in advance for the somewhat rambling nature of what follows but there's a lot I'd like to say and if you wait for me to organize it into MA thesis form, it'll never get posted!!

Before getting down to all the numbers, allow me to set the stage for you. You'll never understand why we did what we did if you don't have a grasp on the problems as they were presented to us. I'd hope that anyone who decided to take the jump into commercial brewing would have more money than we did. At the same time, what follows is proof positive that you can put together a commercially viable brewpub on a shoestring budget. From the beginning, the prime motivating factor behind what we've done at Tumbleweed has been the fact the operation was designed and built without borrowing a single red cent!! If the operation folds tomorrow, we haven't lost any money. We've capitalized all equipment as the need arose. To me, this makes what we're doing at Tumbleweed unique and is why I'm boring you with the details. We have almost 30 years combined brewing experience among the three brewers. And yet 7 months ago none of us could have imagined that we'd be doing things the way we are now! But what we're doing is working, so what can you say?

A bit of background on Tumbleweed. The business started in 1989 as a Southwestern foods restaurant and is firmly established as such. Tumbleweed is a restaurant first. It is not a bar and doesn't pretend to be one. This is important to keep in mind when one considers our weekly sales. I think beer sales are significant despite this fact. I sometimes shudder to think what could be happening if we were a bar.

The restaurant is located in Boone, NC, a small mountain town in the northwestern corner of NC. Population of the town proper is about 13,000. Appalachian State University has an enrollment of 11,000. I think there is about 30,000 people living in the county. Boone is a summer and winter vacation destination point. Believe it or not, Boone is the ski capital of the South. There are 4 major slopes (at least for us) within 30 minutes of town. In the summer, people come up here to escape the heat off the

mountain. Last I heard, some 2,000,000 tourists come through town each year.

Much of our business comes from this tourist crowd. We get hardly any business from the students. We're beginning to get a decent following among the faculty and staff.

Bart Conway, the proprietor at Tumbleweed, began reading about the brewpub movement in restaurant publications and thought it was a great idea. Bart is as enthusiastic a person as one could ever hope to meet. He's a man who definitely appreciates good beer. But as he contemplated starting his own brewpub I think it's fair to say he didn't know the difference between malt and hops. So here's a man who likes the brewpub idea, owns a restaurant, and wants to try it, fully admitting he doesn't know that much about making beer. I have a lot of respect for a man with his intestinal fortitude.

Not knowing the ins and outs, he did not want to invest 100's of thousands of dollars into a business about which he knew very little. One day he was drinking coffee with a homebrewer here in Boone who said, "Sure. I can brew beer. Let's do it." And so it began. In February of 1992, Tumbleweed served its first beer.

They bought a used gas stove, a 10 gallon enameled pot, and turned out the first few batches of Tumbleweed beer \*5 gallons\* at a time, bottled them and walked them down the hill to the restaurant. (Tumbleweed is officially a microbrewery because the brewhouse is not attached to the restaurant itself. We walk the beer - now in 5 gallon cornelius kegs - down to the restaurant when they run out.) Shortly they moved to 10 gallon batches. An assistant brewer, Cam Hedrick, came on board in the May of 1992, is still there, and is the only member of the team who is indispensable. He works forty hours a week, monitors the day to day operation: kegging, transfers, keeping the restaurant in stock, keeping records straight so the BATF stays off our backs, etc. In July, Cam pushed production up to 30 gallons where things stood when Burton Moomaw and I were invited to join the operation in November.

When Cam arrived, they were using an immersion wort chiller. When the 30 gallon kettle was put online, I helped them design a counterflow wort chiller (1/2" copper tubing inside 5/8" garden hose) which they began using in August.

Being the good mountain man that he is, Bart is an inveterate "horse trader". And with his own beer online, beer was a hot topic of conversation at the

restaurant. During the course of one of these "rap" sessions, he scrounged a 30 gallon stainless steel pot that had been used in a restaurant at one of the country clubs close by. Now he needed a gas burner. Somehow this came up in conversation with the guy who sells the restaurant after dinner mints. He knew where there was a 350,000 btu burner that wasn't being used and gave it to Bart. The moral of the story here is that for a couple of free meals, the brewery had a stainless steel pot and a gas ring.

In November Brett Deal, the head brewer moved from Boone, Bart called to ask me if I was interested in working in a kind of head/brewer consultant capacity. Already working two jobs, I actually turned him down, promised to find someone for him, called my brewing buddy, Burton Moomaw, and we decided to form a very loose "partnership" and split the responsibilities with each other. When I'm busy, he brews. When he's busy, I brew. And Cam, our brewery operations manager, always brews.

So here we were. A couple of homebrewers who had never brewed more than 15 gallons at a time. Full of ideas and enthusiasm and no commercial brewing experience. There were a number of changes to be made. In fact, it's fair to say that no part of the existing brewing operation resembles what was going on in November. We've changed everything.

(To be continued)

From: korz@iepubj.att.com

Subject: Irish Moss/overshoot/storing yeast under sucrose/7oz bottles

Jeff writes:

>I'm interested in hearing about people's experience using Irish Moss as  
>a kettle fining agent. I had been using it off and on for years,  
>without being able to notice any difference when I remembered to add it.  
>Eventually, I stop bothering all together, and since I was using 1056  
>yeast almost exclusively, I hadn't any problems with clarity.

I used to use it, but after a discussion with George Fix (which I posted in HBD a while ago) in which he convinced me that the majority of mouthfeel and head retention is from proteins and not from dextrans, I reassessed my use of Irish Moss. Irish Moss works by electrostatically attracting protein molecules to itself as it sinks to the bottom of the kettle. I was dissatisfied with my head retention at the time, so I theorized that I might be taking too much of the proteins out of the wort. I cut back from a teaspoon to 1/2 teaspoon and then eventually stopped using it altogether. Except for my very first few batches, I have always been very careful to not boil my grains. (Chill haze needs big proteins and tannins to form. Head retention and mouthfeel are the result of smaller proteins which can be formed from the big proteins during the protein rest, but that's a whole other issue). In any event, I felt that I was getting acceptable clarity and thus did not miss the use of the Irish Moss.

On the other hand, some of the National 1st-round judges (justifiably) had a higher standard for clarity and I got some "slight haze" comments. Now, I'm thinking about perhaps trying Irish Moss again or one of the other finings, perhaps Polyclar, which (I believe) also works electrostatically, but is used in the fermenter and instead of proteins it attracts tannins (please correct me if I've got this wrong, or confirm).

By the way, the yeasts I use are mostly Wyeast #1056 and Wyeast #1028.

Mark writes:

>Also, what are the dangers of a slight overshoot with a single-step  
>infusion mash? Will a couple of degrees above 156F hurt anything?

The way that higher temperature mashes work to make a more dextrinous wort is that the beta-amylase enzyme is more quickly denatured at the 156-157-158F temperature range than is alpha-amylase. At the lower temps (148-149-150-151-152), they both work together to break the starch molecules down to mostly fermentables, whereas at the higher temps, it's mostly alpha-amylase at work. If you overshoot to 158 or 160F for a minute or two, you may denature a bit of your alpha-amylase faster than at 156F, but you probably couldn't even measure the difference.

Steve writes (in response to a question about storing yeast under sucrose solution):

>The well documented procedure will allow yeast to be stored  
>for as long as two years. The principle behind it is at 4  
>degrees C invertase becomes inactive. This means there is  
>no way for the yeast to metabolize the sucrose. If you are  
>getting fermentation there are a few things you might not  
>have made sure of: 1) you can have no other sugars but sucrose,

>common errors might include; taking the yeast from the  
>primary before it is completely fermented, using a low  
>purity sucrose (it might have glucose in it for example),  
>and 2) the solution must stay under 4 C at all times.

What I don't understand, is why the sucrose solution then?  
I know that long term storage of yeast requires either  
sub-zero temperatures or feeding them (so they don't start  
eating their neighbors), but if they aren't going to eat  
the sucrose, then why have it there at all?

From: chuck@synchro.com (Chuck Cox)  
Subject: weevils

My hop plants have been slowly consumed by something that bites big chunks out of the stem and leaves. I thought for a while that it was the same squirrel that was terrorizing my snapdragons. However today I found a bug munching away on a leaf.

A quick perusal of Hops (R.A. Neve) found a picture of the critter. It is a Clay-coloured weevil (*Otiorrhynchus singularis*). The damage description matches too. Unfortunately, Neve doesn't give much advice about eliminating it.

He states that it is not generally a pest of great importance. He suggests organo-phosphorus or carbamate insecticides, then refers to a report about the possibility of using parasitic nematodes. I would prefer using natural predators instead of insecticides, but Neve seems uncertain of their usefulness.

Does anyone have any experience eliminating weevils? I now only have one living plant left, and am concerned that predators may not be effective on a single plant. Perhaps I should simply kill the weevils by hand.

From: Conn Copas <C.V.Copas@lut.ac.uk>  
Subject: Re : Irish Moss

My experience has been that Irish Moss improves the \_cold\_ break, ie, upon cooling the wort, one obtains a very sharply defined layer of trub, similar to that which could otherwise be obtained by refrigerating the wort for a couple of days. I suspect we get told to add the Moss near the end of the boil for reasons of economy, in other words, to let the combination of heat, hops and agitation do its stuff first.

Jeff, what do the scientists say about the effects of Irish Moss on body/head retention? It would be great if it was selective enough to take out the larger proteins which we don't want and leave the rest, but I presume this is where some of the reservations arise. In fact, this issue of protein selectivity applies to a whole range of brewing practices, starting with the use of a protein rest during mashing, and moving on to issues such as whether to skim the initial boil or not, whether to use kettle finings or not, even whether to employ forced wort chilling (at least in stouts), whether to skim/blow-off the primary, and lastly whether to employ finings after fermentation. I presume a whole lot of trade-offs are involved here, probably involving glucans and lipids as well as proteins, and I for one would like to see more definitive statements than can be found in the homebrewing textbooks.

Subject: **Barreling Beer**

I'd like to barrel my beer.

The only place I have seen barrels for sale was in a catalog ("The Cellar Homebrew, Supplies & Equipment, 1993 catalog, 1-800-342-1871). Their oak barrels ranged in price: \$60/1gal., \$93/5gal., \$115/10gal.

Seems semi-expensive.  
If anyone has a cheaper source for oak barrels, I'd like to know.  
Thanks in advance.

Date: Wed, 14 Jul 93 08:27:23 -0400  
From: pgauvin@hq.crad.dnd.ca (Pierre Gauvin)  
Subject: U-Brew-It-Here

Here in Ontario, this has been a real growth industry for the last year. However, the BIG BEER MAKERS complained about the unfair competition and in the last provincial budget, the government slapped a tax of \$0.26/litre starting 1 Aug 93. The tax is scheduled to go up in the next couple of years. This will spell the end of a lot of the U-Brew places.

The way they worked is that you go there, pick a recipe and are assigned a kettle. You mix the ingredients and cook the beer, then the staff puts it in a keg to age after filtering and cooling through a heat exchanger. Two weeks later, you come back to bottle. I understand that during the interval, the beer is filtered once again and transferred into another keg.

There are some severe restrictions on the places. They do not sell beer. They sell ingredients and bottles, and rent the equipment to users. You are not allowed to sample your beer while bottling so that the place does not turn into a drinking establishment. The only way to sample a beer recipe before brewing is to exchange a bottle with the person bottling next to you or with friends who brew there.

Costs for a batch of 48 litres (roughly 12 gallons) vary between \$60 and \$110 CDN depending on the recipes. This includes the regular sales taxes and a \$25 service charge (equipment rental, storage, etc...). The new tax will add more than \$12 per batch. The old price was half the price of a commercial beer for a clone of same beers to about the same price for a more exotic beer (Chimay clone). Now the price will go up to almost 75% of the cost of commercial stuff.

Advantages of U-Brews: -No mess to clean up. No room required to store beer or ingredients.

- No smelling up the house
- Socializing
- Its almost impossible to make bad beer

there.

Disadvantages: - Cost: Almost twice as expensive as making beer at home, especially if you shop around for ingredients

- Limited choices of beer recipes, with no cusatomization.
- Car required to bring back the bottles
- Cannot experiment with more exotic ingredients such as ginger, fruits, etc...
- Cannot lager the beer

>Does anyone have a suggestion on where to park [in Portland]?

You might check into private long term parking lots at the airport, which might be cheaper (though the bus fare to/from the airport might make up for the cost savings). Your travel agent ought to be able to help you with this.

Btw, it`s also worth mentioning that the conference hotel does not provide a free shuttle bus to/from the airport. There`s a private bus that serves several of the downtown hotels, however. Yet another cost to add to your budget for the week.

In HBD #1181, Derrick Pohl writes:

> He said that boiling does  
> indeed darken malt - he thinks it's actually an oxidation process and  
> that  
> splashing the wort around a lot when hot darkens it even more. His

Since George isn't with us this summer (may the book go well), one of the reactions at working is the "Browning Reaction(s)". (Most of this info comes from George's book via my hazy morning memory.)

Browning reactions START when the extract is being made. They continue while in the can, which means it would be nice if they marked the cans with

date of production. The Browning reactions result in Melanoidins. These reactions will also occur during your boil. The oxidation of melanoidins

is where they begin to play a bigger part in the overall beer. (Not mentioned above, melanoidins are the dark pigment.) If you have George's book, Principles of Brewing Science, the section is only a couple pages long but well worth reading.

re: Brewer's Warehouse

Has anyone out there bought their propane burner? It appears to be in a ceramic base of some nature, which probably would solve the need to build a heat shield.

re: Nitrogen thread

Looking at Superior's catalog last night, I noticed Nitrogen regulators. Just for the knowledge, what is the difference between these and CO2 regs? Range on the dials?

Subject: Plastic Fermenters

I've got a question about plastic fermentation vessels. The kit I started with came with a 6.5 gallon plastic pail with a screw down lid for the primary fermenter. Though the batches I've brewed so far have come out good (with the exception of using old Whitbread yeast for one -- yuck!), I noticed a definite lack of bubbles coming up through the fermentation lock. I asked at my homebrew store and he said it was hard to make a good seal between the lid and pail.

I guess my question in all of this rambling is whether this seems reasonable and whether I should worry or have a homebrew? I've thought of going to a glass carboy for a primary fermenter, but I don't have a 6 or 7 gallon one at the moment. I've thought of using my 5 gallon size with a blow off tube, but the thought of my dogs or two year old son drinking from the blow off bucket has kept me from it so far.

Any comments or suggestions?

Date: Wed, 14 Jul 1993 09:11:00 -0700 (PDT)  
From: gummitch@techbook.com (Jeff Frane)  
Subject: Hot Break Terminology

Judging from the responses I received in regard to my posting on Irish Moss, there is some real confusion about the definition of "hot break". A number of people seemed to think I was advocating adding the IM at the beginning of the boil, which is not at all the case.

So let's be clear: the hot break is at THE END of the boil, not the beginning.

I can understand the confusion; not only have recent postings by theoretically reliable people made the wrong assertion, but the standard homebrewing texts are remarkably vague on the whole subject. Although I found good information in professional brewing texts, the most lucid explanation is from good old Dave Line, in his Big Book of Brewing, from which I quote with abandon:

The "hot break"

If you take a sample of the wort in a hydrometer jar and hold it up to the light it should look reasonably clear; clear, but not crystal clear and bright like one would expect in the finished beer.

The change in clarity is brought about by the boiling process. A closer inspection of a light coloured wort would show that the dullness is caused by a greyish mist of finely dispersed matter. The mist is due to the presence of haze forming degraded protein matter combined with hop tannins and its derivatives.

The behaviour of these nitrogenous substances in the copper is rather remarkable. Long vigorous boils will coagulate these gummy substances and make them insoluble. Regularly observing the clarity of samples taken throughout the boil will demonstrate this fact. A few minutes after boiling commences, the mist forms a haze of small, but visible particles. The particles grow as the boiling ation, coupled with the buffering of hop cones, increases the rate at which these gummy substances combine to form even larger particles.

The "hot break" is said to be secured when all the protein matter has formed into flocculating compact lumps. Always check for this condition (but not before at least one hour's boil) by removing a wineglassful of the wort.

The thermal cycle of cooling, should, if the break is successful, deposit the match head sized particles at the bottom of the glass to leave the wort above clear of suspended matter. If there are still minute particles in suspension which have not combined with the main masses, then the wort is "undercooked" and boiling must be continued.

For those of a more scientific bent, there are similar discussions in DeClerq, who also recommends visual examination of the wort and says: "The appearance of the break serves as a guide to the brewer for the duration of the boil, because it frequently happens that after a good break has been obtained any further boiling gives a turbid wort."

Recommendations on the use of Irish Moss range from 15 minutes (Dr. Fix) to 1/2 hour before the end of the boil.

Subject: brew places/Toronto

Answering the question about brew-it-here places.

I am writing from British Columbia. In Canada (generally) a business is allowed to RENT you equipment for you to brew your beer on their premises. You select recipe, get ingredients from bulk barrels, mix everything together, stand around and wait.

They help you connect hoses to cool beer and pump into a keg. Later, you come back and bottle it. (They store it, in primary and secondary in room-sized coolers, and force carbonate with C02)

Re: Toronto

A bar serving lots of local brews is C'est What? on Front Street. Also Rotterdams and Amsterdam (2 different places) brew their own. There are several microbreweries around. If your pal goes to C'est What, your pal will discover easily from the bar staff their locations.

geoff.

Subject: Parking in Seattle; Hunter Airstat in Milwaukee; DA FLOOD!

Three Amtrak trains run daily from Seattle to Portland. Schedule:

|                       |                       |
|-----------------------|-----------------------|
| Seattle ---> Portland | Portland ---> Seattle |
| 7:30AM 11:30AM #26    | 7:55AM 11:50AM #796   |
| 9:50AM 2:00PM #11     | 2:10PM 6:10PM #25     |
| 5:30PM 9:25PM #797    | 3:50PM 8:05PM #14     |

I just personally saw the Hunter Air Stat in the Builders Square on I-94 on the south side of Milwaukee. It's in the electrical department, about an aisle beyond all the light fixtures and ceiling fans. They had plenty of them, in a display with a bunch of other Hunter stuff, like ceiling fan mounting brackets, speed controls and such.

And those of you who know I live in Chicago may ask what was I doing in Milwaukee? Well, I was in Milwaukee to watch Sprecher Brewing Company (a thriving micro) slide into the river. This same catastrophic monsoon season which has made Middle America into the Mississippi Ocean, got the ground so soaked during the last week of June at the Sprecher Brewery that it gave way and slid into the canal. The building has stayed put, so far, but has developed an ominous crack through which you can see the river outside. Access to the front door is by a hurriedly constructed wooden gangplank. Brewing has continued nervously, but uninterrupted. I understand Randy Sprecher has accelerated his search for new quarters for his brewery. The building, fortunately, is rented.

Anyone know of any other washed out or flooded breweries? What about Dubuque Star, which is on low land by the riverbank?

See everyone in Portland!

Subject: 1/2 bbl SS keg as brewpot (again)

Hi again. Last week I requested a copy of a bygone HBD article posted on converting 1/2 bbl kegs. I never got a response. What I did get, however, is lots of email expressing interest, so I felt compelled to ask again for the article in question. This time my request is for a repost, though, since there seems to be lots of interest...

Anyway, in the mean time, I kind of came up with my own idea on what to do with the rounded stainless steel keg I came across, and since folks asked via mail, I figured I'd reply here. Basically, what I plan on doing is cutting the top off, installing a drain faucet, and sealing off the bunghole. No rocket science there. I am curious what others have done, though, and how different folk use SS kegs to mash/lauter. What I was considering was simply attaching a screen to the inside of the drain faucet kind of like a test tube with the open end sealed around the inlet to the faucet. My friend who uses this method using a cooler with great results calls this his "screen penis". I believe he said he got the idea from an article in a trade magazine, I think it was The Yankee Brew News. Anyhow, look like a fun project, and I'll keep you informed as this project progresses. For now, I've already started hacking away at the top...

From: WESTEMEIER@delphi.com  
Subject: Don't touch the hops!

A note of warning to all novice backyard hop growers:

It's still quite early in the season, but there may be some parts of the country where people are getting ready to start harvesting hops.

If you've done this before, you can skip to the next message. If not, please take a word of advice. Poking around amongst hop vines is an activity that usually required both a pair of light cotton work gloves and (important!) a long-sleeved shirt.

A great many of us are very sensitive to these delightful plants. I don't know if it's the physical action of the tiny spines on the vines, or the hop oil itself, or some combination, but if you're like me, your arms and hands will be covered with nasty red welts and itch like crazy if you don't take these simple precautions.

I was reminded of it today, since my Cascades were so heavy that the twine they were growing up broke last night and I had to replace it with a much heavier variety. I have various varieties planted around the deck in back of my house, and they grow up poles to about 8-10 feet, then up heavy twine to the eaves of the house. Crossing over the deck, they add some shade, and (lucky me!) my wife really likes they way they look.

Again, PLEASE don't try harvesting these beauties with bare arms. Unless you're in the small minority that is not sensitive, you'll itch for at least a couple of days.

From: Alex Simons <alexsi@microsoft.com>  
Subject: Irish Moss

In HBD #1180, Jeff Frane made some observations about the use of Irish Moss. I am in absolute accord with jeff, and have found that adding 1 tablespoon of Irish Moss per 5 gallons makes all the difference. I would also recommend using the flaked rather than powdered as I have had better luck with it.

Using several different Wyeast strains as well as Nottingham Ale yeast, I have found that the Moss aids flocculation immensely. I have also found it helps to settle the "floaties" I often encounter when using specialty malts. I was initially worried that I might have settled out so much yeast as to make carbonation difficult, but have found that in general, bottled with a the standard amount of Corn Sugar, these ales take only a few days (5-7) longer to reach a satisfactory level. And bottling was never so easy....

I might also add that in the same area, I have had a great deal of success using Polyclar added during the last 48 hours into the secondary fermenter. In one batch of a light raspberry wheaten-ale, which I had split into two carboys, the carboy with the Polyclar came out substantially cleaner in both appearance and taste than one without.

I am now a fervent fan of both...

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Storage, Part One

Here is the post I promised a while ago on hop storage.

#### Introduction

Hops have three main ingredients that brewers care about: The alpha acids, the beta acids and the essential oils. Normally we concern ourselves with only two of the three: alpha acids and the oils.

The alpha acids are bitter, but they don't dissolve well in beer so they need to be changed into a form that does dissolve well. In brewing, this is caused by boiling and the process is known as isomerization. The resulting isomerized alpha acids are soluble in beer and are still bitter.

The beta acids are not bitter and they are not isomerized by boiling (nor are they changed into a bitter form). They are, however, bitter when oxidized.

The oils are responsible for the aroma of the hops, and enter into the beer's flavor profile for short boil times, steeping, used in a hop back or dry hopped.

All of these three components undergo changes as the hops age.

#### Hop Harvesting and Processing

All hops are harvested once per year, beginning as early as late August and continuing through October, depending on the hop variety. The hops are dried and in the US, baled in 200 lb bales. The bales are made by compressing the hops and then wrapping them in burlap. Some of the hops will be ground and pressed into pellets. Some hops in the UK are compressed into "plugs" that weigh about 1/2 an ounce. The level of compression in these plugs is much higher than the level in the bale. In Germany, some hops are compressed into 11 lb "bricks" and then vacuum sealed. The level of compression is about 3-4 times that of the US bale. (And BTW, in the UK the plugs are known as pellets)

The hops are then stored in huge warehouses at around 30 degrees F (this temperature differs depending on the broker, and the outside temperature)

They stay there until they are shipped to a brewer or hop supplier. Most small brewers buy enough hops at the start of the hop season to last all year, but they are stored at the hop broker and shipped periodically to the brewer. This keeps the brewer from needing a huge cold storage facility.

Also since most small brewers don't have hop analysis equipment, this allows the hop broker to keep tabs on the alpha acid and oil contents as they change over time.

Only the megabrewers pay to have their hops shipped refrigerated.

#### Hop Deterioration

Hops start to lose their alpha acids and oils as soon as they are harvested. The rate is dependent on the storage temperature, amount of air present and the hop variety. Basically, the lower the temperature, the less the hops deteriorate. Oxygen also causes the alpha acids to oxidize and one of the oxidation components is responsible for the "cheesy" aroma of old hops. The oxidized alpha acids cannot be isomerized and are no longer bitter. So O<sub>2</sub> is definitely bad for alpha acids. If you remember, the beta acids turn bitter when they are oxidized, so some believe that this makes up for the loss of alpha acids. In fact, it has been argued that cold storage and anerobic conditions are not necessary for bittering hops, as long as the boil is long enough and open enough to allow the cheesy aroma to escape. But brewers aren't buying the argument (who can blame them).

The variety of the hop also plays a major role. For reasons yet unknown certain hops store better than others under the same storage conditions. The American Society of Brewing Chemists has a procedure for measuring the "storageability" of hops called the Hop Storage Index and involves taking readings of hops stored at 20C (68F) when "fresh" and six months later. Unfortunately, this only gives us two points on a curve and compares the storage properties of one variety vs. the other, but won't help us predict what happens to the same variety for differing storage times.

The oils also deteriorate and oxidize over time. It is believed that some oxidation of the oils is beneficial to the hop aroma. Since most homebrewers have no idea what the oil content of their hops are (a fact I'd like to see changed), they're not aware of the oil losses. But they should be since knowing the oil content is just as important for aroma additions as knowing the alpha acids is for bittering additions. And consistency of results aside, a lot of brewers end up using more hops by weight for finishing and dry hopping than for bittering. So it makes economic sense to know the oil content. (OK, I'll get off my soapbox.)

#### Hop Storage

So for best storage conditions, the hops should be stored as cold as possible (30 to -5F) and away from air. The compression of the hops into bales, pellets and plugs helps keep all but the surface layers away from air. Even so, air still penetrates and causes some oxidation. The cold temperature slows the oxidation process. As was mentioned earlier, some hop varieties don't store as well as others. At some point in the season, hop brokers will take all remaining unsold bales of poor storage hops and turn them into pellets. Not only does the pellet keep out a lot of oxygen, but since they

take up so little space they can now be vacuum packed to further slow the deterioration.

BTW, the reason pellets are so prevalent in the homebrewing trade is that they deteriorate more slowly than whole hops when stored in less than ideal conditions.

Now the compression of the whole hops slows the oxidation because it's harder for the O2 to get at the hops. But when the bale is broken up to be portioned into homebrewer sized quantities, the compression is lost. Now air can get at the hops much more easily. The plugs are a good compromise between pellets and whole hops.

#### Hop Packaging for Sale to the Homebrewer

Vacuum packing or inert gas packaging in an O2 barrier material is the best. The common type of O2 barrier packaging is the "boiling bag" which is clear and made from a lamination of two types of plastic: The inner layer is a food grade polyethylene (the same stuff zip lock bags are made from). It is \*not\* a barrier material, but does make a good heat seal and is the main reason it's there. The outer layer is made from polyester (aka mylar) and is what provides the barrier. The next step up is the aluminized mylar bag (aka foil bag or pouch) and this adds a layer of aluminum that increases the barrier protection over 10-fold. It also more than doubles the cost so it's not widely used even though it's better.

Some suppliers still insist on selling their hops in polyethylene bags. These provide almost no barrier protection and you should avoid a supplier that uses them as they obviously don't care about the quality of the hops.

To tell the bags apart, I assume you know what a zip lock or sandwich bag feels like. These are polyethylene. You can smell the hops right through the bag (this should tell you something). The clear barrier bags are noticeably stiffer and thicker. They are also "shiny" and not "frosted" like the polyethylene bags. The foil bags look either silver or gold.

To be continued...

Subject: Hop Storage, Part Two

Hop Storage, continued

What To Do When You Get Them Home

Firstly, if the hops are not packaged properly (and you had no choice but to buy them) you need to get them in suitable barrier packaging as soon as possible. If you're going to brew with them in the next week or so, don't worry about it, just put them in the freezer for now. If the hops were packaged properly, don't open them until you need to. Store them in the freezer. Once you've opened them, the biggest problem is what to do with the remainder. If they came in a vacuum sealed bag, the best thing to do is reseal the bag with a "home quality" vacuum sealer. These cost anywhere from \$20 on sale to \$100 depending on the seal width (and length) and the amount of heat they put out. Even the cheapest sealer (the Decosonic from Best Products) will put out enough heat to seal the standard clear barrier bags. They will not unfortunately put out enough heat to seal the aluminized bags. Look around in kitchen supply departments and hardware stores and the best bet is to take an old piece of bag with you and see how it seals. You can always transfer the hops to the bags that come with the sealer, but beware that the bags with the cheap Decosonic are not true barrier bags, but they're better than polyethylene. If you keg or otherwise have CO2 or nitrogen available, you can flush some mason jars with the gas, put in the hops and add a layer of gas and reseal the jar. I advise you to practice with the gas as it's very easy to blast your hops all over the room. And always always always use a regulator! If you can't do any of this, put the hops in a mason jar and put them in the freezer, it's better than nothing.

How Long Will They Last?

Well, like most things in brewing, the answer is "It depends." If you keep them cold and free from O2 hops should "last" a few years. It's not uncommon for hop brokers to be selling hops from 2 or 3 seasons ago that have been pelletized and vacuum sealed. This is not to say that the oils and alpha acids will be exactly the same as when you purchased them, but the hops won't be "bad". There is no practical way I know of to estimate the loss in oils or alphas. We could assume from the hop storage numbers listed below that the relationship is linear and could be therefore calculated, but I'm not sure that's right. As I stated earlier, we have only two points on a

curve to go by. But as a practical matter, you can expect reasonably stable numbers for about 6 months if you store the hops in the freezer (a non-auto defrost freezer is best) at -5F and under gas or vacuum packed and in barrier packaging. Of course you'll get better results from the better storing hops.

#### Hop Varieties and Their Storage Numbers

The following table is compiled from several sources, mainly from data provided by hop brokers and the book "Hops" by R.A. Neve (Neve's data is by his own admission "suspect" since it was itself compiled from lots of sources and lots of different storage conditions. I have used his data only to fill in gaps in the hop broker's data which was compiled in a more scientific manner (generally following the ASBC method). Neve lists only "words" like "fair" whereas the broker's data is listed as a percentage alpha acid remaining after 6 months at 20C (68F). This is how you can tell the two sources of data from each other).

| Variety                   | % Alpha Remaining after 6 mo. at 20C or Storage Quality |
|---------------------------|---------------------------------------------------------|
| Cascade                   | 50%                                                     |
| Fuggle                    | 63%                                                     |
| Domestic Hallertau        | 55%                                                     |
| Domestic Hersbrucker      | 50%                                                     |
| Liberty                   | 40%                                                     |
| Mt. Hood                  | 55%                                                     |
| Perle                     | 85%                                                     |
| Domestic Spalt            | 50%                                                     |
| Domestic Tettnanger       | 58%                                                     |
| Willamette                | 63%                                                     |
| Centennial                | 63%                                                     |
| Chinook                   | 68%                                                     |
| Cluster                   | 83%                                                     |
| Eroica                    | 60%                                                     |
| Galena                    | 78%                                                     |
| Domestic Northern Brewer  | 80%                                                     |
| Nugget                    | 75%                                                     |
| Czech Saaz                | 50%                                                     |
| Tettnang Tettnanger       | 58%                                                     |
| German Spalt              | 55%                                                     |
| Hallertau Hersbrucker     | 60%                                                     |
| Strisselspalt             | 65%                                                     |
| Hallertau Northern Brewer | 75%                                                     |
| Hallertauer Mittelfruh    | good                                                    |
| Huller Bitterer           | moderate                                                |
| East Kent Goldings        | good                                                    |
| Brewers Gold (UK)         | poor                                                    |
| Wye Northdown             | good                                                    |
| Wye Challenger            | good                                                    |
| Wye Target                | poor                                                    |
| Styrian Goldings          | good (this hop is actually a Fuggle)                    |
| Pride of Ringwood         | poor                                                    |

Hope this shed some light on the issue, which reminds me, light can also cause the hops to deteriorate. This is not really an issue at home (but it does finally give us a real justification to determine if the light really goes out in the fridge!) but it is an issue in your local homebrew supply. The hops should not be sitting in a well lighted place if the

packaging is clear.

From: sims@pdesds1.scra.org (Jim Sims)  
Subject: New Orleans area trip report

I just got back from spending a few daze over in and around the Crescent City, checking out the local brewing vista.

Note: I'm not an 'official' beer judge. My taste buds aren't real sophisticated. Your mileage (highly) likely to vary...

In New Orleans, there's Dixie Brewery, the South's oldest (190?). Dixie is located on Tulane Ave, a bit away from downtown and the quarter. They're renovating right now, so no touring of the facility was possible

They make a mediocre lager which was all that was available when i used to live there. But hey, when I lived there coke(tm) was .50 a can, Dixie was .35 a can, you figure out which one a student buys - But honest, mom; i'm saving money by drinking beer ;-)

In the last coupla years they've added two new brews:

Jazz - a nice tasting Amber, good color, really nice Hop nose, not a hoppy taste, though. (I dont much go for strong hop taste, but found I really liked this strong nose and almost no hop taste combination). Of the three brews, this was my favorite - stacks up favorably to any beer, as far as a good, drinkable beer.

Blackened Voodoo Lager - only had one of these, not bad, but i wouldn't go outta my way to get one and would take an amber is offered the choice. I \*like\* dark beers, so it's not that i would just choose any amber over any dark, either. They claim it's aged in cyprus casks. try it, but dont expect too much.

Also in New Orleans, down on Decatur street, across the street from the old Jax Brewery (RIP) and about 2 blocks toward Canal street is the Crescent City BrewPub. Note that their beer cant be sold off the premises. Get it there or do without. My recommendation - GO GET SOME.

They serve beer in small mugs (like most pubs/bars), medium (1/2 litre?) pilsner style glasses, and LITER mugs.

We tried to get a tour of the brewing equipemnt there, but the Brewmaster was in Germany and the other person we were refered to declined.

They brew 4 beers:

Pilsner - tasted like one to me. I tried a sip of someone else's. Not my favorite style of beer so I didn't waste the drinking time on it.

Red Stallion - a light amber sorta thing, kinda seemed like a cross between a pilsner and an amber to me. Pretty tasty. Good beer.

Dark Forest - Here's a great beer. Dark, good chocolate malt taste (at least i think that's what it is, see my (dis-)qualifications above). I really liked this beer, and consumed several liters just to be sure.

seasonal speciality brew

Liberty lager is the current specialty brew - it's kind of a most

amber-like version of the Red Stallion brew. If it weren't for the awesome Dark Forest, i'd been drinking this one. Try it (if you get there soon)

Special mention goes to the Pizza place (cant remember the name) over on the other side of the quarter at the corner of Decatur and Barracks. They do great wood-baked pizza and are the only place I have *\*ever\** seen Chimay trippel (25 oz bottle for \$9, compare to reg bottled beers at \$2.50) on the menu on a regular food establishment.

We stopped by Brew Ha-Ha on magazine street (uptown) and chatted with the owners for a while. He's a transplant from New York who couldn't believe that

there is a brew club, brew pub, brewery, and no homebrew supply store

rent for an apartment and storefront was only \$450 (in NY the same storefront alone would be "about \$5000")

So, he took out a \$4000 loan and opened a store. He's "quitting my day job" after just under a year in business and seemed to be real happy and doing well. Nice folks. his girlfriend was brewing out back while we were there. Offered some good advice/tips also. Check them out if you're in the area.

And across the lake in Abita Springs is Abita Brewery. (take the Abita Springs exit from I-12, go north - you go right past the brewery just before the red light in town) Started by a couple homebrewers back in the mid-80s, now distributed/sold across the south from Texas to North Carolina, "selling more than we brew".

We got an extensive tour of the facility (they're expanding the fermenting stuff to a building down the road). Real nice folks. Currently three brewers and a total (i think) of 14 employees.

They grind 1800 lbs of grain into the masher, hold it at ~150 for ~ an hour, sparge to another tank and 'boil'? for about another hour, then whirlpool it to remove the hops, etc in a third tank for another hour or so, and filter it into the fermentation tanks.

They have an ancient bottling machine, just got a new keg washing/filling setup (used to do them by hand). Pretty interesting setup.

They're currently brewing 4 beers also:

Abita Amber - nice amber beer. good stuff

Abita Golden - only tried a small bit of this, seemed OK, but nothing real notable

Turbo Dog - an interesting dark beer. kinda (excessively) roasted malty tasting to me, you might like it if you like dark beers, hard to say. About the name - "yeah, the owners were sitting around drinking one day after brewing the first batch and came up with that"

the current specialty beer is Abita Wheat - this was a real nice wheat beer. I liked it a lot (and sampled it repeatedly afterwards just to make sure ;-)) Give it a try if you get a chance.

Thats it for now. Enjoy!

Subject: Purchasing Supplies

I was just wondering, I am 20 years old, and plan on brewing as soon as I get my apartment (in Sept.). I know that legally I cannot brew beer until I'm 21, but can I buy supplies as a "minor"? It seems to me that anyone should be able to buy a bucket and some grains. Does anyone know the laws that apply here? Thanks for your help.

Subject: "Seriously Stupid Advice"

OK, several people have misread my previous posting, so let me try again:

1) Thank you Al, for posting and then *\*refuting\** seriously stupid advice from some retailer. It is definitely the case that some who sell homebrewing supplies know something about brewing while others know absolutely nothing and spread bad advice.

2) Starting a siphon with your mouth is probably a bad thing. However, while it is certainly *\*possible\** to get an infection in your beer this way, I personally would put this as not in the top 20 most likely ways of infecting your beer. So, I just wanted to say that Al was going a little overboard in implying that this would certainly result in an infection.

John "I thought everyone was reading this in the context of Al's nice little series. Oh well, sorry for the possible misinterpretation."

From: LLAPV@utxdp.dp.utexas.edu  
Subject: sugar

Howdy,

I've seen discussion brewing (haha) on the topic of sugars. One thing I've noticed is that folks have been saying brown sugar is white sugar with molasses added. Actually, it's more the opposite; it's sugar without the molasses-type syrup removed. When sugar cane is processed (they don't make brown sugar out of beets cuz it tastes nasty), it basically is in a syrup form. It goes through a centrifuge, where the unprocessed white sugar is removed. Brown sugar is then extracted from the syrup. The crystals are covered with a film of colored, highly refined molasses flavored syrup. After this, the remaining syrup is what molasses comes from. You get two kinds, light & blackstrap. They take the light off first, then the rest is blackstrap. The whole process works out to light to dark, crystals to syrups, pure sucrose to lotsa leftover goodies.

Turbinado is the stuff that comes off first but is not completely refined. It's 99% pure sugar. Light molasses is 90% sugar, & blackstrap is 50% sugar & 2.8% protein, with lotsa trace materials, including ash, vitamins, rat hairs, etc. As with brown sugar, beet molasses is too nasty tasting to use.

So, that's the sugar scoop.

From: Spencer.W.Thomas@med.umich.edu  
Subject: Irish Moss/polyclar

Let me relate a story: Last fall a fellow brewer (Josh) & I made 10 gallons of Vienna. We split the wort into two fermenters, pitched the same yeast into both, and each took one home. We fermented at the same temperature for about the same time. At this point, our paths diverged. Josh fined his with PolyClar, bottled, conditioned, and then lagered. I lagered in secondary, then bottled & conditioned. When it came time to taste, we found that

1. Josh's beer was (slightly) clearer,
2. My beer had more of that yummy malt flavor.

Draw your own conclusion.

Subject: Hot Break Terminology

What Jeff says meshes nicely with some of the books on historical brewing I've been reading recently (things like The English Housewife ..., by Gervase Markham around 1600; Wines & beers of old New England, S. Brown, 1978). You find statements like "boil it until it 'breaks'". This seems to imply that the break happens at the end.

From: Wolfe@act-12-po.act.org  
Subject: Mint Beer

The other day I was eating a bowl of mint chocolate chip ice cream that I happened to be washing down with a homebrew (I know, it's sick.), when I got an idea for that mint plant in our yard that has turned out to be more of a tree than an ornamental plant. (I live in Iowa, and those things must love the rain. It is HUGE! I'm talking, about 20 stalks almost 3 feet tall. And I transplanted it from a single sprig in April.). I'm envisioning a mint beer that has an aftertaste that kind of makes you cock your head to one side and raise an eyebrow (like the ginger beer that I just brewed).

Anyway, I've looked all over for a recipe and have yet to find one for mint beer. Has anyone out there experimented with mint? I've used leaves off of this plant in cooking a lemon herb chicken, and it tasted great. I've also used the leaves in tea. I was thinking about brewing about a gallon of mint tea (to see the ratio of mint to water) and using about six times the weight in mint for a five gallon batch of beer (six times, rather than five, because I figured the malt would cover up some of the mint taste).

Any suggestions?

Subject: Anchor Dry Hops Time:10:08 AM Date:7/15/93  
Al Says:

>more difficult to remove the hop bag than loose hops  
>from a carboy (not an issue for Anchor, with their open fermenters)

Sorry Al, Anchor only uses the open fermenters for primary fermentation.  
The  
dry hopping occurs in the secondaries which are closed. The hop bags are  
pillow  
case size.

And...

>It's not NO2 and I don't believe there's any nitrogen at all in the  
cans.

While you are correct that the Draught in the cans is a unique recipe and  
so  
tastes considerably different from what we are used to (the bottled  
version)  
there "is" liquid nitrogen added to the Draught as it is canned. This is  
used  
to increase the pressure in the can to insure that the velocity of the  
beer  
going through the pin hole as it exits the plastic pillow is correct upon  
opening. The nitrogen is really a mechanical device in this respect since  
it  
does not dissolve into solution like CO2 does. It should not add any  
flavor to  
the beer but might be said to alter the "taste" as it is responsible for  
the  
creamininess of the head which will certainly be a factor to one's  
perceptions.  
Using the nitrogen/CO2 combined gas (or guinness gas as our local  
distributor  
calls it) will not in itself alter a homebrewed stout's taste or head  
creation.  
You'll need a tap designed to produce the head coupled with the special  
gas.

Subject: Trip to Belgium

Greetings! I hope this an appropriate question for this forum. I'm off to Europe 2 weeks from today and could use some suggestions on beer and brewing related places to visit in Belgium. I'll be there 2-3 days, arriving in Oostende and eventually making my way to Bonn, Germany. I suppose anywhere in the country is possible since it's fairly small. Any recommendations based on your experiences are welcome.  
TIA - Dave J.

From: cwvandev@hwking.cca.cr.rockwell.com (Craig Vandeventer)  
Subject: BruHeat Insulation

I also had trouble with the BruHeat holding it's heat. I was constantly turning on the element to maintain mash temperatures(a royal pain in the butt). I scorched the element a couple of times even. What I did to fix the problem was I wrapped 2 layers of pipe insulation tape around the entire bucket and then taped it down securely with duct tape. I used an Xacto knife to cut the holes for the spigot and heating element. On my last mash I didn't have to turn on the heating element to maintain mash temp. It also boils alot faster now, too.

From: sc@vcc.com (Steve Casselman)  
Subject: stuff

So let's see ... sucrose is used to store the yeast so they don't swell and burst from osmosis. sucrose is a disaccharide of glucose and fructose that has at least two stable configurations, normal and inverted. Yeast cannot metabolize (break down) normal sucrose without first inverting it with invertase. Inverted sucrose then is more digestable by the yeast - which means it takes less energy to metabolize it and therefore there are less side reactions (and by-products no doubt) in the process.

I also wanted to share an experiment I did regarding bacteria in the mouth and on the hands. I took a plate (agar) and put my thumb and finger prints on one half and spit on the other half. By far the worst offender were the thumb prints which grew over night, the finger prints came next and about day 4 something was growing out of the spit side. This makes sense since the mouth does have a changing pH during eating which prohibits bacteria growth (a good defence for an animal that eats just about anything). My conclusion is that contamination comes not when putting lips to hose but touching said hose with the hands and sticking that into the carboy.

Also I'm going to be up in portland hangin' with the gang and am planing to bring my guitar and harp for acoustic fun if you want to join in!

The number for Brewers Resource is 1-800-8BREWTEK (the K is silent) 1-800-827-3983

For the people who like chewy beer I suggest roll oats roll barley or wheat the chewyness comes more from the proteins than the dextrans.

The hot break begins at the beginning of the boil, anyone unclear on this should bring an all grain (extracts have small hot breaks) beer just to boiling and then turn the burner down to observe the flocculation of proteins. IMHO no hops should be added until a hot break occurs as hops introduce nucleation sites that would otherwise be started by the larger proteins. This will give a brighter beer. By the way the hot break happens when the larger proteins come in contact with the interphase between steam and wort cooking them just as blood will form a solid when heated. I've seen flocs the size of dollar bills in my 40-gal brew system allways at the beginning of the boil.

Subject: Weihenstephan #66

I've seen a couple articles lately about German wheat beer yeasts. Thanks to the person who posted the The Brewer's Resource (BREWTEK) phone number for the wheat beer strains. The guy I talked to was extremely helpful.

Is the Weihenstephan #66 weissbier yeast available commercially? (like from Wyeast or GW Kent...) Phone numbers of known suppliers would be greatly appreciated.

BTW, we had a wheat beer tasting at my last homebrew club meeting. Every German wheat beer brewed was fermented with the Wyeast 3056 strain (the 50/50 mix). And without fail, every beer tasted like an ale with plastic in it. I have used this yeast and found it to be terribly lacking. If you are planning a wheat beer, do yourself a HUGE favor and seek out a good yeast (ie, not the 3056).

I have a dunkles weissbier going now with the 3068, and it tastes terrific! Can hardly wait to bottle this liquid gold.

From: LLAPV@utxdp.dp.utexas.edu  
Subject: More sugar

Howdy,

Here's more info on sugar (I had to look this stuff up).

Invert sugar is primarily used by the food industry. It's sucrose that has been broken down into it's two constituent molecules by hydrolyzation. The two molecules are dextrose (glucose) & levulose (fructose). It has moisture retaining properties good for baked goods, icings, & preserves. I can't see why one would want to brew with it, but who knows, you might discover something really cool & groovy.

I think that candy sugar is 80% white sugar & 20% corn syrup that's been boiled in water. Again, I think it is, but am not sure. Because of variances in language development & because there is an ocean between us, Belgians might be using something different & calling it candy sugar.

Subject: Re : Irish Moss

This Irish Moss thread got me reading a CAMRA brewbook by Wheeler this morning.  
Normally, I regard him as a touch light-weight, but he claims that it is impossible to achieve a decent cold break with home chilling equipment, and that Irish Moss is a good alternative to forced chilling of the wort in order to precipitate trub. In fact, this auxiliary fining effect is supposed to linger on into the bottling stage, where it can be cancelled by oppositely charged finings such as isinglass. Note that Wheeler doesn't seem to have any experience with counterflow chillers, BTW. Over to Miller. He ventures that IM could be useful for ales which have not received a protein rest. As ale malt is not reputed to contain protein digestion enzymes anyway, I presume the problem that Miller is really referring to is that of using wheat malt and/or flaked cereals without a protein rest.

Subject: **Plastin, Hotbreak**

>From: "/platinum/homes/hethmon/.signature" <hethmon@cs.utk.edu>  
>Subject: Plastic Fermenters

Oh Boy! This is my favorite topic.

>I noticed a definite lack of bubbles coming up through the fermentation lock. I asked at my homebrew store and he said it was hard to make a good seal between the lid and pail.

It is difficult to get an airtight seal but the necessity to do so is the great issue here.

It seals well enough to keep anything from falling in and few things are capable of crawling up, under and into the fermenter via the tiny leaks. Furthermore, during fermentation, CO2 is trying very hard to get out through these leaks and tends to keep other stuff from getting in.

The hole in the lid is simply an evil plot by the retailers to force you to buy a fermentation lock to fill the hole. There is enough CO2 generation initially to make it look cool but when the pressure drops off, it looks like fermentation is done but the gas is just leaking out the easy way.

I have been fermenting for several years in a SS kettle with a lid that just rests on and makes no attempt at an airtight fit and see no need to worry about the fit of the lid on the plastic fermenter.

The idea of using a carboy and blow-off system still gives me a headache. It seems to be another one of those solutions to a problem that does not exist.

That is not to say that after primary fermentation is complete, that is should not be transferred to a carboy for secondary and clearing.

>From: gummitch@techbook.com (Jeff Frane)  
>Subject: Hot Break Terminology

The definition you quoted reads a lot like Noonan's but is a bit more clear.

I find it interesting to point out the additional confusion that is created by the fact that in order to test for "hot break", the wort must be chilled.

The stuff at the bottom after chilling, must of necessity be called the "cold break". This leaves us where I proposed several years ago, viz., the hot

break is a point in time, not stuff.

It would be beyond reason to call the stuff hot break while hot and cold break when cold if it is indeed the same stuff. One only knows that one had

a proper "hot break" by chilling the wort and looking for its absence. The

stuff on the bottom is irrelevant because you don't know if you got it all

without looking where it aint no more.

Edition)  
>These are all fermentable by common yeast.

I wonder if someone is confusing dextrose with dextrans here. Dextrose,  
of  
course, is a sugar, and quite fermentable, thus contributing to alcohol  
content and priming/conditioning; dextrans are somewhat sugar-like, and  
contribute to body and mouthfeel, but are not very fermentable by beer  
yeasts. Just an attempt to clear up a little possible confusion here,  
certainly no flame intended.

From: nexgen!bart@olivea.ATC.Olivetti.Com (Bart Thielges)  
Subject: possessed keg and 1.018 is the number of the FG

So I thought I'd be smart and start with a keggng system since I could borrow most of the equipment from a friend who is in quiescent brewing mode right now. I've kegged two batches so far and had the same problem each time. The beer comes out somewhat translucent. It sort of looks like watered down but dark chocolate milk. Also, there is a noticable spicy flavor which some people think tastes like ginger.

When I racked each keg, I also bottled a pint from the batch in a Grolsch bottle. The bottled pint turned out very clear and didn't have as strong of a ginger taste.

Tonight, I'm going to completely disassemble the keg and replace ALL of the rubber, including the poppets. I've got a brush to scrub out the dip tube so I think that it should be completely clean this time. However, I'm not completely confident that this keg has been exorcised from whatever bug is contaminating it, so I've "invested" in some more bottling gear. The third batch, I plan to put 1/2 into the 5 gallon Cornealius keg and the other half into bottles. Am I doing something completely stupid by only filling the keg half way? Of course, I plan to leave the check valve open long enough after priming to allow enough CO2 to evolve and force the O2 out of the large head space, but I really don't know how long is enough time.

Speaking of the check valve, I tried to remove it last night, but it seems to be made of plastic. My mental torque wrench told me that I was straining it too much for the material when I tried to remove it. Is there any recommended method for removing it? Maybe I'll just soak the whole thing in sanitizer.

On another point, all three of the batches that I have made so far (kits supplemented with various other unhopped malt extracts) have ended at a final gravity of 1.018. This seems to be a strange co-incidence since I used different amounts of ingredients each time. Also, the FG seemed stabilize rather quickly, like 4 or 5 days after pitching the dried package of yeast included with the kit.

OK, now back to the yellow pages to look for an exorcist.

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: re: more on sugar in beer

In HBD #1182 Bryan L. Gros asks about sugars. Here's what I've figured out so far. I'll try to give source where appropriate.

To the best of my knowledge there are two reasons for adding sugar to beer: 1) to add a certain flavor, 2) to add additional fermentables without adding much flavor. These are obviously two different purposes.

In the flavoring category are:

Brown sugar: Sucrose w/varying amounts of molasses added  
Molasses: What's left over from refining sugar, strength and character of flavor vary w/brand and type.

Treacle: I don't know if this is simple a British term for molasses or a specific kind (help from the UK please). Anyway Lyle's treacle is called for in some British ale recipes and is readily available at upscale US grocery stores.

Turbinado, demerara: Amber colored sugars, supposedly only partially refined. According to FDA types all sugar sold in US must be refined so I don't know what these really consists of. (Help from you FDA type or food science folks)

C & H sell a product called "Wash raw sugar" which is described as "turginado-style". I haven't used it but in HBD#1141 Paul dArmond says it "doesn't give a cidery taste, and at the 1# level leaves a yummy sweet \*aftertaste\*"

Piloncillo: Mexican brown sugar, various color available. The ones I've found all say refined sucrose.

Dark sucre-candi: Philip Seitz says as near as he can tell rock candy=

sucre-candi. Piere Rajotte says in Brewing Belgian Ales that sucre-candi is sucrose. The dark sucre-candi is caramelized before being crystalized. Nobody seems to have a US source. I've tried camelizing my own sucrose. It's not hard to do.

I don't know how to assess the flavor added by any of these except to try one and taste the finished product. I recently tried a very dark piloncillo and didn't like the flavor it added--a sort of tart edge.

In the adding fermentables category there are:

Sucrose: A double sugar made of one glucose and one fructose molecule. Invert sugar is just sucrose that has already been split. It is used in confectionaries for reasons I know nothing about. Yeast must split

sucrose in order to metabolized it. This happens outside the cell wall

by enzymes secreted by the yeast (per<Spencer.W.Thomas@med.umich.edu>)

However, if the sugar is already inverted it's less work for the yeast.

To my mind this doesn't make it more fermentable just more easily fermented.

Glucose aka corn sugar: A simple sugar directly metabolized by yeast.

White candi-sugar: Per Rajotte, large crystals of sucrose.

There is strong consensus that too much sucrose adds a characteristic cidery taste. According to Miller, it's the fructose half of sucrose that's responsible for the cidery taste. However, some brewers say that even glucose will add a cidery taste in large quantities [per, cjh@diaspar.HQ.Ileaf.COM (Chip Hitchcock)]

Most brewers agree that replacing maltose with glucose or sucrose in beers meant to derive their sugar from malt is a bad idea. At best you brew will have a thin body and flavor. On the other hand high gravity Belgian ales call for sugar as an adjunct. The purpose is to lighten the body and maltiness of these high gravity beers. This is one thing that makes them distinct from say Barley Wine. Rajotte says Belgian brewers may add either glucose or sucrose to their high gravity beers. Some say the already high maltose content hides the cidery flavor. Then again maybe it's the lousy weather they have there most of the year, who knows?

From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: re: Parking in Portland

If you're coming to Portland, be ready for parking shortages. The city Fathers and Mothers decided that persuading everyone to kill their cars was a good idea for the 21st century, so they passed an ordinance that limits the number of parking spaces per downtown block. Ride the bus, eh?

I called the Mariott and spoke with Kim at the front desk. Here's the deal...

The Mariott has limited parking space, it all valet parking @ \$14 per day, if you have a room there or not... Right behind the Mariott, connected by a skybridge, is a city lot @ \$9 per day, plus some in/out fees. I've heard that Portland has pretty good public transit (hey, Jeff! what's it like?), so maybe that will help. Considering what a lot of us will be doing, riding the bus or light rail or whatever the heck it is that they have there might be a good idea while we're wearing the knees out of our trousers looking for more and more good beer.

Paul.

Subject: The last bottle

In korz.digest #1182, Dave Hinz writes:

>ObHomebrewComment: Don't you just HATE finishing the last bottle of a batch?

>It's sort of sad to know that the whole thing is history...

Not at all. It's wonderful. Once you've made a bad batch and had to pour beer down the drain (now there's something to hate!), there is great joy in knowing that every single bottle has been a source of pleasure.

By the way, I use one clear bottle in each batch, and it's the last one I open.

When my wife sees me trudging up the basement stairs cradling a clear bottle of beer in trembling hands, she knows to keep a reverent and respectful silence until the glass is drained. Hmmm, maybe I should us more clear bottles.

Date: Thu, 15 Jul 1993 10:08:37 -0400 (EDT)  
From: Tom Rush <trush@mhc.mtholyoke.edu>  
Subject: Hop harvest and Chico yeast

I have quite a different report on my hops than the one I posted last year (large yields and lush plants) the summer has been and continues to be hostile to all growers. The drought and heat has been a disaster for farmers and home gardeners alike, the prolonged heat wave withers plants even if irrigated--it seems worse in this area since Ct,VT,NY,etc. are hurting but not as badly.

Anyway, my cones are all coming early, very few, and the vines have stopped growing. The Japanese beetles have returned with a vengeance, they invited potato beetles and I have a strange green caterpillar munching on the cones and leaves (this may be a rare type of moth/butterfly which feeds only on hop vines according to a reference book) that's all I need a "spotted-owl" endangered worm and Sierra will be checking on me. I can see where hop growers can have "feast or famine" cycles. Only consolation my "Hersbrucker" is alive and well which I thought I lost last year (only grew 4 inches after being stepped on and crushed also the two Saaz I planted this year are thriving).

Has anyone encountered or has an answer to the following: I use Chico yeast cultured from SNPA, use my own hops, aerate after boiling and cooling to the point of using a sterilized chef's omelet mixer (reason follows) it foams up the wort 3-4 inches but subsides quickly and the yeast is perking overnight. The problem is, the primary gets stuck by the second day--I transfer to the secondary VERY CAREFULLY AVOIDING FURTHER AERATION and the batch takes off again. It works so much in the secondary I can't use an airlock and have a blow-off tube in a bucket to catch the overflow. The beer comes out perfect (deeeeliciuuus) but the procedure troubles me.

Any suggestions or theories are welcome,

-tom

From: CMACK@ssc.wisc.edu  
Subject: Smells like crap!

Hi -- first I'd like to thank everybody for suggesting breweries and pubs in San Francisco and San Diego. Other folks have gone on about how helpful the people on this list are, so I'll let it go and get on with my question.

I'm still relatively new to homebrewing, and on my 6th batch (an Anchor Steam clone), something odd is happening. I thought the smell in my basement was coming from somewhere else, but when I sniffed above the airlock of the primary fermenter, I almost gagged on this nasty, sulfurous odor. Maybe it's just my imagination, and the fermenter isn't actually \*distended\* from the gas production, but it still has me spooked about this batch's chances. (At least I don't have to worry about oxidation?) As far as I know, this was a standard extract recipe, not so different from Papazian's Steam in TNCJoHB. Can anyone tell me what's gone wrong?

Thanks,  
Chris Mack

From: Victor Stevko (Human Genome Center, LBL) <stevko@genome.lbl.gov>  
Subject: Use of sucrose solutions in long-term yeast storage

The purpose of putting sucrose ( or glycerol/glycerin ) in a yeast culture to be stored long-term in a freezer is to keep the yeast from exploding. That is, normally yeast can't survive freezing temperatures - the water inside the yeast freezes, breaking their outer membranes and killing them.

Adding 10-15% glycerol will change the osmotic balance of the yeast and keep them from freezing to death. It should also keep your stocks liquid at freezer temperatures. This is a standard method of keeping bacterial and yeast stocks long-term in the lab, though we usually freeze to -80 C. -20 C, freezer temperature, is fine for stuff you'll use in a year or two, though.

From: SMUCKER@UTKVX.UTCC.UTK.EDU  
Subject: Nitrogen and Carbon Dioxide Regulators.

There have been some question lately about gas regulators. Some general information: Gas regulators are all built on the same principle but with some important differences for different gases. For one thing they have different fittings, threads etc. for different gases. This is for our safety so that you don't get the wrong regulator on the wrong gas. I believe that these difference have been set up by the American Welding Society and are regulated by the Interstate Commerce Commission. As was point out several days ago (I sorry I lost the author) in the case of oxygen this is so you don't kill someone by putting a contaminated regulator on a oxygen tank in the future.

Second oxygen and nitrogen regulator are built to take full cylinder pressure of 2500 psi plus a safety margin. Carbon dioxide regulators on the other hand generally have a different spring in them to account for the lower pressure from the head space gas over the liquid carbon dioxide in your cylinder. Also most carbon dioxide regulators are designed to limit freeze up, which if it occurs can allow high pressure gas or even some liquid carbon dioxide to pass. Not what you want.

A good place to purchase a carbon dioxide regulator is you welding supply store. A generic brand for low flow rate should run about \$ 40.00. You may have to replace the low pressure gauge because it likely will be calibrated for flow rate rather that pressure but your welding dealer will have a replacement gauge and maybe willing the swap one out. My was, but then I buy welding supplies too.

Subject: Neuweiler's Stock Ale

Matthew Mitchell writes:

>Another excellent contract brew from Lion in Wilkes-Barre is the  
Neuweiler's  
>Stock Ale, brewed for Neuweiler's of Allentown. I think they have their  
>own brewery, right? They've been around a while and I never looked  
twice

A few years ago Neuweiler's started up as an upscale-type beer contract  
brewed at Lion in Wilkes-Barre. They bought the name from Neuweiler's,  
which went out of business in the late 60's. Supposedly, the new  
company wanted the name only - the original Neuweiler's was a  
blue collar-type beer, so they didn't use the recipes. The old  
brewery still stands (unused for much of anything?) in Allentown. It's  
a very interesting building with big copper gargoyles and beer mugs.

>So is stock ale a defined style? The last one I had was the Molson  
Stock Ale  
(which had an anchor in the hexagon molson label ref to sea voyage like

>The label says that the story is that the beer was reserved for  
stockholders

That's my understanding - it was distributed to stockholders in lieu of or  
in addition to dividends. Of course, today it is just marketing hype to  
imply it is a higher quality beer. I don't think it qualifies as a  
defined style. I agree that it's a pretty good bargain - not in the  
same class as, say, Stoudts, but a good deal at \$12/case here in  
Allentown.

This may not be of any use to you, but when I was growing up on  
the cotton farm in Texas, we occasionally had infestations of  
boll weevils. The organic solution was to distribute ladybug eggs.  
There is also another insect which will prey on weevils, but I  
don't remember what it was. Check with your county extension  
agent (if you have one), maybe he will know something.

Subject: yet another question - alternative brew vessels

I was rooting around in the place i found the kegging stuff the other day, and noticed several interesting vessels. One was a 100-gallon coffeepot, complete with electric pump. There were two other vessels, with stream heating elements surrounding about a 15-20? gallon reservoir. All were stainless.

Any ideas if these could be readily used for brewing? Or what I would need to consider/look out for to decide for myself?

The 100 gallon coffeepot was a lot cheaper, but it wasn't obvious how to get a heating element/burner 'under' it as it's built on a(n open) stand. It does say "max temp 300 degrees F on the plate.

Subject: Mint in beer

Ed Wolfe asks about using mint.

I have very vigorous mint plants in my back yard, and use them for my annual Christmas spiced ale. I pick about two ounces of fresh mint leaves and drop them in the kettle just at the end of the boil. This gives a mild, but definitely noticeable mint flavor. If you want a strong mint flavor, I would suggest three ounces (this is for a five gallon batch). This is one of my favorite brews of the year, and I use other spices as well, but the minty note is what really makes it special for me.

From: "Anton Verhulst" <verhulst@zk3.dec.com>  
Subject: step infusions

chuckm@pbn73.cv.com asks:

Does anyone have a formula that will help me with Step infusions in order to hit proper temperatures. eg. I mash in a cooler tun. If I have X pounds of grain at Y degrees, how much 212 degree water must I add to raise the temp Z degrees. Given that I know X, Y, and Z all I need to find out is the 'how much'.

In my experience the answer of how much is "too much".

I do a protein rest using 1 quart of water to 1 pound of grain at 50C (122F). I then add 1/2 quart per pound grain of boiling water. This brings the temp up to about 60C (140F). This is a fairly reasonable mash - consistency wise. I wouldn't want to make it much thinner than that. Besides, given an 8 or 9 pound grain bill, this brings the total volume up to the limit for my 5 gallon stainless steelmash tun. What I wind up doing is putting the mash on the burner to bring the temp up (stirring constantly) to sacchrification temperature.

I understand that with a cooler tun, this option is not available to you unless you resort to decoction mashing. IMHO, With your set up I would recommend mashing only with fully modified malts and forgetting about step infusion.

However, assuming to have the space in the mash tun and you are willing to use a much thinner mash, to answer your original question, the formula would be (check me on this HBDers):

Given:

- heat = temperature times mass.
- absolute temerature (kelvin) is 273 plus mash temp (centigrade).
- water boils at 100C.
- The US system of weights and measures suck and we should join the rest of the world and convert to metric.

Assumption:

on the eath's surface, weight and mass are numerically identical.

terms:

sw = starting weight  
st = starting temperature (absolute)  
ft = final temperature (absolute)  
bt = boiling temperature (absolute)  
x = water at boiling temperature to add

$$sw(st) + (bt)x = (sw + x)ft$$

example:

Assume

1 quart of water weighs 2 pounds - about a 10% error, but close enough. (1 gallon of water = 7.5 pounds).

you have a mash of 10 pounds grain and 10 quarts water for a total weight of 30 pounds.

you have a protein rest at 50C (122F) and you want to raise it to sacchrification temperature of 67C (152F).

$$30(273+50) + (273+100)x = (30 + x)(273+67)$$

$$9690 + 373x = 10200 + 340x$$

$$510 = 33x$$

$$x = 15.5 \text{ pounds of boiling water to add (about 2 gallons).}$$

This is off the top of my head, I haven't actually tried it - I could be wrong.

This formula ignores pesky little things like heat stored by the container  
(ya gotta heat the mash tun as well as the mash).

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Hops for Lambic

I was reading Mark Garetz' article on hop deterioration and storage (very informative--thanks) and it reminded me of a question I've always wanted someone to answer. I've read (Jackson and elsewhere) that the lambic brewers in Belgium use old hops, like up to 2 years old! The most sensible explanation I've read is that the aging removes most (all?) of the bittering capability of the hops but they still impart an important flavor to the beer. So my questions for you hop experts are: What's left in two year old hops? What varieties are used for lambic? Should I buy a couple of pounds of hops now and put them in my 90F garage so I can start brewing lambic-type beers in two or three years?

Subject: Irish Moss

Another data point for Irish Moss usage. I have used it off and on over the last seven years when I remembered. It is recently that I have become a believer. This spring I began using a 15.5 gallon keg (capacity 15 gallons) as a boiler and a 48 qt Coleman cooler as a mash tun. Previously I had used a ZapAp for lautering. The switch came about to reduce HSA and increase capacity; 30 lbs vice 12-17 lbs (mash thickness dependent).

Well, the classic copper manifold lautering approach does not (for me) produce as clear a run-off as the ZapAp. I started out with the cooler/copper manifold approach in 1987 and when I made the switch to ZapAp I noticed better clarity.

Lately I have been using one Tablespoon of Irish Moss per 12-14 gallons of boiling wort. I have noticed a clearer wort post-boil and better clarity post-fermentation using the Irish Moss. In my next brew I will try using one Tablespoon per 5 gallons in my next batch.

Alex (alexsi@microsoft.com) talks of using PolyClar successfully. I have used it in the past also with dramatic results. My experience has paralleled that of Dan Carter, BrewMeister at Oxford Brewing Co in Baltimore. They chill their infusion mashed ales, do a course DE filter and place the beer in a bright beer tank. Here they chill to 2-4C and add "two scoops" of PolyClar. What Dan feels he gains by this is prevention of chill haze without doing a sub-micron filtration thereby negatively effecting mouthfeel.

Hot Break:  
- - - - -

It is good to see someone has finally made some sense in the hot break thread. Steve (sc@vcc.com) has described exactly my observations on hot break.

> The hot break begins at the beginning of the boil,  
> anyone unclear on this should bring an all grain  
> (extracts have small hot breaks) beer just to  
> boiling and then turn the burner down to observe  
> the flocculation of proteins. IMHO no hops should  
> be added until a hot break occurs as hop introduce  
> nucleation sites that would otherwise be started  
> by the larger proteins. This will give a brighter  
> beer. By the way the hot break happens when the  
> larger proteins come in contact with the interphase  
> between steam and wort cooking them just as blood  
> will form a solid when heated. I've seen flocs  
> the size of dollar bills in my 40-gal brew system  
> allways at the begining of the boil.

In my 15 gallon boiler fired by the Kin Kooker rocket engine I see hot break within 15 minutes. For my recent 60/40 Weizen (I am bring a 5 gallon keg to Portland) I did a one hour boil before adding hops. I did indeed see protein goobers the size of canned hams within 15 minutes.

Now, in summer time I use a two stage heat exchanger. I use an

immersion chiller with 40 ft of 3/8" soft copper to get the wort to ~100F. Next, I have 20 ft of ice packed 3/8" copper that I gravity feed the wort through to get the final chill. on a 90F day I have beer going into my fermenters at 45F. It is really nice to see that condensation on the fermenters.

Why do you care how I chill my beer? Well in the winter with only an immersion chiller I get almost no cold break. With the combo chiller I see a dusting of cold break. Make of this what you want.

Summary:

Hot break: happens at the beginning of the boil. Consists of coagulated proteins that are insoluble at 212F.

Cold Break: happens when the beer is chilled. Consists of proteins (not necessarily coagulated) that are insoluble at pitching temperatures.

Chill Haze: happens when beer is chilled to serving temperatures. This is, essentially, the "colder break" that occurs when beer is chilled below fermentation temperatures and those proteins that are left over after the cold break that can precipitate at temperatures somewhere above 32F come out of solution into suspension.

See you in Portland.

Cheers, Rick

The laws may vary from state to state, but it is definitely legal in Iowa to purchase brewing supplies as a minor, and even to brew and drink your own beer (in the privacy of your home)! The various alcohol laws cover purchase of alcohol and public consumption, but not this case. I think you are not allowed to give this beer to underage friends, though, even in your own home.

Your best bet is to ask at a good homebrew supply store in your state; that's what I did here in Iowa. If you ask the police or some other state agency, they probably won't really know and just tell you "no, you can't do that". I found that out when I tried to call the Chicago airport customs office about details on beer importing: they are supposed to enforce the laws, but they don't really know the details themselves.

Subject: Kegs to kettles

Mike writes:

> Hi again. Last week I requested a copy of a bygone HBD article posted  
> on  
> converting 1/2 bbl kegs. I never got a response. What I did get,  
> however, is lots of email expressing interest, so I felt compelled to  
> ask again for the article in question. This time my request is for a  
> repost, though, since there seems to be lots of interest...

OK, I don't know about the original article, but maybe it would be useful  
to describe my own equipment.

#### START WITH THE KEG

Obtain a half-barrel stainless steel keg (the Budweiser ones seem to be  
the best, but most should work). Be sure you obtain one legally, as  
these are the property of the brewery and cannot normally be sold except  
by a licensed reconditioning firm. The fact that you can obtain one  
easily by simply getting a keg of beer for a party, then failing to  
return it to the distributor and forfeiting your ten dollar deposit,  
does not mean that you should even consider this method, I strongly  
advise against it, and sundry other assorted disclaimers.

#### CLEAN AND GUT THE BEAST

Make CERTAIN the keg is empty and that there is NO pressure left in it.  
Press down hard on the ball bearing in the top to be sure. Remove the  
built-in valve as follows: Take a small flat blade screwdriver and  
insert it just under the lip of the housing. You will find that a flat  
circular strip of spring steel is holding the assembly together. Pry  
under the end of this ring until you can coax it out toward the center,  
then grab it with a pair of pliers and pull it completely out. Then use  
your pliers again to grab one of the two opposing lugs, turn the whole  
assembly counter-clockwise about half an inch until it lines up with the  
openings in the housing. Then simply lift it up and out of the keg,  
tube and all. This may not sound simple, but if you read this with an  
actual keg in front of you, everything will be quite obvious.

#### PERFORM SURGERY

You need to cut out the top and make a hole in the side. Here's the way  
I did mine: Draw a 12-inch diameter circle with a magic marker on the  
top of the keg, centered. That's plenty of opening, and allows you to  
leave the top rim attached, with its built-in handles. Mark a spot on  
the side, an inch or so up from the bottom rim. That's where your  
spigot will be. I used my power drill to cut a hole at that spot just  
large enough to accommodate a half-inch ID Stainless coupling. I took  
the keg to a friendly neighborhood welder who specializes in TIG  
welding, and had him use a plasma cutter to remove the 12-inch circle on  
top. First, he partially filled the keg with water to catch the sparks  
dropping inside (made later cleanup much easier). Then he welded the SS  
coupling in the side hole, about half inside the keg and half outside,  
grinding and polishing the weld for smoothness. Cost me \$30 and well  
worth it. Stopped at the kitchen gadgets section of a local store and  
picked up a pot cover for the top for a few bucks.

#### SIMPLE PLUMBING

Date: Fri, 16 Jul 93 09:43:18 PDT  
From: dra@jsc-ws.sharpwa.com (Darren Aaberge)  
Subject: hot break

I think the confusion about when the hot break happens is coming from the fact that we are trying to pinpoint an exact moment in time that it happens. In hbd 1183, Steve Casselman writes:

>The hot break begins at the beginning of the boil,  
>anyone unclear on this should bring an all grain  
>(extracts have small hot breaks) beer just to  
>boiling and then turn the burner down to observe  
>the flocculation of proteins.

the key word here is \*begins\*. The hot break does begin at the beginning of the boil but takes about 60 minutes to complete. I think the key about adding hops is to wait until enough of the hot break has occurred to give the uncoagulated proteins nucleation sites of other protein instead of hops.

Date: Fri, 16 Jul 93 10:16:57 PDT  
From: nuke@reed.edu (Bill Newcomb)  
Subject: Regulators

Someone asked about regulators for nitrogen (N2) and carbon dioxide (CO2) specifically whether there is any difference between the two. The main difference between two such regulators in a scientific catalog would probably be either the range of output pressure adjustability, or the graduation of the gauges, as CO2 has a much lower primary (tank side) pressure than N2 (800 vs. 2100). Oh, and the connection to the tank is a different "nipple" (not my word) for different gases, except that most of the real inert gases (He, Ar, N2) use the same one (#580). Interestingly, the CO2 fitting (#320) is also used for some freons.

Caveat: Your homebrew store regulator may not be rated to such a high tank side pressure, as it may have been designed with CO2 expressly in mind. Simply connecting the correct nipple for N2 to it (most of the connections to the regulator are 1/4" NPT) might not be such a good idea. This is based on a certain regulator I saw once that was mostly machined aluminum. For all I know, it's probably fine. YMMV.

>brew ... in general, can anyone give us the low down on this beer (its  
>not in Jackson, Finch or anywhere in Papazian) ... thanks.

I had the pleasure of having Jever (pronounced yay-ver) while in Ekenforde, Germany last year. This is a beer in the north German pilsener style, which in general is very dry with lots of hop bitterness, but Jever is even more so. I think the "fresnian herbs" are simply referring to the flavoring hops used, which give a nice spiciness to this beer. I'm not sure which type although I would guess Satz. When I first tasted this beer I thought it was too bitter for my tastes, but since returning home, I've been longing for more.

By the way, Jever is mentioned in Jackson's pocket guide, in the northern German section (I don't have my copy handy). It is one of his 4 star beers. Fresnia is the name of a province in Northwestern Germany.

> ingredient for All Grain recipes, but not for Extract recipes. Am I  
> correct to conclude that only All Grain recipes will benefit by  
> using Irish Moss during the last 15 minutes of the boil?

Up until last Fall, I was only brewing with extract and adjuncts, and I  
"always" used Irish Moss. The "break" material would settle out and I  
wouldn't have any chill haze. The couple of times that I did forget the  
Irish Moss, chill haze was a major problem. I'm not sure how much of the  
haze  
was from the extract as opposed to the adjuncts (I always used adjuncts)  
. In  
any case, I strongly recommend using adjuncts if your brewing with  
extract  
(past HBD issues have had lots of discussion on the merits of using  
adjuncts),  
and using Irish Moss (or some other clarifying agent).

Both may benefit, but I suspect that some of the hot break that occurred during the production of the extract has been removed (judging from the much smaller amount of hot break in extract brews). I'd also like to add that I just read the article by George Fix that Jeff referred to in his post and that, based on George's tests, different forms of Irish Moss behaved very differently. All reduced haze in varying amounts, but some also reduced head retention significantly. The best results, in my opinion were from "refined flakes" at a rate of 1/8th grams per liter, which performed slightly better than "large flakes" and much better than "powdered flakes." I'm not sure what type of flakes I was using -- they were not powdered and were on the order of 2mm wide and 10mm long -- so I'm off in search for a supplier of "refined flakes!"

The

and then later:

>The oils also deteriorate and oxidize over time. It is believed that  
some  
>oxidation of the oils is beneficial to the hop aroma. Since most  
homebrewers

I've read somewhere that Hallertauer hops benefit from a small amount of aging (most certainly under controlled conditions), but don't recall where.

I'll look for that source over the weekend and see if I can post something about it on Monday.

Since I brew pureculture Lambieks, I intentionally have been buying more hops than I can use and then storing part of them at room temperature in bags open to the air. As has been reported in various articles (one that quickly comes to mind is in the Hops Special Issue of Zymurgy) different

the bouquets of different varieties of hops change differently with age.  
I

have at least six varieties of hops aging and I can attest that some age more gracefully than others. The dominant bouquet of well-aged Fuggles is

"cheezy." No doubt about it. No other hops have as much of this "cheezy"

aroma as do the Fuggles. Hallertauer and Willamette have a definite "piney" smell which is quite pleasant, but the Willamette also have a "grape soda"

aroma which is highly distracting when associated with beer. Goldings seem to age incredibly gracefully, their "candylike" classic aroma just simply fades. Perhaps a bit of a grassy aroma is also evident, but only very slightly. Well-aged Cascades also have the "piney" aroma, but their characteristic "citrusy" aroma is still noticeable, even after two years!

The point I'm trying to make is that "cheezy" aromas are not the only ones that manifest themselves as hops age. The other lesson to be learned here is that for pLambieks, Hallertauer and East Kent Goldings are the best choices of the hops I happen to have tried (reportedly Saazer hops are also very good for pLambieks, but I've yet to take them out of CO2-purged/oxygen-barrier cold storage -- I will when this year's crop becomes available). I feel that Willamette and Cascades may be a bad choice, but the Willamette are not that old yet, so time may tell otherwise.

>Liberty 40%

>Perle 85%

While the data I have (from HopUnion) is consistent with all the other storagability factors Mark listed, the averages I have are 45% for Liberty and 83% for Perle.

The story I heard was that it was selling poorly under another name and when they changed the name to "Turbo Dog" they couldn't brew it fast enough.

Subject: Hot break & hop utilisation

Spencer writes:

>What Jeff says meshes nicely with some of the books on historical  
>brewing I've been reading recently (things like The English Housewife  
> . . . , by Gervase Markham around 1600; Wines & beers of old New  
>England\_ , S. Brown, 1978). You find statements like "boil it until  
>it 'breaks'". This seems to imply that the break happens at the end.

Then Steve writes:

>The hot break begins at the beginning of the boil,  
>anyone unclear on this should bring an all grain  
>(extracts have small hot breaks) beer just to  
>boiling and then turn the burner down to observe  
>the flocculation of proteins. IMHO no hops should  
>be added until a hot break occurs as hop introduce  
>nucleation sites that would otherwise be started  
>by the larger proteins. This will give a brighter  
>beer. By the way the hot break happens when the  
>larger proteins come in contact with the interphase  
>between steam and wort cooking them just as blood  
>will form a solid when heated. I've seen flocs  
>the size of dollar bills in my 40-gal brew system  
>allways at the beginning of the boil.

With all due respect to Jeff and Spencer, I have to say that in my experience, the majority of the hot break occurs within the first 15 minutes of the boil. When I got home yesterday, I checked Papazian, Miller, Noonan, Fix and Hough (The Biotechnology of Malting and Brewing)

Papazian says: "After a short period of boiling, your wort begins to exhibit a cloudiness and has flakes of coagulated protein floating in it." Miller does not say exactly when he feels the break begins to occur, but does mention that "wort can stand at the boiling point for any length of time and, unless it is agitated, will remain turbid. It is the rolling action of the boil which bumps the protein molecules into one another, causing them to clump together." From this I'd like to point out that the geometry of the boiler, whether or not there are mechanical stirrers and the intensity of the heat source all are factors in the intensity of the hot break and it may be \*that\* which influences various authors' opinions on when the break occurs. Personally, I noticed a much quicker hot break when I switched from my electric stovetop to a 12,000BTU gas burner. I'm only speculating, but since the Electric Bins are quite popular in the UK, perhaps Line's experience has been with these types of heat sources and not with the significantly hotter heat sources some of us are using (I know brewer's around here using upwards of 100,000BTU burners! Jack? Tim?).

Moving on to Noonan, this is another one of those sources that Jeff mentioned, that is quite unspecific as to when the hot break occurs. Fix appears to confirm Jeff's position: "For standard boiling temperature (100C), the precipitate increases sharply during the first hour, and often continues to rise (though at a diminishing rate) for 1 1/2 to 2 hours. Excessive boil time (3 hours or more) can lead to a redissolving or the precipitate." However, this is still does not contradict my assertion that a large portion of the hot break occurs during the first 15 minutes of the boil. Later, he says: "[hot

break] comprises the the coagulated material and gums suspended in otherwise clear hot wort at the end of the boil." I'd like to caution reading this statement as if the "end of boil" means that that's when the break occurred, rather that at the end of the boil, this material is \*still\* suspended in the hot wort.

Finally, Hough also is not clear as to when the break occurs, but has a very detailed description of the protein reactions during the boil. Several interesting points are: "The larger denatured [protein] molecules tend to exceed their solubility, especially if close to their isoelectric point [this is dependent on the pH of the wort]. When they coagulate, often tanned by the malt and hop polyphenols, hop resins tend to adsorb to them and so valuable hop material is lost. Indeed it is common for only 30-50% of the alpha acid material to be represented as iso alpha acids in the wort. The utilisation falls to 20-40% by the time that beer goes into package."

Conn writes:

>could be useful for ales which have not received a protein rest. As ale  
malt  
>is not reputed to contain protein digestion enzymes anyway, I presume  
the  
>problem that Miller is really referring to is that of using wheat malt  
and/or  
>flaked cereals without a protein rest.

I just checked Miller's TCHoHB and I can't find where he says that Pale  
Ale  
malt deficient in proteolytic enzymes. He does say that the higher  
kilning  
temperatures mean that Pale Ale malt is lower (overall) in enzymes, but  
does not specifically say that proteolytic enzymes are denatured  
excessively.

Pale Ale malt actually has less need for proteolytic enzymes because of  
the  
fact that it is more fully modified (than traditional, undermodified  
Lager  
malt) and therefore more of the proteins have been broken down during the  
malting process (this is from Papazian's TCJoHB).

An additional piece of interesting data I recalled from re-reading Miller  
was that just as there are two main types of amylase enzymes (that break  
starches down to dextrins and sugars), similarly there are two main types  
of proteolytic enzymes: proteases and peptidases. The optimum range for  
the action of the proteases is 122 to 140F and for peptidases, the  
optimum  
range is 113 to 122F. The proteases prefer to work on larger proteins  
and  
the peptidases can only break down smaller proteins. Sound familiar?  
Therefore, a higher temperature protein rest will favor the proteases and  
leave more small proteins (which we want for head retention, body, etc.)  
and a lower temperature protein rest will favor the peptidases and cut  
more of the smaller proteins down to amino acids. Miller does mention  
that a high-temperature protein rest could result in a wort low in the  
amino acids needed by the yeast for nutrition, but adds that well-  
modified  
grain already has quite a bit of the amino acids already (this is  
confirmed  
in Papazian) and thus should not be a problem. Since there are few  
modern,  
severely undermodified malts available, I don't think this should be a  
problem for us to worry about. In any event, this is just one more  
factor  
that we should be wary of when considering the big protein/small protein/  
amino acid composition of our wort, and not just write "I did a 30 min  
protein rest, then raised the temperature to..."

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: correct measurement of alcohol?

Anybody know how to do accurate alcohol measurement? I'm looking for the equipment to do a single post-fermentation measurement; I'm trying to get away from the initial/final SG "potential alcohol" approach. I know the principle: distill a known quantity enough to get all the alcohol, add water to get a known final volume, measure gravity of result. What I \*don't\* know is where to get the equipment to do it with reasonable accuracy, and the details of the procedure. It doesn't seem like it should be rocket science. (Aside: is there a procedure other than the one I've described?)

Also, since I mentioned the naughty "d" word in the process...and since I'm not interested in meeting any of the nice government folks who watch weapons, beverages, and carcinogens...what are the legal implications of measuring alcohol by the process I described?

Incidentally, the reason I need to get away from initial/final measurements is that they don't work when you've got lots of fermentable solid matter (such as fruit pulp) at the start of fermentation.

From: rcd@raven.eklektix.com (Dick Dunn)  
Subject: 6oz bottles, bottling mead

Rex K. Perkins <70651.1611@CompuServe.COM> asked:  
> I am about to start my first mead and was recently pondering the  
problem  
> of bottling the stuff. As it is going to be mighty strong, I won't  
really  
> want to drink it 12oz at a time...

Let me interject before we get to the main point: Are you sure you won't want 12 oz bottles? My experience is that most of the meads I've made, I've wanted either in 12's or a combination of 12's and 25's--the latter for parties, the former for home. The only exceptions for me have been a rather dearly obtained prickly-pear melomel, and a very strong, spicy, sweet metheglin that's almost like a liqueur.

I reason thus: Most mead is comparable to wine, both in alcoholic strength (10-12%) and in general character and strength of taste. The standard size of a wine bottle is just over 25 oz, and that's just right for two people. Thus half of that (a standard 12 oz beer bottle) is theoretically right for one person.

Two more bits, one on either side. In favor of small bottles, mead is precious stuff; you don't want to be pouring heavy just 'cause that's the bottle size you've got. BUT!...remember that a mere 5-gallon batch is one \*hundred\* 6-oz bottles! If you like bottling as much as most of us do.. need I say more?

But all of that is just an "are you sure...?"

> It will also be sparkling, so re-sealable  
> screw caps won't help either. So, the natural solution would be for  
> smaller bottles.

...  
> My question is: Where can I get 6-8oz bottles from?...

Old Foghorn (Anchor's barley wine) comes in 187 ml (6.3 oz) bottles... that's an excellent way to get some. Now, you may object "But if I get the bottles that way, they'll already have something in them!" This, however, turns out to be an easy problem...;-)

Thomas Hardy's Ale (another barleywine) comes in 180 ml bottles, so there's another source, but quite expensive.

Both OF and TH are nice bottles, though. It's probably not an immediate solution to your problem (people don't seem to drink much barleywine in mid-summer) but over the longer term it's a way to acquire nice bottles, a taste for very strong beer, and either incipient liver damage or a bunch of friends who are glad to help you obtain empty bottles.

My turn to ask: Since Anchor has had to obtain the little bottles,

somebody somewhere makes them in substantial-but-not-staggering quantities.

Might it be possible to find out who supplies the bottles to Anchor and see

if they'll supply in few-case quantities?

**Subject: Burton water treatment**

I recently bought some Burton Water treatment salts from Alternative Beverage. Unfortunately there is no info on what is in it or how much to use to attain a target PPM. Any help would be greatly appreciated.

Also the stuff contains Papain (not mentioned in the catalog!). Since Papain acts at pretty low temps (~120-125) I assume that it is deactivated in a single step infusion mash at ~150-155?

Why would someone add Papain to a water treatment. Isn't it generally used in the secondary? And why wasn't it mentioned in the catalog?

Subject: Belgian Ale Book Reply - At last

hi all,

sorry for the long delay - to refresh your memories - many months ago several people posted directly to me questions about Pierre Rajjottes book Belgian Ale. The questions were delivered to Pierre (just after the blizzard) started this past winter/spring. Pierre has been very busy looking up source to give the best answers possible. I now have the answers in hand.

only a small problem prevents me from posting them here: they are on MAC formatted disks and hard copy - i have a dos PC - damn computers. any way what i am going to do is either scan and ocr them or c convert the media. in either case i will post the results to the net of your choice. if the original posters could email me at jdr@wang.com i would thank you : the original posters i have are:

Al Korzonas  
Conn Copas  
Tim Fahrner  
Martin Lodahl  
Jim Liddel

The document Pierre has given me (today, in person) is about ten pages long and contains several pointers to other docs. Sorry if i have missed anyone e else that has posted questions to me - but Pierre has mentioned that you may contact him directly in Montreal. Please do not post messages thru HBD as of late i do not read this list as often as i would like. please reply to me directly at the email enclosed.

again pierre is sorry for the large delay as am i. we both hope the info resolves the errors/problems you have had.

later.....and good brewing.....

From: jim@n5ial.mythical.com (Jim Graham)  
Subject: Advertising / Beer in the White House

Regarding the subject of adverts here, I think I might have a solution that would make everybody happy. I, for one, would prefer to keep a list of my options in terms of who I buy liquid/dry extract, hops, kits, etc.

from, and when I eventually get the money and space for mashing, there'll be a lot more that I'll want to keep up-to-date on. But not everyone wants that here on the digest, which is a side I can see, as well (I don't necessarily agree with it, but I can understand it).

A list could be published here on the digest either every two weeks or every month (probably once/month would be enough) of all of the people here who own mail-order homebrew supply shops. As far as the digest would be concerned, it ends there.

This list, however, would give an e-mail address for each supplier. The suppliers could then keep a mailing list of people who want to receive new product announcements, price lists, etc., and could then send that stuff along via private e-mail (this would need to be indicated in the list published on the digest in order to really work).

In other words, you get the list of the homebrew suppliers here, and a pointer to the address for getting the rest via e-mail.

Sound like a good idea?

- - - - -

Now, regarding the White House beer recipes listed here by scott.powell@amail.amdahl.com, I've got a few questions.....

First off, are these actually beers, or are they more along the lines of something like root beer (which, btw, is something I'd like to try brewing sometime, too, if I ever find out how)?

> Hop Beer  
>  
> Take five quarts of water, six ounces of hops, boil it three hours;  
then  
> strain the liquor, add to it five quarts of water, four ounces of  
bruised  
> ginger root; boil this again twenty minutes, strain and add four pounds  
of  
> sugar. When lukewarm put in a pint of yeast. Let it ferment twenty-  
four hours  
> it will be ready for bottling.

Let's see if I've got this right.... Five quarts (not gallons) of water, a \*pint\* of yeast, and it only needs to ferment 24 hours? Is that just because of the incredibly large amount of yeast? (Well, wait a minute, the next recipe doesn't use that much yeast, and it still looks like a 24 hour ferment.)

> Ginger Beer  
>

> Put into a kettle two ounces of powdered ginger root (or more if it not very strong), half an ounce of cream of tartar, two large lemons, cut into slices, two pounds of broken loaf sugar and two gallons of soft boiling water. Simmer them over a slow fire for half an hour. When the liquor is nearly cold, stir into it a large tablespoon of the best yeast. After it has fermented, which will be in about twenty-four hours, bottle for use.

What exactly is ``broken loaf sugar'' ??? Where would one get powdered ginger root to use for this? And again, only 24 hours?

Final question---how long would these need to age in the bottle? Anyone have any idea?

Thanks,  
--jim

Date: Fri, 16 Jul 1993 09:57:33 -0600 (CDT)  
From: jim@n5ial.mythical.com (Jim Graham)  
Subject: Update on cidery beer / siphoning / Spec. Prod. Intl / etc.

First off, an update to my last post about the two batches that came out tasting cidery. Shortly after I'd posted that, I had to run to the local homebrew supply store anyways, so I took a bottle of one batch with me. The owner tried it, and most of the cidery taste was gone...or so it seemed. He was pretty sure that it just needed to age out.

Well, as time went on, the cidery taste actually started getting worse..  
.or  
so it seemed..... As it turns out, I discovered last night, while dumping some of the bottles down the drain to re-use when I ran out of bottles while preparing to bottle some more beer, I noticed (after opening an entire 6 of the ``bad'' batch's bottles) that some of the bottles from that batch seemed fine. Others could kill you by the smell alone.

It seems that the severity of the problem varies from bottle to bottle, which leads me to believe that there \*WAS\* an infection, and that it was caused by improperly sanitized bottles.

But there's only one small problem in that theory---a coincidence that's just too much to believe. The next two batches, which also relied simply on boiling water (as opposed to bleach water, which is what I'm using now), came out just fine. Also, the two batches that went bad were both the same brand, and I'm told that sometimes, quality control within different companies can cause some brands to behave differently at times.

Could it be, for some reason, that this particular brand of extract is more susceptible to infection? Or is it just a wild coincidence?

Oh well, it's more or less a non-issue now.... It's a lesson learned, but I'm sanitizing bottles with the same strength of (HOT) bleach water that I use on dishes (pretty strong!)...and no bacteria is going to survive that!

As for the bad batches, I'm basically taking the advice someone here gave me---keep 'em around until I need the bottles. Every so often, I put one in the 'fridge and see if it tastes ok. I've yet to find one that did (well, there were those 6 last night, but room temps here aren't exactly at a level you'd want to drink beer at...78 deg beer doesn't sound too great!).

- - - - -

Now, someone had asked about siphoning into two different carboys at the same time to do some experimenting, and was wondering about using a Y-shaped siphon hose, etc., to avoid any possible problems with different strengths/flavors of beer by siphoning one, then the other.

I have a simple solution for you (as far as I know, there's nothing wrong with this suggestion...someone please correct me if there is)---use two siphon hoses side by side. Nice and simple...and cheap.

- - - - -

> From: Elaine <EBORIS@UGA.CC.UGA.EDU>  
> Subject: re: Specialty Products Intl  
>  
> About the review of "Home Beermakers Guide" by Leigh P. Beadle  
> Sad but true:  
> When I first tried my hand at brewing over 10 years ago I bought an  
> equipment kit which included Superbrau and L.P. Beadle's ~guide~.  
> Looking back, I am amazed that I didn't get any truly BAD beers from  
> following his advice. It took some time (and much better books on  
> homebrewing) to rid myself of bad brewing techniques I gotten from that  
> book.

I found the review interesting, too...but for different reasons.

When I got into homebrewing early this year, my starter kit also included the ``guide'' and Superbrau, but with one big difference---the owner of the store made some modifications to the guide. He basically went through the instructions one by one, and said things like: ``Ok, see where he says to do this? IGNORE IT. Do it this way instead. See where he says to do things in this order? That's backwards. Here's how you really do it.'' And so on.

When I read the review here, I was going through the changes marked up in my own copy, and for the most part, they all matched.

Either way, I quit using that particular reference after the first two batches, anyways (I'd learned the mechanics, which is about all the modified version of that really covered).

- - - - -

Final note.... I'm going to be brewing what I hope will turn out to be a very nice batch either today or tomorrow. It looks something like this:

BierKeller Premium German Malt Extract (Unhopped Dark)..... 3.3  
lbs  
Munton & Fison dark malt extract (dry) instead of corn sugar..... 4  
cups  
One packet bullion hop pellets

In other words, more or less the instructions on the can, except using malt extract instead of corn sugar. I've also got the same basic batch in bottles right now, except it uses corn sugar (it'll be ready in about another 8 days or so).

One question: Is this going to give me a true German bock beer? Or are there enhancements I need to make the next time around? I'd like to brew a \*REAL\* bock, and possibly even a doppelbock. So far, as far as I know, the closest thing I've had to a real bock was a German import, Fiedlers Bock im Stein (in those nice re-usable stone bottles). I like it enough to know that I'd like to brew a true bock. I also know enough to know that if it comes from a store, it probably isn't....

Suggestions? Comments?

Subject: Irish Moss vs. Hog's Nose Cartilage; Jever heard of Friesia?

Hi. My name is Joe and I use Irish Moss.

I boil the wort for about an hour and add the IM anywhere from 10-30 minutes before the end of the boil. I add somewhere between a heaping teaspoon to a tablespoon to a shake or two of the bag when there aren't any utensils handy. Never very much. By the way, I've been brewing on the porch lately. The sight of a 10 gallon pot on a cajun cooker will often elicit queries from even the shyest of neighbors. I get a little porch time, meet some neighbors (they love chucking in the hops), spread the quality beer gospel, water the lawn with the immersion chiller run-off, and end up with 2 logs of quality beer. Plus, I don't have to scrub boil overs, I just hose them down.

Back to the IM.- Sometimes I do a little experiment: When the boil is over, I scoop out a cup of stirred up hot wort, pour it into my hydrometer test jar and watch the hot break settle. Then I cool the wort to, say, 80 degrees, creating a discernible cold break. After rousing the break by gently stirring, I take another sample and put it in my other hydrometer test jar. (They are both actually the cheap plastic tube the hydrometer & thermometer came in.) Five minutes after collection, the break matter settles out. The sample from the cooled wort is always deeper than the sample with only the hot break. No surprise, but it's neat to actually see a quantitative demonstration of what we're talking about when discussing the hot & cold break.

I lay out my hops and irish moss before I start the brew. That way I don't have to think too much. One day my little experiment didn't work. The hot break sample resembled suspended goo (or "juj", the technical term). It didn't go anywhere. The cold break sample was even cloudier. I said to myself "HMMMMM what happened?" whaddya know? The Irish moss was still on the counter (this was when I still brewed in my kitchen); I hadn't added it. I am a true believer in Irish Moss. I know it works. So does Break Brite. And it's a lot easier to find (in my part of town) than ground hog's nose cartilage.

Send beer, quick!

Joe "Noise" B. from Austin, brewpub mecca of America - just you wait and see...

p.s. in response to Chris Pencis' query: Friesia is in the Netherlands. I think. It's supposed to be chilly there, but the highly productive milk cattle there dig it that way. Any folks from the Netherlands read the HBD?

If so, send parsley so we can make some Jever! Maybe the Friesian spices the Jever label referred to were hops. Like those skunky things in Heineken.

-JB 4 days b4 printing.

From: tinsethg@ucs.orst.edu (Glenn Tinseth)  
Subject: hop\_storage

In the July 1 HBD, Jonathan Knight asks about storing whole hops, (having been caused to worry too much by something he had read in some hop catalog;^) Let me first apologize for contributing to your stress levels and second try to assuage any worries about hops instantly turning to a quivering pile of moldy cheese if improperly stored.

I *have* to worry about storing hops because I need to keep them year round in top condition, ready to send out. Barrier bags, exclusion of light, and sub-freezing temperatures are how I slow the inevitable deterioration of whole hops. I also try to start with the highest quality I can find. You are already able to provide three of these four requirements:  
Buy (or grow) the best hops possible and store them in your freezer (after first making sure that the light *really* does go out when you shut the door:) At this point you are doing a better job than even some homebrew supply retailers I have seen, frequent contributors to the HBD excepted of course (Al Korzonas packs his hops for his Sheaf and Vine business as good as I have seen anywhere). Big (and small!) breweries rarely store their hops properly relying on the fact that they use hops quickly to prevent problems.

In order to exclude oxygen, two things need to happen: The hops need to be in a container that won't let O<sub>2</sub> (or H<sub>2</sub>O) in, and that container needs to be purged of O<sub>2</sub> before sealing. Glass mason jars fit the bill for the first requirement, wide mouth being the easiest to load. Some homebrew suppliers carry barrier zip-lock bags that will also do the job. The second requirement is a matter of degree. In my research in P-Chem, I worked with equipment that could get down to 10e-10 torr. A good bag sealer should be able to get to 150 torr (0.2 atm) or less. For long term storage I would say that vacuum removal of the air is the only way to go. However if you don't keep opened bags of hops around for very long I think that a vacuum sealer is definitely overkill. Pack a jar (or barrier zip-lock) as tightly as you can with hops and seal it. Put it in the freezer, and...RDWHHB. If you happen to have CO<sub>2</sub> around go ahead and use it to purge the air from the jar or bag before packing the hops for added O<sub>2</sub> removal.

The bottom line is if you get your hops from a reputable supplier (or grow them yourself) and use common sense in storing them, you'll have no problems.

Subject: cider

Help!

I recently made a cider using the dregs of my last cider which turned out beautifully clear and dry. I added nonpreserved apple juice concentrate directly to the drega in a glass carboy and allowed it to ferment.

After six months it still hasn't cleared and when chilled gets a flocculant

haze. I tried adding gelatin fining without much success and also tried rechilling to about 32F. Has anyone used pectinase with success? Can I add pectinase at this stage and if so how much do I add to 5 gallons and how do I prepare it? By the way I also added sucrose dissolved in water to try to clear this. After about a month a one inch clear layer formed

on the top with a white fluffy haze below.

Thanks

From: dhholscl@rs6000.cmp.ilstu.edu (David Holsclaw)  
Subject: Use of B.E.S.T. Sanitizer

Help!!!

I have had my last three batches head south with a strange medicinal type of a smell and taste. I pitched the first two but am letting the third sit in the secondary (hoping the flavor will mellow). I have just figured out that the beginning of these off-flavors corresponds to my purchase of a bottle of iodophor. I also noticed that the sanitizing solution seems to have the same medicinal taste/smell as the beer.

My question is. How do those of you that use iodophor, use it. I have been using it like bleach: mix up solution in a 5 gal. bucket, let the utensils, carboy, etc. soak for about twenty minutes, rinse well, use assuming sanitation.

I have reread the bottle of B.E.S.T and it says that the stuff does not need to be rinsed, but should air dry. Is the stuff impossible to rinse off?? What is the networks accepted method for using this stuff?

Do you think the beer is 'safe' to drink. I tastes funky (but after loosing three batches my supply is dwindling).

I think I'm going back to bleach!! At least until this problem has been identified.

From: "Roger Deschner " <U52983@UICVM.UIC.EDU>  
Subject: Alcohol as a sterilizing agent

Many of us have switched to ordinary vodka for sterilizing critical things where bleach residue would be bad. Just buy the cheapest rot-gut store brand vodka in your liquor store. I keep it in a plastic garden sprayer, and spray things I want to sterilize, such as stoppers, fermentation locks, etc, and then I always use vodka to fill the fermentation lock itself. If some gets sucked in, who cares? Why use vodka and not some other form of alcohol? Because vodka is "food-grade" - i.e. it is intended to be fit for human consumption. With vodka you are sure that you are not accidentally using one of the other forms of alcohol that is SERIOUSLY poisonous.

And for rinsing out carboys, kegs, and such which have been sterilized with bleach solution, just use the cheapest lawnmower beer. Finally somebody found a use for Old Milwaukee Light Dry Draft.

>When I racked each keg, I also bottled a pint from the batch in a  
Grolsch  
>bottle. The bottled pint turned out very clear and didn't have as  
strong  
>of a ginger taste.

Well, several things can cause cloudy beer. Yeast is a common one. Some  
bacterial infections can give you a cloudy beer too. Since the beer you  
bottled cleared nicely, I suspect one of several things. Both wild,  
poorly-flocculating yeast can give you a permanent haze and your pitching  
yeast can too. Remember that your keg is much taller than a bottle and  
that it will take proportionately longer for your pitching yeast to  
settle

into the bottom of the keg than it took in the bottle. Another problem  
may be that you carried over a lot of yeast from your fermenter and thus  
have a lot of yeast in the bottom of the keg. Even after it settles, it  
may take a couple of glasses of beer before it starts to flow with good  
clarity. Note that every move of the keg will stir up the yeast a bit  
and thus you may get some cloudy glasses for a while. I've cut about  
1 inch off the end of my liquid dip tubes and thus I can't get the last  
4 ounces of beer out, but then again, most of that is yeast anyway.  
I strongly suggest that you use a tubing cutter or you will have a hard  
time getting the tube back into the keg (if you don't want to buy one,  
just see if you can bring the tube into a hardware store and use theirs)

.  
It may be better to leave the dip-tube full length because you can  
eliminate  
some of the yeast that would otherwise just sit there in the keg  
(potentially  
autolysing) and minimize the amount of yeast that will get shaken up  
when you move the keg. I don't know which would be better -- ideas?

You may also have an infection, but I suggest you let the beer carbonate  
or force-carbonate the beer and then put it in the fridge to help the  
yeast settle faster. Give it about a week for the yeast to settle. Don't  
expect crystal-clear beer for the first glasses. If this works, then you  
don't have an infection problem. If it doesn't, then you will have look  
more closely at your sanitation techniques.

>On another point, all three of the batches that I have made so far (kits  
>supplemented with various other unhoppped malt extracts) have ended at a  
>final gravity of 1.018. This seems to be a strange co-incidence since I  
>used different amounts of ingredients each time. Also, the FG seemed  
>stabilize rather quickly, like 4 or 5 days after pitching the dried  
package  
>of yeast included with the kit.

It depends on the Original Gravity. If the OG was 1070, then perhaps 1018 is not unreasonable. Another thing that can cause your OG to be high is insufficient aeration. Finally, if you temperature-shock the yeast or ferment at too-low a temperature, your yeast can settle out prematurely leaving a high FG.

> and at the 1# level leaves a yummy sweet \*aftertaste\*"

I put 2# of C&H Raw Sugar (from my local supermarket) in a recent batch of IPA. The OG of this beer was 1065 and was hopped with 45 or 50 IBU. It turned out, in a word... "cidery" at first. As it ages, it is smoothing -out. Initially, there were two distinct flavors present -- beer and this "cidery" flavor. It was almost as if you mixed some alcohol with water and a few teaspoons of sugar in a glass and then took a sip of that, swallowed and then followed this with a sip of a relatively decent beer. It was amazing how the flavors were distinct. They are blending better now (after two months of aging) but it's still not a good beer. I now feel that 2 pounds is just too much sucrose for a 5 gallon, 1065 OG batch. But maybe it will be great in a few more months. Perhaps I should ship it to India and then have them ship it back to me?

Some yeasts produce sulphury odors during fermentation -- this is especially true for some strains of *S. Uvarum* (lager yeasts) -- fear not, your beer is probably just fine.

Have I

>finally gone off the perverbial 'deep end'?

This has been done and with success. I wish I had done it on my last Imperial Stout (which finished at 1050 (down from 1120) and then would not carbonate -- see what happens when you try to rush a beer?) It's a good idea if you want to get some characteristic of a particular ale or lager yeast, such as the woodyness of Wyeast #1028 or the raspberry esters of Wyeast #2035 (fermented at 65F) and then finish off the rest of the sugars with a more alcohol-tolerant yeast.

>(besides replacing all the rubber seals as someone mentioned), and  
>where to get parts, rebuild kits, etc. I've got a batch of beer ready  
>to bottle, er, keg right about now....

I recommend, of course, that you replace all the rubber seals, and then clean and sanitize (I recommend iodophor for SS -- some disagree with me) the keg. I simply fill the kegs with hot water, seal and shake, dump, repeat. I do this perhaps 5 or 7 times to get all the syrup out of the keg. If there's some dried on, you may have to let it soak. Don't use hot water with the iodophor -- use cool water! I know that B.E.S.T. and B.T.F. iodophors have surficants, which should help clean a bit also. I recommend that you use plain water for the first 5 or 7 rinses and then iodophor on the last one. I rinse then with a little hot water or industrial beer (a good idea if you suspect your

water to have bacteria in it) -- just a couple of cans of Bud Lite (nothing will live in that!) swished around and then dumped. I pump a half-gallon or so of each rinse out of the keg with CO2 to clean the inside of the dip tube and connector too. Note that the makers of iodophor say that if you let it air-dry, you don't need to rinse out the iodophor. I'm usually in a hurry, so I rinse either with hot tapwater, boiling water or industrial beer that some of the well-meaning, as-yet-uninitiated have left at my house during a party.

Keg reconditioning parts: Foxx Equipment, KC, MO -- 1-800-821-2254. Ask for Scott. As much as I'd like to say you can get these parts from me, I have neither the space nor capitol at this time to stock the 100 or so parts for all the various kegs... perhaps some day... till then, Foxx is the best place I've found.

2 to 3 years old, actually. This aging removes virtually all the bittering and (in my experience) flavoring potential of the hops. It is the preservative quality of the hops that still remains and is what is desired. My suggestion is to strike a deal with a retailer in which you will buy his/her old whole hops (pellets age much more slowly and unpredictably) at a discount when they get fresh hops in. By the way, I used 3 ounces of 1.5 year old Hallertauers, baked for 20 minutes at 250F. Also, I suggest that you use hops such as Hallertauer, Saazer, Tettnanger, Mt. Hood, Liberty, and East Kent Goldings, and not hops such as Cascades which have a characteristic aroma that is not normally associated with Lambieks. Also, if you age them yourself, high temperature will increase the rate of aging, but make sure the humidity is not too high or they may begin to mold.

From: John Mare <cjohnm@ccit.arizona.edu>  
Subject: RE: Jever? Fresia? More on IPA

Chris Pencis asks about "Jever" and about "Fresia", what is the former, where is the latter? "Jever Pils" is in my opinion one of the truly exceptional German Pilsners, brewed in N. Germany near Hamburg. I tasted a draught version on a recent beer tour of Britain, and was extremely impressed with its exceptional hop aroma, its pleasant bitterness, and a good malt presence. The hops used are Hallertau and Tettnanger, the latter probably imparting the delightful aroma. I hope to find a bottled or kegged version of this fine lager in the US. Any suggestions? Friesland is that part of N. Germany adjacent to both Holland and Denmark. I was not aware of the fact that the hops in "Jever" are from Friesland.

On another subject, Jim Busch in commenting on my earlier post re IPA's noted the high OG (1.048) of the R&D Deucher's IPA which has a final ABV of 3.9%. Sorry Jim, a typo slipped in! The OG is 1.038, not 1.048 as posted. This truly exceptional ale by Caledonian Brewery of Edinburgh is available in Scotland and parts of England as "real ale" in cask (not keg! They don't keg any of their beer!)  
>From John's Alehouse, where "the ale cures what ails ye".

Subject: Is a trip to Yakima worthwhile?

In August I am planning to visit Seattle and make side trips to Portland, Oregon and Yakima, Washington. I've been to some brewpubs in Seattle and the Tumwater (Olympia) brewery .

Is the trip to Yakima worth it to visit Grant's? Are there other breweries or brewpubs in Yakima? What else is there in Yakima?

What are the best breweries and brewpubs in Portland?

From: "Michael Barre" <MBARRE@NOMVS.LSUMC.EDU>  
Subject: Batch #2 and Cheap Carboys

Firstly, I would like to thank everyone who sent suggestions for improving my brew methods. Reading TNCJOH more closely, I noticed that Papazian stated that you MUST use the blow off method for the primary fermentation when using pellettized hops, which I neglected to do. My second batch, made from Wyeast American Ale, Northwestern malt extract, Cluster hops, spring water and gypsum, has been in the primary fermentor since Thursday and is beginning to settle down. It smells as much cidery as malty, but I am not worrying.

I seem to have found the cheapest carboys. I called four or five bottled spring water companies until I found one using glass. I then signed up to get 5 gallons of spring water every two weeks (the minimum obligation) delivered to my house for \$4.75 a carboy. The first 10 gallons were free, and the deposit on the two carboys was \$10.50. Even the dispenser was free.

p.s. Singing potatoes?

From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>  
Subject: Measuring color, how?

I have a beer that is somewhere around the color boundary for brown-robust porter and would like to enter it in competition in the right category. However, try as I might I could not find the definition of SRM or EBC anywhere. The best I found was Eckhard's conversion between the two. I have access to spectrophotometers and sticking beer in is trivial if I know what to do with the absorbance figures when I measure them. So can some kind soul out there please email me definitions of either or both of these color conventions.

From: krueger@comm.mot.com (Kevin Krueger)  
Subject: What happened to Sprecher??

What happened to Sprecher? That is a loaded question.

I just caught someone's comment about a barge hitting Sprecher? Was this discussed previously? I went through my old HBD's and didn't see any discussion about this event, so can someone please fill me in on the latest.

BTW, would the barge have anything to do with the downfall of Sprecher (in my eyes)? Yes, I said downfall. I was there at Sprecher when it was but an infant . . . when the tours were 5-6 people and the beer was better than sex. Actually, I was only getting beer at the time, so it's an unfair comparison :@)

Anyway, I think Sprecher has gone downhill based mainly on the quality of the recent beers I've had and also the fact that they use twist top bottles. I was a bar in Milwaukee recently and had their Special Amber and it was weak. In fact, I even considered drinking Beck's Dark instead! Even so, that hasn't been the first time that I thought their brew was weak. What has happened to the almighty Sprecher?!?!?!?

Here is some news from the rumor mill . . . someone in Milwaukee please comment.  
The East Side Lakefront down by the River Brewery has burnt down. Is this true?  
I heard it was the brewery and I also heard it was just the store for the brewery. Beans and Barley and the dance hall Esoterica also went up in flames (for those present and former East Siders.)

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Hotbreak

>From: korz@iepubj.att.com

>but since the Electrim Bins are quite popular in the UK, perhaps Line's experience has been with these types of heat sources and not with the significantly hotter heat sources some of us are using (I know brewer's around here using upwards of 100,000BTU burners! Jack? Tim?).

Like Pavlov's dog, I respond to my name.

I don't have a clue as to how to determine tthe BTU's of my heat source but it is a NG/forced air furnace I designed for melting aluminum for MM castings. It will melt 4 lbs of aluminum in 20 minutes. However, it is not terribly efficient when used to boil beer because the flame is directed horizontally instead of up toward the kettle. I put a firebrick in at a 45 deg angle to help facilitate that. Having said all that, it will boil 14 gallons of wort furiously and I normally do not run it wide open.

I previously reported an interesting experience when I recently made a batch of EASYBEER on the kitchen stove to verify the procedure in the EASYMASHER brewing instructions. My stove barely will boil 6 gallons of wort but I managed to evaporate the required amount of liquid in the 90 minutes allotted and produce a decent beer. What was noteworthy was the fact that the coagulated protein floating around was several orders of magnitude larger than what I am used to seeing in my normal, more vigorous boil. Clearly the size of the so-called "hot break" is totally irrelevant and it is the quantity that settles out after chilling that is important. The vigor of the boil seems only to effect the amount of time it takes to achieve the evaporation required.

I would also like to propose that the "hot break" phenomenon could be more easily comprehended if we just changed the term to agglomeration, coagulation or some other such expression. "Break" implies that there is some sort of sudden transition when, in fact, there is no such thing. It is a continuous process that gradually diminishes as the boil proceeds.

Date: 20 Jul 1993 13:42:51 -0500  
From: Chris McDermott <mcdermott@draper.com>  
Subject: On sugars

On sugars  
In HBD #1184 William A Kitch says:

> Dark sucre-candi: Philip Seitz says as near as he can tell rock  
candy=  
> sucre-candi. Piere Rajotte says in Brewing Belgian Ales  
> that sucre-candi is sucrose. The dark sucre-candi is  
> caramelized before being crystalized. Nobody seems to have  
> a US source. I've tried camelizing my own sucrose. It's  
> not hard to do.

Correct; but more specifically it is inverted sucrose. This seems (at  
least to  
me) to be important.

While I have not tried it myself, I know of at least one person that has  
used  
carmalized sucrose in belgians with sucess. I think that carmalized \*  
inverted\*  
sucrose would work even better. If you want to carmalize it yourself you  
can  
do so in a sauce pan over the stove. Remember to use \*low\* heat and stir  
\*continually\*.

>There is stong consensus that too much sucrose adds a characterist  
cidery  
>taste.

I agree with this to a point. My experience leads me to beleive that if  
sucrose (or almost any sugar for that matter) is used judiciously that  
cidery  
flavors can be easily avoided. I think the key is to avoid sugars in all  
low  
gravity beers (say < 1.040) and in moderate (say 1.040 - 1.60) gravity  
beers  
not to exceed 20% extract from sugars. I think that extract brewers  
should be  
carefull here to really consider that quality of the extract that they  
are  
using. Some of the cheaper extracts may contain a significant quantity  
of  
non-malt sugars to start with. In higher gravity brews (say > 1.060) I  
think  
that the amount of sugar that can be used is only limited to what the  
yeast can  
ferment. What I mean by this is that you could use an infinite amount of  
sugar, but after a point even the most ethnol-tolerant strain will quit  
fermenting and leave the remaining sugar as is.

>On the other had high  
>gravity Belgian ales call for sugar as an adjunct. The purpose is to  
>lighten the body and maltiness of these high gravity beers. This is  
>one thing that makes them distinct from say Barley Wine.

I think everyone would agree with this. An all-malt tripple having the  
body of  
a dopple bock just wouldn't cut the mustard, so to speak.

>Rajotte says  
>Belgian brewers may add either glucose or sucrose to their high gravity  
>beers. Some say the already high maltose content hides the cidery  
flavor.

I read this in a slightly different light. What I got out of it is that  
with a  
significantly high proportion of malt to sugar, the yeast would not  
produce  
those cidery flavors. What's your opinion?

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: The Tumbleweed Report (Part 2)

On to the brewing equipment decisions we've made.

The Brewhouse:

The brewhouse is literally a house. A 12' x 12' bedroom was plumbed and gas lines run in to give us our brewing room. The boiler sits on top of 4 or 5 courses of concrete blocks encased by 2 x 4's. It's located right by a window. A window fan vents the place. It gets a little hot in the summer. But we're working on cooling the place down now by adding more fans to the other windows. In the winter it's fine.

The old living room (14 x 24') is our "fermentation chamber" and office. Nothing fancy. In one corner of the room we have an 8' x 8' walk in cooler. Four insulated walls were built in one corner of the room along with a raised floor on 2 x 4 "floor joists". Plywood floor and walls. A compressor cools the room. Cost was around \$2000. The restaurant uses the cooler some but mostly we have it filled with kegs going through final conditioning before being taken to the restaurant. We store our malt and hops in there as well.

In the winter we used a thermostatically controlled heater to keep the fermentation room around 65 degrees. This past winter we had temperature fluctuations of plus or minus 5 degrees. This isn't ideal, I know. But it works. We've made some modifications to things this summer, so I think we can do better next winter and hold temps within 5 degrees. That's good enough by anyone's standards.

During the summer, we use a common, garden variety window air conditioner.

We just put a 11,000 btu air conditioner in a couple of weeks ago and with temperatures above 90 degrees, the fermentation room has been staying right at 65 degrees. Again, pretty good.

Fermenters:

When Burton and I arrived in November, Tumbleweed was fermenting in 6 1/2 gallon carboys. Some of you know that I designed the BrewCap. Since Burton was a BrewCap fan, too, the first thing we did was attach BrewCaps to each of the carboys Tumbleweed had and turned them all upside down. At one point, we had 50 carboys turned upside down in a two-tiered rack merrily fermenting away! For me it was one of the most beautiful sights I'd ever seen! But after a month, we realized the care and feeding of 50 glass fermenters was too labor intensive even using BrewCaps. While the BrewCap works great for the average home-brewing operation, things were getting out of hand at the brewery. Moreover, in December darned if Bart didn't trade for a 42 gallon stainless steel pot that had been salvaged from a cheese factory about 40 miles away. So Burton and I found ourselves dealing with 40 gallon batches after just one week of brewing at 30 gallons.

It had become clear that we had to move away from carboys. And I want to place the blame squarely on the shoulders of one this forum's esteemed members for being the prime cause for us having to move up in size. We were using Larry Barello's idea for a wort aerator and it was foaming the

beer up so badly (nicely?) that we could only fill a carboy half-full before moving on to the next one and by the time we had come back to the first one, the foam usually hadn't settled down so we had to shake and stir and do whatever to collapse the foam head so we could get the blasted carboys full!! Thanks, Larry! :-) Filling carboys had become a nightmare.

But what to do? Glass is one of the best materials in which to ferment and carboys weren't working out. Stainless steel would have been great but we couldn't find them much less afford them. Bart, on the recommendation of someone in the brewing industry had purchased three 31 gallon black HD polyethelene drums back in October but we were reluctant to use them, being well aware of the complaints about fermenting in plastic. At the same time, I also know of some world-class brewers who ferment in plastic. Darryl Richman comes immediately to mind. I had always figured that most of the problems people have with plastic fermenters stem more from not cleaning and sterilizing them IMMEDIATELY after using them than anything having to do with the plastic itself. So with Bart hounding us to give the drums a try, we took the plunge.

I'm happy to say that, on the whole, they've worked very well for us and I would heartily recommend them to anyone wanting to brew on this scale. We use open-head fermenters. That is to say, the entire lid comes off the top so you can get down inside them and scrub off the resins and junk that forms during primary fermentation. These jewels cost about \$50 each delivered. Can't beat the price. Once used, they never see the light of day again. Immediately after using them, we fill to the brim with clorox and water and let 'em pickle until the next time we use them. We've had no infections and I don't anticipate any -- at least from the fermenters.

We are currently using 18 fermenters. We always need one free for transfers so we can have 527 gallons of beer fermenting at once. Total investment in fermenters is roughly \$900.

Cam makes up homemade dollys to put them on and we wheel the drums around the brewhouse from that point on. The dollys cost about \$35 each to make. Total investment: around \$600.

(To be continued...)

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: The Tumbleweed Report (Part 3)

Brew Kettle:

As mentioned earlier, we found a 42 gallon stainless steel pot that had been salvaged from a cheese factory. We had had enough experience with the 30 gallon fermenter to know that we had to get away from siphoning through our wort chiller. So we had a 1" pipe welded about 4" up from the bottom of the pot to allow for the settling of the hops and trub left over from the boil. We have a copper pot scrubber tied around the end of the pipe that sticks into the kettle. This keeps the hops from clogging the pipe and stopping the draining of the wort.

On the other end of the 1" pipe we have a reducing "T" fitting (reduces down to 1/2") that splits the draining wort into two directions. First stop is our hop back.

Hop Back:

If any of you read my article in the Special Gadgets issue of Zymurgy you know I'm a big fan of the hopback so it was high on our list of improvements to make to the brewing operation. We even used the mason jar hop back for a couple of batches when we were brewing 30 gallons at a time. The hassles of changing the hop back every time we switched carboys caused us to rethink things for the 42 gallon pot. We settled on using two 1 gallon stainless steel pressure cookers. 1/2" from the top we had 5/8" OD holes drilled, into which we placed a 1/2" ID bulkhead union to receive the 1/2" copper tubing carrying the wort from the reducing "T". 1/2" from the bottom of the hop back, we had another 5/8" hole drilled and fitted with its 1/2" bulkhead union. The wort flows from it to our counterflow wort chillers. We tie our hops up in paint strainer bags, the kind made from mosquito netting, and tie the bag around the inlet pipe at the top of the pressure cooker. The vent on the lid of the pressure cooker was welded shut so when the lid is closed we have an airtight fit. Works great. And the bag of hops gives yet another filter for the trub that makes it past the chore boy in the kettle.

Wort Chiller:

We use 30' of 1/2" copper tubing inside of a 5/8" garden hose as a wort chiller. In the winter, we can flow full force through the chiller into the fermenters. In the summer, we have to prechill our cooling water to get a decent flow into the fermenters. On the wort outlet side of the chillers, we have a gated valve to restrict the flow of wort. We back this up or down until we achieve our desired pitching temperature. We shoot for 70 degrees.

Kegs:

We keg in cornelius kegs. We've scrounged them from several sources. We have right at 80 kegs now. About half of them we bought for around \$25. The other half cost us an average of \$15 each. All were rebuilt. We spent about \$130 rebuilding the kegs. We can do it for less now. We have approximately \$1600 in kegs + the \$130 for rebuilding.

Dispensers:

We dispense in two dual tower keg dispensing units, the kind that holds

one standard 15 1/2 gallon commercial keg. So we have four beers on tap at all times. Again, Bart the scrounge found these used and I assume we got 'em for a song. I'm not sure of the price. But I doubt he paid more than a hundred or so dollars for each one. (To be continued...)

I'm off to Seattle Thursday and then to Portland for the AHA conference. I'll continue these musings when I get back. Hope to see some of you renegades at the conference!

Cheers!

Had the pleasure of drinking a lot of Jever at our regular pub while I lived in Germany. I believe the correct phrase that people are refering to is "Friesisch Herb", which means bitter (or dry, astringent, etc) in the Frisian style. The Frisian islands are a chain that run along the North sea coast from the Netherlands along the German coast, perhaps as far as the Danish border (little shaky on my Geography there). Jever is very close to the coast, just across the water from these islands.

Date: Tue, 20 Jul 1993 12:27:56 -0700 (PDT)  
From: gummitch@techbook.com (Jeff Frane)  
Subject: Noble Aroma Hops

Last December I wrote to Al Haunold, who is the acknowledged expert on hops in the US (he's in charge of Hop Breeding and Genetics for the USDA in Corvallis, Oregon, and developed, among other things, Liberty and Mt Hood hops). I wanted to understand what "noble aroma hop" meant and got a very authoritative answer.

I just received your letter regarding the term "noble aroma" hop and I will try to answer it.

The Germans and the Czechs (remember, Saaz--now called Zatec was a German town in what is now Czechoslovakia--soon to be only the Czech republic)--anyhow they instilled in the older brewing generation (turn of the century and earlier) the idea of a "hochfeines Aroma, Edel-Aroma" if you know German you would know what it means-- it is very hard to translate into English but would be something like "super-fine aroma, Noble Aroma, etc" On and off these terms are found in the literature, but there is always a clear distinction between continental hops (German, Czech, perhaps also Polish) but never are English hops included in this category, nor are the Yugoslavian (Slovenian) hops included in this group.

The EBC (European Brewery Convention) and the IHGC (International Hop Growers Congress) have repeatedly used such terms to differentiate from kettle-aroma hops (also called kettle hops) and the high alpha hops (now often referred to as super-aroma hops). I have simply used the term (admittedly not always consistently) in some of my publications to refer to the similarity of our newer continental (European-type) aroma hops with the older aroma hops which the Germans called Deutscher Edelhopfen--and which they often stated can only be grown in certain areas of the world, where the climate, the soil and the know-how of the grower produce such superb results. A lot of it is humbug, but there are certain traits which these noble aroma hops share: balanced alpha and beta, relatively low alpha and beta (5 to 3, sometimes as low as 2), relatively poor storage stability (typically lose 50% of the original alpha through transformation), low cohumulone content, low myrcene in the oil (below 50% of the oil), high humulene in the oil, ratio of humulene/caryophyllene above 3, preferably above 3.25. Thus we come back to Hallertauer mittelfruher, Tettninger, Saazer, Lubelski (Polish) that is it. (Hersbrucker is not in that illustrious group although they have tried to include it after Hallertauer mittelfruher had to be thrown out because of Verticillium problems -- they also tried to include Perle -- not many brewers agree!) There are now two new German hops, Hallertauer Select and Hallertauer Tradition which are supposedly noble aroma hops. Goldings and Fuggle are not included, although Fuggle and perhaps Goldings (a large diverse group) come close. We think Mt Hood and Liberty come close also.

I always hate to ruin a perfectly good opinion with data, but certainly Dr. Haunold comes as close to the Word of God as we can get, I think.

From: arne thormodsen <arnet@kaibutsu.cup.hp.com>  
Subject: Another data point in the hot break debate

After reading this forum recently, I decided to let my latest all-grain stout hot break *\*before\** adding the hops.

After half an hour of rolling boil there wasn't a sign of a hot break, so I added the hops. Bang! I got a hot break within 5 minutes. I guess this may be showing that hops do promote the coagulation of proteins.

Since I've never done this before maybe I didn't wait long enough. I've always added the hops at the very beginning of boil, and seen the hot break start within 20 minutes or so.

How can I get the hot break to occur *\*without\** adding the hops? I'm on an electric stove, so the boil can't be made *\*really\** turbulent (it's a big burner, but not that big). What other options are there?

From: Bob Devine <devine@postgres.Berkeley.EDU>  
Subject: sharing articles?

Nearly every club has a newsletter. However one of the persistent problems is coming up with a source of articles.

Is there any interest in having a shared collection of articles? For example, if someone writes about experiences with a new yeast, that information is likely to be of interest to several newsletters. Through the wonders of the internet (and other billboards), the sharing would be very easy.

I giving this as an "idea" posting, not a "I have the time" posting. Spencer Thomas informed me of the newsletter archive at Cornell but it is not used for sharing articles.

So, I suggest that when someone writes an article, it be placed in a convenient spot (perhaps at [sierra.stanford.edu](mailto:sierra.stanford.edu)).

**Subject: Belgian yeast strains**

A friend of my brought back two Belgian beers from a trip to Europe. One of the bottles is labeled Maredsous, the other is labeled Lucifer. >From the sediment of each bottle I have plated out a yeast culture. Does anyone know anything about either of these yeast strains. Will either of these yeast strains be suitable for fermentation, or are they just used for bottle conditioning?

Also, does anyone know anything about either of these beers? I cannot read either label, and I do not know what style either of these beers are.

Thanks.

From: sims@pdesds1.scra.org (Jim Sims)  
Subject: uh-oh!

I know my beer has an infection. The question is:

What to do about the beer and the (plastic) fermenter?

I was experimenting with adding fruit to beers by racking ~ a gallon of beer from the primary or secondary to a gallon jug with fruit. One of the jugs had about 2 lbs of cherries, and apparently (verified by experiemntal evidence :-)) not enough airspace. The airlock clogged, the pressure built up, and we had to clean cherry beer off the walls.

Most of the beer and cherries were still in there, so i figured i'd keep going and see what happened. I racked it to an empty plastic fermenter (I know, should keep those things filled at all times with fermenting beer :-)). Went off on vacation, came back, and decided to bottle the stuff last nite.

The strawberry and raspberry versions seemed fine, but the cherry beer had a coupla small 'colonies' of white-ish, grayish, blue-ish thingies floating on the top of the cherries. The wort had an acid taste.

Have I just re-invented the ~pLambic beer infection?

(how can tell if) Is the beer safe to drink?

Will i ever get the 'bugs' out of that plastic ferementer? I left it soaking overnite (so far - still going) in a very strong bleach solution, filled to overflowing.

Subject: Cheap Carboys

Well, I've been to two Corning/Revere factory stores (both in VA), and neither of them had carboys, for \$9 or otherwise.

Someplace I can vouch for is the Williamsburg, VA Pottery. Huge place, and well worth driving several hours to go shop at. They definitely have 5 gal. glass carboys in very good shape, for \$10. I got three. <g> Now, I can start that batch of mead I've always been meaning to try (of course, I never let it interfere with my regular batches of brew...you have to keep your priorities straight, after all; besides, I didn't want to use wine yeast in a container that had beer yeast in it).

Anyway, there you go. For people anywhere near VA. And no, I don't think they ship.

>the 100 or so parts for all the various kegs... perhaps some day...  
>till then, Foxx is the best place I've found.

I've used BCI in Brighton TN (800-284-9410) for my parts and kegging needs. They sell all the seals (very cheap) and lots of re-conditioned equipment. Reconditioned, tested 10# CO2 tanks for \$36 or so. Recond 5 gal soda kegs for \$26.50, etc,etc. They even sell recond. half-barrels, Sankey kegs, etc for \$35 so odd \$\$ or so. Ask for Chuck Young; tell him that JC from Littleton MA sent ya. Shipping costs on the heavy bulky stuff does add up, but, on some items, it is still a good deal (the CO2 tanks especially!).

BTW, I don't think Foxx accepts CC orders, nor does BCI. My first order w/ BCI I had to send 'em a personal check up front, then they sent me my stuff. Ever since "establishing" myself, I've ordered things and they bill me (I get the stuff in 3 business days from TN to MA!)

> Any ideas? Do the stores you found know what a carboy is? Do they  
> have them? Do they ship?

You're not the only one a little confused. I visited an outlet store  
in Martinsburg, WV and initially the lady at the counter said they  
didn't stock them. She asked someone in the back of the store and  
came up with two 5 gallon carboys, btw, they call them water  
bottles. I bought the last 2 carboys in the store. You may just  
have to be a little persistent since it's an item they carry in  
other areas. For \$9 its a great deal. Good luck.

Subject: Very Smooth Ales

I am new to homebrewing (on my 5th batch) and am wondering if anyone out there has any ideas....

I tasted 2 totally AWESOME beers at a brewpub in the Twin Cities called Sherlock's Home, a Scottish Heavy and a Traditional Porter. The beers were dark in color (pub listed the OG's at 1.046 and 1.042) but extremely light, creamy and smooth in texture. Does anyone know what the secret is to this texture?? Could it be some kind of mollasses or maybe a special carbonation trick. I have tasted beers on tap and in the bottle from all over (including Scottish Heavy's right from the source in Edinburgh) and have never had anything like this. I'd like to try and emulate it with my homebrews.

By the way if you're ever in Minneapolis or St.Paul, check out:  
Sherlock's Home - at Shady Oak Drive and Hwy 62 in Minnetonka  
Britt's Pub - on Nicolet Ave downtown Minneapolis  
Johnny's - on Univ. Ave just East of Hwy 280 betw. Minneapolis/St.Paul  
and the Summit Brewery - just across the street from Johnny's

Anybody know of some good brewpubs in Indianapolis or Chicago?

Cheers,  
Mike Westra

Well Al, when I went to the unveiling of Pub Draught Guinness in San Francisco I met the man who designed the plastic pillow. (Sorry but his name escapes me. It could have been Alan Frage. I'm sure it's in the original article (posted here) I wrote after the event.) To quote him, "a dollop of liquid nitrogen is added to the can just prior sealing." I remember trying to visualize this at the time and I'd still be interested in watching the process. Hope that clarifies the source.

Subject: Is Pete's a real Micro? / Pub List Changes

I 've been seeing Pete's Wicked Ale in the stores for some time now and decided to give it a try. Actually I went in for the Wicked Ale and came out with their Golden Lager. It tasted fine with much more body than most American lagers. Now I have a question about this Brewery.

I've heard in the past that some larger breweries were jumping on the micro bandwagon by selling beers that looked the part. I was wondering if someone from St. Paul was familiar with Pete's. I realize that the term "micro" is somewhat undefined (I've heard under 15,000 bbl/year), but I'm wondering what the thoughts are on this.

Next topic: is there an e-mail address to submit additions to the publist?

Thanks,

Date: Wed, 21 Jul 93 10:01:46 MDT  
From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: Heat Output of Stoves

Jack Schmidling says:

> I don't have a clue as to how to determine tthe BTU's of my heat source  
but  
> it is a NG/forced air furnace I designed for melting aluminum for MM  
> castings. It will melt 4 lbs of aluminum in 20 minutes.

Wow, that's a hell of a way to measure the heat output! Actually, you \*  
can\* get  
an estimate of the heat output from this. Although I realize that Jack  
was just  
using rough numbers and that you can only tell how much heat was \*  
absorbed\* by  
the aluminum, not how much was put out by the flame, I am going to forge  
ahead  
and figure out what this means in terms of BTUs/hr.

Say that you start out with 1.82 kg (4 lbs.) of Al at 300 K (80 F).  
First,  
raise it to the melting point of Al, 931 K (1217 F):

$$\text{Heat} = (931 \text{ K} - 300 \text{ K}) * 1.82 \text{ kg} * 215 \text{ cal/kg/K} = 247,164 \text{ cal}$$

Then, melt it:

$$\text{Heat} = 1.82 \text{ kg} * 94500 \text{ cal/kg} = 171,990 \text{ cal}$$

Then, figure out the rate:

$$\begin{aligned} \text{Heat output} &= (247,164 \text{ cal} + 171,990 \text{ cal}) / 20 \text{ min.} = 20,957 \text{ cal/min} \\ &= 4,982 \text{ BTU/hr} \end{aligned}$$

Let's compare this with a stove that will heat 5 gallons of water from  
20 C to 100 C in 20 minutes:

$$\text{Weight} = 5 \text{ gal} * 8\text{lbs/gal} * 1000\text{g}/2.2\text{lb} = 18,181 \text{ g}$$

$$\begin{aligned} \text{Heat output} &= 18,181 \text{ g} * 80 \text{ cal/g} / 20 \text{ min} = 72,727 \text{ cal/min} \\ &= 17,305 \text{ BTU/hr} \end{aligned}$$

These last numbers were for a stove quoted at 35,000 BTU (probably per  
hour), which gives a heat efficiency factor of about 50%. Then again,  
this calculation gets the water right to the boiling point, and any  
additional heat will go into the production of steam, so the efficiency  
could be higher.

Bottom line:

1. You probably lose up to half your heat in a regular brewing setup.
2. Jack's setup is either lower in heat output or heat efficiency than a regular brewing setup. Of course, I realize that these numbers were just quoted quickly by Jack and may not be his true numbers. This is especially true since Jack also states that his setup will "boil 14 gallons of wort furiously". Don't look at me,

I'm just doing the numbers :-)

Reference numbers:

Specific heat of Al at 25 C: 0.215 cal/g/K

Heat of Fusion of Al: 94.5 cal/g

Subject: Yakima & Portland

Yakima worthwhile?

>  
>

> In August I am planning to visit Seattle and make side trips to  
Portland,  
> Oregon and Yakima, Washington. I've been to some brewpubs in Seattle  
and the  
> Tumwater (Olympia) brewery .

>  
> Is the trip to Yakima worth it to visit Grant's? Are there other  
breweries  
> or brewpubs in Yakima? What else is there in Yakima?

>  
Yakima is smack in the middle of the largest hop-growing area in the  
U.S. I haven't been in the brewery for years, but they used to offer  
Grant's beers as cask-conditioned ales. In those days it was the only  
place that this was true, and may still be so.

> What are the best breweries and brewpubs in Portland?

>  
>

Well, there's a subject for debate! Try the Pilsner Room, where John  
Harris brews Full Sail beers and his own incredible pilsner. Try B  
Moloch, which is connected to the downtown Widmer brewery, has a wide  
range of local micros on draught, and excellent food. Try the brewpub  
at BridgePort, where several of their beers are available as  
cask-conditioned ales, and the pizza is excellent. You can walk from  
there to the Portland Brewery, where their beer is quite good (eschew  
the Timberline Ale) -- I generally don't drink it anywhere else.

There is also the McMenamin Empire of brewpubs, which are scattered all  
over the Portland area and throughout the state. Several of them  
feature movies in conjunction with the beer. It is occasionally  
possible to get a potable beer at one of these places, depending on who  
the local brewer is. A lot of people love their beer; I personally  
avoid it whenever possible.

I'm out of touch; there are other brewpubs that have started up which  
I've never visited. One called Star, I believe, and others which I  
haven't even heard of. There is a brewery producing "lagers", the  
Liberty Brewery, but frankly the beers I've tasted were terrifically  
boring.

There are also two connected breweries in Newport and Ashland, bottling  
and kegging their beers as Rogue. These are terrific, IMO, and brewer  
John Maier, once AHA Homebrewer of the Year, is one of the most creative  
and consistent brewers in the Northwest. Teri Fahrendorf makes  
excellent beers down in Eugene, which are, I believe, only available at  
the brewpub. Another former homebrewer is brewing good stuff down in  
Cave Junction. ?? where? etc etc etc

Oregon \*IS\* beer heaven. Sorry, Chris.

From: jdsgeoac@osg.saic.com (Karen Jdsgeoac Hyrum GEOACOUSTIC)  
Subject: CO2 Cylinder filling and gas

I just had my CO2 cylinder refilled for the second time and I think I was ripped off. To 'fill' my cylinder the people connected my small tank to their big tank for about 30 sec and handed it back to me. This was done at a bar. They did not weigh my tank or use any pump to transfer the CO2. I think all I got was about 875 psi of gas, but not a full 10 lb CO2 tank.

The first time I filled the tank, I took it to a fire ext. company. When they filled the tank it took about 5 min and they used a loud machine which sounded like a pump. They also weighed the cylinder before and shut off the pump when the tank was 10 lbs heavier.

Questions: What is the proper way to fill a CO2 tank? Did the bar's method work? Is the gas from a fire company safe to consume?

Thanks

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)  
Subject: hops: Arizona/hermaphrodite/antique

Arizona Hops:

I am taking a stab at growing hops here in Phoenix. I planted rhizomes of Tettnanger, Nugget, Cascade, and Centennial in April in good soil, using an automatic drip system for watering. The plants grew in fits and starts, but all except the Tett are about 8 ft long now, with hop cones on them in various stages of maturity.

If anyone is interested in this experiment, or has tried this and would like to compare notes, let me know.

Hermaphrodite Hops:

I have discovered that one of the Centennials has a few male flowers on it. Is this common? If so, how do commercial growers prevent pollination?

Should I allow the male flowers to pollenate the other cones? I believe that Centennial is a hybrid, and therefore that the offspring may not be true to type. Still, I was wondering how bad they will be. Any ideas?

Antique Hops:

A portion of my parent's farm in Oregon was once used for raising hops. Apparently this was a fairly large scale operation, since there was a rather large outbuilding dedicated to hop drying (oast?). The previous owners probably quit hop farming in the thirties or forties, but some hop plants have persisted in the wild.

Could anyone hazard a guess as to the variety of these hops? I suspect that they are not considered a desirable type any longer, but I would like to brew a batch with them, for sentimental reasons, and I would like to get as much information as possible beforehand.

BTW, their farm is in the Willamette Valley.

Thanks in advance for your help.

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Briess Malt

I'm looking for some input from those of you who have used Briess Malt Extract successfully or unsuccessfully. After 6 months of extract brewing with mostly Northwestern Malt extract, my roommate/brewmate and I went halves on a 60 lb pail of amber Briess in the interest of economy. Between the two of us, we have yet to make a decent batch of brew with it. In my own humble opinion, I was making pretty good beer with the northwestern, and I have not grown lax in sanitation or other brewing technique. My brews seem to have what I can only describe as an excessively estery (diacetyl?) aftertaste on the tongue and palate. As I do not have a trained beer palate (yet!) it is hard for me to accurately describe. On the other hand, my roommate's brews have an astringent (phenolic) quality up front, with the same aftertaste as mine. In between bad Briess brews I have brewed better brews with Northwestern (don't you just LOVE alliteration?) so I am wondering if I should waste more of my time/hops/expense/worry/etc using what may be an inferior (batch of) malt? (No offense to the Briess Maltsters.)

BTW, I took care to store the malt in a cool, dry place, and the batches made with malt taken from the freshly opened container were just as bad as later ones. My homebrew supplier (Brew and Grow) is staffed by helpful competent people who I don't think would have mishandled the Malt (i.e. leaving it in a 150 F warehouse for 5 years and then selling it to a customer.)

Help,

>stuff and leave the trub behind? Thanks,

Time for my periodic posting on filter-siphoning:

-----  
Here is my pot-scrubber-in-a-mesh-bag technique for filtering hops:

Buy a copper wound pot scrubber and a fine mesh hop bag. (Get a Chore Boy. They are made from 100% copper. Also get a rather thick rubber band. It also helps to have a copper pick-up tube if you're going to siphon hot wort into your fermenter. If you're cooling it first, one of those plastic pick-up tubes will do the trick.

Tie the pot scrubber around the bottom of the pick-up tube (the end that's going into the wort). Then tie the fine mesh hop bag around that, in effect putting the pot scrubber in a bag. (Oh, yes, "No see-um netting" from a camping store works well, also.)

Tie a small 1/4" overhand loop in one end of the rubber band. Loop the other big end around and through the handle on your boiling pot. Now slip the pick-up tube through the small end of the rubber band. If you've tied the small loop small enough, the rubber band will grab the pick-up tube at whatever position you want. Suspend the pick-up tube a couple of inches below the top level of the wort. Start your siphon.

Note: By siphoning from the top level of the wort, you'll always be siphoning off the clearest portion of the wort. As the level of the wort recedes, slowly inch the pick-up tube down accordingly, always keeping it an inch or two below the surface. This technique will give you the cleanest possible run-off into the fermenter without clogging the siphon. (There are a couple of gizmos on the market now [one is made by Fermentech]

that clip to the pickup tube, attache to the rim of the brewpot and suspend

the pickup tube off the bottom of the pot.)The mesh bag/pot scrubber combo will effectively filter out all the hop leaves and particles. But the mesh can still clog and I consider it a flourish to the technique and not essential. Should it clog, the easiest thing to do is to just take it off and resume your siphon with the pot scrubber alone. An alternative is to raise the brewpot which increases the flow rate of the siphon.

It's also a good idea to stir the wort, just after the end of the boil, to create a whirlpool action in the kettle. This will cause the precipitate matter to settle out into a cone in the bottom of the vessel. At the end of the siphon you'll find a "moat" of wort around

the cone and be able to siphon off almost all of the cleared wort.

Cheers!

From: Rich Ryan <ryancr@install4.swin.oasis.gtepsc.com>  
Subject: priming/sanitizing

I have read that there are three methods (possibly more) for priming your beer. The first method is to add 3/4 cup of corn sugar per 5 gallon batch. The second method is to add 1 1/4 cups dried malt extract. The third method is by adding a measured amount of gyle. Can someone discuss the pros and cons of each? Does your beer condition better using one over another?

On another note, I have currently been using B-Brite as a sanitizer, primarily because that's what my local homebrew shop recommended. Papazian talks about using chlorine (household bleach) as a sanitizer. I noticed that B-Brite does not contain chlorine, bisulfate or organic compounds. Am I wasting my money on B-Brite or does it do a superior job of sanitizing? Speaking of chlorine, how can you remove chlorine from your tap water without buying an expensive filter kit? I am presently boiling my tap water before using in the brewing process. What minerals are removed when you boil your water? TIA.

From: Kieran O'Connor <koconnor@mailbox.syr.edu>  
Subject: Brewing Techniques

HI--I saw Chris Dalton's article about Brewing Techniques--and had to drop a quick note

Issue 2 of Brewing Techniques arrived yesterday.

Only 42 pages, but packed with info.

Just what the heck is Zymurgy worth anyway?

These are the articles in summer Zymurgy:

- 1) Summer Brewin'
- 2) Boost Hop Bouquet
- 3) Stalking the Wild Meads
- 4) Institute for Brewing Studies (essentially a paid promo)

Total: maybe 15 pages.

Then there is the filler middle--buy a shirt for 20\$ deal (plus shipping)

'  
the standard row of letters stating how good Zymurgy is and how people dont know how they brewed without it, and 900 pages of ads.

There really isnt even a reduced price for AHA members for books like there used to be.

Frankly, I've found Zymurgy to be a bit lame. Most of the stuff in it is fluff-Brewgal Gourmet?

I guess Im a bit pissed in general at the AHA. As some of you know I did some research on brewing in the Spring. What better place to write than to the AHA--right? Wrong. I asked some fairly specific questions for sources and/or ideas--here's what I got:

- 1) A winner's circle card with a recipe.
- 2) An application to join the AHA (of which I was a member)
- 3) A how to brew a batch of beer sheet
- 4) An index of articles (which, I must say, was helpful).
- 5) No letter.

So I wrote to you know who--and actually got a reply. he said I know of no source where I cant point you to!

Then I wrote to the Institute of Brewing Studies, whose prowess is indicated in this months Zymurgy--no shit--i got the EXACT same handouts!

Anyway, I credit the AHA and Zymurgy with increasing homebrew awareness--but I dont even recommend it to brewers. i tell them to get online--its cheaper--especially if they are at a University.

To be honest with you--when mine runs out--I'll use the \$29 to buy a re-new on Brewing Techniques (BT) and use the \$5 to go buy a six.

Please don't send me hate mail--if you disagree lets discuss this intelligently. Thanks. :-)

Subject: Oostend?

Dave Justice <DD24005@UAFSYSB.UARK.EDU> (I assume he's not the Braves' all-star right fielder) asked about suggestions for stops in Belgium, to which Timothy Dalton replied about Oostende:

>Unfortunately, my experience in Belgium is limited to Oostende, as thats  
>where I was to drop off a rental and get on the ferry to Dover,  
>but there is a bar in Oostende, across from the ferry terminal  
>that served generic 'trappist dark and trappist blonde'  
>Very good beers. One of the standouts of European beers,  
>after a week in southern Germany!  
>If you can visit this bar, its a great little place, sorry I don't  
remember  
>the name. (strange how that happens)

Having just been in Oostende, I'd recommend (as Jackson does in his Belgian book) a visit to the Taverne Botteltje. It's at 19 Louisastraat, about 6 blocks NW from the ferry terminal, between the Wapenplein and the beach. After all, why go to a place offering up 'generic' stuff when you know what you're getting.

Taverne Botteltje has six beers on draft: DeTroch Kriek, Hoegarden Wit, Speciale Palm, Grimbergen Dubbel, Jupiler Pils, and Guinness. If you don't like that, you can opt for their well kept and served bottle selection. The thick, bound, beer menu offers pretty much anything you'd want. Trappist dark? Trappist blonde? You won't be offered anything like that here. How's about the full range from Chimay, LaTrappe, Westmalle, Rochefort...? And if you don't have at least one bottle of Cantillon (take your pick), you're crazy! You can also spend the night in the adjacent hotel, or have a meal in their steak house.

Jackson also recommends the t'Ostens Bierhuis, at 48 Kapucijnenstraat. I've not been there (it was a Tuesday, and the joint was closed), but it's probably cool. It's only about a block from the Taverne Botteltje (Kapucijnenstraat is the next street to the east).

From: "Dennis Lewis" <DLEWIS%jcsdh6@jesnic.jsc.nasa.gov>  
Subject: Propane vs. Methane: Costwise

As I sat, tending my mash on my propane-fired Country Cooker, I wondered if it would be cheaper to fire up the cooker on natural gas (methane) as opposed to tanks of propane that are liable to give up the ghost in the middle of your boil.

According to the CRC Handbook:

Heat of Combustion

Methane (CH<sub>4</sub>) = 212.79 kg.cal/gram-molecular-weight

Propane (C<sub>3</sub>H<sub>8</sub>) = 530.57 " " " " "

A gram-molecular-weight is a "mass in grams of a substance numerically equal to it's molecular weight."

Essentially, it is one "mole" of this gas.

gram-molecular-weight of methane = 16.04 g

propane = 44.11 g

1 mole = 22.4 liters at STP (Std Temp and Press 25 deg C and 14.7 psi or 1 atm)

This is really nice because the heat output numbers are for burning the same volume of gas, namely 22.4 L or one mole. So we can see that propane puts out

$$(530.57/212.79) = 2.493$$

times as much heat a methane. That's why people who use methane note that it takes twice as long as propane-fired burners. So for it to be economical, natural gas has to be 2.5 times cheaper than propane (all other crap being equal).

Now on to the pricing. I pay \$8 to fill a 20# tank of propane. I also pay about \$0.65 per 100 cubic feet for natural gas at my house (The 0.65 is average. There's a base charge and use charges vary with the season. My total bill goes from about \$1.00 per 100 cu.ft. in the summer to \$0.50 cu. ft. in the winter.). This is delivered at 4 PSI. Converting cubic feet to liters:

$$100 \text{ ft}^3 * (30.48 \text{ cm})^3 / (1 \text{ ft})^3 = 2831600 \text{ cm}^3 \\ \text{and 1 liter is } 1000 \text{ cm}^3, \text{ so } 100 \text{ cu.ft.} = 2832 \text{ L @ 4 psi.}$$

Correcting for the volume change from 4 psi to STP,

$$V_2 * P_2 \quad 2832 * 19.7$$

$$\text{-----} = V_1 \quad \text{-----} = 3794.8 \text{ L}$$

$$P_1 \quad 14.7$$

So, dollar per liter of natural gas is:

$$\$0.65 / 3794.8 \text{ L} = \$0.00017128 \text{ per liter}$$

Now for propane, 20 lbs \* 0.4545 lbs per kg = 9.091 kg or 9091 g. Since 44.11 grams of propane equals a mole and a mole takes up 22.4 L at STP, we can convert directly from grams to liters:

$$9091 \text{ g} * 22.4 \text{ L} / 44.11 \text{ g} = 4617 \text{ L}$$

So at \$8 for 4617 L, we get \$0.001732 per liter. This means that propane is ten times more expensive than natural gas. But propane gives off 2.5 times more heat than methane during combustion. So for equivalent heat output, propane is 4 times more expensive.

\*\*Note: The prices are for Houston, Texas. Dealer invoice may not

reflect actual dealer cost. Your mileage may vary.

Subject: Re-Filling CO2 - Tank to Tank

I have a couple of 20 Lbs CO2 tanks. I can get them re-filled for \$10 so that's pretty cheap. I also have a 5 LBS tank which is much smaller and convenient to keep in the refrigerator (I haven't had the guts to drill through the fridge yet) to carbonate kegs.  
Question: Is it possible to re-fill a 5 LBS tank from a 20 LBS tank or is this a "don't try this at home kids"?

.

method  
>work? Is the gas from a fire company safe to consume?

If you got it filled from a bar with a standard regulator on it, you were  
had.

The way to do it is like you described by the fire ext. company. They  
put it  
on a scale and force liquid into it, the ones I've seen tend to blow CO2  
around  
all over while this is happening. I would never try to xfer liquid CO2  
from  
one tank to another at any bar I've ever worked at, if they had a really  
big  
tank that could tap liquid (which does not happen when you tap beverages)  
you  
could do it, but not thru a std regulator. I guess you could turn one  
CO2 tank  
upside down and have a direct superhi pressure hose going to the other  
one but  
it would be crazy to try it IMHO. I've been getting CO2 from fire ext.  
places  
for 12 years and I'm still alive, as I recall most CO2 found is produced  
by  
commercial breweries anyway (makes sense but I have no refs. on me)

Subject: RE: kettle breaks

Arne asks about hot breaks:

<From: arne thormodsen <arnet@kaibutsu.cup.hp.com>  
<Subject: Another data point in the hot break debate

<After reading this forum recently, I decided to let my latest all-grain  
<stout hot break \*before\* adding the hops.

<After half an hour of rolling boil there wasn't a sign of a hot break,  
<so I added the hops. Bang! I got a hot break within 5 minutes. I  
<guess this may be showing that hops do promote the coagulation of  
<proteins.

<How can I get the hot break to occur \*without\* adding the hops? I'm  
<on an electric stove, so the boil can't be made \*really\* turbulent  
<(it's a big burner, but not that big). What other options are there?

One of the factors influencing the coagulation of proteins is the amount  
of calcium ions that survive into the kettle. Depending on your brewing  
water and whether or not you use gypsum in the mash, you may have a  
calcium deficiency in the kettle. Some brewers add a small amount of  
gypsum directly to the kettle to ensure adequate calcium levels. Be  
careful  
not to overdue this, as a "chalky" astringency may result. I would  
suggest  
a 1/2 tsp for an experiment (into a 5 gallon batch).

From: Brew Free Or Die 22-Jul-1993 1206 <hall@buffa.enet.dec.com>  
Subject: My kind of town, Sam Adams is

This morning I received a poster advertising The Great New England  
Brewers'  
Festival, which is to take place in Northampton, Massachusetts on  
Saturday,  
July 24th. I was perusing the poster and came across something that made  
me  
chuckle. Here is exactly what is printed on a portion of the poster:

-----  
-----  
25 participating microbrewerys and brew pubs bringing  
as many as 3 types of beer a piece. A sample of participants:

Northampton Brewery, Ma.  
Portsmouth Brewery, N.H.  
Catamount Brewing Co., Vt.  
John Harvard Brewery, Ma.  
Cambridge Brewery, Ma.  
Boston Beer Co.--Sam Adams, Ma.  
Commonwealth Brewery, Ma.  
Hartford Brewing Co., Ct.  
Frank Jones Brewing Co., N.H.  
Sunday River Brewing Co., Me.  
Mountain Brewers, Vt.  
Vermont Brewing Co., Vt.

-----  
-----  
Look at the entry for the Boston Beer Company. "Sam Adams, Ma." Ba ha  
ha!

I know what was intended but, still, it's funny. I envisioned poor old  
Jim Koch, chagrined that a nasty old judge wouldn't let him have  
exclusive  
use of the word "Boston". "Why, I'll show that old fart," I imagined  
little  
Jimmy saying. "I'll show them all! I'll start my own town, and  
trademark  
\*that\* name!"

If you happen to be passing through Sam Adams, Mass., and see Jim sitting  
on  
his porch, whittling and whistling "I Did It My Way", honk the horn,  
wave,  
and give him a wink.

Subject: chlorine

At the risk of starting up the whole "my sanitation method is better than your sanitation method" discussion, I have a simple question on the use of chlorine. Should you use chlorine with hot or cold water? I have read somewhere that chlorine has a low boiling point and hot water will boil it off before it can sanitize. Is this true? Is this a momily?

From: Edward Croft <CROFTE@delphi.com>  
Subject: Fruit Chart, Cointreau extract

Well I didn't get any responses to my previous post. I was looking for a table that would tell you how much fruit you should add to the wort for the various types of fruit beers. I was going to use Alan Wrights ale recipe as a base to try my hand at fruit beers. The problem is where do you start, how much, when to add, how to prepare. I was looking to see if there was a chart that would look something like the following:

| Fruit   | Amt | Conditioning  | Wort | Primary | Secondary | Bottle |
|---------|-----|---------------|------|---------|-----------|--------|
| Apples  | 10# | Peeled, 1/4rd | x,   | last    | 5m        |        |
| Oranges | 5#  | Blanchedx     |      |         |           |        |
| Prunes  | 2ea | Rehydrated    | x    |         |           |        |

.....  
Since it appears that such a chart does not exist, maybe I should try to take the initiative. If I could get private E-mail with suggestions on fruits that people have tried, quantities used per 5 gal batch, Conditioning, and when to add the fruit to the wort, I'll try to compile the chart. Once I have everything together and charted, I can repost the completed chart. TIA, for the help.

\*\*\*

Spices, etc has a new line of extracts used in cooking. One of these is a Cointreau extract. I was wondering if it is possible to use these extracts in processing beer? With these extracts, you could possibly create whole new flavours. Possibly even Rum Beer, all the flavour of real rum without the heavy alcohol. Or how about, Beer Noisette, ah the distinctive hazelnut flavour emanating from the bottle. Okay, okay, so I'm going off the deep end. It was just a thought.  
Later, Ed.

I've been to the Rathskellar room at the Landmark Brewery - maker of  
the dreadful Pig's Eye Pilsener. I was surprised to see they had  
Pete's Wicked Ale on tap, so I inquired about it. They make it on  
contract for Pete. It used to be contract brewed at Schell's in New Ulm,  
MN,  
but exceeded their capacity. What I don't know is how many other  
places contract brew Pete's Wicked Ale around the country. Of course,  
once I discovered the PWA, I didn't drink anything else they had to  
offer.

Subject: Draught Guinness in Can

Here is a repost of an article on Guinness in a can.  
Maybe someone can place this text in the archives.

Rick

The article is titled:

"The extra ingredient in a can of draught Guinness"  
NEW SCIENTIST, 22 July 1989 p. 34

Written by Andy Coghlan

"Guinness, the maker of the black, creamy beer for which Ireland is famous, has managed the impossible. The company has succeeded in canning a form of Guinness that, until recently, was available only on draught in public houses and restaurants.

The world's seven million Guinness lovers have a choice between two products: draught Guinness, a thick, smooth stout with a creamy-white head and Guinness Extra, which is available in bottles and cans. Guinness Extra has a coarser texture than draught Guinness and a head that is less smooth and creamy.

According to Alan Frage, the product development director at Guinness, the majority of people who drink draught Guinness do not drink Guinness Extra. "We knew that draught Guinness in cans would give them the opportunity to enjoy their favourite brand at home as well as in the pub," he said.

Forage and his colleagues began working to solve this problem in 1984. After four years of development work costing 5 million pounds, Forage and his team had perfected a tiny diaphragm, made of plastic, that cracked the problem.

They tested more than 100 different techniques before settling on the so-called "in-can-system". People who buy draught Guinness in cans, which have been available throughout Britain since March, will find this system if they slice open the empty can. The device, which sits on the base of the tin, helps to mimic the tap in the pub.

Draught Guinness owes its creamy texture to a surge of bubbles in the beer as it passes through a series of tiny holes in the special dispensing tap. The tap has a system of tiny holes which creates pressure differentials.

These differentials force the gases out of solution and produce a "surge". Unfortunately, the gasses will remain in solution if people simply pour Guinness from the barrel into a glass.

The new system essentially mimics this process from the inside of a can. The device is a plastic chamber with a minute hole at the top, which sits on the base of the cans.

For the system to work, the pressure in the can must exceed atmospheric pressure. The canners fill the can with beer that is cold

enough, at between 0 C and 1 C, to retain gas that would bubble out of solution at higher temperatures.

The canners put 440 milliliters of Guinness in a can that can hold 500 milliliters, in order to leave enough room for the creamy head to form.

They also "dose" the beer with extra nitrogen, which raises the pressure when the can is opened.

Once the lid is on, the pressures in the can and inside the chamber reach an equilibrium that forces beer and gas into the device. When someone

opens the can of beer by pulling the ring-pull, it initiates the same process that happens in a tap for Draught Guinness.

As the ring-pull comes off, the resulting drop in pressure forces beer and gas out of the chamber through the tiny hole, creating small, stable bubbles.

As the bubbles rise up through the liquid, they act as centres where other bubbles form. This is what causes the characteristic surge. The

number of bubbles created and the small diameter of the bubble dictates the

density of the head of the drink and its creaminess. The smaller the bubbles, the creamier the texture, says Forage,

The only remaining problems for the designers related to the canning process. They had to invent a filling device that expels oxygen from the can, because the gas impairs the flavor of the beer.

Now, Guinness has patented the system and owns the registered designs of all the engineering equipment that is unique to the packaging line.

The secret for drinkers, says Forage, is to make sure that the can is cooled in the refrigerator for two hours before serving. Otherwise, the

beer bubbles out uncontrollably as too much gas has come out of solution to

create excessive pressure. He says that the product is selling much better

than expected"

> castings. It will melt 4 lbs of aluminum in 20 minutes.

<I am going to forge ahead and figure out what this means in terms of BTUs/hr.

I knew I could count on someone taking the bait.

>Say that you start out with 1.82 kg (4 lbs.) of Al at 300 K (80 F).  
First,  
raise it to the melting point of Al, 931 K (1217 F):

Correction here.... aluminum doesn't pour worth a damn at the melting point.

I pour at between 1600 and 1700 F.

> Heat output = (247,164 cal + 171,990 cal) / 20 min. = 20,957 cal/min  
> = 4,982 BTU/hr

Needs correction for pouring temp...

>Let's compare this with a stove that will heat 5 gallons of water from 20 C to 100 C in 20 minutes:

Some stove! My kitchen stove takes over an hour and I suspect electric ranges are even worse.

> 1. You probably lose up to half your heat in a regular brewing setup.

Considering the bricks all around and the crucible are red hot, I would suspect the efficiency is far worse than that.

> 2. Jack's setup is either lower in heat output or heat efficiency than a regular brewing setup. Of course, I realize that these numbers were just quoted quickly by Jack and may not be his true numbers. This is especially true since Jack also states that his setup will "boil 14 gallons of wort furiously". Don't look at me, I'm just doing the numbers :-)

You can only use the number you have but here is another one that should help a bit.

The furnace uses about 75 cuft of gas per hour, which comes out to about 25,000 BTU's in 20 minutes with the gas we get here.

That compares to 14 cuft for my stove burner and 36 cuft for the water

heater.

Hmmm.... seems like I already knew the number but didn't know I knew it.

>From: jdsgeoac@osg.saic.com (Karen Jdsgeoac Hyrum GEOACOUSTIC)  
>Subject: CO2 Cylinder filling and gas

>I just had my CO2 cylinder refilled for the second time and I think I was ripped off. To 'fill' my cylinder the people connected my small tank to their big tank for about 30 sec and handed it back to me. This was done at a bar. They did not weigh my my tank or use any pump to transfer the CO2. I think all I got was about 875 psi of gas, but not a full 10 lb CO2 tank.

Why think, just weigh it. A full 10 lb tank should contain 10 lbs of liquid CO2 and the empty weight of the tank is stamped on the outside somewhere.

From: Ed Hitchcock <ECH@ac.dal.ca>  
Subject: Brewcap / Spelt

Since Mr. Baughman mentioned his Brewcap, I thought I'd ask a question or three about it. First, there are two holes, one larger than the other.

The larger hole fits a siphon hose, airlock, or whatever. What, exactly, fits

in the smaller opening, or does the smaller opening fit into a siphon hose?

What sort of clamp do you use to hold it on, just a plastic strap? A pipe

clamp? And thirdly, is the material of the Brewcap completely inert in beer? I appologize if these questions sound ignorant, but the local brewshops sell the Brewcaps under the assumption that they are simply for racking upright carboys (ie stick racking tube in short wider hole, blow into

tall thinner hole to start the siphon).

On another note, I was in a bulk store yesterday and noticed what looked like flaked wheat, but the bag was labelled "Spelt, no wheat". The TerriblyUnhelpfulShopkeeper Explained to me that it was "Spelt, it's not wheat". Thanks. When pressed further, she said it was a grain "as old as

time...Biblical times...". Thanks again. I looked it up later, and it IS

in fact a wheat, Triticum spelta, used mainly for livestock feed. Of course, at the bulk store the labell extolled the virtues of the proteins in Spelt ad nauseum. Anyway, has anyone used spelt (flaked or otherwise) in brewing? If not, would anyone like to know the results of a side-by-side Wit brew-off between regular flaked wheat and spelt?

From: gummitch@techbook.com (Jeff Frane)  
Subject: Dry-Hopping, etc. etc. etc.

The Tumbleweed Report: The thing I love about this, Kinney, is that you are actively disproving the central theme of the brewpub explosion -- "you have to spend a lot of money on fancy stainless steel equipment, brew boring beer, or forget it." To avoid libel suits, we will call this the "California Brewpub Theorem", which \*requires\* startup costs of about \$500,000 to \$750,000. (The Hart Brewery, which makes Pyramid ales, was capitalized in about 1984 for \$20,000; there is very little that has changed since then for someone willing to put in some work.) Bravo, Kinney.

> Only 42 pages, but packed with info.

>  
Don't forget, that's 42 pages with almost no advertising. So, it's 42 pages of real information; compare with the most recent issue of Zymurgy, which is a real embarrassment: what little editorial matter there is is almost indistinguishable from the vast amounts of advertising (including the AHA's own catalog stuffed in there), and most of what passes for editorial is composed of (a) self-promotion and (b) lists, lists and more lists.

>  
Both of these are or have been available in Portland, and are reasonably good beers. The Maredsous is unremarkable, and I don't remember much about it; the Lucifer is a sort of Duvel knock-off, inferior to the original but still pretty good. Hey, the trick with those yeast strains is to culture them out, then add them to a small amount of 1.030, unhopped wort. You will be able to tell \*a lot\* about the flavor profile by tasting the resulting beer, and you can answer your own question about whether it seems suitable for brewing.

>  
Whoa, Thomas, get your terminal at 80 characters!

> > > Any suggestions would be appreciated.  
> > >  
> > >

No't te preocupes. Don't worry. The amount of time you dry-hop is dependent on how much hop character you want to draw off. Seven days really isn't enough, and two weeks is, IMO, a minimum to actually express some hop character. My own experience, going back six or seven years of dry-hopping, is that six weeks is optimal for a really

distinctive dry-hopped beer, but that's only a recommendation for kegged beers. (It also happens to gibe with the recommendation of the brewers at Sierra Nevada for their Celebration Ale.) Leave the hops in until you bottle.

You need to uncompress them on a Unix system with the "uncompress"  
command. As a fellow-Unix illiterate and DOS user, I sympathize, but  
how are you getting ftp service on a non-UNIX system? Me, I have a  
shell account at a local access site and dial them up from my DOS  
computer; the UNIX programs run there and if I want to I can transfer  
from that computer to mine. You can probably get a similar arrangement  
somewhere near you.

Subject: Degrees of Extract

Don Doyle writes:

> As a real example, I brewed 11gals with 26.5 lbs of grains and got  
> a 1.065. What extraction am I getting and is it good?

Well, plugging the numbers into the equation,  
 $DE = 1.065 * 11 / 26.5 = .44$   
or 44 degrees of extract. From this, I would guess that you  
added some malt syrup or adjunct.

Most malts are "theoretically" capable of producing about 35  
degrees of extract. I usually get around 32 degrees, which is  
pretty good. The degree of extract tells you how effecient your  
mash was. If you are getting less than 30 degrees, there is room  
for improvement in your technique.

>I have reread the bottle of B.E.S.T and it says that the stuff does not  
>need to

>be rinsed, but should air dry. Is the stuff impossible to rinse off??  
What is

>the networks accepted method for using this stuff?

The reason that often iodophor packages often advertise that iodophor  
does

not need to be rinsed is because some brewer's water has bacterial  
problems

and rinsing with the water can re-introduce bacteria. I've never had  
problems

with using hot, Chicago tapwater for rinsing, even in the summer (when  
everything is more microbiologically active -- that's why the water  
supply

often has increased levels of chlorine added in the summertime).

I'm quite confident that your problem was not from the iodophor, rather  
that

the medicinal flavor/aroma came from one of the following sources (in  
order

of probability):

1. yeast -- I've noticed that some dry yeasts, if not stored in a fridge,  
after

while, will produce increased levels of phenolics. Perhaps this is  
because

there was some more hearty wild yeast in the dry yeast or maybe it's a  
result

of poor storage. Other dry yeasts, even when stored properly produce  
phenolics.

2. airbourne wild yeast infection -- it seems as if your sanitation  
technique

is good -- could some wild yeast have gotten in via the air? Could your  
problem correlate with the warmer weather, when the air is more active  
microbiologically?

3. wild yeast infection from the water -- maybe you do have a problem with your rinse water... the solution would be to boil the rinse water or to air dry the iodophor-sanitized equipment.

\*\*\*\*\*

Don says he got 11 gallons of 1.065 wort from 26.5 lbs of grain and wants to know what his extraction rate is and is it good.

Well, the maximum extraction varies depending on the type of grain, but you got 65 "points" and this translates to:

$$65 * 11 / 26.5 = 26.98$$

or basically 27 points-per-pound-per-gallon, which is quite good for most types of base grain. Some get as much as 30 or even 31 points (Miller does this partly because he re-circulates the runoff an awful lot and this not only gives him great numbers, but also it has been reported that Dave's beer is on the astringent side).

\*\*\*\*\*

Jeff writes:

>A friend of my brought back two Belgian beers from a trip to Europe.  
>One of the bottles is labeled Maredsous, the other is labeled Lucifer.  
>From the sediment of each bottle I have plated out a yeast culture. Does  
>anyone know anything about either of these yeast strains. Will either  
>of these yeast strains be suitable for fermentation, or are they just  
>used for bottle conditioning?

I don't know whether Lucifer is bottled with the fermentation yeast, but my guess on the Maredsous is that it is a bottling yeast. My reason for this assertion is that Maredsous is made by the same brewery as Duvel (note the bottle shape is distinctive and the same as Duvel) and I've read (here in the HBD) that Duvel is packaged with a bottling yeast and not the fermentation yeast. Oh, yes, I recall the brewery -- it's the Moortgat Brewery in Breendonk, if memory serves correctly.

>Also, does anyone know anything about either of these beers? I cannot read  
>either label, and I do not know what style either of these beers are.

Maredsous is an Abbey ale, and it comes in four types which, I believe, are associated with the Belgian degrees of the OG. If memory serves, they are 4, 6, 8 and 10. I've had only two and the numbers were NOT on the label (stupid US laws!). One had a Gold and Black label and the other had a Gold and Green label. I'd be interested in the colors of your label and the number on the bottle, if you could send me email or post it. 4 Belgian degrees is 1040, 6 is 1060, etc.

I have not tried Lucifer, but have read about it in Jackson's pocket guide, big book (I forget the name too) and the Great Beers of Belgium book. Basically, it is a beer of the type that was originated in the beer Duvel. Duvel means devil and therefore virtually all the breweries that imitated this beer have chosen names that are associated with the devil: Lucifer, Satan, etc.

\*\*\*\*\*

JC writes:

>BTW, I don't think Foxx accepts CC orders, nor does BCI. My first order  
Hmmm, from Satan to JC... anyway, Foxx does now accept CC orders. This

is a pretty recent change.

remove  
>the hops on Friday but I wouldn't be bottling for a least a week after  
that.  
>Any suggestions would be appreciated.

Leave the hops till you can bottle. The reason I posted that "you should  
not  
dryhop longer than 7 to 10 days" is that, empirically, I've found, that  
more  
than 10 days gives less hop bouquet than 10 days. This is for 65F or so.  
At cooler temperatures (although I haven't done this -- this is based  
upon  
what I've read about commercial breweries procedures), like 50F or so,  
two  
weeks seems to be the consensus.

**Subject: Keg Parts**

I have purchased a pair of old but clean Firestone 3-gallon kegs similar to Cornelius. In the process of replacing the gasket for the lid, which is screw-down, and circular, not spring-clamp and semi-oval, I discovered the regularly mentioned suppliers do not carry the part.

The Firestone keg was manufactured by a company now called Spartansberg Steel Company in Spartansberg, South Carolina. They do not have parts, and say the keg is very old.

Help... does anyone know a source for the gaskets, or a functional substitute? The other fittings are standard pin-lock, and the kegs are too fresh to dispose of, even if they are old...

Thanks

Bob Stovall

From: Gene Zimmerman <ezimmerm@hp.uwsuper.edu>  
Subject: Beer Hunter NOT on Discovery Ch.

Salutations!

I was curious about Jackson's series Beerhunter, so I called my cable company and asked for the Discovery Channel's phone number and was given: 1-301-986-0444 x5298, this was to put me in touch with the people who would tell me when this delightfully sounding show would next appear on this channel. I was asked by a recorded voice to leave a message and my phone number and was told I was to be called back. I was. The next day I found on my machine a message from the Discovery Channel saying, "The Beerhunter will not be running anytime in the future on The Discovery Channel."

They did not give any justification for this decision. I was, however, given the name and number of the distributor, "Channel 4 TV" of London. This number is 011-44-71-631-4444. They will reportedly sell the video.

All in all, I was disapointed.

Date: Fri, 23 Jul 93 08:54 CDT  
From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Crushoff in Portland

There have been rumors that a certain grainmill producer plans on conducting a mill evaluation of sorts in Portland. My first reaction was to grab a new

MALTMILL and head for Portland to defend the fort. This was based on information he is promulgating that portrays the MM as no better than the

Corona. Turns out, all his hype is based on unscientific tests that seem to

prove nothing. As it is unlikely that the proper equipment will be available

in Portland, I decided it was not worth the expense and hassle just to prove

what most of us already know.

To avoid the feeling of fiddling while Rome is burning, I dropped some samples of milled product off at Siebel Institute for an unbiased evaluation

of the grist of the MALTMILL and the other mill.

The results confirmed what George Fix reported a year ago and experience on

over a thousand units has demonstrated. The adjustable MM provides a grist

that is comparable to a multistage commercial mill. The fixed MM provides a

very satisfactory grist but is a bit coarser and somewhat grain dependant.

The other mill, when properly adjusted provides a sieve analysis similar to a

fixed MM on paper but visual analysis shows more husk damage.

Unfortunately,

the sieve analysis can not tell the difference between small husk particles

and similar sized malt particles that pass through a sieve. It was designed

to test roller mills and not grinders or hybrids such as the other mill.

For those going to Portland, there will be a MM on display in the TKO Software booth and Tom Nelson will have flyers and data sheets to hand out.

Feel free to fondle it. I am confident you will conclude that there is far

more than the nuances of grist variation involved in selecting a grain mill.

From: John Mare <cjohnm@ccit.arizona.edu>  
Subject: RE: Priming, sugar vs. malt extract vs. gyle

Rich asks for comments about the virtues of corn sugar, dry malt extract and gyle as priming agents. When I first started brewing I used corn sugar which worked OK, but then having decided to brew "all malt" only I switched to gyle which was also good, but less convenient to use. I now use only dried malt extract for priming. For English or Scottish style ales I use 1.25 cups light dry extract dissolved in 2 pints water, boiled for 10 minutes, cooled, & poured into my sanitized "bottling bin" (a plastic fermentor with spigot). I then siphon the beer from my glass carboy (which allows good mixing without much oxygenation), allow it to stand for about 15 minutes while arranging bottles, and then bottle. For American style ales, California Common beer, or lagers I use 1.33 cups of malt extract which results in slightly higher carbonation. No more gushers as I had with corn sugar. John of John's Alehouse.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: CO2, Old book, Portland

Several posts have appeared recently about filling CO2 cylinders:

To the poster that got it filled at the bar, yes you got ripped off. Go to a welding supply, fire ext. supply or look in the YP under Carbon Dioxide. It does pay to shop around as prices vary.

When I bought my second CO2 tank, I asked if it was possible to fill an empty tank from a full one. Technically, it will work, but it was explained to me as being very dangerous! This was because the tank being filled will heat up and explode if it is done too fast and without the proper equipment. In fact, most of the welding gas suppliers in my area don't actually fill tanks anymore, but exchange them. The filling is done in a central facility. Bottom line: Don't mess with it. It can be fatal to you and your neighbors!

On another topic, I was at the UC Davis library's "brewing room" recently and I came across a very old book by E. R. Southby called "Practical Brewing". It had a lot of interesting information on hops and hopping rates (the only stuff I copied, naturally) but the book had no date on it. The library's computer (actually the Melvyl system) also had no date for the book or the author. The book was published in England, I would guess around 1890, but I like to know for sure. Does anybody have any clues? Southby had died a few years previous to this edition (the third). If anyone has any info on Southby or the book, I would appreciate it. There were many other old books there and I copied the hops data out of three. I'll summarize and post soon. You'll find it very interesting.

Related to my trip to Davis, I also got some better info on the "hop storage curve". There were two good articles and as soon as I've had a chance to digest them, I'll post an update to my storage post.

Lastly, I'll be in Portland for the Oregon Brewer's Festival (but not the AHA event) at the Hopunion booth if anyone wants to drop by and chat or say howdy. How many of us will be there on the weekend? Should we do a pub crawl on Friday night maybe?

Date: Fri, 23 Jul 93 13:58:22 PDT  
From: bill@oilsystems.com (Bill Vaughan)  
Subject: Blowoff, Iodophor, Sterilizing bottles

Here are a few data points to add to the debates:

Blowoff -- fortuitously, my last batch of "plain jane" got split into its carboys unevenly. Consequently, one blew off and one didn't. Of course, the best test would have been if I had kegged both carboys or bottled both, but in fact I kegged the one that did blow off and bottled the other. Anyhow, at kegging/bottling time, I could definitely taste the difference between the with-blowoff and without-blowoff carboys. The without-blowoff carboy had a tad more bitterness and was slightly "harsher."

I have never done this kind of direct comparison before and frankly did not expect to taste any difference at all. Surprise. The only problem is that I just bought 2 more acid carboys (7-gal) and I can't ever fill them enough to get a blowoff. Maybe I shall use water carboys for my delicately-flavored brews and acid carboys for the chewy dark ales. I dunno.

Iodophor -- I have been using iodophor (BTF, I think) to sterilize my kegs. I use the recommended amount for the recommended time and air-dry. Then I give the keg the sniff test. If I smell ANY iodine, I rinse the keg with boiling water. So far I have ALWAYS smelled iodine. I am not about to buy another bottle of iodophor. To me, the slightest iodine flavor would spoil the batch and I hate to throw out 5 gal. I suspect that boiling water alone may work -- or else I shall go back to weak clorox followed by boiling water rinse. Let's face it -- kegs aren't that expensive. If I get pinholes in the s/s after, say, 5 years, the keg has cost me maybe 5 bucks a year. (Of course, if it's only ONE year, I'd feel different.)

Sterilizing bottles -- I have always sterilized my bottles in the dishwasher. I clean the bottles thoroughly with TSP, in the sink, scrub them and rinse them carefully. Then they go in the dishwasher for a full wash cycle with NO detergent, and a HEAT DRY (not air dry) cycle. Naturally I prepare the dishwasher first by cleaning all the guck out of it and running it once while empty. Bottom line -- Mary and I have never had a bad batch that could be attributed to unsterile bottles. (I.e. either the whole batch was uniformly bad or uniformly good. We did have an episode where our yeast starters got infected once.)

I have mild asthma and Mary has it bad. We have to be careful about sulfites. All you homebrewers, please remember that Campden tablets and bisulfite sterilants can make your homebrew toxic to those with respiratory problems.

BTW, whenever I have a chance I sterilize with boiling water in lieu of chlorine. This only works for small stuff like airlocks but is quite effective and there is no danger of chlorophenol or iodine contamination. I think it is just common sense to eschew toxic substances wherever possible.

American hops were not highly thought of in brewing circles until quite recently, and for good reason. I would be willing to bet that the stuff growing on your parents' farm are Clusters in some form or other. It's amazing to me that some people are still brewing with these hops, which used to be considered high alpha -- they have no other redeeming quality as far as I can tell. The British referred to American hops as being "catty", which meant nothing to me until I smelled some Clusters: they smelled just like a catbox.

I have some terrific old photographs, courtesy of the Oregon Historical Society, of old hop farming, some dating back to the turn of the century, and some from the period in which your old hop farmer quit. During the 20s-40s (judging from the clothing), at least some of the Oregon hop growers were training their hops along low-lying strings,

From: waltman@BIX.com

Subject: What is a microbrewery?

Maybe we should come up with terminology describing individual beers by the size of the batch. (My understanding that the legal definitions of microbreweries [for tax purposes] are based on the aggregate annual production of the entire brewery.) I think this would help differentiate those beers that are brewed in megabrewery size batches a few times a year as opposed to those that are brewed more often in smaller batches. This is not to imply that smaller is better, but I think it could make for more rational comparisons. Just my \$.02 worth.

From: Kieran O'Connor <koconnor@mailbox.syr.edu>  
Subject: Brewing Techniques Info

Hi--a fair number of you sent me mail regarding Brewing Techniques.  
here's  
the info:

Brewing Techniques  
PO BOX 3222  
Eugene, Oregon 97403

(503) 687-8534.

They take credit cards for orders--so it looks like you could just call.  
Its 24\$/yr for six issues.

You should be able to find it in your local supplier--and the one around  
here discounted the first issue since the second issue is now out.

The first issue had 42 pages of text--a fair amount of which was  
articles:

- 1) Factors Affecting Hop Quality, ...and Brewers Preference.
- 2) Belgian Malts--some practical observations
- 3) Reinheitsgebot and the fifth ingredient
- 4) The Troubleshooter--an advice column--w/o the Hbd
- 5) Brewing in styles--a changing discussion on styles and how to brew them
- 6) Thinking about recipe formulation
- 7) Spreadsheet recipe design
- 8) And a bunch of assorted smaller depts--a book review, and a few others.

Overall I think the first effort was quite good. In fact a few of the  
articles mentioned above were written by HBD'ers with extensive  
knowledge.

BT looks quite promising and I think I got more info from this one issue  
than I got from that other thing in a year.

From: SMUCKER@UTKVX.UTCC.UTK.EDU  
Subject: RIP OFF

Hyrum Laney

>Questions: What is the proper way to fill a CO2 tank? Did the  
>bar's method work? Is the gas from a fire company safe to  
>consume?

Well it sure sounds to be like you got ripped off! What you most likely got was your tank filled with 800 psi CO2. There are two types of large tanks (50 pound tanks typical) those which bars and welders would normally use where they want gas and those with a liquid tube than runs to the bottom like our kegs so that liquid is forced out. The latter type is used mostly for high pressure fire protection systems. In industry these are often called high pressure CARDOX tanks. You could easily fill a smaller cylinder from these liquid tube type cylinders. It is possible to fill small cylinders from a normal gas type cylinder but you have to turn them up side down. Not an easy thing to do safely with a cylinder that weights in at about 160 pounds.

There is another type of CO2 storage tank and that is the low pressure CARDOX tank. These very large systems use a insulated tank with a refrigeration system which allows the CO2 to be stored as a liquid under lower pressure. These tanks typical run between 10,000 and 30,000 pounds of storage. (That would handle a lot of homebrew.) These large systems are used for major fire control systems on things like rolling mills used to roll all of the aluminum for beer cans. Also tank trucks which transport large amounts of CO2 use this low pressure refrigeration systems.

Back to Hyrum Laney questions the fill you got from the Fire company may very well have come from on of these low pressure, refrigerated storage systems. This would required a pump to fill your tank, or to fill fire extinguers.

Safety of the gas? Well, within reason I consider industrial CO2 gas from a welding supply company or the Fire company safe. (The fire company most likely got their supply from one of the large industrial gas supply companies.) Purity levels of industrial gases are very high and I have only had a problem once and that was argon which had some cotamination of H2O (water), that came from the cylinder, remaining from a hydrostatic test. Screw up the TIG welding very badly, doesn't take much H2O to do that. Bottom line of all this I have my 50 pound cylinder filled at my welding gas supplier--- 50 pounds lasts more that a year, costs \$ 19.00 to fill, but the 160 pounds filled cylinder will not fit in the refrigerator.

From: SMUCKER@UTKVX.UTCC.UTK.EDU  
Subject: Zymurgy Hate Mail

Kieran O'Connor" is worried about getting hate mail because he is critical of Zymurgy. Hate Mail" ? well I guess I hate Zymurgy too. Zymurgy could be so much more than it is. I think the real question is that as homebrewing has been growing up into a wider appeal hobby, "has Zymurgy been growing up too?" I don't think so and that why this forum and new magazines like Brewing Tech. have so much appeal.

It is time for the staff of Zymurgy to listen to some constructive criticizing and to start making some improvements. After all for many in this forum who are members of AHA, Zymurgy as the publication of a non profit organization is our magazine.

Homebrewing has become, some will say always was, a serious hobby. While I enjoy jokes about the hobby and brewing in general the Zymurgy "Don't worry" kick gets real old, real fast. Most of us want good beer and we do care about what we invest a lot of time and spend hard earned cash on. The "don't worry" it may not taste like what you want but it will be drinkable just doesn't match up with the serious brewer today. My recommendation --- drop it.

I think the ads are useful but once a year would be enough for all of the AHA ad pages. Same goes for the filler page listings. Not ever club, ever donor needs to be listed each issue. Put those pages in articles about brewing. While on the subject of articles, include more information and more data, and above all tell readers where one can get follow up information. A full page wasted on someone falling into a pile of hops rather than more information on dry hopping is just that, a wasted page.

And last, but not least, the Zymurgy staff should, if they haven't all ready done so, go out and look at the magazines of some other hobbies. They will find that the publications try to include as much information and help as possible in the pages they print, not just print the same filler again issue after issue. By the way, why isn't Zymurgy a monthly magazine? From the amount being published in this forum it would not seem that it is a lack of authors or information. Is the Zymurgy staff too busy living off a non profit organization?

By the way if you disagree send the hate mail to Kieran O'Connor. I intend to stay a member of AHA but would like to see Zymurgy improve in the '90ies.

Beer? Just push a button

By Greg Joyce  
THE CANADIAN PRESS

VANCOUVER - It's a drinker's dream - a machine that turns water into beer at the push of a button. Canadians will soon be able to have beer on tap at home, thanks to the FH2000 Beer Machine - a device about the size of a coffee maker, says Tim Crosby, president of Vancouver-based marketing company Fountain House Holdings Corp.

Crosby says the cost of a pint from the machine will be about \$1.50.

The Beer Machine was introduced last month at a news conference in England, drawing rave reviews in several British newspapers.

Operating instructions are simple, Crosby said Friday.

Perhaps too simple for the ale aficionado.

The machine is attached to the home's water supply - most likely near the kitchen sink or wet bar.

On one side of the machine is attached the beer syrup. On the other side is a refillable carbon dioxide cylinder.

The lager lover simply pushes a button and waits a few seconds. The carbonated water fills a mixing chamber at the top of the machine along with a shot of syrup.

The mixing process takes about 10 seconds and the golden nectar flows into the waiting glass.

The alcohol content is now 3.5 per cent but Crosby said that could be increased later to the more standard 5 per cent.

After the machine's debut in England, the London-based Star newspaper headlined the story "Tip-Tap Tipple" and quoted citizens as approving of the beer's taste.

Another newspaper quoted British trade leaders as saying the machine posed a threat to an already struggling pub industry.

Crosby said his company planned to try to make the machine available to Canadian consumers by January. It was demonstrated for a reporter at the company's downtown office on Friday.

"The cost in Canada (for the machine) will be between \$150 to \$175 (plus taxes)," said Crosby. He said the Beer Machine retails for about \$200 in Britain.

Consumers must also buy the carbon dioxide cylinder and the syrup, which is currently made at a brewery in

Britain and sells there for about \$12 a can, said Crosby.  
In Canada, the syrup will be subject to liquor  
taxes.  
Fountain House is listed on the Vancouver Stock Exchange.

Subject: Re: Sterilizing bottles

In the HOMEBREW Digest #1189 of 7/26/93, Bill Vaughan tells us how he sterilizes his bottles in a dishwasher. It sounds like a good method, but he is only sanitizing them, not sterilizing them. I use the dishwasher myself to clean empty bottles of homebrew. When they drip dry, I store them away. Before I bottle though, I soak them in a bleach solution, rinse them and let them drain. This, I believe, will kill all the bugs rather than a good washing will.

From: kulick@ebs330.eb.uah.edu (jeff kulick)  
Subject: co2 gas vs. liquid

CO2 at room temperature vaporizes at about 45 atmospheres, or about 800 psi. So, a 20 lb tank of co2 gas (which i guess is about 1 cu ft.) has about 45 cu ft of gas. However, it is rated at about 800 cu ft. capacity, so the liquid form is much denser.

If you pump just a little co2 liquid into the tank, it vaporizes, and may get 46 or 47 cu ft. You must pump the liquid into the tank, which you can't do from another co2 tank at room temperature.

So, if you filled it at bar, you didn't get very much.

I've been getting co2 at a welding supply, and they say they supply the pop companies so I guess their co2 is ok.

When I bought my second CO2 tank, I asked if it was possible to fill an empty tank from a full one. Technically, it will work, but it was explained to me as being very dangerous! This was because the tank being filled will heat up and explode if it is done too fast and without the proper equipment. In fact, most of the welding gas suppliers in my area don't actually fill tanks anymore, but exchange them. The filling is done in a central facility. Bottom line: Don't mess with it. It can be fatal to you and your neighbors!

- ----

I'd like to add an emphatic second to that. I've done quite a bit of high-pressure work, and I've seen some pretty impressive failures (shown as visual aids on "why you shouldn't do it this way").

When we fill air tanks for our fire department (to about 3000 PSI), we use what's called a "cascade" system - we have four large tanks, at about 750psi, 1500psi, 2250psi, and 3000psi. We slowly open the first valve, bring the tank to 750, close the first valve. Open the second slowly, etc. etc. Once the top one gets down to about 2300, we rotate the tanks, and get the lowest one filled up to 3000. Do not try this at home - this is pretty expensive equipment, and we had a professional (certified) fitter do all of the plumbing for it. Only about 3 of us on the department are trained to use the cascade system.

- -----

I wrote a few days back about my 200 gallon milk chiller - I'm still looking for good ideas of what to do with the silly thing. What do y'all think about using it as a big lagering vessel?

Silly idea time here (best way to get lots of responses, like the paper-shredder grain mill),

CAN I FILL IT WITH WATER AND LAGER MY BOTTLES (of beer) UNDER WATER?

The reason I ask this is like this: At night & on weekends, my electricity costs 1/6th of the daytime rate. If I had this thing full of 200 gallons of water (minus the volume of beer), it would have lots and lots of thermal mass,

and I could probably get by with not running the compressor when power is expensive. The tank can chill 200 gallons of milk from cow temperature (presumably around 37C, 98.6F) to 35F degrees (nice temp, eh?) in less than an HOUR, so obviously this is a powerful chiller, and will suck lots of current when running.

Subject: RE: Priming, sugar vs. malt extract vs. gyle

<snip  
<No more gushers as I had with corn sugar.

I wont argue the issue of sugar vs wort vs krausen vs DME other to say dont blame the sugar on your gushers. Proper carbonation is obtainable using any of the listed alternatives. Pick what suits your environment and ease of use. When I am brewing tons of beer and have krausen available, it is great to use. Usually, 1/2 of each batch I make is primed with corn sugar due to ease of use. It works fine.

Subject: CO2, Old book, Portland

<When I bought my second CO2 tank, I asked if it was possible to <fill an empty tank from a full one. Technically, it will work, <but it was explained to me as being very dangerous!

Hummm, this is news to me. I had my local CO2 shop put together a F-F CO2 coupling and hose for \$15. I hook one end to a 20Lb tank, the other to a small 2-5 Lb and fill it up. I guess I dont open the valve all the way at once, but I have found a freezing/chilling effect as opposed to a heat build up. It only will fill 1/4 or so depending on how full the 20Lb is, but It doesnt seem that dangerous. The whole process takes about 20 seconds to "fill".

From: bill@oilsystems.com (Bill Vaughan)  
Subject: Blowoff, Iodophor, Sterilizing bottles

<Blowoff -- fortuitously, my last batch of "plain jane" got split into its carboys unevenly.

The real test between this constant blowoff no blowoff debate is what is the change if you skim the trub/yeast from the top of the nonblowoff fermenter??

This is how we traditional top fermenting ale brewers do it and it works great. The point is removal of the trub/hop/yeast junk prior to falling back in.

<The only problem is that I just bought 2 more acid carboys and I can't ever fill them enough to get a blowoff.

Pitch more healthy cultured yeast and they will blow.

<Iodophor ...So far I have ALWAYS smelled iodine. I am not about to buy another bottle of iodophor.

Fine, dont use it for dumb reasons. My experience over the last year of only using Iodophor (Diversy)\_ at 12.5 ppm (1 Oz into 10 gal) is it is the best, easiest to use non corrosive cleaner on the market. Fill the keg, add 1/2 oz let stand 15 minutes, empty and lately I rinse once. Sometimes hot water, sometimes cold. Like Al noted, my water is clean enough for rinsing kegs without infection. Using this method, I have dispensed over 15 batches without any iodine troubles. I think you may be getting overworked on the smell thing, or are using too strong a solution.

<If I get pinholes in the s/s after, say, 5 years, the keg has cost me maybe 5 bucks a year

It will be interesting to see just how much a keg costs in 5 years.

<From: ab126@freenet.carleton.ca (Jay Cadieux)  
Subject: Calories and beer

<Does anyone know a formula to calculate the amount of calories in beer, <based on original gravity, terminal gravity, etc.?

Check the archives, George Fix posted this about a year ago, excellent stuff, but I dont want to feel guilty by actually calculating that my beer is 400 calories a pint.....it is interesting to see the difference between the amount of calories from alcohol vs from sugars/dextrins.

Portland....been there, done that, whats next?? Waaaaaaaaaaaaa,  
I miss Bridgeport Blue Heron Cask Ale.....One of the top 5 cask ales in the US.

Good brewing,

This is wrong. It should have been:  
 $DE = 65 * 11 / 26.5 = 26.98$   
or 27 degrees. Not bad, but you could probably get a little better.  
most people I talk to are happy to get around 25 degrees.

I use a Recirculating Infusion Mash system, which helps boost my  
extraction. Also, the way the grains are crushed can make a big  
difference.

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Briess, Northwestern

Thanks to all of those individuals who let me know that kBriess and Norhtwestern malt extracts are one and the same, the only difference being the packaging. Now I have a real problem on my hands, namely figuring out what the Hell is going on with my brew!!!

A few questions to those who know (or think they do):

- 1) Can malt extract go bad upon prolonged storage? How can you tell if it is bad? Will molds, or other beasties grow in undiluted malt extract, or will the osmotic pressure prevent this, much like with honey?
- 2) If malt extract is able to support unwanted life, will any byproducts of these vermin survive a 60-90 min boil or will they be evaporated away?
- 3) If Briess and Northwestern are one and the same, how is it that both my brewmate and I have both noticed significant differences in brews which used equal amounts of either, when all else has been held constant?

An unrelated question:

I am hoping to receive my M.S. in organic chemistry later this year and would like to pursue a career in brewing. Of what value to me would it be to pursue another degree in fermentation science? What is the best way to get a job at a "small" brewery? (Not necessarily micro, but not a at AB/Coors/Miller?) I've tried the classifieds, but rarely see anything listed under BREWING, BEER, or FERMENTATIONS. Anyone in the business who could offer advice (or a job), private e-mail would be very appreciated.

Sincerely,  
Anthony Johnston

> find one that did ....

My experience is just the opposite. Every time I've put a batch aside to give it a chance to age, the problems have disappeared. I have had bad initial experiences with using whole grains. The results were just awful for months. But somewhere in the time frame of 6 to 9 months later, the beer improved and is now VERY good.

Date: Mon, 26 Jul 93 10:26:18 PDT  
From: Victor Stevko (Human Genome Center, LBL) <stevko@genome.lbl.gov>  
Subject: calculating ppms

PPM stands for parts per million, figured (usually) by weights. It has nothing to do with molecular weights at all. So, one PPM of sodium atoms indicates one gram of sodium atoms per megagram, or 1000kg, of water.

Where chemistry enters is that these salts are ionic solids - they dissociate into component ions when dissolved in water. So, salt (NaCl) becomes Na<sup>+</sup> and Cl<sup>-</sup> ions. You should get the PPM of the components by figuring the percentage weight of each component, and multiplying by the appropriate factor. If I add 100 grams of salt to my 1000kg of water, the sodium will be  $23/58 * 100g$ , or about 40g, and the Cl<sup>-</sup> will be about 60g, from the proportion of their atomic masses. So, my tank of water will be 40 ppm in Na<sup>+</sup> and 60 ppm in Cl<sup>-</sup> ions, when I've dissolved & stirred, since

I started with perfect water.

Does this help any? I haven't looked at the charts in the books.

---Victor

From: pohl@unixg.ubc.ca (Derrick Pohl)  
Subject: Digital vs. lexical yeast

Is there some reason why most people on the HBD refer to the Wyeast yeasts by number rather than by name? Like for instance, are the same numbered yeasts sold by different names in different parts of the continent? Or do the numbers refer to some universal system of identifying strains of yeast? Or do people just like the scientific ring to using a number rather than a name? If each number has a unique name and the name is the same wherever Wyeast is sold, then why not use the names? I for one find it much easier to remember the names, and when I go to the brewing store I don't ask for a pouch of "good ol' number 1038" (or whatever), I ask for "London Ale" or "Bohemian Lager" yeast. I suppose I could tape an old package up on the wall by my computer for quick reference, but this seems a little awkward, and people are liable to think I'm even more obsessed with brewing than they already do.

Maybe people could at least include the name along with the number for those of us whose brains haven't entirely melded with our silicon yet.

>Has anyone converted a hot water heater into a hot liquor tank? I have two options: 220V electric with 2 elements or a gas fired unit.

One problem with a closed water heater you may want to think about is the fact that chlorine and other volatiles in the water have nowhere to go. In an open vessel they evaporate continually.

>From: Conn Copas <C.V.Copas@lut.ac.uk>  
>Subject: Re : syphoning through hops

>I employ Kinney's tip on using pot scrubbers to prevent hops clogging the syphon, but my system is more a mesh-bag-in-a-pot-scrubber than a pot-scrubber-in-a-bag. Reason? It makes sense to apply a series of progressively finer filters in order to prevent the mesh from clogging too quickly.

All of this, of course, is unnecessary with an easymasher installed in the mash tun/boiler. However, in my one experience dryhopping in a carboy I solved the problem of siphoning by simply sliding the em strainer tube over the end of the siphon and being the same diameter, it fit like a glove and worked like a champ.

For those not wanting or needing the em, you can still solve the siphon problem with a tube made of screen slid over the end of the siphon with the end pinched. You can slide it up or down to expose as much screen as you wish and when you get near the bottom you just push the tube down so only a 14 inch or so is exposed.

Just roll a 2 X 6 inch piece of screen over 3/8" diameter rod and pinch and bend the las half inch to seal it off. Slip this over the end of siphon tube. BTW, if you put this on the end of piece of coppur tubing and bend it so that the screen lies flat on the bottom and the other end rises over the edge of the pot, you have a portable easymasher.

From: jgibbens@polyslo.csc.calpoly.edu (Jonathan Gibbens)  
Subject: Intro & a question

Howdy fellow brewers,  
My name is Jon Gibbens and I've been brewing for about 7 months now. I've been reading the HBD for about 2 years now and figured it was time to "show my face."  
Anyway, all my recipes so far have been your standard Papazian-influenced dry extract recipes with a little of my own creative flair thrown in for good measure. I just got done brewing my 14th batch, a raspberry porter a la "Goat Scrotum Ale" with 9 lbs of raspberries added for good measure.

My question is: This last batch was my first batch to go in a plastic fermenter, all my previous ones have been in glass. How do you sufficiently aerate your wort before it goes into the fermenter? In glass it's easy..just cap the carboy and start shakin' like mad, turn it this way and that, upside down, you know the whole story. I was thinking that maybe the next time I do this, I'll FIRST put it in a glass fermenter and shake it up, then pour it out into the plastic fermenter and THEN pitch my yeast.

Now for an obligatory recipe: Being unable to find a recipe anywhere for a weizenbock, I made up my own. I'm not sure about the "authenticness", but who cares?

Wacky Weizenbock

6 lbs Brewmaster Dried Wheat Extract  
3 lbs Brewmaster Dried Amber Malt Extract  
1/2 lb chocolate malt  
2 oz Hallertauer fresh hops (boiling - 1 hour)  
1/2 oz Hallertauer fresh hops (flavor - last 20 minutes)  
1/2 oz Hallertauer fresh hops (aroma - last 2 minutes)  
Wyeast Liquid Wheat Beer Yeast

Prepare according to the standard Papazian method for extract beers.  
Starting gravity: 1.61 Starting Potential alcohol: 9%  
Ending gravity: 1.16 Ending Potential alcohol: 2%  
Primary and Secondary fermentation took 1 month. I believe that the high alcohol content (7%) pickled the yeast and stopped fermentation in it's tracks. Bottled with 1 1/4 cup DME.

It turned out really good! Fruity and dark with a very noticeable alcohol smell.

Anyway, keep on brewin'  
Jon Gibbens

Subject: BT mag / Foxx Equip CC orders

re: Brewing Techniques

I too have received and started reading BT #2. The editor pledged to keep advertising always less than 50% of the mag's content. Apparently, a few people wrote in letters complaining about the size of the mag., but, when added up, it compares favorably to others.

Hey, if you think Zymurgy is bad with advertising, go check out one of the Woman's magazines, like Glamour or something. They are 95% advertising!  
!

re: Foxx Equip and CC orders

Al is correct, they do accept CC orders...

BUT...

You must send them a letter, beforehand, authorizing them to use your CC when you place orders. In other words, you can't call today and have something shipping to you immediately! You need to send in the authorization letter first. This is the policy as of yesterday when I placed an order for some keg parts.

<From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Briess, Northwestern

<questions about extract & a brewing career, snip

First, if you are serious about being a pro brewer, you should really switch to all grain brewing ASAP. Its not that much harder or expensive and you will start to learn what its like to do the real thing.

Secondly, we need more brewers with backgrounds in Chemistry. This is not enough by itself, but you can augment this knowledge by inrolling in Seibels short course in brewing technology or whatever they call it. It is a 12 week course in Chicago. Before or after this, work in a brewery doing anything to gain knowledge/experience.

<From: Robert Pulliam <Robert\_Pulliam@aja.rand.org>  
Subject: Various questions

<1. For a 30 foot chiller, what might I expect the temperature of the exiting water to be. Must I use a hot water rated hose?

Close to water temp.

<2. When calculating my extraction efficiency, do I use the gravity of the wort fresh from the tun or after the boil?

after.

<3. Is there an advantage to using a thick mash compared to using an extremely thin one that would give me say 7-8 gallons on first runnings without having to add additional sparge water?

Thin is Ok up to about 2 litres/lb of grain.

<4. I seem to recall a thread somewhere that discussed having to bring up the temperature of cold fermented beers near the end of the fermentation cycle to help remove something or other. Is this a figment of my imagination or something I need to be doing?

Its called a diacetyl rest. It reduces (guess what??) diacetyl. To be an authentic continental lager, ferment at 48-51F for 1 week, drop temp 2F per day until it is 42F. Rest here 2-4 days (diacetyl rest), then drop 2F per day until you hit 31F. Hold 4-8 weeks depending on style. Either lager in kegs, and bung to create natural CO2, or krausen with fresh krausen (fermenting yeast & wort, at 7-15% of volume). Those who "bring up" the temp are preaching the American fast lager approach. This is where ferments are done quite warm (up to 60F) and lots of diacetyl is produced that requires reduction by the yeast. It has been demonstrated that bringing the temp up to 68-70F for 2 days or so will reduce the diacetyl to "normal" levels. Taste tests of experienced panels have shown a preference for the traditional techniques.

In  
> an open vessel they evaporate continually.

You can use a hot water heater, but not connected as a household water  
heater. Connect the water input line as usual, but leave the top outlet  
open, perhaps with a wide clear open tube connected to the top outlet.  
Your actual outlet will be the drain spigot on the bottom of the heater.  
Open an inlet valve to fill the heater, but shut off the supply when the  
tank is almost full (a clear tube connected to the top outlet will tell  
you  
your tank is full, then you can drain a little). You may then heat your  
water, and volatiles will escape through the top opening. This will  
work  
best if there is some headspace at the top of the tank. If you want to  
get  
REALLY fancy, have a split connection at the top outlet tube, one end  
going  
to a stopcock and one end going to a vessel containing a toilet tank  
float  
valve. That way you can shut off the stopcock, turn on the water input,  
and the float valve will stop the inflow of water when the tank is just  
over full.

Disclaimer: I have not done this. Although I may someday...

From: gorman@aol.com  
Subject: Dry-hopping in Cornelius Kegs

Just tried the dry-hopping technique described in the recent Zymurgy.

Whole hops (used Hallertau in a weizen) in a mesh bag placed into a Cornelius Keg at keggung time. I weighted the bag down with a handful of marbles. I boiled the bag and marbles (w/o hops) to attempt sanitization.

This produced the most pronounced hop bouquet I've yet experienced from an ounce of hops. I haven't noticed any off flavors introduced by the bag in the keg.

Makes sense, the aroma doesn't have anywhere else to go.

N.B. An ounce of whole hops requires more marbles than you might think to get it to sink. Try a big handful.

Enjoy,

Bill Gorman

Subject: More AHA/Zymurgy bashing

To add to Kieran O'Connor and Dave Smucker's dismay about the AHA and Zymurgy, I recall that the latest price hike from the AHA (from \$25 to \$29, I think) was because Zymurgy was costing so much to print. So everyone in the AHA was called upon to pay for the wasted pages full of AHA ads and other self-serving crap, because, evidently, it wasn't paying for itself.

Does anyone know if The New Brewer is of the same "quality" as Zymurgy? It's published by the Institute for Brewing Studies (all in the same office as the AHA, and others) and is billed as a "must-have" for anyone interested in or working in the micro/brewpub field.

I'm looking forward to my Brewing Techniques subscription. Sounds like quality work.

>try this cr\*p. One other thing, I thought this was a Coors  
>product? The can said Zima Brewing Company? Is this a Coors  
>subsidiary or am I just confused (not unusual).

I don't think that there is a separate company called Zima Brewing Co. The "subsidiary" approach is Coor's way of separating itself from the Zima product, just in case it sucks (from what I understand, it does). If Zima does not sell, then the company will die a quiet death at the hands of lawyers and the Coor's name will remain clean.

One thought: maybe we have been too harsh on Zima because we have been judging it against our standard criteria for beer. I don't think that Zima claims to be beer, but a malt beverage maybe (?), and it's probably labeled "malt liquor" because of the goofy alcohol laws we have in this country. So maybe Zima isn't bad for the \*style\* (whatever the hell that may be...), just like Bud is an excellent example of the American Standard Lager.

Not!

Subject: Lager under water

Dave Hinz asks about lagering beer bottles under water in his 200 gal milk cooler. Technically, it sounds like a great idea. The bottles are sealed and there's no way to contaminate the beer.

However, I've noticed one thing about my bottle caps: I always boil a couple extra when bottling and then out the unused ones back in the bag afterwards. I have noticed that if I don't dry them really well, they get rust spots. (This may just be the caps I bought this time....)

The caps are made of regular steel or maybe tin, but not stainless or aluminum, and are coated with some sort of anodizing (I guess from the color inside only.) I know they aren't SS or Al because the magnet in my capper holds onto them.

In the process of capping, the cup that seats the cap may scrape off enough of the coating to expose the underlying metal. While this rust would only be on the outside, it would make you think twice about drinking the contents. I suggest capping a couple bottles of water and testing it out first.

Subject: calories

Someone wanted a formula. This was posted some time ago.  
bb

.  
.  
.

I know that there have already been answers to this question, including disclaimers by George Fix and a nice linearized version with analysis by Robert Bradley, but I thought someone might like to see yet another version of the formulas. These are the same formulas that George Fix gave, except that they have been converted to FG and OG (using the Plato to SG (divide by four) conversion that is not exact according to George). This is probably what Robert did, before he linearized them. Anyway, here they are:

Note that OG and FG are used in the full form (e.g. 1.045). C stands for the calorie content per 12 ozs., and the [alc] and [ext] subscripts signify the fractions from alcohol and extract respectively.

Other definitions:

A = alcohol content of finished beer in % by weight.  
RE = real extract of finished beer in degrees Plato.  
OG = original gravity of the beer.  
FG = final gravity of finished beer.

76.8 (OG - FG)

A = -----  
(1.775 - OG)

RE = 250 (0.1808 OG + 0.8192 FG - 1)

(OG - FG)  
C\_[alc] = 1881.22 FG -----  
(1.775 - OG)

C\_[ext] = 3550 FG (0.1808 OG + 0.8192 FG - 1.0004)

C = C\_[alc] + C\_[ext]

[ 0.53 (OG - FG) ]  
C = 3550 FG [ ----- + (0.1808 OG + 0.8192 FG - 1.0004) ]  
[ 1.775 - OG ]

Subject: Re: Various questions, White House beer

> 1. For a 30 foot chiller, what might I expect the temperature of the  
> exiting water to be. Must I use a hot water rated hose?

Well, the closer the exiting water is to 100C, the more efficiency you're getting. I've never measured the temp of the water coming out of my 40-foot counterflow chiller, but I can empirically say that it's \*hot\*. Hot enough to scald. The plain old garden hose used in my chiller seems just fine, though, after 20 or so batches.

> 2. When calculating my extraction efficiency, do I use the gravity of  
> the wort fresh from the tun or after the boil?

Assuming you add no water during the boil, both measurements should give you pretty much the same thing. The amount of water evaporating will be proportional to the increase in gravity.

I usually measure both: right after sparging, so I can make any needed adjustments, and after the boil to make sure of my original gravity. I calculate total points of extract right after the sparge using:

$$v * p = T$$

where v is volume, p (points) = (gravity-1)\*1000, and T is total points for the batch (e.g. collected 6 gallons @ 1.055 = 6\*55 = 330 points). You can then solve v\*p=T for either v or p, depending on what you're shooting for (e.g. if I had wanted a beer at 1.060, I would need to boil down to 5.5 gals; if I boiled down to 5 gals of beer, my original gravity would be 1.066. On the other hand, if I wanted a lighter 1.045 beer, I'd need to add water so I ended up with 7.33 gallons \*after\* the boil was completed).

> 4. I seem to recall a thread somewhere that discussed having to bring  
> up the temperature of cold fermented beers near the end of the  
> fermentation cycle to help remove something or other.

I believe this is called the diacetyl rest. Although diacetyl, which produces a buttery or butterscotch aroma, is desirable in some styles of ales, it is usually not wanted in lagers. Yeast produce diacetyl, but will re-consume it later in their life cycle if allowed to do so. This raising of the lager temp is supposed to "reactivate" the yeast to some extent to encourage them to consume the diacetyl. If you're brewing ales, this step isn't necessary.

> >hours, bottle for use.

>

> >And again, only 24 hours [of fermentation]?

Yup, or maybe 48. I don't know about the hop beer recipe, but I make my ginger ale using an almost identical recipe. You want a "soft" drink like this to have much less alcohol and more carbonation than beer; you achieve this by bottling 24-48 hours after pitching yeast. Why no exploding bottles? I believe the theory is that there is very little yeast nutrient in the recipe, so in spite of all the sugar the yeast poop out pretty quickly.

You can also avoid trouble by using strong bottles (champagne bottles work well, as do 2l plastic soda pop bottles) and refrigerating the bottles after only a couple of days of conditioning. I've never had a ginger bomb yet.

There was some noise on this some time back. From what I recall Miller advocates raising the primary fermentation temperature of lagers after active fermentation has subsided, but before racking to the secondary. The belief is that in the absence of oxygen the yeast will be better able to reduce the diacetyl levels. I've found that this advice works great. What I do is wait until the diacetyl odor is substantially reduced before racking to the secondary. Typically two to three days after after fermentation has ceased. Look at Miller's book for a more indepth explanation.

Subject: HOW TO KEG?

Hello,

A friend and I have got a hold of a soda keg and we're supposed to get some of the other stuff, like the C02 canister and a cold plate...

Now here is my question. How do we "keg"? We've been making extract beers for quite some time, where we add the corn sugar to the wort just before we bottle. Now that were gunna try the keg setup do we add the corn sugar to the wort, let it ferment out completely, then rack to the keg? And then since the beer at that point is "flat" how much C02 and when do you add it? What keeps the trub out of the keg? I think you get where I am coming from. What I need are pointers on how to keg from a beginers perspective.

Thanks, KRUSE\_NEIL@tandem.com

>Well, plugging the numbers into the equation,

>DE = 1.065 \* 11 / 26.5 = .44

>or 44 degrees of extract. From this, I would guess that you

>added some malt syrup or adjunct.

>

BZZZT! The number calculated above is meaningless. You need to subtract out the SG of the water before doing multiplication. Don has already seen my input on this in private email, but when I saw the above information I felt that a posting was necessary. The equation should be:

$$DE = (OG - 1.0) * \text{<gallons of extract>} / \text{<pounds of grain>}$$

Plugging Don's numbers in gives us:

$$DE = .065 * 11 / 26.5 = .02698 \text{ (or approx 27 degrees of extract per pound of grain)}$$

While this isn't great extraction, it may not be all that bad. It could be that Don used several pounds of malt adjuncts that provide fewer extract points. When I do these calculations on my own brews I usually subtract a value based on the expected yeild of malt adjuncts from the numerator and the amount of said adjuncts from the denominator in the above equation. This kind of calculation breaks down when a significant portion of the extract is from multiple malt sources such as a 40% wheat mash. For those types of mashes I treat the wheat malt as base malt also. For example; purely hypothetical but probably not uncommon :-)

Brew length(BL): 5G

OG = 1043

Grain bill: 6.5# 2-Row, 1# 40L (AWght)

Approximate extract for 1# 40L = 20 (AExt below)

$$DEbase = (((OG - 1.0) * BL) - AExt) / (GrainTotal - AWght)$$
$$DEbase = (((1.043 - 1.0) * 5) - 20) / (7.5 - 1)$$
$$DEbase = (215 - 20) / 6.5 = 195 / 6.5 = .030$$

Let's not forget that the density of water does not increase with volume (at least not for our purposes).

Subject: CO2

>From: Jim Busch <busch@daacdev1.stx.com>

>Hummm, this is news to me. I had my local CO2 shop put together a F-F  
CO2  
coupling and hose for \$15. I hook one end to a 20Lb tank, the other to  
a small 2-5 Lb and fill it up. I guess I dont open the valve all the  
way  
at once, but I have found a freezing/chilling effect as opposed to a  
heat  
build up. It only will fill 1/4 or so depending on how full the 20Lb  
is,  
but It doesnt seem that dangerous. The whole process takes about 20  
seconds

First of all, this will only work if we assume that the source tank was  
a  
siphon type, i.e., dispenses liquid CO2 and not the type one could use  
for  
beer dispensing. If you use a top venting tank, all you get is gas and  
will  
only get the 800 psi that is in the source tank. This might be enough  
to  
dispense a bunch of beer but nowhere near what you would get if filled  
with  
liquid CO2. It's like filling a tire from a compressor that is shut  
off.  
When the tire pressure equals the tank pressure, that's all you get.

Secondly, if you fill with liquid CO2, the head pressure in the  
receiving  
tank must be vented while filling or you can't fill it at all. If  
frosty gas  
was not hissing out while you were filling it, you were not filling it.

As I mentioned before, the best way to know what is going on is to weigh  
the  
tank. If it does not weight 2.5 lbs more after filling than before, it  
aint  
full.

**Subject: Aeration**

If you are doing a partial boil and dumping the hot wort into cold water you probably don't have to worry too much about aeration (unless you've preboiled your cold water). Pouring the hot wort through a sanitized strainer will also aerate it (as well as help remove hops and break material). I used this method for a full boil after cooling with a wort chiller and it seemed to work OK.

If you don't like the strainer idea and want to siphon, you can simply put the lid on without an airlock and shake well. Other folks have used an aquarium pump and aeration stone.

Someone the other day suggested that washing bottles in a dishwasher would merely sanitize and not sterilize. He was right, but sanitizing is all that is really necessary and is all bleach/iodine/whatever solutions will do anyway.

From: Lee=A.=Menegoni@nectech.com  
Subject: Extract efficiency / Diacetyl Rest

Re: Extract efficiency - I was under the impression that measuring the pre and post boil extract efficiency would result in unequal values. That the post boil value would be lower due to the precipitation of break materials. Has any one measured this? Do they differ? By how much?

Re: Diacetyl rests - I too use the method described in Noonanan's book on lagers. I do a primary at 45F, diacetyl rest for 3 days at 48F then rack to 2ndary and "Hunter lager" at 40F I then chill to near 32F for the last week before kegging to precipitate out yeast and haze.

Re: Brewing Techniques  
I too agree it is a fine magazine and that the 40 or so pages is a lot of material. I am not an AHA member, but doesn't the \$29 sent to the AHA cover annual dues and the subscription to Zymurgy? I too agree that the "don't worry" philosophy gets old fast.

From: chips@coleslaw.me.utexas.edu (Chris Pencis)  
Subject: jever thanks/low head retention/spiced beers

Hey everyone - first I want to thank everyone for the responses to my question about Jever...I believe I received something like 15 or 18 responses (please forgive my not responding to each individually). I now own a copy of Michael Jackson's Pocket Guide where the virtues of Jever are detailed - and yes, Fresia is in the northernmost regions of Germany (including the Fresian Is.).

Here's my questions:

I seem to be having trouble with head retention in all of my beers including store bought Sierra Nevada Summerfest et al. I believe cause may be residue in my glassware. However, I wash the glasses in the dishwasher with Cascade detergent - I use energy saver settings for the dry cycle. Let me clarify problems - there is sufficient carbonation in everything - the bubbles form about a 1/2-1" head on pouring but quickly subside to no more than 1/16" head to none at all. Any ideas....is this paranoia?

Secondly - I am considering brewing a spiced ale for Christmas this year (its early but a few good months in the bottle and it takes me a while to get going anyway). I have done thread searches on back issues of the HBD and have looked in the Cat's Meow and have yet to see a clear agreement among brewers/recipes (\*is such a thing possible\*) as to the best way to add the flavoring: dry to the boil, dry hop, spice \*tea\*, or gloegg. Opinions (open the flood gates...)? Note: I am an extract brewer and am looking for o.g.s from 1040-1060.

One last thing - I was watching STNG last night and it occurred to me to wonder just how the stardates are calculated...any answers?

Sorry for the longwindedness ... thanks in advance  
good luck and good beer  
Chris

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>  
Subject: My First Batch

Hello Bruce (and all you other Bruces; "Crack Two")

I made my first batch of Homebrew a month ago, and it is yucky. It was a kit beer from our local brew shop, Fun Fermentations in Orange Ca, and was supposed to be an American Lite beer. The batch seemed to have a cidery smell and taste the day I bolttled, (took me forever to get the @#&\$#! siphon to work) and after a month of aging, it doesn't taste any better. The beer has great color, a nice head, but the flavor is reminiscent of swamp water cider vinegar. Does anyone have a clue? Had a similar batch? I am wondering if my fermentation temperature was too high, it was often in the upper 70's in the house, probably 78. Yes, it was an ale yeast. BTW, I had a bottle of Paulener Salvator the other day, and it had some of the same flavor tones as my beer. Was that bottle of Salvator too long on the shelf at the store ie. light damaged? Is that why it tasted like mine, or is mine actually good? (nah) And another thing, Has anyone ever noticed the laxative qualities of homebrew in general or is this another symptom of my first batch?  
John Palmer  
PS. I am really bummed that the Beer Hunter won't be on the Discovery Channel again, I only have a couple episodes taped, and have been waiting to get the others.

It beats me why this should be a problem. Jim is simply suggesting using a hot water heater to provide very hot water for mashing, sparging, etc. Why should this be a chlorine problem?

In answer to Jim's question, at least one of the McMenamain brewpubs in Oregon uses exactly this system -- lots of pipes running out of that water heater that aren't standard!

Jack, every hot liquor (water) system I've seen in a brewery is closed.

- --Jeff

PS. I made it to one day of the AHA conference, attending the Board of Advisors meeting and judging in the 2nd round of the competition. All of you stay-at-homes will be glad to know that the weather yesterday was gorgeous (in the 80s), the programs were interesting, the beer was excellent, and Portland is better than wherever you are. Today, of course (I'm back at work), it's cloudy, it'll probably rain, and all the beer has spoiled.

Aint if fun seeing an article the morning after you submit it. Knew something good had to come from the AHA conference. Got all those loudmouths away from their keyboards. :) < for the benefit of the humor impaired.

re: Brewing Techniques

>I too have received and started reading BT #2. The editor pledged to keep advertising always less than 50% of the mag's content. Apparently, a few people wrote in letters complaining about the size of the mag., but, when added up, it compares favorably to others.

It will be interesting to see how long BT keeps that pledge. Money and sometimes survival have a strange way of making people forget their pledges.

If a non-profit group like AHA has degenerated to 90% ads, what do you expect from a for-profit company like BT? At the moment, BT can survive on fewer ads because they don't pay contributors for articles. And remember, it is always easy to get fresh new articles for a new publication but down the road, they will have all the usual problems of getting stale.

BT is a breath of fresh air but only subscribers and a much higher subscription rate can keep it pure if combined with a rigid policy of ad restriction. However, ad sales people just do not say NO to one more ad.

>From: Ed Hitchcock <ECH@ac.dal.ca>  
>Subject: Hot water tanks

>You can use a hot water heater, but not connected as a household water heater. Connect the water input line as usual, but leave the top outlet open, perhaps with a wideclear open tube connected to the top outlet.

Sounds like you have re-invented the EASYSPARGER. Not sure why one would want to heat a large amount of water and just let it sit or have to keep it hot till needed. The ES allows a continuous flow of hot water at any desired temp, evaporates the chlorine, takes up only about .5 cuft of space and needs to contain only one gallon of water.

>In HBD #1190 Jonathan Gibbens asks:

> How do you sufficiently aerate your wort before it goes into the fermenter? In glass it's easy . . .

The simplest method is to fill a one gallon jug and shake this a bit and then just plug it into the fermenter. With two jugs, you can be filling one while glugging the other.

The only problem is that this works so well, you will have to beat down the foam to get all your wort in and you must, of course, use sanitized jugs.

I did this for years with great success but now I have a pump and a narrow nozzle at the end of the hose which provides aeration as it squirts into the fermenter.

>Subject: inoculating a starter from a petri dish

>I just started culturing yeast and have two ale yeast cultures in petri dishes..... I was wondering if it was possible that there was enough yeasties in the glob that I picked up to make a decent starter in only a few hours.

How much yeast should you pick up to inoculate a 6 or 7 oz starter??

You can, theroretically, inoculate a whole batch with a single cell but this and your approach are not recommended for a very good reason.

One cell of culture yeast would be competing with many cells of uninvited stuff, even in a sanitary environment, and would probably lose the race to get established. The larger the amount of culture and the smaller the batch size, the better the prospects of winning.

I would not start more than 50 ml or so with a loop-full of culture. When this is fermenting, you can start 200 ml and to do it right, start 500 ml with this. I would never attempt to start a batch with less than 500 ml of working wort.

You would be much better off to transfer the petri culture to slants and use these to start your starter. I cover the slant with wort and use this as a one time, pure culture starter.

The petri stage can be eliminated entirely if you are confident of the quality of the original slant culture. Just transfer a single inoculation to a half dozen slant tubes and use these to start others. You don't have to go back to the original unless you screw up or something changes.

> >the wort fresh from the tun or after the boil?  
>  
> Assuming you add no water during the boil, both measurements should give  
> you pretty much the same thing. The amount of water evaporating will be  
> proportional to the increase in gravity.

The above statement is not correct. The gravity before the boil is usually quite different from the gravity after the boil. After all, one of the purposes of the boil is to increase the gravity.

What I meant was that the total number of points stays constant. Using the  $v \cdot p = T$  formula, if T is constant, then v and p are inversely proportional. So obviously if v goes down, p (gravity) goes up.

> So maybe Zima isn't bad for the \*style\*  
> (whatever the hell that may be...), just like Bud is an excellent  
> example of the American Standard Lager.  
>  
> Not!

We hear a lot of "Bud bashing" in this forum. Having drunk my share of Bud, Miller, Old Style, Red White & Blue, Huber, etc., I'll step out on a limb and defend the megabreweries (he says, as he dons his asbestos undies).

Most serious beer people pooh-pooh the "American Standard Lager", but that style certainly fills a niche. The term "lawnmower" beer is not inappropriate, as a Budweiser is exactly what I feel like drinking after mowing the lawn on a hot day. Why not just drink water, some would say. To my palate, the slight bitterness of American swill is more refreshing.

I would also challenge many skeptical homebrewers to brew a lager as light and clean as a Bud. Ingredients are quite different from your average homebrew (uncured malt, adjuncts, etc.), you need techniques to minimize wort darkening and esters, and sanitation is paramount, as the slightest off flavor or aroma will be noticeable.

In fact, early in my homebrewing career I tried to brew a Bud clone, and didn't even manage to come close. Becoming a homebrewer actually increased my appreciation of what the big boys do.

From: pmiller@mmm.com (Philip . Miller)  
Subject: New Brewer

Dennis asks:

>Does anyone know if The New Brewer is of the same "quality" as  
>Zymurgy? It's published by the Institute for Brewing Studies (all in  
>the same office as the AHA, and others) and is billed as a "must-have"  
>for anyone interested in or working in the micro/brewpub field.

My wife bought me a subscription to NB last year as a present. While the magazine still has a fair amount of advertising (but it's INTERESTING advertising because it's for bottling lines and 2 bbl systems rather than cans of syrup), the content is better than the average Zymurgy article in my opinion.

Typically there will be an interviews or articles written by microbrewers about some facet of running a brewery. A couple of issues ago, a brewer talked about cobbling together a bottling line and the difficulties therein. This issue, there was a very interesting article about a pair of brewpub owners philosophy of running their business. (Basically, they said to concentrate on the food and atmosphere because just having good beer won't pay the bills.) There are also opening and closing notices of breweries across the country as well as a page or two describing events of general interest to the brewing community (such as pending legislation.)

If I were a microbrewer or a brewpub owner, I think I'd find the \$55 subscription fee worth my while but NB falls somewhat short of a "must-have".

Since much of the information in NB doesn't pertain to me, I'll probably let the subscription lapse....

make a  
>decent starter in only a few hours. How much yeast should you pick up  
to  
>innoculate a 6 or 7 oz starter??  
>

That must have been some glob! Generally, a good starting volume when  
picking colonies (globs) from agar is probably no more than 2-4  
milliliters of media (wort) - remember, less is more. You will see yeast  
sediment in your container (usually a small one, e.g. test tube) and  
bubbles trapped at the surface by the next day. At this point the volume  
can be increased 10-20 fold and then doubled each day thereafter, until  
you  
reach your pitching volume (1-2 liters).

Why start with such a small volume and work your way up? Well, when  
culturing unicellular organisms such as yeast, bacteria, or animal cells, a  
minimum cell density is often required in order to promote and maintain  
vigorous growth. The stimulation of growth and metabolism requires the  
presence of factors that are secreted into the media (in this case  
secreted  
by the yeast into the wort). A low cell density probably means a low  
level  
of growth factors. Thus, you may experience either no growth or an  
incredible lag time, when innoculating large volumes.

The schedule that I have suggested for increasing your culture volume  
requires nearly a week. Some planning ahead is required. You could  
start  
a culture anytime, work it up to a liter, allow the yeast to grow to  
saturation, and then stick the culture into the refridgerator for a week  
or  
two, until you are ready to pitch. Such a scheme would supply you with  
an  
excellent pitching culture, allowing your fermentation to get underway  
quite rapidly. Certainly, 1-2 liters seem like quite a lot, but those  
40-ml Wyeast pouches are quite a little, though many people do get by  
with  
that amount.

When picking from a plate, I would suggest that you pick more than one  
colony. Each colony originates from a single cell. Many commercial  
yeast  
cultures contain more than one strain of yeast (e.g. Whitbread). The  
fewer

the colonies picked the better the chance that you have eliminated a strain from your culture (you know what that means). Pick from a region where many colonies have grown together. Scrape your loop along the entire region and inoculate your culture.

Hope this proves useful.

From: npyle@n33.stortek.com

Subject: I'm back/Brewing careers/Chiller h2o/Mash thickness/Zima

Well, I return after a few weeks off to change jobs. In the meantime, I've brewed a wonderful American Pale Ale called Pyle Style Pale Ale. It is all-grain, using Mt. Hood and Cascade hops. If there is interest, I'd be glad to post the recipe.

Jim Busch said in the last digest:

><questions about extract & a brewing career, snip

>

>First, if you are serious about being a pro brewer, you should really >switch to all grain brewing ASAP. Its not that much harder or expensive >and you will start to learn what its like to do the real thing.

>

>Secondly, we need more brewers with backgrounds in Chemistry. This is >not enough by itself, but you can augment this knowledge by inrolling in >Seibels short course in brewing technology or whatever they call it. It >is a 12 week course in Chicago. Before or after this, work in a brewery >doing anything to gain knowledge/experience.

I agree completely. If you are serious about it, get serious about it.

You

won't impress any brewmeisters with a background in extract brewing. I

have

heard of some brewpubs that extract brew but I can't imagine how they make a

profit; also, there are very few of them. That said, read on:

I went to a Brewer's Dinner at the Walnut Brewery in Boulder last month and ate,

drank, and talked with the Brewmaster, Head Brewer, and Assistant Brewer.

It

was a wonderful evening, with awesome food and a brewery tour to boot!

The

Brewmaster, Mark Youngquist, is a young professionally trained brewer who really knows his stuff. He was very impressive, although he basically works in

a management/advisory role now. He sets up new breweries (ala the Rock Bottom

Brewery in downtown Denver; also a new one is opening in Minnesota, I think),

fixes up old ones (Boulder Brewing Company, now Rockies Brewing), and

solves

problems. The Head Brewer is an ex-kitchen guy, who knows food at least as well

as he knows beer. He, with the Assistant Brewer, brews all of the beer sold

at the brewpub. I think they brew twice a week, which are 12 hour days to do

two batches. The rest of the time is maintenance, stocking, cleaning, etc. etc.

The Assistant Brewer was off to Minnesota (I think) to become the Head Brewer at

the new Rock Bottom and a new assistant brewer was introduced. This guy had no,

absolutely no, brewing experience. I was more than a little surprised. I guess the lesson learned is: anyone can get a job in a brewery if you are willing to do a lot of hard work for, I guess, very little pay. If you stick with it, you can learn a lot and go places.

Jim also comments on Robert Pulliams questions:

><From: Robert Pulliam <Robert\_Pulliam@aja.rand.org>  
>Subject: Various questions

>

><1. For a 30 foot chiller, what might I expect the temperature of the  
> exiting water to be. Must I use a hot water rated hose?

>

>Close to water temp.

I don't think this clears it up. The exiting water will start out being very close to boiling with an immersion chiller. This is because you place the immersion chiller in the pot while the boil is still active (to sanitize the chiller). The temperature will quickly drop several 10's of degrees for the first few minutes and eventually approach the temperature of the tap water. counterflow chiller will be a bit different, I think, since the exit water is only in contact with the hottest wort for the last few seconds. This one will probably cause the exit water to start out something less than boiling and remain near this temperature until all of the hot wort is siphoned.

><2. When calculating my extraction efficiency, do I use the gravity of  
> the wort fresh from the tun or after the boil?

>

>after.

It doesn't matter (now watch me contradict myself!). In theory, if you use the before-boil gravity, use the before-boil volume. If you use the after-boil gravity, use the after-boil volume. The number should be the same. The real question is whether to include losses such as liquid trapped in the kettle hops, or break material left behind in the boiler. Since everyone is most concerned with the efficiency of the mash/lautering process, I propose that the before-boil numbers be used to ignore the later losses. An overall efficiency could be calculated which would indicate where your losses are occurring, but I suggest this is only important to commercial operations. And remember: In practice, the difference between theory and practice is greater than it is in theory.

><3. Is there an advantage to using a thick mash compared to using an  
> extremely thin one that would give me say 7-8 gallons on first

> runnings without having to add additional sparge water?  
>  
>Thin is Ok up to about 2 litres/lb of grain.

This is the short answer. I've read about this a bit and, from memory (this is probably a bad idea), I recall that thick mashes favor one enzyme, while thin mashes favor the other (good, I didn't try to name which was which!).

In practice, if you have a mash tun without a heat source (or even if you do!) you can have both. Start out with a thick mash (maybe 1qt/lb). When the temperature drops below your desired range, add hot water to bring it up to temp, which of course thins the mash. You can do this several times. At the end, you can add lots of hot sparge water to bring the temp up to mashout range. Then, you can drain the entire contents of the tun without adding sparge water. This method, and variations on it work for me, a professed lazy brewer, but my efficiency is only around 23-26 points per pound of grain. This of course doesn't bother me in the least since I have more time to play with kids and wife while brewing.

About Zima: you guys are all up in arms about nothing. It is not beer, they don't sell it as beer. They sell it as a new alcoholic beverage. It tastes sweet, with some citrus overtones. It does not taste like beer, not even like Coors Light. It is selling like crazy, too. Don't worry about it; it keeps the barley farmers in business, which is good.

Glad to be back. Hope you all are glad to have me, or at least aren't unsubscribing at too fast a rate!

Cheers,  
Norm

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: misc

I wasn't too clear on a few points made yesterday. Here's an attempt to clarify things:

RE: counterflow chilling, the exit temp of the chiller water can be quite hot. I have 12 feet of prechiller that exits over 100F, then feeds 50 feet of main line chilling. This water wasn't measured but is still warm. The great part of this thing is it doubles as a wort pipeline between my brewery in my backyard and my cellar.

<From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: CO2

First of all, this will only work if we assume that the source tank was a siphon type, i.e., dispenses liquid CO2 and not the type one could use for beer dispensing. If you use a top venting tank, all you get is gas and will only get the 800 psi that is in the source tank. This might be enough to dispense a bunch of beer but nowhere near what you would get if filled with liquid CO2. It's like filling a tire from a compressor that is shut off. When the tire pressure equals the tank pressure, that's all you get.

I should of prefaced my comments with: I use four CO2 tanks in my brewery. 3 are 20# tanks used for carbonating and dispensing. The fourth is a small tank that I use for traveling (I hate to lug a tank as big as a 5 gal keg). I can get enough gas into a small tank from a 20# to dispense several 5 gal kegs so this is a convenient way to put gas into a travel tank. It is certainly impossible to "fill the small" tank from the big one.

<Just tried the dry-hopping technique described in the recent Zymurgy.

Whole hops (used Hallertau in a weizen)

A nit here since I am a weizen nitter: If you dry hopped it, it isn't a weizen!  
It may be an excellent American wheat ale though.

Good brewing,  
Jim Busch

Subject: Wort Chiller Efficiency

Jeff Benjamin sez...

> 1. For a 30 foot chiller, what might I expect the temperature of the  
> exiting water to be. Must I use a hot water rated hose?

> Well, the closer the exiting water is to 100C, the more efficiency  
you're  
> getting. I've never measured the temp of the water coming out of my  
> 40-foot counterflow chiller, but I can empirically say that it's \*hot\*.

I don't agree, at least about the hot exit water indicating efficiency.  
What is important is the total energy transfer, which happens  
much more efficiently with a greater delta T between the cooling water  
and  
the hot wort. Chillers are by definition more efficient at the first  
contact  
point than the last. A high flow rate of cooling water with a minimum  
delta T OF THE COOLING WATER between outlet and inlet can be more  
efficient  
than a lower flow rate and higher delta T, since the efficiency along  
the  
length of the chiller is more constant and representative to the initial  
efficiency.

I could be wrong, but this always worked out on the ranch....

Subject: Re: Lager under water

(The caps are made of regular steel or maybe tin, but not stainless or aluminum, and are coated with some sort of anodizing (I guess from the color inside only.) I know they aren't SS or Al because the magnet in my capper holds onto them.

In the process of capping, the cup that seats the cap may scrape off enough of the coating to expose the underlying metal. While this rust would only be on the outside, it would make you think twice about drinking the contents. I suggest capping a couple bottles of water and testing it out first.)

I had the same problem except I had rust on the bottle caps of the brew that had been aged for an extended time, so someone suggested putting petroleum jelly on the caps to keep them from rusting. I have tried this and it works. All you need to do is take an old rag and put some petroleum jelly on it then rub a little on each cap after the bottling is finished, it's easy if you have the bottles in a case container.

Subject: Dallas beer info - Thanks!

Thank you, Craig, Keith and Jay!!

The info I received was right on the nose, and I'm quite sure I couldn't have found these places without your help.

To the net: the folks above responded with pointers to my query 'where to drink in Dallas'. The info I got was, there aren't any brewpubs yet (just recently legalized) but there are some pubs worth going to.

Number one for any Dallas visitors:

The Gingerman  
2718 Boll St.  
Dallas TX  
(214) 754-8771

Right behind Hard Rock Cafe off McKinney Ave. 50+ beers on tap, and a lot more than that bottled.

Number two: Head to the West End. Plenty of bars, pubs, lots of outdoor nightlife, at least in July. :) Live bands playing free outdoors, at lam on

Sundays and Mondays (the two nights I was there)??? Is this normal? Wow. There's a brewery there, whose products I didn't get a chance to sample, but they're available at the Outback Pub, an Aussie/English/yuppie style pub.

I received recomendations for Flip's restaurant and the London Tavern, which I also unfortunatly didn't have time to see.

I sampled 3 Texas brews:

Shiner bock, which is not bad but not impressive. An American bock, basically, but you justhave to have it if you're down there. :)

Celis White, the finest American brewed (as opposed to American style) wheat beer I've had. It rivals it's Bavarian ancestors, and is unlike the American wheats made by e.g., Widmer.

Celis Grand Cru, an interesting attempt at a Belgian style. It's too light in color and body to be a true Grand Cru, but they really have the flavor down. How do they do this? Anyone know? It tastes like a true lambic. I'd love to get a bit of that into the raspberry ale I just made. A must try!

Thanks again to the folks that responded to my query. Made life so easy to zip around a town I've never been too, but knew exactly where to go in. :

What you will have to worry about is not whether enough  
aeration takes place, but if the correct aeration occurs. It  
sounds to me like you would be introducing Hot Side Aeration (HSA).  
George Fix had a good article about this in the 1992 Fall Zymurgy  
issue. Basically, cool the wort to under 86 F (30 C) (Fix's  
number) before introducing aeration. Otherwise, you can seriously  
harm the stability of the beer. This happened to me on some of my  
very first batches. I was extract brewing and pouring relatively  
hot wort through a strainer into a carboy with cold water. The  
beer tasted good, but after about 3 to 4 months it really started  
to deteriorate.

Celis White is a Belgian Wit (White) beer in style, not a  
German wheat beer. The yeast makes a big difference.

I think it is a very good Grand Cru. I've never felt that  
Belgian beers have rigid style parameters (as compared with German  
Beers). I believe the Celis fits into the rather broad Grand Cru  
guidelines. As for tasting like a "true lambic", I can only say  
"What?!!!???"

Make sure you are not using a rinse agent (like "Jet Dry") in your  
dishwasher. Rinse agents will leave a transparent film on glasses  
which can destroy the head.

From: Mark A Fryling <mfryling@magnus.acs.ohio-state.edu>  
Subject: culturing Belgian yeast

Howdy all,

You regulars may remember my post awhile back asking for hints on what beers my girlfriend should bring me back from her trip to Belgium. Well she's back and I have (had) in my possession:

St. Bernardus Abt 12  
Chimay Blue  
Hoegaarden White and Verboten Vrucht  
Duvel (red label)  
Orval  
Rodenbach  
Gordons Highlander Scotch Ale  
Mort Subite Frambois

The question I'd like to pose, is does anyone know if the yeast in the Hoegaarden samples and the Abt 12 is fit to culture and brew with? I know that the Chimay is good stuff, and I already learned (from a recent posting) that the Duvel yeast is not. Ditto for Orval. The others were pasteurized and filtered. TIA

BTW, just as a comment, the Gordons Highlander Scotch Ale was absolutely fantastic. Surely the finest example of the style I have ever tasted. Rich, sweet, malty and oh so strong. Why in the h\*ll is this stuff sold only in Belgium? I'd consider all sorts of unspeakable acts to get my hands on a case of it.

Oh well, any advice is appreciated. Hopefully I'll be attempting my own Belgian styles soon.

Subject: DON'T - Pour hot wort thru a strainer

DON'T POUR HOT WORT THRU A STRAINER TO AIRATE YOUR WORT. This can produce unwanted flavors and darkening. Hot wort should be treated gently. It should be cooled before introducing air. See George Fixes article on Hot Side Airation.

Date: Thu, 29 Jul 93 10:51:24 -0400  
From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)  
Subject: Sparge water aeration and pH

As I'm just getting into the all-grain world, and I've got a few questions.

I'm well aware of the perils of hot-side aeration. My question concerns the aeration of and oxygen content of sparge water. One common technique in professional breweries to sprinkle the sparge water from a rotating arm (similar to the Phil Sparger). I would think that this would do I good job of aerating the water. The solubility of oxygen in water at 170 F is about half that at room temperature, so a significant amount can dissolve into the sprinkling sparge water. Doesn't this result in hot-side aeration of the wort in the lauter tun? Even without sprinkling, the water will still have significant dissolved oxygen at 170 F unless first brought near boiling and cooled.

My other question is about pH measurments of the mash and sparge water. How important is it to cool the samples before taking this measurement? I've been using a hand-held pH probe (which is supposed to be temperature compensated), which I just stick into the mash. Am I getting a correct measurement without cooling a sample of the mash?

Thanks

Steve Zabarnick

> <2. When calculating my extraction efficiency, do I use the gravity of  
> the wort fresh from the tun or after the boil?  
>  
> after.

It doesn't matter when you try to calculate the efficiency; all you have to do is measure gravity and volume /at the same time/. Consider, for example, a wort that is 7 gallons at 1.050 when you quit sparging, and 5 gallons and 1.070 when you stop boiling; regardless of the number of pounds of grain you used, the efficiencies calculated from these two sets of #'s will be the same.

It may be easier to measure gravity after you've boiled and cooled the wort; I've never seen a table correcting for temperature above ~100F, so you'd probably have to cool the runoff before measuring. (I'm not even sure such a table would be correct for all plausible concentrations of wort; the effect of temperature on the density of pure water is very well mapped but I couldn't swear this would be valid for water/sugar solutions at more extreme temperatures.)

An interesting comparison, seeing as how Belgian Wit (White) beer is not related to Bavarian Weizen as far as I know, except for the fact that they both use wheat.

Belgian Wit traditionally uses 30-40% unmalted wheat and is spiced with Curacao oranges and corriander. Bavarian Weizen uses 60-70% malted wheat, and no spices, but gets its characteristic "spiciness" (often reminiscent of cloves) from esters produced by special strains of yeast. By comparison, an "American Wheat" beer typically has 40-50% wheat malt as its only distinguishing feature from an American pale ale.

Ahem... the Grand Cru is good as well, but I don't think it bears much relationship to a true lambic. I vaguely remember hearing someone say that Pierre Celis does add some sort of souring bug (a *Pediococcus*, perhaps?) to both the White and the Grand Cru, but one bug does not a lambic make.

Which leads me to my last topic...

> A close friend, and business associate is going to Brussels for a week, and  
> asks what beers to bring back for me? If you could select three or four,  
> what would they be?

A very tough call. If you like the sour stuff, I recommend either the Cantillon or Boon lambics. My favorite trappist-style beers are Rochefort dubbel and Westmalle trippel. Try a bottle of Kwak Pauvel(sp?) for an example of a good Belgian ale that defines its own category.

If only you could bring back a pitcher of young lambic from Becasse!

Subject: Hot liquor tanks & slants

In the last digest:

<From: gummitch@techbook.com (Jeff Frane)  
Subject: Re: Hot Water Heaters

<It beats me why this should be a problem. Jim is simply suggesting  
<using a hot water heater to provide very hot water for mashing,  
<sparging, etc. Why should this be a chlorine problem?

<In answer to Jim's question, at least one of the McMenamin brewpubs in  
<Oregon uses exactly this system -- lots of pipes running out of that  
<water heater that aren't standard!

<Jack, every hot liquor (water) system I've seen in a brewery is closed.

I agree in principal that chlorine is a nonissue. A lot of big breweries  
dont do anything to remove chlorine (big = 25 BBl in this sense). The  
argument is that the chlorine is driven off in the kettle anyway. The  
only relevent issue to me is solids/heavy metals etc. I like to remove  
this "junk" prior to mashing. I can see a issue with build up of salts  
in a hot water tank, but at one brew every 3 weeks or so I am not  
concerned.

The hot liquor tanks I am familiar with have a vent tube that overflows  
when the tan k is full. As the water heats this drives some water out  
of the tube and the brewer shuts off the inlet valve feeding the tank.  
My only decision here is the rebound time for a tank to reheat to 180F.  
For this reason, I think I am going to put in a propane fired tank with a  
high temp thermostat.

JS writes:

what do you expect

from a for-profit company like BT? At the moment, BT can survive on  
fewer

Is it true that BT is for profit?? I wonder how "profitable" this kind  
of  
thing is. I bet its like brewing, a lot of sweat equity in every issue/  
batch.

<sounds like you have re-invented the EASYSPARGER.

I dont know if a on demand hot water heater would be capable of providing  
26 gallons of 180F water in a 30 minute time frame. This is my  
requirement.

In Namur, Belgium , I witnessed such a beast. It fed a SS tank that had  
another direct fired burner to boost/maintain the temp. The brewer would  
"ladel" the water over the grains and use a bit spoon/paddle to stir the  
lauter.

JS:

<snip on general useful points of culturing, sounds like the instruction  
manuel  
from the Yeast Culture Kit Co.....

<You would be much better off to transfer the petri culture to slants and use these to start your starter. I cover the slant with wort and use this as a one time, pure culture starter.

This is not what's referred to as a "slant". The first sentence is correct. The second sentence is a technique of preparing a starter. Covering the slant is not a good idea in my opinion. You cover a small sample of yeast with wort, the slant is where the yeast is maintained and cultured from. The difference is a slant has agar with yeast growing on it. A starter has no agar.

Good brewing,  
Jim Busch

Date: 29 Jul 1993 11:23:15 -0600 (CST)  
From: RBSWEENEY@msuvx2.memst.edu  
Subject: wort aeration

Many people have mentioned the use of an airstone connected to an aquarium pump for wort aeration and this is the system I have been using for my last 5 batches with great results. I have seen vigorous fermentations started in less than 3 hours after running the pump continuously for an hour after racking into the primary and pitching. One way my little system from the way most of these setups have been described (for example Dave Miller's book Brewing the World's Great Beers) is that I don't use any type of air filter on the hose between the airstone and pump. I do sanitize everything but the pump using a Iodophor solution and have not had any infection problems.

I did not include an air filter for two reasons: cost and the fact that all the other aeration methods I am familiar with don't go to trouble of air filtering so why should I? I'm not worried, but I was wondering if anyone else uses a similar system, and if so, why they chose to include or not to include air filtration. Email comments would be appreciated and interesting results can be forwarded to the digest.

Thanks in advance,

Bob Sweeney

Date: Thu, 29 Jul 93 12:45:04 EDT  
From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: diacetyl rest, head retention

Hi All,

In HBD#1191, Jim Busch writes:

>Its called a diacetyl rest. It reduces (guess what??) diacetyl. To be  
>an authentic contential lager, ferment at 48-51F for 1 week, drop temp  
    ^^^^  
>2F per day until it is 42F. Rest here 2-4 days (diacetyl rest)

>Those who  
>"bring up" the temp are preeching the American fast lager approach. This  
>is where ferments are done quite warm (up to 60F)

I'm a little confused here. I don't ferment lagers warm, 48F-50F, and I've always used the Noonan method of raising the temperature for the diacetyl rest (~55F for 2 days), with good results. Can you clarify this point, Jim?

\*\*\*\*\*

In HBD#1192, Keith A. MacNeal writes:

>If you are doing a partial boil and dumping the hot wort into cold water  
>you probably don't have to worry too much about aeration

If you are doing a partial boil and dumping the hot wort into cold water you have to worry very much about oxidation. Splashing \*hot\* wort around causes oxidation reactions, which both darken the wort and produce off flavors in the finished beer. \*Chill\* the wort below 80F first before aeration. In the absence of high temperature, the oxygen remains in it's free form, and can be utilized by the yeast during it's reproductive stage.

From reading this forum and r.c.b, it's clear that this distinction between oxidation and aeration is confusing to a lot of brewers. I'm aware that this practice of adding hot wort to cold water is recommended in a certain popular book on homebrewing. IMHO, this is just one of several pieces of horrible advice contained in said book, and why I recommend to beginners that they get the "other" book written by the less relaxed, more worried guy.

>Pouring the hot wort through a sanitized strainer  
>will also aerate it (as well as help remove hops and break material).

I used this method routinely when I did partial boils, pouring my 2 gallons of \*chilled\* wort through a sanitized strainer. As Keith mentions, it is an effective way to aerate the wort, and does filter hops and trub well.

\*\*\*\*\*

Also in HBD#1192, Lee Menegoni writes:

>Re: Extract efficiency - I was under the impression that measuring the  
pre and  
>post boil extract efficiency would result in unequal values. That the  
post  
>boil value would be lower due to the precipitation of break materials.  
>Has any one measured this? Do they differ? By how much?

I compute extract efficiency after the sparge, and take an OG reading  
after the boil, and I have found that the post boil number is always  
slightly lower, adjusting for volume of course. My brewpot has  
graduation  
marks on the inside in one gallon increments, which allows me to  
"eyeball"  
the finished volume within a quart or so. It's \*possible\* that what I  
have  
observed is nothing more than measurement error, since one quart as a  
percentage of five gallons is larger than the observed difference in  
gravity  
readings. However, if that were so, I would have had cases where the  
second reading was higher than the first, but that has never happened.  
Intuitively, I believe the post boil value is lower due to the  
precipitation  
of break materials. The hydrometer, after all, simply measures SG - I  
don't  
think it can distinguish between sugars and soluble proteins. Comments?  
All that said, the differences I have measured are sufficiently small  
that  
they can be ignored, with respect to getting an OG that's within range  
for  
the style.

\*\*\*\*\*

Chris Pencis writes about head retention:

>I seem to be having trouble with head retention in all of my beers  
>I wash the glasses  
>in the dishwasher with Cascade detergent

I wash my beer glasses in the dishwasher with Cascade as well. Many  
commercial dishwashing soaps have something in them that prevents  
spotting, but which leave a film. I suspect that is your trouble. I  
keep  
a bucket of BBrite under the kitchen sink, rinse the glasses in that,  
then  
rinse well with warm water. The glasses feel different after this, and  
I get good head retention with my beers.

Cheers,  
Jim

From: sims@pdesds1.scra.org (Jim Sims)  
Subject: [fwd: DIXIE CUP 1993 Announcement (long)]

ANNOUNCING  
THE 10th ANNUAL  
DIXIE CUP  
HOMEBREW COMPETITION

Yes, folks, it's that time of year again.  
And if you didn't notice, the Houston Foam Rangers  
are trying to get off their backsides and actually  
get this thing organized early this year!

The 1993 Dixie Cup will be held October 15 and 16  
at the Houston Holiday Inn West.

The official Dixie Cup Entry stuff can be requested  
from the folks at DeFalco's Home Wine and Beer Supplies  
5611 Morningside, Houston, TX 77098 (713) 532-8154.  
The contents of the official stuff takes precedence  
over anything in this post (in case I goof).

ELIGIBILITY

Anyone can enter, the competition is open to all non-commercial,  
home-produced beers. Beers produced on the premises of a  
commercial brewery are not eligible. You may enter as often as  
you wish, but only two entries per category/subcategory per  
person please.

ENTRY REQUIREMENTS

Each entry shall consist of 3 bottles, preferable 11-12 oz.  
All labels must be removed, but caps don't have to be blacked  
out. An entry label must be attached to each bottle of the  
entry, with all information required on the form filled in.  
(Actually, all we need is you name, a telephone no., full snail  
mail address, category abbreviation, club affiliation, and  
any special ingredients or deviant style info, so you could  
type this up yourself and forgo the "official" form)  
PLEASE USE RUBBER BANDS TO ATTACH THE FORM TO THE BOTTLE.  
A complete recipe form should accompany each entry. (We want to  
print the recipes later in the newsletter, if you win. You  
can always give it to us after you get a ribbon).

ENTRY DEADLINE/FEEES

Entries, paperwork and cash moola must be in the hands of the  
staid employees of DeFalco's Home Whine & Beer Supplies no  
later than 4PM, SATURDAY, 9 OCTOBER. The Fee is \$6.00 before  
1 October, \$7.00 after. A \$1.00 discount is given to club  
members. (Start your own club?) DeFlaco's address is  
5611 Morningside, Houston, TX 77005. Phone: (713) 523-8154  
FAX: (713) 523-5284.  
NO ENTRIES WILL BE ACCEPTED AFTER 9 OCTOBER!

PACKING/SHIPPING

It is suggested that each bottle be wrapped in bubble pack or  
newspaper. Place one entry (3 bottles) in a small box and  
fill with paper or other packing mat'l. Line a bigger box  
with a

plastic bag and put all smaller boxes in it. Pack the smaller boxes into the big box with paper or packing mat'l. Tie the bag, and seal the box securely. Label the box FRAGILE and THIS END UP appropriately. We suggest that you ship via UPS, if they ask tell them it's bottles, but they're well packed. Try labelling the box KITCHEN SUPPLIES.

WE SUGGEST THAT YOU SEND YOUR ENTRIES ASAP, BEERS THAT ARRIVE EARLIER SEEM TO DO BETTER IN COMPETITION.

#### JUDGING

Judging will take place in three open sessions 15 & 16 October. The first round will be Friday night, the second round and best of show judging will be Saturday afternoon.

WE NEED JUDGES! We expect approx. 650 entries, and need help getting the work done. The competition is AHA/HWBTA recognized, and we'll get you as many BJCP points as is humanly possible for this gig (1 for judging, etc.).

#### AWARDS

THE DIXIE CUP TROPHY is awarded to the club that garners the most points on the following basis: 1st in category - 3 pts. 2nd in cat. - 2 pts., 3rd in cat. - 1 pt.

CLUB QUALITY AWARDS are given to the clubs with the top five scores (I've never understood how this works) in the preliminary round. The awards are sponsored by

Crosby and Baker, and consist of gift certificates redeemable at any homebrew shop that does business with Crosby&Baker.

1st place \$50, 2nd place \$35, 3rd place \$15.

#### INDIVIDUAL AWARDS

1st place - A magnificent stein and a swell ribbon

2nd place - A nifty ribbon

3rd place - A nice ribbon

#### BEST OF SHOW

Best Beer overall - Super Deluxe Pedestal for your stein

Best All Grain - Deluxe Stein

Best Extract - Deluxe Stein

Best Mead - Deluxe Stein

MIKE TEMPLETON AWARD given in memory of one of the original Foam Rangers, the is awarded to the individual who collects the most points using the same scale as the Gulf Coast Homebrewer of the Year.

GULF COAST HOMEBREWER OF THE YEAR is awarded to the brewer who accumulates the most points in the Dallas/Fort Worth Bluebonnet Brew-off, the New Orleans Crescent City Challenge, the Orlando Sunshine Challenge, and the Dixie Cup. Points are awarded as follows: 3 pts. for 1st place in a category, 2 pts. for a 2nd place, and 1 pt. for a 3rd place. The Dixie Cup is the last competition of the series, and the winner will be announced at the Dixie Cup.

CATEGORIES (abbreviations for labels given in parens)

#### I. LAGERS

##### LIGHT/PALE LAGERS

1. American Light (AL)

Continental Lights

2a. Pilsner (CLP)

2b. Munich Helles (CLM)

2c. Dortmund Export (CLD)

#### AMBER LAGERS

3. Oktoberfest/Marzen/Vienna (OV)

4. Steam Beer (SM)

DARK LAGERS

- 5. Continental Dark (CD)
- SPECIAL STYLE LAGERS
- 6a. Traditional Dark Bock (BKD)
- 6b. Light Helles Bock (BKL)
- 7. Strong Lagers (SL)

II. ALES

LIGHT&AMBER ALES

- 8a. Alt Beers (GAA)
- 8b. Kolsch Beers (GAK)
- 9. Light Ale (LA)
- 10a. Classic Pale Ale (CPA)
- 10b. India Pale Ale (IPA)
- 10c. American Pale Ale (APA)

DARK ALES

- 11. Brown Ales and Milds (BAM)
- 12. California/Texas Brown Ales (CTB)
- 13a. Traditional Porter(POT)
- 13b. East Coast Porter(POE)
- 14. Sweet Stout (SS)
- 15. Dry Stout (DS)

OTHER ALES

- 16a. Old Ales (SAO)
- 16b. Barley Wines (SAB)
- 16c. Imperial Stouts (SAI)
- 16d. Trappist Ales (SAT)
- 16e. Strong Scotch Ales (SAS)
- 17a. Light German Wheat Beers (WLG)
- 17b. Light American Wheat (WLA)
- 17c. Amber and Dark Wheat Beers (WBD)

III. UNUSUAL BEER STYLES

- 18. Novelty Beers
- 19. Fruit Beers
- 20. Specialty Beers

IV. MEAD

Meads will be judged as Traditional or Flavored

- 21. Still Meads (MST)
- 22. Sparkling Meads (MSP) note -this was left off the mail-out thing!

Descriptions of the beer styles can be found in the official stuff.

Please enter early and often!

all.  
> Any ideas....is this paranoia?

Many dishwasher detergents have "sheeting action" or some such, which is designed to reduce the drip spots on your glassware. This stuff is indeed a surfactant which will kill your head retention. I find in many cases I can smell the stuff on the glasses, and they have a really squeaky-clean feel which gives me the heeby-jeebies. I suggest you either hand wash your beer glasses or get a detergent (or soap) that does not have a surfactant. You may have to wipe a few drip spots off your glasses, but your beer is worth it.

Date: Thu, 29 Jul 93 12:12 CDT  
From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: 6 Row Barley Malt

Someone recently posted some comments about megas using adjuncts to cover up the foul taste of 6 row barley malt. I presumed this was a joke until I looked over the grain bill of my last two batches which have a very peculiar taste. Turns out, about 1/3 of the base malt in these batches was 6 row.

Not accepting anecdotal evidence as proof, I set up a set of experiments to find the source of the off taste. Just so happens that I also doughed in both batches the night before mashing so I had two possible causes to deal with. I set up the following experiments with my 500 ml pilot brewery:

#1 100 gr Belgian Munich, doughed in at 10PM. Mashed in the morning, sparged to 700 ml and boiled 60 min with .5 gr Chinook hops to 500 ml. Pitched with PU yeast after cooling to room temp and moved to fridge at 40F after 12 hours.

#2 Same as #1 except that mashing immediately followed doughin.

#3 Same as #1 except used 6 row malt from Minn Malting.

#4 Same as #2 except used 6 row malt from Minn Malting.

Results:

#3 and #4 had the off-taste I noted in the full batches using 6 row malt and #1 and #2 were clean. The samples were tasted every 24 hours for five days and nothing changed other than a reduction in sweetness. The off-taste remained in the 6 row beers.

Not sure how to describe the off-taste but it is quite strong though not necessarily unpleasant in the full batches but quite overpowering in the samples which were all 6 row malt. I would incline to call it sort of a rancid taste.

The good news is that the overnight doughin on the Belgian Munich samples had a very positive effect on the beer. It had far more malty flavor and seemed richer and fuller in body. Doughin the night before fits my lifestyle and I am now confident that the only affect is to improve the beer so I will make it SOP for all future batches.

The effect on the 6 row samples was to just increase the level of the off taste and it even seemed to produce a rather foul odor.

I suppose it is possible that I got a bad batch of malt but I really doubt it as I have had extensive experience with Minn Malting and the malt tastes fine on "chew-in".

>From: gummitch@techbook.com (Jeff Frane)  
>Subject: Re: Hot Water Heaters

>Jack, every hot liquor (water) system I've seen in a brewery is closed. Perhaps it is something they should look into.

>It beats me why this should be a problem. Jim is simply suggesting using a hot water heater to provide very hot water for mashing, sparging, etc. Why should this be a chlorine problem?

Could, not should.

>In answer to Jim's question, at least one of the McMenamin brewpubs in Oregon uses exactly this system -- lots of pipes running out of that water heater that aren't standard!

My guess is that those non-standard pipes are part of the solution.

I simply pointed out that, without venting, the water coming out will contain exactly the same volatiles as the water going in. So if removing chlorine is necessary to the process, than some other means is necessary if the tank is not vented.

I did not mean to imply that a hot water tank could/should not be used. Just a data point for those contemplating same.

>From: Jeff Benjamin <benji@hpfcbg.fc.hp.com>  
>Subject: Bud bashing

>I would also challenge many skeptical homebrewers to brew a lager as light and clean as a Bud. Ingredients are quite different from your average homebrew (uncured malt, adjuncts, etc.), you need techniques to minimize wort darkening and esters, and sanitation is paramount, as the slightest off flavor or aroma will be noticeable.

It is not difficult at all to make lite colored beer if you dilute it with enough water. The most important adjunct to maintain "Bud quality" is corn syrup. This exotic ingredient produces as much alcohol as needed to compensate for water dilution at the end and contributes no color. Virtually every characteristic and lack thereof in Bud can be explained by this simple expedient.

From: LLAPV@utxdp.dp.utexas.edu  
Subject: stuff

Howdy,

The following four issues were brought up in HBD 1192.

Chris Pencis is worried about his glassware. Soap & detergent are no-no's for beer glassware, unless you can rinse it off very well with very hot water. I can tell a difference between my glasses at home that have been washed out with soap & water & those that have been washed with hot water. Also, chilling the glasses supposedly prevents a nice head, but I haven't been able to tell too much of a difference. If you are particularly worried about cleanliness, a quick dunk in chlorine water should take care of any little bugs.

Also, Chris is wondering when to put the spices in his Christmas ale. I made one last year, & I boiled my spices (fresh ginger root, grated orange zest, dried nutmeg, & a cinnamon stick) in a nylon bag with the extract. I was very happy with it.

John Palmer brings up the issue of homebrew as a laxative. While I personally have not had that problem, I have talked to people who tried other people's homebrews & complained that it gave them the runs. It's almost always folks who have never had homebrew before, I've noticed. Maybe it's an overdose of vitamin B12, but I haven't the slightest.

Michael Fetzter gives a review of Celis Grand Cru. Celis Grand Cru IS a true Belgian beer, brewed right here in America. Pieter Celis brewed beer originally in Belgium, including the very same beer that he now calls Grand Cru (it was Hoegaarden Grand Cru in Europe). I think you may be noticing a difference because it's good, fresh beer & not something that went across on ocean on a boat, sat in a warehouse in New York, sat in another warehouse in your hometown, then sat on a shelf for two months because people were afraid to try it. (Whew.) By the way, it is brewed with Curacao orange peels & a "secret" ingredient, & has a alcohol content of ~7%, all which give it the interesting flavor you probably noticed.

Happy brewing,

Alan, Austin

From: ron\_hall%80@hp6400.desk.hp.com  
Subject: Cheap Kegs?

I have been searching for a cheap source of Cornelius kegs. I noticed in the classified ads of the Celebrator, Brewing Techniques, and maybe Zymurgy an ad for used pin lock kegs for \$17 + shipping and used ball fitting kegs for \$22 + shipping from The Beverage Co., Anderson, CA. Has anyone ordered or seen any of these? Are they really beat up? Have they been leak checked? The price seems too good to be true.

Please reply off-line unless it seems of general interest.  
Thanks in advance.

Date: Thu, 29 Jul 93 15:32:09 -0400  
From: polstra!larryba@uunet.UU.NET  
Subject: Re: inoculating a starter from a petri dish

In HBD# 1191, "atzeiner" writes:

>I just started culturing yeast and have two ale yeast cultures in petri  
>dishes. Out of curiosity, I used my innoculating loop to scrape up a  
>glob of  
>yeast and put it into a starter bottle(~1/2 full 12 oz. beer bottle). I  
didnt  
>really see much sign of fermentation, but after about 3 or 4 hours I  
looked at  
>it and it seemed to have yeast sediment in it. I was wondering if it  
was  
>possible that there was enough yeasties in the glob that I picked up to  
make a  
>decent starter in only a few hours. How much yeast should you pick up  
to  
>inoculate a 6 or 7 oz starter??  
>

Depending upon the size of the glob it is entirely reasonable that you  
see  
sediment pretty quickly. At room temp yeast doubles roughly every three  
hours. I would guess that your 6oz of wort will start fermenting pretty  
strongly after about three days.

Usually I start with around 30ml of wort and put my glob o yeast  
(from the slant, but occasionally from a plate) in it three days before  
brewing. Within 8 hours the wort is turbid and some sediment is showing.  
Usually between 24-48 hours the 20ml is actively bubbling and I can raise  
a head by swirling. Then I pitch into 150ml and twelve hours later I  
pitch into my main starter, 500ml. I try to time the final pitch the  
evening  
before brewing. If things are going too fast I just let the 180ml (150 +  
30)  
sit and ferment out. Usually once the 30 ml is going it only takes 12  
hours  
(at room temp) to get the next size going.

Another important point to remember is to aerate your growth medium a  
lot.  
This is important for yeast growth. I do this by pouring the media +  
yeast  
back and fourth between two sterile ball jars (I bake at 350 for a half  
hour  
to sterilize - cover with aluminum foil).

Oh, on last tidbit: I use reclaimed wort from my hot break/hops and  
dilute  
with water to roughly 1.020-25 before canning in ball jars (process for  
20-30 minutes in boiling water). Although the experts claimn that boil  
process for 20 minutes doesn't sterilize the media I have never \*ever\*  
had any hopped wort go bad, even stuff stored for over a year at room  
temp.

Date: Thu, 29 Jul 93 14:11:19 MDT  
From: npyle@n33.stortek.com  
Subject: Pale Ale Recipe

There was sufficient reponse to post the recipe so here 'tis:

PYLE STYLE PALE ALE  
(an American Pale Ale ala Sierra Nevada Pale Ale)

Brewed 7/10/93  
Recipe for 5 US gallons (after losses)

5.00 lb American pale malt from Briess  
4.00 lb English pale malt from Hugh Baird  
0.75 lb Belgian crystal malt from ???

1.00 oz Mt. Hood pellets (a=3.9)  
2.00 oz Cascade pellets (a=5.1)  
0.60 oz Cascade leaf hops (a=5.6)\*  
\*from Mark Nightingale's garden 1992 crop

1056 Wyeast American Ale yeast dated 6/23/93\*  
\*made a one quart starter 24 hours in advance

1.00 tsp Irish moss (added in last 10 minutes of boil)  
0.75 c corn sugar for bottling

Mash water was 9 qts of 168F water poured into a room temperature 48 qt rectangular cooler mash/lauter tun. Doughed in pale malts only. Mash-in temperature was 150F after stabilizing. Mashed at 145-155 (added 1 qt of 180F water when temp dropped to 145F). Conversion complete in one hour. Crystal was added at mash-out. Dumped 20 qts of 180F water into tun and stirred (mashout and batch sparge in one step). Sparge was very slow, nearly stuck twice, so I back flushed the copper manifold to loosen it up (need to adjust my grainmill!). Start of boil, the volume was around 32 qts. Boiled down to 22 qts. at 1.045.  
Points of extract = (45pts. \* 5.5 gal.) / 9.75 lbs. = 25 pts/lb/gal.

Hopping schedule:

60 min: 0.50 oz MH IBU = 8.3  
30 0.50 MH 4.5  
0.50 Cp 5.8  
10 0.50 Cp 2.5  
dry 0.50 Cl 1.0 (leave on for 10 days)

-----  
Approximate Total IBU = 22.1 (Balanced beer at 1.045 = 20 IBU)

A note about hopping: I was attempting to get most of my IBUs later in the boil to reduce some back of the tongue bitterness. I wanted this to be a hop flavored beer, rather than just have bitterness to balance the malt. On most beers I try for 50-60% of the bitterness at the 60 minute addition, but as you can see, I did not do that here. I achieved my goal I think (see tasting notes).

Full fermentation in 12 hours, high krauesen in 36 hours. Dry hops were just thrown on top of beer in secondary.

7/14/93 Racked to secondary and added dry hops, SG = 1.010 (after 4 days)  
7/24/93 Bottled FG = 1.008 (after 14 days)  
7/27/93 Tasting notes (I like my beer fresh!)  
- About 50% carbonated

- Hops! Cascades are all over the place, mostly aroma. This is not a bitter beer, but is loaded with aroma. I expect some of this to fade with time, bringing out the malt. At this point, the hops dominate, which I expected.

- Very clean tasting, very little esters
- Still a bit cloudy (need more patience)
- Color is pale, about like a Sierra Nevada (the lightest colored brew I've ever brewed)

- This is a keeper. It is rare for me to brew a recipe more than once, but this one will happen again. This is only the second in 16 batches that I vow to repeat. Enter it in a contest? Hah! I wouldn't waste 3 bottles of this on Michael Jackson...

Enjoy!

From: Stephen Brent Peters <sp2q+@andrew.cmu.edu>  
Subject: Brewery Addresses.

Does anyone know of a publication I could look up that would list mailing addresses for breweries in CA, OR, & WA?

I'm sad to report that Zima seems to be selling well in Pgh. Several people I know think it's the greatest thing ever. After all, lots of people don't like the taste of (commercial) beer, and Zima doesn't taste like beer. It tastes like a bad mixed drink. I expect they will do well for a while, then probably people will get bored with it's zippy image and it will dissapear.

Date: Thu, 29 Jul 93 14:36:37 PDT  
From: tpm@wdl.loral.com (Tim P McNerney)  
Subject: Re: inoculating a starter from a petri dish

My biggest problem with inoculating a starter from a petri dish is that I don't want to go through 5 different sized, sanitized starters to build up enough yeast. I tried inoculating a few ml of wort in a 1 liter flask, but did not see the activity I was used to with 10 ml testtubes. I got the testtubes with presterilized wort from the Yeast Kit Culture Company (along with 50 ml testtubes) and these worked great. So my questions are:

1. Did the fact the the wort in the flask was so shallow cause problems with yeast growth or just with the visible effects?
2. Since I only tried this once, did I just mess up this one inoculation?
3. How do other people build up a healthy sized started with spending half their life preparing storage vessels?

From: ulrich@sfu.ca

**Subject: Frisia**

The last week or two there has been much discussion of Frisia (under a variety of correct and incorrect spellings), so I checked it out.

Friesland

is a province of the Netherlands. Ostfriesland (East F.) and Nordfriesland

(North F.) are in Germany. The Frisian Islands are divided among the Netherlands, Germany, and Denmark. The Frisian language (or Friesisch, as they call it) is more closely related to English than either is to Dutch or

German. It is largely being replaced by Dutch (in the Netherlands) and German (in Germany).

Charles Ulrich (linguist by trade, brewer by nature)

And now back to beer...

End of HOMEBREW Digest #1193, 07/30/93

\*\*\*\*\*

-----

Date: Fri, 30 Jul 1993 13:25:34 +0930  
From: Murray Robinson <robinm@mr.dsto.gov.au>  
Subject: Possible solution to commercial posts ?

After reading the discussions about whether or not commercial posts should be allowed on the Homebrew Digest I checked up on an automatic mailer package that may hold one solution to the problem.

Mail-Net (automatic mailing list handling software) allows users to subscribe to different "channels" of the same news group. For example, the HBD could have a "commercial" and "non-commercial" channel. When users subscribe to the newsgroup they would specify which channel they wish to receive and when posting articles they would specify which channel the article should go to. Non-commercial submissions would appear on both channels of the HBD whereas commercial submissions would only appear on the commercial channel of the HBD.

eg If I wanted to receive both commercial and non commercial postings of the HBD I would subscribe to the HBD with the following keyword in either the header or first line of the message: "X-Mn-Key: commercial"

Then if I wanted to post a non commercial submission I would specify the subject in the header as usual and put the keyword "X-Mn-Key: non-commercial" in the first line of my message. Similarly if I wanted to post what would be deemed to be a commercial submission I would specify "X-Mn-Key: commercial" in the first line of the message.

This approach obviously doesn't solve the fundamental differences of opinion about the content of the HBD but it does offer some freedom from commercial posts if that is what you want. Ofcourse the whole system falls down if the keyword "X-Mn-Key: commercial" is not put on the first line of commercial posts.

Food for thought anyway.

Cheers,  
Murray.

From: Sean C. Lamb 335-6669 Loral <slamb@milp.jsc.nasa.gov>  
Subject: Dixie Cup 1993 (long)

ANNOUNCING  
THE 10th ANNUAL  
DIXIE CUP  
HOMEBREW COMPETITION

Yes, folks, it's that time of year again.  
And if you didn't notice, the Houston Foam Rangers  
are trying to get off their backsides and actually  
get this thing organized early this year!

The 1993 Dixie Cup will be held October 15 and 16  
at the Houston Holiday Inn West.

The official Dixie Cup Entry stuff can be requested  
from the folks at  
DeFalco's Home Wine and Beer Supplies  
5611 Morningside, Houston, TX 77098 (713) 532-8154.  
The contents of the official stuff takes precedence  
over anything in this post (in case I goof).

ELIGIBILITY

Anyone can enter, the competition is open to all  
non-commercial, home-produced beers.  
Beers produced on the premises of a commercial  
brewery are not eligible. You may enter as often  
as you wish, but only two entries per  
category/subcategory per person please.

ENTRY REQUIREMENTS

Each entry shall consist of 3 bottles, preferably  
11-12 oz. All labels must be removed,  
but caps don't have to be blacked out.  
An entry label must be attached to each bottle  
of the entry, with all information  
required on the form filled in.  
(Actually, all we need is your name, a telephone no.,  
full snail mail address, category abbreviation,  
club affiliation, and any special ingredients or  
deviant style info, so you could type this up  
yourself and forgo the "official" form)  
PLEASE USE RUBBER BANDS TO  
ATTACH THE FORM TO THE BOTTLE.  
A complete recipe form should accompany each entry.  
(We want to print the recipes later in the  
newsletter, if you win. You can always give  
it to us after you get a ribbon).

ENTRY DEADLINE/FEEES

Entries, paperwork and cash moola must be in  
the hands of the staid employees of  
DeFalco's Home Whine & Beer Supplies no  
later than 4PM, SATURDAY, 9 OCTOBER.  
The Fee is \$6.00 before 1 October, \$7.00 after.  
A \$1.00 discount is given to club  
members. (Start your own club?)  
DeFlaco's address is

5611 Morningside, Houston, TX 77005.  
Phone: (713) 523-8154  
FAX: (713) 523-5284.  
NO ENTRIES WILL BE ACCEPTED AFTER 9 OCTOBER!

#### PACKING/SHIPPING

It is suggested that each bottle be wrapped in bubble pack or newspaper. Place one entry (3 bottles) in a small box and fill with paper or other packing mat'l. Line a bigger box with a plastic bag and put all smaller boxes in it. Pack the smaller boxes into the big box with paper or packing mat'l. Tie the bag, and seal the box securely. Label the box FRAGILE and THIS END UP appropriately. We suggest that you ship via UPS, if they ask tell them it's bottles, but they're well packed. Try labelling the box KITCHEN SUPPLIES.

WE SUGGEST THAT YOU SEND YOUR ENTRIES ASAP, BEERS THAT ARRIVE EARLIER SEEM TO DO BETTER IN COMPETITION.

#### JUDGING

Judging will take place in three open sessions 15 & 16 October. The first round will be Friday night, the second round and best of show judging will be Saturday afternoon.

WE NEED JUDGES! We expect approx. 650 entries, and need help getting the work done. The competition is AHA/HWBTA recognized, and we'll get you as many BJCP points as is humanly possible for this gig (1 for judging, etc.).

#### AWARDS

THE DIXIE CUP TROPHY is awarded to the club that garners the most points on the following basis:

1st in category - 3 pts.  
2nd in cat. - 2 pts.,  
3rd in cat. - 1 pt.

CLUB QUALITY AWARDS are given to the clubs with the top five scores

(I've never understood how this works) in the preliminary round. The awards are sponsored by Crosby and Baker, and consist of gift certificates redeemable at any homebrew shop that does business with Crosby&Baker. 1st place \$50, 2nd place \$35, 3rd place \$15.

INDIVIDUAL AWARDS for each category

1st place - A magnificent stein  
and a swell ribbon

Best Mead - Deluxe Stein

MIKE TEMPLETON AWARD given in memory of  
one of the original Foam Rangers, it is

awarded to the individual who collects the most points at the Dixie Cup using the same rules as the Gulf Coast Homebrewer of the Year.

GULF COAST HOMEBREWER OF THE YEAR is awarded to the brewer who accumulates the most points in the Dallas/Fort Worth Bluebonnet Brew-off, the New Orleans Crescent City Challenge, the Orlando Sunshine Challenge, and the Dixie Cup.

Points are awarded as follows:

3 pt.s for 1st place in a category,  
2 pts. for a 2nd place,  
and 1 pt. for a 3rd place.

The Dixie Cup is the last competition of the series, and the winner will be announced at the Dixie Cup.

#### CATEGORIES

(abbreviations for labels given in parens)

##### I. LAGERS

###### LIGHT/PALE LAGERS

1. American Light (AL)

Continental Lights

2a. Pilsner (CLP)

2b. Munich Helles (CLM)

2c. Dortmund Export (CLD)

###### AMBER LAGERS

3. Oktoberfest/Marzen/Vienna (OV)

4. Steam Beer (SM)

###### DARK LAGERS

5. Continental Dark (CD)

###### SPECIAL STYLE LAGERS

6a. Traditional Dark Bock (BKD)

6b. Light Helles Bock (BKL)

7. Strong Lagers (SL)

##### II. ALES

###### LIGHT&AMBER ALES

8a. Alt Beers (GAA)

8b. Kolsch Beers (GAK)

9. Light Ale (LA)

10a. Classic Pale Ale (CPA)

10b. India Pale Ale (IPA)

10c. American Pale Ale (APA)

###### DARK ALES

11. Brown Ales and Milds (BAM)

12. California/Texas Brown Ales (CTB)

13a. Traditional Porter(POT)

13b. East Coast Porter(POE)

14. Sweet Stout (SS)

15. Dry Stout (DS)

###### OTHER ALES

16a. Old Ales (SAO)

16b. Barley Wines (SAB)

16c. Imperial Stouts (SAI)

16d. Trappist Ales (SAT)

16e. Strong Scotch Ales (SAS)

17a. Light German Wheat Beers (WLG)

17b. Light American Wheat (WLA)

17c. Amber and Dark Wheat Beers (WBD)

##### III. UNUSUAL BEER STYLES

18. Novelty Beers

ANNOUNCING  
THE 10th ANNUAL  
DIXIE CUP  
HOMEBREW COMPETITION

Yes, folks, it's that time of year again.  
And if you didn't notice, the Houston Foam  
Rangers are trying to get off their backsides  
and actually get this thing organized  
early this year!

The 1993 Dixie Cup will be held  
October 15 and 16 at the  
Holiday Inn Houston West.

The official Dixie Cup Entry stuff can  
be requested from the folks at  
DeFalco's Home Wine and Beer Supplies  
5611 Morningside, Houston, TX 77098  
(713) 532-8154.  
The contents of the official stuff  
takes precedence over anything in this  
post (in case I goof).

ATTENDING THE DIXIE CUP

HOTEL RESERVATIONS can be had by calling the  
Holiday Inn 800 number (don't have it with me)  
or by calling the Holiday Inn Houston West  
directly at (713) 558-5580. The rate is \$52  
per room per night, and don't forget  
to ask for the Dixie Cup rate, and mention  
the quoted rate. The address of the hotel  
is 14703 Park Row, it is on the north side  
of Interstate 10 at the junction of Highway 6  
on the far west side of Houston.

SCHEDULE OF EVENTS

Friday, 15 October  
1200-1700 Set-up, call DeFalco's to help  
1745 sharp Assembly of first round judges  
1800-1830 Judge and Steward orientation  
1830-2230 1st round judging  
2230-2315 Potluck dinner  
2315-2400 Fred Eckhardt Epicurean  
Extravaganza

Saturday, 16 October  
0830-1130 Milli-Conference and Breakfast  
(\$12) or BJCP EXAM (\$40)  
1130-1200 Lunch (Free for judges/stewards  
otherwise \$5)  
1200-1400 2nd round judging  
1400-2000 Pub Crawl/Microbrew Tasting/  
Jambalaya Feast  
2200-2400 Awards Ceremony

Sunday, 17 October  
1200 - ? World's Fastest Hombrewer  
Competition

FRED ECKHARDT EPICUREAN EXTRAVAGANZA  
THIS year we return to the original sin:  
Beer and Chocolate!

MILLI-CONFERENCE

Presentations by George Fix,  
Paul Farnsworth and  
Pierre Celis

\$12, including breakfast buffet

PUB CRAWL/MICRO TASTING/JAMBALAYA FEAST

The Pub Crawl will wend its way to the  
Orange Show, where the Micro Tasting  
will be held. The Crescent City  
Homebrewers are supplying loads of the  
most excellent jambalya, and we'll have  
as many Micro/Craft brewed beers as we  
can scrounge. The pub crawl is \$14,  
including the micro tasting.  
The micro tasting and food is \$3 if  
you don't crawl.

We are looking for beer for the micro  
tasting, so if you're coming and feel up  
to it, bring a couple of sixes of your  
favorite local brew. Also, if you know  
a brewer personally, have them contact  
us if they feel like getting their  
product "exposed" to the Houston Market.

WORLD'S FASTEST HOMBREWER

Come to Malibu Grand Prix and try to  
wrest the title from Chuck Cox!

From: P\_LABRIE@UNHH.UNH.EDU (Paul LaBrie)  
Subject: re: clean glasses and head retention

RE: Chris' question (and subsequent replies) about head retention, dish-washing detergents, etc., an old trick to make a "beer clean glass" (i.e. to cut through an existing "film") was to wet the glass then rub good old fashioned table salt around the inside of the glass. Typically you can only reach the upper 1/3 of the glass with your fingers but this seems to do the trick. When you've finished with this "salt scrub", be sure to give the glass a THOROUGH rinsing with plenty of water before pouring your beer.

I worked for several years for a beer distributor who was a zealot about presenting his product in a "beer clean glass". As I recall, he used to give out free bags of trisodium phosphate to his draft customers so that they might better clean their glassware. "If the bubbles stick to the side, the glass ain't clean."

Subject: aha93.txt

These are the winners of the 1993 annual American Homebrewers Association competition, announced Thursday, July 29, 1993, at the final banquet of the AHA convention in Portland, Oregon.

BARLEY WINE (Sponsor, EDME Ltd.):

Third: Bill Clawson, Diamond Springs, Calif., Gold Country Brewers Assn.  
Second: Chuck Boyce, Cincinnati, Bloatarian Brewing League.  
First: Ray Call, Stockton, Calif., Sonoma Beerocrats.

BELGIUM-STYLE SPECIALTY (Sponsor, Manneken-Brussel Imports):

Third: Phil Markowski, Norwalk, Conn., Underground Brewers of Connecticut.  
Second: Tony Babinec, Flossmoor, Ill., Chicago Beer Society.  
First: Brian Bliss, Dallas, North Texas Homebrewers Assn.

BROWN ALES (Sponsor, Premier Malt Products):

Third: John M. Roberts, Jamaica Plain, Mass., American Brown.  
Second: Jim Dilldine, Craig, Colo., American Brown.  
First: Douglas Brown, Redondo Beach, Calif., Maltose Falcons Homebrewing Society, English Mild.

ENGLISH STYLE PALE ALE (Sponsor, Wynkoop Brewing Co.):

Third: Matt Hussey and Casey Lott, Portland, Ore., India Pale Ale.  
Second: Russell Levitt, Bloomington, Ind., Classic English Pale Ale.  
First: Kelly Dunham, Pacifica, Calif., The Brewbirds of Hoppiness, India Pale Ale.

AMERICAN STYLE ALE (Sponsor, Northwestern Extract):

Third: Daniel R. Bell, Grass Valley, Calif., Foothill Fermenters, American Pale Ale.  
Second: Mike and Dina Kraft, Austin, Texas, Zymurgic Enthusiasts of Austin, American Pale Ale.  
First: Jack H. Denny, Lenexa, Kan., Kansas City Beer Meisters, American Wheat.

ENGLISH BITTER (Sponsor, The Brewery):

Third: Steve Klover, Thornton, Colo., Hop Barley & The Alers, English Special.  
Second: Byron Burch, Santa Rosa, Calif., Sonoma Beerocrats, English Extra Special.  
First: Donna Lynn and Brian F. Johnson, Palo Alto, Calif., San Andreas Malts, English Special.

SCOTTISH ALE (Sponsor, Something's Brewing):

Third: Jay Ankeney, Manhattan Beach, Calif., Maltose Falcons Homebrewing Society, Scottish Light.  
Second: Ted Andersen, Petaluma, Calif., Sonoma Beerocrats, Scottish Heavy.  
First: James E. Edgins, Highlands Ranch, Colo., Hop Barley & The Alers, Scottish Heavy.

PORTER (Sponsor, The Cellar):

Third: Joel Rosen and Nancy Simon, Hermosa Beach, Calif., The Strand Brewers Club, Robust Porter.

Second: Scott Keohane, Carlisle, Mass., The Boston Wort Processors, Robust Porter.

First: Marvin Crippen, Seattle, Robust Porter.

ENGLISH AND SCOTTISH STRONG ALE (Sponsor, Wine and Hop Shop):

Third: Rick Garvin, Arlington, Va., Brewers United for Real Potables (BURP),

English Old Ale/Strong Ale.

Second: Mike Schaefer, Wauwatosa, Wis., Brewtown Brewmasters, English Old Ale/Strong Ale.

First: Ray Call, Stockton, Calif., Sonoma Beerocrats, Strong "Scotch" Ale.

STOUT (Sponsor, Alternative Garden Supply):

Third: Mike Rego, Amherst, N.H., Brew Free or Die Club, Foreign Style.

Second: Chris Stamp, Rock Stream, N.Y., Ithaca Brewers Union, Sweet Stout.

First: David and Melinda Brockington, Seattle, Foreign Style.

BOCK (Sponsor, Yakima Valley Hop Growers):

Third: Alan Barnes, Nashville, Tenn, Mashville Brews, Helles (Light) Bock.

Second: Bob Tullmann, Pine Mountain, Calif., Doppelbock.

First: Ron Kribbs and Rick Skillman, Naples, Fla., Eisbock.

BAVARIAN DARK (Sponsor, Crosby and Baker):

Third: Dennis Kinvig, Toronto, Ont., Canadian Association for Better Ale and Lager (CABAL), Munich Dunkel.

Second: Tom Altenbach, Tracy, Calif., Draught Board Home Brew Club, Schwarzbier.

First: Jay Hersh, Medford, Mass., The Boston Wort Processors, Munich Dunkel.

DORTMUND/EXPORT (Sponsor, Briess Malting Co.)

Third: Thomas J. O'Connor III, Rockport, Me., Maine Ale & Lager Tasters (MALT).

Second: Rob Brunner, Windsor, Colo., Mash Tongues.

First: Robert Henke, Whitefish Bay, Wis.

MUNICH HELLES (Sponsor, L.D. Carlson Co. [Formally Wines Inc.]):

Third: Richard Kowalski, Wantagh, N.Y., Paumanok United Brewers (PUB).

Second: Keith Weerts, Windsor, Calif., Sonoma Beerocrats.

First: Donald J. Weaver, New Freedom, Pa., Libation Association.

CLASSIC PILSNER (Sponsor, California Concentrates):

Third: Chris Moes, Woodside, Calif., German.

Second: Ron Page, Middletown, Conn., The Boston Wort Processors, German.

First: Steve and Tina Daniel, League City, Texas, Bay Area Mashers (BAM)

,  
German.

AMERICAN LAGER (Sponsor, Coors Brewing Co.):

Third: Charles P. Hessom, Redwood Valley, Calif., Sonoma Beerocrats, American

Standard.

Second: Steve & Tina Daniel, League City, Texas, Bay Area Mashers (BAM), American Dark.

First: Gene Muller, Westmont, N.J., HOPS, Cream Ale/Lager.

VIENNA OKTOBERFEST/MARZEN (Sponsor, F.H. Steinbart Co.)  
Third: Ron Page, Middletown, Conn., The Boston Wort Processors, Marzen/  
Oktoberfest.  
Second: John M. Roberts, Jamaica Plain, Mass., Marzen/Oktoberfest.  
First: John E. Janowiak, Adelphi, Md., Marzen/Oktoberfest.

GERMAN-STYLE ALE (Sponsor, The Beverage People):  
Third: Keith Weerts, Windsor, Calif., Sonoma Beerocrats, Dusseldorf-  
style  
Altbier.  
Second: Bruce Cornell, Baton Rouge, La., Redstick Brewmasters, Kolsch.  
First: Bill Yearous, Galt, Calif., Brew Angels, Dusseldorf-style Altbier.

FRUIT BEER (Sponsor, The Purple Foot):  
Third: Kelly Mower and Brent Stromness, Salt Lake City, Zion Zymurgists  
Hops  
(ZZ HOPS) Club.  
Second: Vern Wolff, Esparto, Calif., Gold Country Brewers Assn.  
First: Gene Muller, Westmont, N.J., HOPS Club.

HERB BEER (Sponsor, Marin Brewing Co.):  
Third: Michael Millerick, Fairfield, Conn.  
Second: Mike Schaefer, Wauwatosa, Wis., Brewtown Brewmasters Club.  
First: Richard Mansfield and Mike Smith, San Jose, Calif., Washoe Zephyr  
Zymurgists Club.

SPECIALTY BEER (Sponsor, Beer and Wine Hobby):  
Third: Ronald B. Moucka, Fort Collins, Colo., Mash Tongues Club.  
Second: Frank F. Miller, Libertyville, Ill.  
First: Ron Page, Middletown, Conn., The Boston Wort Processors.

SMOKED (Sponsor, Jim's Homebrew Supply):  
Third: George Mika, Warrenton, Va., Brewers United for Real Potables  
(BURP).  
Second: Mike Fertsch and David Koresh (!?), Woburn, Mass., The Boston  
Wort  
Processors, Bamberg-style Rauchbier.  
First: Paddy Giffen, Cotati, Calif., Sonoma Beerocrats.

CALIFORNIA COMMON BEER (Sponsor: Anchor Brewing Co.)  
Third: Strom C. Thacker, Gainesville, Ga.  
Second: Robbie Enrico, Greensburg, Pa., Three Rivers Alliance of Serious  
Homebrewers (TRASH).  
First: Michael Dennis Bell, Pleasant Hill, Calif.

WHEAT BEER - ALE (Sponsor: American Homebrewers Association):  
Third: Bruce A. Brandt, Casnovia, Mich., Prime Time Brewers, Berliner  
Weisse.  
Second: Steve Dempsey, Fort Collins, Colo., Hop Barley & The Alers Club,  
German-style.  
First: Walter Dobrowney, Saskatoon, Sask.

TRADITIONAL MEAD (Sponsor, Havill's Mazer Mead Co.):  
Third: Paddy Giffen, Cotati, Calif., Sonoma Beerocrats, Still Mead.  
Second: Byron Burch, Santa Rosa, Calif., Sonoma Beerocrats, Sparkling  
Mead.  
First: Walter Dobrowney, Saskatoon, Sask., Still Mead.

MELOMEL, CYSER, PYMENT (Sponsor, National Honey Board):  
Third: Peter Knight, St. Helena, Calif., Sonoma Beerocrats, Still.  
Second: Bob Gorman, Waltham, Mass., The Boston Wort Processors.  
First: Gordon Olson, Los Alamos, N.M., Los Alamos Hill Hoppers.

CIDER (Sponsor, Lyon's Brewery of Dublin):

Third: Gabriel Ostriker, Somerville, Mass., Still.  
Second: Gabriel Ostriker, Somerville, Mass.. Sparkling.  
First: Gabriel Ostriker, Somerville, Mass., Specialty Cider.

SAKE (Sponsor, Hakusan Sake):

Third: Fred Eckhardt, Portland, Ore., Oregon Brew Crew.  
Second: Jim Long, Sacramento, Calif., Gold Country Brewers Assn.,  
Sparkling.  
First: Jim Long, Sacramento, Calif., Gold Country Brewers Assn.

From: Ed Hitchcock <ECH@ac.dal.ca>  
Subject: hot water / starting starters

>I dont know if a on demand hot water heater would be capable of providing  
>26 gallons of 180F water in a 30 minute time frame. This is my  
>requirement.

Perhaps what you need is a flow-through water heater. That way it heats the water to the desired temp as it passes through the pipe, no worrying (not that homebrewers worry) about the time to heat up 40 gallons of water.

\*\*\*\*\*

Recently I made some starters the quick and dirty way, since I realized Friday morning I hadn't started the yeast for Saturday's brewing session. I scrapped the slant into a 640 mL Beck's bottle, added 500 mL sterile wort, capped it, SHOOK VIGOROUSLY for 5 minutes, removed the cap and put on an airlock.

The satrter was cloudy with yeast by Saturday Night pitching time, and the kraeusen was crawling out the airlock (oops!) Sunday morning. Of course, this was a fairly fresh slant. One of my older slants took two days to get to that point.

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: Overnight mashing

In HBD #1193 Jack Schmidling mentions doing the mash-in the night before the rest of the mash. According to Jack, the overnight mash-in "had far more malty flavor and seemed richer and fuller in body" than the same recipe using a normal mash-in.

Very interesting experience! I could certainly go for mashing-in the night before. Have others tried this? With what success? Jack, what temperature do you mash in at and how does it change overnight?

From: tmgierma@raphael.acpub.duke.edu (Todd Gierman)  
Subject: yeast culture miscellany

I posted some ideas for yeast culturing in HBD #1192. For some of the questions pertaining to yeast culture in #1193, I refer you to those notes.

I'll add a few more comments here. But, first the disclaimer. I am not a yeast expert; outside of homebrewing I do not work with yeast. However, I do a fair amount of culturing of E. coli and animal cells, I have a reasonable level of knowledge concerning the biochemistry and molecular biology of yeasts, and I have access to a number of technical writings concerning yeast physiology and growth. The methods that I have described are idealized. I realize that they are not always suitable to the setup of most homebrewers. I urge anyone reading them to take them as guidelines that can be adapted to one's own system - deviation is the accepted norm.

>From: tpm@wdl.loral.com (Tim P McNerney)  
>Subject: Re: inoculating a starter from a petri dish  
>  
>My biggest problem with inoculating a starter from a petri dish is that  
>I don't want to go through 5 different sized, sanitized starters to  
build  
>up enough yeast. I tried inoculating a few ml of wort in a 1 liter  
flask,  
>but did not see the activity I was used to with 10 ml testtubes. I got  
>the testtubes with presterilized wort from the Yeast Kit Culture Company  
>(along with 50 ml testtubes) and these worked great. So my questions  
are:  
>  
>1. Did the fact the the wort in the flask was so shallow cause problems  
with  
>yeast growth or just with the visible effects?

Probably not, to the first part. Who knows for sure, to the second.

>2. Since I only tried this once, did I just mess up this one  
inoculation?

Possibly. Allow your flamed loop to cool before picking (stab it into a clear area of the agar - it should sizzle). A hot loop may kill your colony on the spot. For a few mls in a liter, you're talking a long time before you will even begin to see activity (see my previous posting). Presumably, you successfully picked a colony, as evidenced by the activity seen in the "few ml" starter starter.

>3. How do other people build up a healthy sized started with spending  
half  
>their life preparing storage vessels?

Again, my previous posting explains how I do it under ideal conditions. It really isn't a matter of five sterile containers, more like two or three. Here's a suggestion: start with 2 ml in your sterile tube, add 8 ml the

next day to make 10 ml (assuming your tube holds 12-15 ml), the next day, add 50-100 ml to a thoroughly sanitized, if not sterile, mason jar or juice jar (glass) (avoid detergents), pitch the 10 ml into the 50-100, bring your starter up to volume with successive additions over the next two days. At each stage you really want to see vigorous growth before increasing the volume. A healthy, actively growing culture is the best way to minimize bacterial growth. If you add a little bit of yeast to a large volume, you run the risk of pitching a highly contaminated culture. Some bacterial growth (acetobacter for one) may actually inhibit the growth of yeast.

FYI: During exponential (or log phase) growth, yeast double every 90 minutes @ 30 degree C with vigorous and constant aeration in specialized media - this does not make for good beer, however. Log phase can be divided into three stages based on the rate of cell division (or the proportion of budded cells within a culture): early log phase (cell-density <  $1 \times 10^7$  cells/ml), mid-log phase ( $1-5 \times 10^7$  cells/ml), and late-log phase ( $5 \times 10^7$ - $2 \times 10^8$  cells/ml). At  $2 \times 10^8$  yeast cultures are considered saturated and the cell enter stationary phase. So you can see, if you dilute your culture well below  $1 \times 10^7$  cells/ml, you may lose your log phase growth. Thus, even a ten-fold dilution may be detrimental to your growth rate. Pitching 500 ml of starter into 18.9 liters (5 gallons) constitutes a 38-fold dilution. A saturated culture @ 500 ml may get you to early-log phase. BTW, bacteria may have a doubling time 1/3 that of yeast.

>From: Mark A Fryling <mfryling@magnus.acs.ohio-state.edu>  
>Subject: culturing Belgian yeast

>The question I'd like to pose, is does anyone know if the yeast in the  
>Hoegaarden samples and the Abt 12 is fit to culture and brew with? I  
know  
>that  
>the Chimay is good stuff, and I already learned (from a recent posting)  
that  
>the Duvel yeast is not. Ditto for Orval. The others were pasteurized and  
>filtered. TIA

I have similar questions myself. I can tell you that I have a wit going using a Hoegaarden culture. It has been fermenting quite vigorously for 4 days now. The fermentation is actually giving off some very pleasant odors. I've seen recipes that have used Hoegaarden yeast, so I assume that it is okay. I know nothing of Abt 12. Chimay may be good, but I know of one person who had a complete failure with it, and his skills are quite esteemed in our local HB club. Although the Duvel may be a conditioning yeast it may not be complete junk. Watch out for bacteria that may be lurking in the bottle dregs. I have tried culturing the Duvel yeast. I have succeeded in only culturing the bugs instead, which may be lactobacillus. I know that the live yeast was present, but the bugs seem to have overgrown the culture. Orval is not necessarily junk either. Michael Jackson writes that Orval does two fermentations with single-cell cultures and conditions with a 5-strain culture. I don't know, but what do you think the chances are that the yeast in the single cell culture is present among the 5 strains during conditioning? I'd guess it is there. You could probably isolate it, but is it worth the trouble? Probably not.

However, it would be interesting to use the 5-strain culture to condition that trappist ale that you might attempt someday. One thing to remember is that many of the Belgian ales require a variety of yeast strains to yield the final product. If you plate them out, be sure to pick many colonies for your stock culture.

From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>  
Subject: Extract Efficiency & Duvel Yeast

My personal preference is to measure the extract efficiency at the start of the boil. It is, as someone said, the efficiency of the mashing and lautering processes that are of the most interest. At this point, the character of the wort is set, and you have recovered all of the sugars you are going to get.

A point which no one has brought up is that if you are using any kettle adjuncts (honey, sugars, etc.), you definitely want to do the calculation before you add them.

To get a good number, you must be very careful in the measurements taken, and adjust the measured volume as well as the SG to your reference temperature. I am amazed at the number of people who fail to include this correction. At 100 C, it will swing the apparent extract yield by 4%. To measure the (hot) volume in my half-barrel kettle, I use a stainless ruler to get the distance from the edge of the 12-in hole in the top to the surface of the liquid - to the nearest mm. I made a calibration curve which I then refer to get the volume, which should be within 0.12 liter or so.

It goes without saying that an accurate hydrometer is needed as well. I prefer the type with an integral thermometer and correction read-out. As far as the correction for temperature goes, the best strategy is to cool the sample to the reference temperature, or as close as is possible. The correction is indeed dependent upon the wort gravity as well as its temperature, but the closer you are to the reference, the smaller the error in ignoring it.

\*\*\*\*\*

Moortgat's Duvel is fermented with two strains of yeast, in separate unequal volumes. One of these two strains is used for the bottle conditioning, after the yeast from the primary is filtered out. These details are from Jackson, "The Great Beers of Belgium". I have a Duvel culture which was obtained from a bottle a couple of years ago, shortly after it appeared in the local market. Interestingly, the bottles out there now seem to be DOA, as several recent attempts have yielded nothing. A fresh one from Belgium could be a different

story. The culture I have makes wonderful beer, though. It has a distinctive Duvel flavor profile, and seems to build a livelier head than most others in my experience. Two or three times a year, when I regenerate my collection of twenty or so yeasts in 6-ml tubes of pale, un-hopped wort, I always observe these same characteristics.

believe the special Belgium color malts make all of the difference.

<From: dipalma@banshee.sw.stratus.com (James Dipalma)

<>an authentic contential lager, ferment at 48-51F for 1 week, drop temp  
^^^^  
>2F per day until it is 42F. Rest here 2-4 days (diacetyl rest)

<I'm a little confused here. I don't ferment lagers warm, 48F-50F, and  
I've  
always used the Noonan method of raising the temperature for the diacetyl  
rest (~55F for 2 days), with good results. Can you clarify this point,  
Jim?

I have received a bit of mail on this topic so it seems I have hit a  
nerve  
on lagering. The final test is in the finished product, and whether any  
detectable amounts of diacetyl survive. The most important factor on  
this  
is yeast strain selection. G. Fix in the latest issue of Brewing  
Techniques  
lists two tables relating the correlation between production and  
reduction  
of diacetyl levels and yeast strains over time. Two of the strains,  
including  
the ever popular weihenstephan 34/70 produce much lower levels of  
diacetyl  
than a third strain. In all of the cases, each yeast is able to reduce  
the  
level of diacetyl but the one that produced a lot initially was not able  
to  
reduce the levels very low. If one is using a strain that is a big  
diacetyl  
producer, then it would seem that a higher temp diacetyl rest is in order  
to  
accelerate the yeasts ability to metabolize and break down the diacetyl  
into  
the two less bothersome constituents, see Fix's article. It is my  
opinion  
that if a strain does not produce much diacetyl, like 34/70, and primary  
fermentation is carried out at 48F, then there is no need to raise the  
temp to further reduce the levels. Raising the temp to 55F is not that  
radical. Raising it higher is done for rapid fermentation & lagering ala  
Dr. Narziss. This is a natural and easy technique where at the end of  
primary at 48F, the attemperater is turned off, allowing the temp to  
slowly  
rise into the upper 50s. After the rest, the lager period is reduced to  
2-

3 weeks time. If I remember the Fix article, not much reduction of diacetyl occurs under 40F, so it would seem that this is a lower limit.

I suggest leaving out the 55 stage on a batch using 34/70 and substitute the brief rest at 42-44F for 2-3 days, and see if anything changes. Whatever is easier for you and works is what counts.

Subject: Supply Stores in Berkeley/Oakland CA Area

Greetings, all,

Next week I will be moving from Cambridge (and the wonderful "Modern Brewer" supply store) to Berkeley CA. Does anyone know of any good stores in the area with a decent selection of grains and fresh hops?

Things in San Francisco and Palo Alto (home of Pete's Wicked) would be accessible to, so far as anything in CA is accessible from anywhere else.

Thanks in advance,

Jed parsons1@husc8.harvard.edu

Hmmm, really? I've yet to try the Grand Cru - I've been happy enough with the White, now I've found a regular supply :^). I'll have to pick some

up this weekend when I re-stock.

If you *\*really\** like sour beer, get him to bring back some Rodenbach. The regular Rodenbach is delicious, with a powerful fruity sourness. They also have a Grand Cru if you can stand it...

I found some Rodenbach at Liquor Barn in San Francisco about 2 years ago, but haven't seen it anywhere since. Anyone ever tried to make it? The sourness comes from aging in oak, and young and old agings are blended. The

Grand Cru is just the "old" beer that has been aged for up to two years!

From: Wolfe@act-12-po.act.org  
Subject: Chili VS Jalapeno

I am ready to harvest a few quarts of chilis and jalapenos from my garden. I've seen a few recipes for jalapeno or serrano peppers in beer, but haven't seen any for chilis. I prefer the taste of chilis (to jalapenos) in my cooking. My question is: How do jalapenos and chilis compare for flavor and burn in beers? Is there any noticeable difference between them when they've been roasted and tossed into the secondary? Also, can chilis be safely substituted for Jalapenos in a recipe without fear of burning the lips off of one's face?

Date: Fri, 30 Jul 93 16:18:14 EST  
From: Ulick Stafford <ulick@michaelangelo.helios.nd.edu>  
Subject: Efficiency question

James DiPalma mentions that his efficiency seems higher pre boil than postboil. I am not going to deny the possibility that precipitated break material could account for the difference, but is it also possible that the temperature of the wort might be a factor in the volume estimation? If you eyeball the volume of warm post sparge preboil wort it is going to higher than at postchill temperature by quite a bit. The sg at 80C is .971, at 90 .965, and at 100 .958. At 20 C it is 998. (figures actually kg/m3/1000). I usually measure both - but the initial sg is to see how much to boil off, I I don't have volumes calibrated well anyway.

Also, why is everyone so concerned about Zima? It isn't beer and doesn't pretend to be. It is aimed at the wine cooler-prepackaged mixed drink crowd. A frined brought me back a Canadian drink called Durango that was a fruit flavored malt beverage a few years ago, so Zima isn't the first. It has a similar relationship to beer as a single malt Scotch - an alcoholic drink made of malt, and noone complains about Scotch. Give it a break! If you have to complain about Coor's use a better reason - like Union relationships, Environmental damage, false advertising claims, or the fascist belief of the founder. Zima is surely one of their venial sins, and it isn't as bad as Miller Clear, whcih does pretend to be a beer.

From: reeves@lanl.gov (Geoff Reeves)  
Subject: pts-gal/lb NOT pts/lb/gal

It occurs to me that a lot of the confusion over extraction rate, or yeild  
may be due to the fact the people keep referring to pts/lb/gal (points  
per pound per gallon). These are not the correct units and that may be why  
some people are confused. The formula used is

$$(\text{OSG\_beer} - \text{SG\_water}) * \text{Volume\_of\_Beer} / \text{Pounds\_of\_Grain}$$

Specific gravity is dimensionless but is referred to by "points" in  
brewing so the dimensions are gallons/pound or point-gallons/pound (pts-gal/lb  
for the abbreviation inclined).

I know it doesn't sound right but it is. What you are really trying to  
find out is how much total disolved sugars did you get out of your total  
grain bill. 30 gallons of 1.056 beer has more dissolved sugars than 5 gal  
of 1.056 beer so if you have the same extraction rate you need 6 times as  
much grain.

I hope this clears up some confusion for someone besides me.

Subject: Sparging, Slants

>From: steve@snake.appl.wpafb.af.mil (Steve Zabarnick)  
>Subject: Sparge water aeration and pH

>My question concerns the aeration of and oxygen content of sparge water. One common technique in professional breweries to sprinkle the sparge water from a rotating arm (similar to the Phil Sparger). I would think that this would do I good job of aerating the water.

I doubt that it would do a "good" job and suspect it is pretty much in the noise. More importantly, sprinkling the sparge water is totally unnecessary if the level is kept above the grain an inch or so. There simply is nothing to be gained by spreading it around. Someone put a shower head in a mash tun and they have been used and misused ever since. A homebrew equipment manufacturer fell into the same trap and confused the hell out of beginners with his rotating gizzmo.

>My other question is about pH measurments of the mash and sparge water. How important is it to cool the samples before taking this measurement? I've been using a hand-held pH probe (which is supposed to be temperature compensated), which I just stick into the mash. Am I getting a correct measurement without cooling a sample of the mash?

I have never been able to tell from the instructions or in use whether the temp compensation means the instrument will function in a wide range of environmental temps or if it will measure liquids at a wide range of temps. As a result of my confusion, I cool all samples to room temp before measuring.

>From: Jim Busch <busch@daacdev1.stx.com>  
>Subject: Hot liquor tanks & slants

>I agree in principal that chlorine is a nonissue. A lot of big breweries dont do anything to remove chlorine (big = 25 BBl in this sense). The argument is that the chlorine is driven off in the kettle anyway.

That is a tough point to argue. However, it is not the chlorine that is the problem in the first place but the byproducts of combining chlorine with organics in the water. There's lots of this stuff in the water by the time it gets to your house and the grist supplies a monumental source of organics for the chlorine to act upon. It has also been pointed out that the

by-products are also volatile and boil off but lots of things are said and I have not seen that documented to my satisfaction yet.

> Is it true that BT is for profit??

Probably not but certainly not by choice.

> I wonder how "profitable" this kind of thing is. I bet its like brewing, a lot of sweat equity in every issue/batch.

That is not the point. The less profitable it is, the more ads they are going to need to survive.

>I dont know if a on demand hot water heater would be capable of providing 26 gallons of 180F water in a 30 minute time frame.

Anything is possible, it just depends on how much heat you have available. I have found that my stove top will produce about 10 gallons per hour at 180F.

This is the rate that I sparge at and it just marginal for ten gallon batches. If you need more water faster, you just need more heat.

Just as an aside, in Africa, every place I went had gas fired demand water heater in hotel and lodge bathrooms. These hung on the wall near the sink/shower and provided continuous very hot water.

In Costa Rica, they use and electric shower head (scary huh?) that heats water as one showers. There's lots of stuff out there and it just seems like there has to be a better way than holding large amounts of hot water.

JS:

<You would be much better off to transfer the petri culture to slants and use these to start your starter. I cover the slant with wort and use this as a one time, pure culture starter.

>This is not what's referred to as a "slant". The first sentence is correct.

The second sentence is a technique of preparing a starter. Covering the slant is not a good idea in my opinion. You cover a small sample of yeast with wort, the slant is where the yeast is maintained and cultured from. The difference is a slant has agar with yeast growing on it. A starter has no agar.

I am using the terms correctly. It is the fact that I use slants in an un-traditional manner that may be confusing.

I make one-shot agar slants from petri cultures and from other slants but I use them as one time starters like most people use Wyeast packs.

Covering the slant with wort is an ideal way of starting the yeast as long as it is not used again. There is vastly more yeast on the agar than in a typical liquid pack and a much stronger culture is introduced into the

starter flask.

>From: tpm@wdl.loral.com (Tim P McNerney)

>Subject: Re: innoculating a starter from a petri dish

>My biggest problem with innocualting a starter from a petri dish is that

I don't want to go through 5 different sized, sanitized starters to build up enough yeast.

>3. How do other people build up a healthy sized started with spending half their life preparing storage vessels?

The hard way. What you perceive as a problem is just a necessary evil. However, if you sterilize a pint of wort, you can add this in increments to the flask and only sterilize the flask once and the wort once. Still, there seems something very unprofessional about starting 50 ml in a 1000 ml flask but no real reason not to.

From: r.wize@genie.geis.com  
Subject: Agar availability?

I recently have become an all grain brewer and am now using the Brewers Resource Culture kit. My question is does anyone know of a recipe or a source for just Agar? Most of the catalogs I have seen sell Agar slants but at a price of about .80 to \$1.00 each (then adding shipping it hardly seems worth it) I'm sure I could get my hands on some test tubes, it is the Agar which mystifies me.

Also I noticed alot of discussion about MaltMills in some older HBD's. I have just purchased a MaltMill and did my first brew this weekend (previously I was using a Corona). My yield increased by about 40%. It really has made what was a difficult chore (the corona) into something which takes about 1/2 the time and has definitely improved my efficiency. I'm not sure of the relative merits of the Philmill but definitely sign me up as a satisfied customer of the MAltMill!!!!

> A note about hopping: I was attempting to get most of my IBUs later in  
> the boil to reduce some back of the tongue bitterness. I wanted this  
to  
> be a hop flavored beer, rather than just have bitterness to balance the  
> malt. On most beers I try for 50-60% of the bitterness at the 60  
minute  
> addition, but as you can see, I did not do that here. I achieved my  
goal  
> I think (see tasting notes).

I too have been thinking about trying something like this for quite a while. I have been shooting for 60-70% of my IBUs with an initial addition of hops to the kettle and pick up the rest with 45-20 minute boil additions (the hops are in for 45 to 20 minutes) depending on the style I am trying to brew.

I have found that the beers are different when hopped this way. The differences that I have noticed are: 1) young beer isn't as harsh for more bitter styles, 2) more hop flavor comes through in the finished beer (as would be expected). I suppose that the technique has the desired effect of producing a beer with a more well-rounded bitterness at the expense of some additional hops used in the brew.

Are there other brewers out there that are doing something similar with their hopping techniques? I would be interested in hearing about experiences with beers that get a significant percentage of their IBUs in later stages of the boil.

From: Sean C. Lamb 335-6669 Loral <slamb@milp.jsc.nasa.gov>  
Subject: All About Beer Magazine

Chuck's post asking about a contact for Mr. Jackson has roused me from my summer lethargy enough to type up a short review of the latest issue of All About Beer magazine. (I suggested to Chuck that he try this mag because Jackson writes a column and does a taste-testing panel for them). I've been a sbuscriber to AAB for the last couple of years, mostly to get Jackson's and Fred Eckhardt's columns. Often there has been info that is of value, but many articles were just press-release puffery. I've read rumors that the cover of the mag was for sale to an advertiser.

Mr. Daniel Bradford, late of the AHA marketing Dept. and the GABF, has taken over publishing the mag. Knowing what we do about these endeavors, this may or may not speak well for the future of the mag, but I'm willing to give people a break now and then (Bob knows I need 'em).

To the point, the latest issue looks stupendous, had a decent article by James Robertson (can you say beer nerd?) on brew in New Zealand, an hilarious article by a C. S. Porter on being out and about with Alan Eames at the Beer Camp in Cincinatti/Ft. Mitchell, a great profile of Carol Stoudt and her brewery in Pennsylvania, and the return of a beer industry column written by Mr. Frank McNeirney, who is identified as the retired director of communciations and industry affairs for the the Nat'l Beer Wholsalers Assoc. All in all a keeper. The info on brewpubs and good pubs new and old is good and getting better (I wouldn't have know about the Old Peculier pub in NYC if I hadn't seen it in AAB. Came in handy when I was there a couple of years ago.) They've even toned down the length and look of the industry news section. I hope that they can sustain the effort.

Anyone else read this thing and have any thoughts, opinions or rants?

Subject: beer runs

John Palmer writes:

>another thing, Has anyone ever noticed the laxative qualities of  
homebrew in  
>general or is this another symptom of my first batch?

Letting the fermentation finish and the yeast settle out usually solves  
that problem (wait another 2 months at cool temps). Most new brewers  
can't  
wait that long. Darker Malts (i.e. roasted barley in stouts) also can  
cause  
a dramatic increase in the amount of toilet paper used. Severely  
oxidized  
beer also upsets me, and the beginner's "strain the hot wort into the  
cold  
water" method cerainly adds to that.

Date: Mon, 2 Aug 93 08:20:16 EST  
From: "Thomas Kavanagh, Curator" <TKAVANAG@ucs.indiana.edu>  
Subject: Wild Hops

As a recent mover to Indiana, I dutifully re-established my brewery, planted new hop vines--cascade and nugget--both of which are doing fine, thank you, and I should harvest in a few weeks. While exploring my new digs, I discovered what appeared to be wild hops behind the flower beds. Always interested in wild things--except wild yeasts-- I trained them up and over a trellis. They are now flourishing and are quite long and busy. But, in contrast to my less than year old cascade, they do not appear to be flowering at all. What do I have here? Are they really hops? The vines are called wild cucumbers in these parts, but have all the markings of hops--fuzzy vines, etc. I tried matching the leaves with the examples in the Hops special issue of Zymurgy, but no match. Could this be the basic first year syndrome, and it mightnot be until next year that they bear fruit? If they do bear fruit in the future, is there any way to test for AA content without devoting an entire 5 gallon batch to them?  
TIA.

From: sims@pdesds1.scra.org (Jim Sims)  
Subject: Wyeast question

(actaully two questions)

My wife purchased some Wyeast liquid yeast for the next coupla batches of brew. I had read about possible infection of the nutrient packs here, so I figured I play it safe and re-hydrate (what do you call it since it's already liquid?) it myself. The date on the 'bag' said July 1993 - is that the 'manufacture' date, or the 'use-by' date?

I added the 'bag' of yeast to about a cup of slightly dilluted and still warm (~80 degrees) wort while the rest was boiling. I've used this method inthe past with dry yeast and by the time the wort cools, the yeast has a head that's bulging out of the 2 cup container it's in. This time, the yeast wasn't doing \*anything\*, just had a sediment on the bottom of the cup. I pitched in into the cooled wort anyway, not having much choice. This morning (brewed last nite about 9, pitched about 11 PM), theres still no head on the fermenter.

Should I wait till this evening and if there's still no head re-hydrate and pitch some other yeast?

From: pascal@netcom.com (Richard Childers)  
Subject: The Advertising Channel

"Date: Fri, 30 Jul 1993 13:25:34 +0930  
From: Murray Robinson <robinm@mrd.dsto.gov.au>  
Subject: Possible solution to commercial posts ?

"After reading the discussions about whether or not commercial posts should be allowed on the Homebrew Digest I checked up on an automatic mailer package that may hold one solution to the problem."

Look, folks. Let's go through this again.

Home Brew Digest. Note the word 'home'. This is not a channel for free advertising or would-be get-rich-quick schemes for capitalists lacking the capital to pay for their advertising, or trying to capitalize on a free alternative to shelling out their own bucks.

To attempt to distort it into something it is not is to create trouble. I, personally, will not accept advertising on the Home Brew Digest - ever.

If you want to start a Commercial Brew Digest, go ahead. But keep your !@#\$ing commercials off of my screen. The Internet is based on the model of a commonwealth, not on the model of a bunch of cheap-o parasites who can't pay for their own advertising and have to piggyback on freebies.

The same goes for long and windy lists of who won what where at some contest over a thousand miles from where I am ... or postings eliciting entries. Use yer brainz. Post that entries are open and invite people to mail you for the entry form, instead of posting the entry form to the entire goddamned planet. If you're too lazy to do this, then move over and get someone else to do it. Simple etiquette, nothing complex, just good manners.

No, that wasn't a flame. Just the facts, ladies and gentlemen.

Subject: The FaceMail Project

I'm just back from Portland. It was a real mind-bender to meet people from th digest face-to-face. I was constantly reevaluating my mental images of peoples personalities. I'll have more to say about the conference later, but first.....

THE FACEMAIL PROJECT

At my booth I set up an S-VHS camera and passed the word that I would be videotaping any electronic brewer. I asked people to hold to 3-5 seconds of time, just enough to say their name and mug for the camera a little. I will be editing the tape into short clips and converting them into motion-video files, QuickTime for Mac tribesmen and standalone DOS files for the "rest of us". The DOS files will probably be converted first.

I will then upload these files (they'll be pretty big) to the archive at sierra.stanford.edu. Then you'll be able to download the file and actually see (and on some systems hear) what various elctronic brewers look like.

This is an experiment, so we'll see how it goes. It was remarkably difficult to pass the word at the conference, so I'll apologize right now for missing anybody. If this works out, next year can be better organized...

Paul.

Subject: Where to drink in...

I've been noticing many requests for information on where to drink in...

It may be time to put together a list of good drinking spots in the USA with comments/reviews from HBD readers. With all the new brewpubs and extended selection bars popping up, it can be difficult to discern good ones from bad ones, hence the inclusion of comments.

As a beer-loving frequent traveller, I'd find such a list helpful. Any volunteers?

Cheers, mab

Subject: Counterflow Questions

I am thinking about turning my immersion chiller into a counterflow chiller and have a couple of operational questions:

1. Some have mentioned that they sanitize their counterflow chillers by running boiling water through them. How do you get the boiling water in the chiller without scalding yourself?

For those who use chemical means, I generally use bleach to sanitize. What do you use on a counterflow chiller and how long to you let it soak or do you just run the solution through? What concentration do you use? (I apologize if this sounds like a re-opening of the recent sanitation thread.)

2. Similar to the above, How do you get it started? I am assuming that I will need to siphon the hot wort through the chiller to the primary fermenter.

Thanks in advance.

Subject: KiWheat recipe

I recently made a KiWheat beer (Kiwifruit Wheat beer) and I thought I would share the recipe:

KiWheat Ale  
-----

6# William's Weizenmalt Extract (60% wheat, 40% barley)  
1.5 oz Hallertauer hops (2.9% alpha acid) - 60 min  
1 oz Hallertauer hops - 5 min  
0.5 tsp Irish Moss

Wyeast Belgian Ale yeast

O.G. 1.041

Fermented at ~70°F.

After 5 days, I peeled and diced about 7# of kiwifruit, added 2 campden tablets, and put them in the freezer overnight to help breakdown the cell walls.

The next day, racked to secondary and added the kiwifruit (brought up to room temperature).

After 1 week, when the secondary fermentation was complete, I bottled;  
F.G. 1.009

Results:

I had intended to add more hops but miscalculated (and I didn't even have a homebrew while I was making it!). It is a rather light beer with a slight kiwi nose. As you drink it, it has a tartness that helps take the place of added hop bitterness. It does not hold a head worth beans.

If I make this again, I think I will add a few more hops and leave it on the kiwis MUCH longer. I think that after I bottled I saw on the digest that krieks are left on the cherries for 2-4 months. I guess I was a little too hasty to have my summer brew before the summer was over!

Subject: Dough-in

>rom: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
>Subject: Overnight mashing

>In HBD #1193 Jack Schmidling mentions doing the mash-in the night before the rest of the mash. According to Jack, the overnight mash-in "had far more malty flavor and seemed richer and fuller in body" than the same recipe using a normal mash-in.

>Very interesting experience! I could certainly go for mashing-in the night before. Have others tried this? With what success? Jack, what temperature do you mash in at and how does it change overnight?

I boil my mash water and either chill it or let it cool naturally, depending on the time but in either case it is near room temp or cooler when I dough-in and IS room temp by morning.

There is no doubt a multicultural flora ready to do a number on the mash but if it is kept cool and kept to a reasonable length of time, it will cause no grief. Mashing and boiling will destroy its viability. If allowed to get established however, it could impart an off flavor even if the organisms that started it are long gone.

It has been my experience that the aroma in the morning is clean and pleasant and not significantly different from the night before.

For what it is worth, however, in the experiments cited in the original article, the mashes made with 6-row developed a putrid aroma by morning and the controls using Belgian Munich did not.

This could also be a clue that the six-row malt I have is rancid or mouldy and the whole experiment is for naught.

I would appreciate hearing from anyone else with comments on six row malt and in particular, whoever it was that made the comments about the flavor of this type of malt.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)  
Subject: spigot in stainless kettle

I am toying with the idea of buying a large stainless kettle for brewing purposes, and I would like to know what the consensus is on the easiest way to put a spigot in it. What I would like is a 1/2 inch ball valve or equivalent. The kettle will probably be a 10 gallon Vollrath.

I know that a lot of you out there use a converted keg and weld a fitting in the side. Will this be a problem with the Vollrath kettle, i.e. are the walls thick enough?

I would like to try something like my EASYMASHER (tm), but larger. However, when I tell the guys at the plumbing store what I want to do, they really don't know anything about it. I would hate to buy a straight pipe tap and die just to make one fitting.

I have seen bulkhead compression fittings advertised, but I can't find a retail source. A friend gave me a SWAGELOK (tm) bulkhead fitting, but it is way too small (1/8 inch Cu tube).

I would prefer not to go the route of the modified keg, because I don't want to buy a outdoor gas burner and boil outdoors in the Phoenix heat. Can putting a spigot in a stainless pot really be that difficult? Surely someone has done this before.

TIA,

Subject: Going Blind

Dear Fellow Homebrewers,

I have an unusual request. Recently my girlfriend went to child mediation with her ex because he wants full physical custody of their two children (7 and 9). He claimed to the mediator that we let his children drink home-brew (of course this is absolutely untrue) and that drinking homemade beer can make you go BLIND! (Her lawyer said `isn't that true about mastrubation too?`) Anyways, the mediator wanted to know if that was true or not. I remember a few months back we had some posts on this issue and that the going blind part was due to something else. Anyhow, if someone knows the real information about this issue, or where I can get the real article that talked about this, or if you have any of these old posts, could you please email them to me so I can get them to the mediator.

Thanks,  
Dan

By the way this guy is such a dork that to get the kids he tried the excuse that our house was so dirty that his wife wouldn't even use the bathroom and that we even ran out of bathroom tissue once - for shame.

Subject: Toronto Star Article

Re: Wayde Nie's submission of July 12,1993 article from Toronto Star article on "beer machine". In the 1970s (I believe), Phillips Petroleum did some work with Coors on dehydrating beer. The idea was to reduce shipping costs with a minimal impact on the product. Talking to some of those involved, what I can reconstruct is this:

Fractional crystallization was used to remove water and create a "syrup". Many panel evaluations were done and the consensus was that the re-hydrated product was virtually as good as new. There was a snag however.

Consumer surveys showed that even though people found no problems with the beer, they would have turned their noses up at the label. The product would have to have been labeled "reconstituted beer". I did not get to taste any of the product myself.

I believe that Phillips and Coors still hold patents in this area. I wonder how the syrup for the Beer Machine is produced and how it is labeled.

What goes around comes back to haunt you.

From: bgros@sensitivity.berkeley.edu (Bryan L. Gros)  
Subject: honey basil ale: the sequel

I guess summer is the time for sequels, so I made another version of the honey basil ale that I posted last year (and is in the Cat's Meow I believe). The last try (my fourth or fifth batch as a homebrewer) was too bitter and overpowering as far as the basil.

Since then I have learned about IBUs and how to calculate them, my beers have become much more balanced and the bitterness more consistent. I learned what maltiness tastes like!

anyway, here's this years recipe:

#### Honey-Basil Ale II

3 lbs 2-row barley  
2 lbs Munich malt  
3 lbs honey (I used raw, wild mesquite honey from Trader Joe's)  
1/2 lb 10L crystal malt  
1/2 oz basil (fresh leaf basil from grocery store or farmer's market)

20 IBU Willamette hops  
Wyeast American Ale yeast

Standard mash and boil. I added the basil and 3/4 oz hops at the end of the boil and turned off the heat. Cooled with immersion chiller after 5 or 10 minutes.

OG: 82 I added 2.5 qts of water to bring it up to 5 gallons  
with a gravity of 1.062  
FG: 8 !!

The final gravity was lower than I had thought, even with the honey. Actually, the OG was higher than I had thought also.

#### Comments:

The beer is great, not as thin as I feared, and complex. There is an alcohol note in the taste, as you might have guessed. The beer is smooth. The bitterness is very slight, the maltiness is good and the basil is subtle. There is a slight basil nose. It is very drinkable, which means all the alcohol will sneak up behind you and knock you over the head. I was very happy with this version.

So for others who want to use herbs: I think 1/2 oz of basil in 5 gallons is fine. A little more wouldn't be bad, but 1 ounce is definately too much. I used rosemary once, and it is a stronger herb, so go lighter. I would like to hear your experience with vanilla beans: I'm thinking of putting one in the fermenter with a porter. Is one enough?

Subject: Back from Portland/Bud-quality[sic]/Dishwasher glassware

Hey! Back from Portland to the flat land of limited varieties of good beer on tap (Chicagoland). First of all, I'd like to commend the Pacific Northwesterners for having the good taste to support so many fine breweries.

My favorite two beers however are of very limited supply:

1. a 135IBU IPA brewed by Thom Thomlinson (which will, by the way, soon be available commercially, albeit only in Thom's area -- CO, I believe), and
2. the conference beer, a Nut Brown Ale, made with Hazelnut extract (YUM!).

Other memorable beers were:

hand-pumped Bridgeport Blue Heron Pale Ale,  
hand-pumped Pike Place Pale Ale,  
hand-pumped Hale's Moss Bay Extra,  
Red Hook Summer Rye,  
Red Hook Blackhook Porter,  
a blueberry ale (if someone knows who the brewery is -- please email),  
Vermont Pub & Brewery (Greg Noonan's) Wee Heavy,  
Steelhead IPA,  
F. Boon Faro, Gueuze and Kriek (at the Belgian tasting -- thanks Mike!),  
Cantillon Gueuze (also at the tasting),  
Rogue Maier Bock,  
Rogue Rogue'n'Berry  
Pyramid Pale Ale,  
Deshutttes Koelsch,  
Squatter's Rocky Mountain Wheat,  
Eugene City Brewing Red Tape Ale, and  
Schmaltz Alt.

Okay, so not all are Pacific NW brews, but remember, there were beers brought to the conference from all over the world, not to mention all the beers at the Oregon Brewer's Festival.

A final point on the Pacific Northwest brews: they were not as hoppy as I had expected. This stems from comments by Pacific Northwesterners after the Milwaukee Conference, that the Midwestern beers are all underhopped.

Well, maybe I agree that the Midwestern beers ARE underhopped, but then, we should also agree that many PNW beers are underhopped too.

Before a flame war erupts, indeed, the PNW brews are, in general hopper than most MW beers, but from what I read here a year ago, I expected them to be twice as hoppy. On having a large variety of good beers, the PNW has the MW beat by a mile. I just hope it doesn't take 20 years for us to catch up!

\*\*\*\*\*  
Jack writes:

It is not difficult at all to make lite colored beer if you dilute it with enough water. The most important adjunct to maintain "Bud quality" is corn syrup. This exotic ingredient produces as much alcohol as needed to compensate for water dilution at the end and contributes no color.

To make Coors or Old Style or Henry's (yes, there are crap beers in the PNW too) or Miller, you are correct -- they use corn as an adjunct. Budweiser is made with rice as an adjunct and I don't think it's that hard to duplicate. Brew up a 1044 beer using 2# of rice syrup in place of some of the lager malt. Hop it to about 14 IBU using Tettnangers (not that hop variety really makes that much difference at such low rates) and ferment it at 50F using Wyeast Pilsen yeast (why it's called Pilsen yeast, I don't know -- it's from St. Louis). I tasted a beer made using these guidelines about two years ago -- it was made from Alexander's Extract, I believe, and was a dead ringer (in flavor) for Bud. Filtering would make it even more authentic as it would lower the body and head retention to be more in line with Bud.

\*\*\*\*\*

I've had luck with getting beer-clean glassware directly from the dishwasher by using a detergent that did not have a sheeting agent and making sure that there was none of that liquid sheeting agent in the little reservoir that's in the dishwasher.

From: SMUCKER@UTKVX.UTCC.UTK.EDU  
Subject: ULTRA LONG MASHES

Like "William A Kitch" in HBD 1194 I am interested in the potential, problems and effects of a mash that extends beyond the conventional 2 hour time frame.

I am aware that some homebrewers have in fact done this by what they have called an oven mash. The way I understand this is that they bring their mash up to the desired temperature and then place the mash pot in the oven with the oven temperature at 140 to 150 F and leave until the next morning.

I am interested in the effects of doing this but in my case with a 15.5 gallon keg for a mash pot I don't have an oven big enough for it to go into.

I insulate my keg after bring it to mash temperature and typically get about 1 degree C or 1.8 degree F temperature drop per hour. My mash would for example drop from 152 F to about 138 F in 8 hours.

What would be the expected effects of a 6 to 8 hour mash vs. the typical 2 hours? At what temperature do you have the potential for a sour mash effect/problem? -- Something I don't want for most of my beer. Do you leach tannins at a low level at mash temperature such that the 8 hours mash will have the potential for astringency? -- It is well accepted that you leach tannins above 168 degrees F.

Thanks in advance for your answers.

Subject: Celis

Ok ok... I'm getting a lot of mail from friendly folks pointing out my mistakes with Celis beers.

First, let me state I'm quite aware of what wit is supposed to be/taste like. Unfortunately, when I tasted Celis white, I tasted a Bavarian. Having no idea that Celis is a Belgian, I found nothing wrong with that. Honest. It tasted more 'weizen' to me than 'wit.' Until I get to try another I'll have to stick with that. No sourness, orange, or coriander came to mind!

As for Grand Cru, I guess I mistakenly assumed Grand Cru is a style, which it's not. I compared it to the only other Grand Cru I know, Rodenbach, and the two are clearly not similar. There is a lambic-ish sourness, and I assumed all Grand Cru's are 'zuur' beers, which sometimes have lambics mixed in as far as I know. Someone has suggested that Celis' GC is actually a Trippel. I don't really know enough about these styles to say, but I guess I proved what happens when you ass-u-me once again. :)

Thanks to all the folks sending me corrections and/or info. I'd love to learn more about these styles, so keep it coming.

One thing I will not back off on: Celis' beers are damned good, no matter what they're supposed to emulate, or be called.

Mike

>  
>Very interesting experience! I could certainly go for mashing-in the  
>night before. Have others tried this? With what success? Jack, what  
>temperature do you mash in at and how does it change overnight?

Actually Jack didn't say he did mash-in the night before, he said he did "dough-in" the night before. I suspect he did dough-in at room temperature in order to dissolve the starch well. I seem to recall a thread about this months ago. I have done overnight mashes myself, ala Dave Line. It works, I have had no undesirable effects from this, although it seems ripe for having a sour mash type of event. A side note: Dave Line is (was) one of the more "relaxed" homebrewing authors around; draw your own conclusions.

Martin Manning writes:

>My personal preference is to measure the extract efficiency at the start  
>of the

>  
>A point which no one has brought up is that if you are using any kettle  
>adjuncts (honey, sugars, etc.), you definitely want to do the  
>calculation  
>before you add them.

This is a point worth mentioning. If you are brewing a certain style and really want to nail that OG, measuring before the boil is a must. At that point, you can do several things: boil more/less to adjust the OG, add DME to adjust the OG, etc. If you don't care as much about the perfect OG, change the hopping schedule to balance the beer for more/less malt (this is what I typically do). After the boil, you have no such options, you are just measuring the efficiency of your process.

Cheers,  
norm

> astringency into the beer, but want feedback on this mashing procedure.

Decoction mashing is used for more than just lagers. Eric Warner details  
the use of decoction mashing to produce Bavarian Weissbier in  
\_German Wheat Beer\_. With a large fraction of wheat (> 50%) as part of  
the grain bill, decoction mashing makes lautering easier by breaking  
down more of the high molecular weight proteins which removes the  
'gumminess' typically associated with high percentage malted wheat  
mashes.

Decoction mashing also tends to increase extract yield.

I've used decoction mashing to make two weissbiers with good success  
(using double decoction mashes) and most recently, a triple  
decoction to make an Oktoberfest which yielded 32.4 pts-gal/lb (to follow  
Geoff's revised unit scheme).

Boiling the grains does not cause a problem with tannin extraction  
as long as the pH of the decoction being boiled is correct i.e., acidic,  
around 5.5.

Use something like a bottling bucket (bucket with a spigot, thought I  
never use one of these things for bottling), connect the spigot to the  
inlet of your chiller, and let gravity do the work.

> 2. Similar to the above, How do you get it started? I am assuming  
Same thing.

One other note, for those who haven't been around for about a year.  
Now you will be running wort through the inside of your chiller. Make  
sure there are no nasties on the inside of your tubing, eg, oils from  
machining, mold from letting water sit in it, etc. To check for oils  
take some kind of solvent (rubbing alcohol, paint thinner, etc) and  
put some on the end of a Qtip. Swab around the inside of your tube.  
If there's gunk on it or some dark discoloration, you should think  
about cleaning it.

As in the past, I have my designs on line and will mail them to anyone  
who wants them for free.

From: mcharry@cw.com (McHarry)  
Subject: Overnight mashing

I have been mashing overnight in my oven for quite some time now. I dough in at room temperature and shove the kettle (my EasyMasher) in the oven set on warm. It is a bit too warm at the lowest setting, but that seems not to be a problem. The temperature rises overnight to about 160 F. This seems to produce a nice, highly fermentable wort with a good extraction rate. I have mashed all sorts of stuff this way, including batches with unmalted wheat flour in them. No problems. I just get up in the morning and put the sparge water on with the coffee.

One other note, I have been draining the lauter tun about half way through the sparge, refilling with sparge water, and stirring well. This seems to prevent any sugars from hiding in gobs of goo, which can be a problem with some adjuncts. It seems to raise the yield a bit.

<From: lfk@veritas.com (Lynn Kerby)  
Subject: Hopping techniques (was Pale Ale Recipe)

<Are there other brewers out there that are doing something similar with their hopping techniques?

Sure. All my pale ales /ipas are multihopped. I usually go for centennial and cascade at 60 minutes boil to the end, about 60% of the total hop quantity. then at 30 minutes a additional 10% or so goes in, and then tons of cascade from 12 minutes until the end of boil.

<From: Don\_Doyle@Novell.COM (Don Doyle)  
Subject: Decoction mashing

<I was wondering if many people use decoction mashing and what the pro's/con's to it are. I have Noonan's book and he swears by decoction for lager's however can one do an ale this way. I have a little voice in my head saying "No" because you will impart unwanted flavors i.e. astringency into the beer, but want feedback on this mashing procedure.

Decoction is a must for all grain weizens, and is very beneficial for many styles of lagers, pils and bocks in particular. It is not worth the extra effort for ales, esp if you are using domestic 2 row pale or any ale malt (M&F, Belgium...;). Its just not worth the effort. If you are looking for more body and chewyness, boost your dextrin pool by using lots of caramel malts. I love the CaraVienna and CaraMunich, as well as english caramel malts. Additional munich malts will also result in more malt/and body. I even gave up the protein rest on my pale ales, opting for a infusion at 160, resulting in rests of 152-154 for 60 min, then mash off at 170 and lauter. I really love making these "easy" beers.

Best,  
Jim Busch

Pts/lb/gal and pts-gal/lb are EXACTLY the same thing. Think about it.

Rick, I find it is much cheaper to buy food grade agar than the stuff  
sold as culture media. You can find it in oriental or natural food  
stores.  
Sometimes the oriental stuff comes in sticks (white or red) which is a  
less  
convenient form. The best stuff to find is in a flaked form. Make sure  
you use TWICE the recommended amount of agar for a given volume of wort.  
I find that if I make it up as recommended the agar throws off a lot of  
water that interferes with my using it as a culturing surface (of course  
the directions assume that you are going to eat the stuff). Since you're  
from Syracuse I can recommend Discount Natural Foods in DeWitt as a  
source.  
Feel free to contact me if you have any procedural questions. I've been  
culturing yeast for some time.

The pros include better extraction, less trub, more complete degradation  
of proteins to soluble components, more well developed malt flavor in the  
finished beer. The cons include more hassle and more time. I do not  
brew  
any classic lager styles, but always use decoction for wheat beer and  
occasionally use it when I want a richer maltiness. Give yourself about  
twice the amount of time you normally need to do a mash.

I hate to nitpick, but the formula pts\*gal/lbs is the same as the  
formula pts/(lbs/gal). I know it's mathematical smoke and mirrors, but  
just thought I'd point it out. Of course, we could also write pts\*gal\*  
lbs^-1  
(that's pounds to the minus one). Or, for that matter, gal/(lbs/pts),  
or...

From: wegeng.XKeys@xerox.com  
Subject: Yet Another Grain Mill

One of my goals for the Portland Conference was to determine which grain mill I should buy to replace the Corona that I've been borrowing. At the risk of starting yet-another flame war, I thought I'd mention that there was a mill on display at the conference that I don't remember seeing discussed here before.

This new mill is from Glatt Machining (address: 820 Stanley Drive, College Place, WA 99324, no phone number given). This is an adjustable two roller mill, with a 2.5 pound hopper capacity. Adjustments are made by loosening one of two screws (one for coarse adjustments, the other for fine adjustments) and then moving a scaled plate. It appeared to be very easy to repeat the settings on this mill. The rollers had large grooves cut along their lengths, quite different than the rollers on the PhilMill (I haven't seen the rollers on the Malt Mill). The handle was very easy to turn while crushing. The crush coming from this mill looked very good to my eye. The entire mill is made of heavy gage metal, with a powder coat finish. Guarantee is 90 days (defects and materials). Cost is \$80 plus \$5 shipping.

Comparing Glatt Mill to the Phil Mill, I liked the fact that the Glatt Mill has two rollers, is easy to adjust, and has an integrated hopper. I didn't get a good opportunity to compare it with the Malt Mill, except to note that it is much less expensive than an adjustable Malt Mill. Finally, the people from Glatt seemed very honest about their product. At one point a friend and I took some grain crushed on a Phil Mill to the Glatt booth, to compare the two crushes. The Glatt Mill appeared to give better crush (eyeball determination), but then the Glatt representative pointed out that it wasn't a fair comparison (even though his mill seemed to win) because we didn't run the same type of grain through both mills. He didn't have to point this out.

I'm probably going to order a Glatt Malt Mill in a couple days.

Date: Tue, 3 Aug 93 09:08:03 -0600  
From: John Adams <j\_adams@hpfcjca.sde.hp.com>  
Subject: Wyeast question

There is no need to hydrate the liquid yeast (it is already hydrated).  
The  
problem you are experiencing is that the number of yeast cells in a  
liquid  
packet is far less than that of dry yeast. It will take more time for  
the yeast from the liquid (when pitched directly from the bag) to "get up  
to  
speed."

The best method for liquid yeast to to make a starter thus allowing your  
yeast more time to grow before pitching into the fermenter.

To make a yeast starter:

obtain a 1/2 or 1 gallon juice jug (or any similarly size glass  
container).  
obtain an appropriate sized rubber stopper and fermentation lock.  
santitize your starter, fermentation lock, and liquid yeast packet.

boil 1 pint water with 2/3 cup light dry extract for 5 mintutes.  
add 1 point cold water to your starter jug.  
add your "mini wort" to your starter.

The additional pint of cold water helps to bring the mixture's temp.  
down to 80-90degress. I usually fill my sink with more cold water and  
sit the starter jug in the water until the temp. drops to ~70.

figerously shake the starter to help oxygenate the "mini wort."  
carefully open the liquid packet and add the contents to the starter  
jug.  
cap with the fermentation lock and wait.

The starter should be ready in about 2 days, I usually prepare my  
starters  
3-4 days prior to brewing. Remember the liquid yeast in the packet  
usually  
take 1 day to "puff up" so plan for 1 day for the packet + 2 days in the  
starter before brewing.

You want the starter to beactively growing before you add it to your  
fermenter. If the yeast activity drops before you are ready to brew then  
make  
another 1/2 batch (1 pint & 1/3 cup extract) to the starter to keep the  
yeast  
growing and active.

Starter's have two maoin advantages:

1) You lower the risk of contamination in your main fermenter by  
giving your  
yeast the advantage.

2) If your yeast gets contaminated then you only lose your starter and  
NOT  
your 5 gallon (or more) batch of beer.

Subject: Homebrew blindness

Dan,  
I read your post to the Digest, the answer is no. There are two (main) types of alcohol: Ethanol and Methanol. Hmmm maybe thats spelled ethenol and methenol... Anyway, Methanol is the one that causes blindness and death. It is also called wood alcohol, de-natured alcohol, rubbing alcohol. It is made by the fermentation and distillation of cellulose ie wood. Grain alcohol is made by the distillation of sugars. The only way to get serious methanol contamination of your beer is to not strain the grain husks out of your wort (at all) in all-grain brewing when its put into the fermenter. The beer would be very nasty tasting to say the least.

Date: 3 Aug 93 11:29 CST  
From: Wolfe@act-12-po.act.org  
Subject: Chilis are Jalapenos

With respect to my last posting on peppers in beer, a number of people pointed out that "chili" refers to a genus of plants under which there are many species of peppers including jalapenos. (Hey, I'm only a statistician.) The "chili" peppers I grew are actually called "Super Chili Pepper, F1 Hybrid." The peppers are about 2.5" long and are cone-shaped (similar to a miniature Hungarian Wax pepper, but they turn a bright red with age). They are still green but are already as hot as (and better tasting than) my jalapenos.

The folks that responded to my first posting said that I could probably substitute these peppers for jalapenos in any recipe, noting that I need to be careful of the variability of heat of different chili species. I'm planning on using a standard amber ale recipe, lightly hopped. Which brings me to my next question. I've heard of three ways to introduce peppers into the brew: 1) boil them with the wort, 2) add roasted peppers to the secondary, or 3) add slices of roasted peppers to the bottles. I'm thinking about using method #2 (from Charlie P's book).

Has anyone used this method successfully? Does anyone have any suggestions for "special ingredients" to sprinkle over the peppers as they roast (like garlic)? Also, How many peppers should I start out with? Should I put the peppers in a steeping bag so I don't get seeds and stray pieces of pepper in the bottles?

Thanks,

From: tims@ssl.Berkeley.EDU

Subject: when to harvest hops?

I have two hop plants, (out of three planted last March), and I am wondering when to collect the flowers. There are already some nice big flowers on the Perle, and lots of tiny flowers on the Chinook. should I take each flower off as it reaches maturity (define that, please), or wait and harvest the whole mess at one time?

The Perle flowers look to my mind just like what hops should look like, while the much smaller Chinook flower seems smaller than I was expecting. As one would expect, I haven't seen all that many flowers this first year, perhaps 2-4 oz total.

Thanks,

Tim Sasseen

I feel that it is still correct to say points-per-pound-per-gal if you remember what it means. Note that in addition to determining the average contribution to your OG from y pounds of grain in z gallons of wort, a more important use of these numbers is to predict an OG when you are formulating a recipe. What you want to know is "how many POINTS you will get if you were to use a POUND of this particular grain to make a GALLON of wort?" This can be also read as "POINTS gotten from grain x at a particular ratio of POUNDS PER GALLON" or finally, "POINTS gained PER POUND PER GALLON." Maybe parentheses would help:

points/(pound/gallon)

> with his rotating gizzmo.

I've been thinking about this for a while, but not too intensely, since I make sure to keep the level of the sparge water about 1/2" above the level of the grain bed. I feel that all the spray-attachments for sparging

are a waste of money. There is another reason for keeping the sparge water level above that of the grain bed: if the level drops below the top of the grain bed, the grain bed begins to compact. If you insist on sparging with a spray head, then you must shell out a few more bucks as well as add some elbow grease and add a raking mechanism to your grain bed. I have an experiment in mind that will take some of the mystery out of this topic, but I have to find the time to do it!

>  
> Should I wait till this evening and if there's still no head  
> re-hydrate and pitch some other yeast?

You probably won't see much activity for about three or four days. If your sanitation techniques are impeccable (very difficult to accomplish in the summer) you stand a chance that it will turn out alright. If you suspect your sanitation at all, I suggest you get some clean dry yeast, rehydrate that and pitch it. A four day lag time in the summer means your odds of infection are VERY high.

Subject: Japanese Homebrew?

Some friends of mine (Japanese) are having a baby in November and I'd like to brew a Japanese style homebrew to mark the occasion. This is a bit of a stretch because I refuse to brew a beer that is too light and tasteless, like the typical Japanese lager. I may brew a dark lager, which is not common but is available in Japan. I plan to use some rice, but not too much. How many SG points can I expect to get from a pound of rice? Will a 2-row pale malt have the enzymes to convert the rice? Any suggestions for hops, or for that matter a yeast choice? This could be a real challenge....

Cheers,  
Norm

From: ghultin@sfu.ca

Subject: overnight mashes

The question was asked about experiences with long mash times:

I have done two overnight mashes, and although I have only just tasted the results from one batch, found no problems.

I mash in a plastic tub swathed in a garbage bag and a sleeping bag. When I put the lid on the pail, the temp is 154, in the morning when I take the lid off, the temp has fallen to 142-146.

I don't know how to tell-other than by taste-if there is any contamination of this wort, but having tasted the beer last night, I think it is just fine.

The book Old English Beers and How to Make Them (or something like that) has recipes calling for 4 hour mashes. This is for undermodified grain, granted. But 4 hours, 8 hours, as far as I can tell, no problem.

>temp for several hours until there is noticable seperation, then pour  
>the top liquid layer off. I again add about a cup of cool water to the  
>yeast, mix it up good, cover and let sit at room temp for several hours.  
>Pour off top layer, pour the resulting yeast cake into a sterile canning  
>jar, cap and store in the refridgerator until you're ready to brew  
again.  
>This is better know as washing yeast and the method can be used with  
>either dry or liquid yeasts. I have been usually re-use a package of  
>yeast anywhere from 7 to 10 brewing sessions before it starts to appear  
>suspicious.

This is great, but knowing that there are always several ways to do anything in the realm of brewing, I am interested in other people's methods and observations on this topic, especially on the matter of storing the yeast for future use. The typical situation I have in mind is storing yeast from the slurry for a few weeks, until one has time to brew again. Also, is the primary or the secondary better for this?

>astringency into the beer, but want feedback on this mashing procedure.

Not many, probably due to the increased work, the increased time and the availability of well-modified lager malts. When using undermodified malts, like those used by Pilsenski Prazdroj (sp?), the brewery that makes Pilsner Urquell, the decoction mashing method is the only way to get a good extraction efficiency. The flavor is also a bit different than with controlled temperature mashing or infusion mashing, or so I've read (having not done a side-by-side comparison using the same ingredients).

Darryl Richman has hypothesized that: a reason that the decoctions do not extract copious amounts of astringent tannins from the grain is due to the pH of the mash. As yet, there has not been a confirmation of this theory, but there has been very little argument with it in the HBD. I don't see why you could not use it for an ale -- I've tasted a PU-clone made by Jack, imitating Pilsenski Prazdroj, which did not have noticeable astringency. The bottom line is, you could do it, but the reasons would be mostly academic.

\*\*\*\*\*

Jack writes (quoting WAK):

Very true. Others in this same issue of HBD suggested overnight saccharification, which in the microbiologically active air of the summertime, I feel, will almost guarantee a sour mash. Indeed, keeping the mash cool overnight is key to making non-sour mash beer using this technique.

**Subject: Flora & Fauna**

Jack writes:

>There is no doubt a multicultural flora ready to do a number on the mash  
but

I've read that yeast are technically a "slime mold" and that they are animals, which would make them fauna rather than flora. I would then assume that non-slime molds would then also be fauna. However, what are bacteria, flora or fauna? My guess would be, again, fauna. I have seen "microflora" and I think I've used the word myself, but I'm playing with this topic just for fun anyway (so don't take it too seriously).

From: reeves@lanl.gov (Geoff Reeves)  
Subject: Algebra and extraction rate

I got quite a bit of mail regarding my assertion that extraction should properly be expressed as pt-gal/lb. Basically most people said that I had forgotten my algebra and that  $\text{pt-gal/lb} == \text{pt/lb/gal}$ . Their argument depends on where you mentally draw the parentheses.  $\text{pt-gal/lb} = \text{pt}/(\text{lb/gal})$ . However this is not the common way of expressing things. Think of gravity.  $g = 32$  feet per second per second.  $32 \text{ ft/s/s}$  is not the same as  $32 \text{ ft}$  similarly energy flux is expressed as particles/second/steradian/keV or similar units. Dimensional analysis assumes that  $a/b/c = a/(b*c)$ . Similarly computer codes that evaluate  $a/b/c$  will evaluate  $a/b$  and then divide by  $c$ .

Now this may seem nit-picky but it pisses me off when people tell me that I don't know algebra. I didn't get one of those mail-order physics PhDs.

Finally to pick one more nit, some people said that SG was not dimensionless but has units of kg/liter. Nope. Specific gravity is density of liquid divided by the density of pure water at 4 degrees Centigrade. Since the density of water is 1 kg/liter the magnitude doesn't change going from density to SG but the UNITS do.

Cheers  
Geoff

From: SMUCKER@UTKVX.UTCC.UTK.EDU

Subject: Wyeast 1007, (German)

I brewed up a batch of German Dusseldorf style Alt over the weekend with about 20 % German wheat malt and Wyeast 1007, (German) and got the strongest fermentation I have ever seen. This is in a 15.5 gallon batch and by strongest I mean the speed and amount of blow off that was generated. I had between 1.5 and 1.75 gallons of blow off and after it settled I had a least 3/4 of a pint of yeast. (Of course the batch is still going strong.) Am wondering if this is the effect of the 1007 yeast, the wheat malt or both. The fermentation temperature was normal for me in summer at 68 degrees F. (Self heating took the temperature to 71 even with my water cooled keg as a fermenter set up.) Just a data point, we will see how this beer is in a few weeks/months.

lfk@veritas.com (Lynn Kerby) writes about boiling all hops << 1 hour:  
>Are there other brewers out there that are doing something similar  
>with their hopping techniques? I would be interested in hearing about  
>experiences with beers that get a significant percentage of their IBUs  
>in later stages of the boil.

Perhaps It's my water (soft, though certainly not softened),  
or the pH, or maybe something else, but I never seems to get  
as much bitterness out of my hop additions as would seem to  
be correct from HBU/IBU/boil time charts. For instance, a recent  
barleywine with 9.5 oz of fresh goldings/fuggles/N Brewer plugs,  
the longest of which was boiled for over an hour (should have had  
150+ IBU) was criticized as being way too sweet in a contest.

To compensate, I have taken to longer hop boils. So far, I have not  
had any problem with off-tastes in young beers (even barleywines).  
Note also that I use a blowoff, which loses some hop bitterness,  
and that I do not use high-alpha american hops.

Many (Most?) breweries (PU and Traquair I know for sure)  
boil the bittering hops 4+ hours. As long as you have an handle  
(from experience) on how much hop bitterness to expect, I see no  
reason to boiling the bittering hops for an extended period of time.

Yes, longer boils diminish hop flavor, but that's what the flavoring  
hops are for.

...  
>What would be the expected effects of a 6 to 8 hour mash vs.  
>the typical 2 hours? At what temperature do you have the  
>potential for a sour mash effect/problem? -- Something I  
>don't want for most of my beer. Do you leach tannins at a low  
>level at mash temperature such that the 8 hours mash will  
>have the potential for astringency? -- It is well accepted  
>that you leach tannins above 168 degrees F.

I have had no problems with an overnight mash, but don't stretch  
it past, say, 12 hours. As long as the temp stays >> 120-130,  
everything keeps fine, but it doesn't take the mash more than a  
few hours to sour, once it drops back into the 80-100F range.

I have NOT tried mashing in overnight and leaving the beer  
in this range for an extended period of time BEFORE mashing.  
With such such a practice, the majority of the malt sugars have  
not formed yet and souring may be less of a problem.

Date: Tue, 3 Aug 1993 21:34:47 -0700 (PDT)  
From: Paul dArmond <paulf@henson.cc.wvu.edu>  
Subject: more on FaceMail...

I've had a request via private e-mail to be more forthcoming about the facemail project, so here goes...

There are several software packages available that produce low-quality, motion images on your, well maybe not your, but many computer screens. They go by a number of names, of which Quick Time and Video for Windows are the most advertised. As usual with multimedia, the advertising is overblown and deceptive.... (I will skip my usual rant on the damage done by advertising hype in my field)

None of these packages do video. What happens is that the incoming video stream is sampled and converted into a bitmap for every so many frames. Very few of the systems offer 30 frame per second (video speed) display rates. Those that offer sound with the video interleave digitized audio with the picture bitmaps at substantial reductions in frame rate.

The net result is much more like the cartoon flip books than true motion video. Some systems use special hardware to get the frame rate up, but this is an expensive compromise.

Most of the animated images occupy only a small portion of the screen, a postage stamp....

So don't get your hopes up too much...

The good news: I should be able to prepare complete runtime packages for DOS, this will require a 33Mhz 386DX with a standard vanilla VGA for acceptable performance. These systems should be widely available. I will also produce a Quick Time version for the user-interface impaired, uh I mean the rest of them, uh, you know, the fruit machine people.... Quicktime viewers are reasonably available among the Mac tribes. The Quick Time version will be later in arriving, since I have to steal machine time at another site to convert the video. Any Quick Time users out there (Spigot owners?) who want to volunteer to speed up this process will be very welcome.

So, I should be able to get stand alone programs for DOS and Mac owners should be able to lay hands on the appropriate drivers.

These motion video (sic) files are pretty big, even when heavily compressed. Expect to spend a while downloading them. Don't even consider sending them UUencoded....

As I slowly work my way into this project, I'll be posting progress reports. The next step will be to do a rough edit on the videotape. At that time I'll report how things are looking and approximate runtimes. With any luck, this will be a Xmas present. While I was in Portland, I had a huge backlog of high-priority stuff pile up on me....

patience,

Paul.

Subject: Ice Beer--now there's a concept!

NY Times, Page D3, August 3, 1993:  
"Our northern neighbor is putting ice in our beer."

Banking on strong performance of a new product called "ice beer" in Canada, Molson Breweries plans to introduce Molson Ice next week on a trial basis in Atlanta and Michigan.

Basically they go on to say that they almost freeze the beer--and then remove the ice crystals. It supposedly leads to a smoother and (this is true) more alcoholic brew. However, "It is being marketed for its smoothness and distinctive, full flavored taste. The fact it has higher alcohol is a fact not a market element" (yeah right!)

Anyway, an interesting "New Brew From Molson," too bad the Germans already invented it.

From: "Andy Phillips, Long Ashton, Bristol, UK" <phillipsa@afrc.ac.uk>  
Subject: Recipe for Dunkelweizen needed

I'd like to have a go a making a dunkelweizen soon. I have a few questions about recipe formulation:

1. What grain should I use, and how much, to get the colour right? I can get hold of chocolate, black patent and crystal malt, and roast barley. I could probably roast my own malt to give an amber malt. I can't buy Cara or (mainland) European speciality grains. My best guess is crystal plus some chocolate.
2. Hops? Hallertauer?
3. Yeast? I know of no source of liquid cultures of wheat beer yeasts in the UK. I can buy several HefeWeizens, which of these do you think would make the best starter: Thurn und Taxis HefeWeizen or Roggen, or Erdinger DunkelWeizen? The last of these seems to throw a good sediment, so this is my first choice. Are all HefeWeizens bottle conditioned, or are some pasteurized?
4. Temperature? Unfortunately, I have no control over this, so I may have to wait for autumn before I start. The temperature in Bristol today is a sizzling 67F.

Thanks for any help,  
Andy Phillips

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hops,1007,overnight mash

FYI, male hops flowers are easily distinguished from the female cones we all know and love. Whereas mature female flowers are, well, cones, like pine-cones, male flowers are quite different. The male flowers will consist of a number of short stalks, maybe 6 or so, about 1/2" to 1" long, with a ball (hopefully) at the end of each, which contains the pollen. I say hopefully a ball, because if it's not a ball, it's an small open flower, and the pollen has been (is being) released.

Wyeast 1007 (German ale) has produced a very vigorous fermentation every time I have used it. Probably a good yeast to use in the summer. Surprisingly, it can make a very fine Porter.

Never mashed overnight, but I have mashed and sparged, and then boiled the next day. I know it sounds dangerous, but I've seen no indication of souring. My mash/sparge technique is such that exposure of the wort to spoiling organisms is minimized, but then again, I may have just been lucky. It is a very convenient way to brew. I don't think I'd recommend it during the summer though, or in a less than squeaky clean environment.

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Multiple Styles from single mash/boil

I have just recently begun doing 10gal batches, and am looking for ways to get two separate styles from a single mash/boil. For example, my last batch was a 50% wheat mash. After boiling and cooling, I separated the wort into two 5gal fermenters. Into one, I pitched Wyeast 3056 (a Weizen strain). Into the other, I pitched Wyeast 1007, with which I have had good luck making wheat beers. In a few days, I will add some fresh fruit to this batch (perhaps blackberries or peaches), thus I will end up with two separate batches from a single mash/boil.

Does anyone have suggestions for other mixed-batch recipes, from a single mash/sparge/boil?  
For example, I had considered making both a Helle- and Dunkel-Weizen by doing a separate, very small steep of some chocolate malt, boiling the resulting liquor, and adding this to one of the fermenters. Would this have worked out? Any other suggestions?

E-mail is fine; I'll post any interesting suggestions.

From: chiz@atmel.com (Robert Chizmadia)  
Subject: rebottling

Hi,

As a favor for my upcoming wedding, I decided to brew a batch, print up a label and give it out. My usual container for bottling is a two liter glass container ( carry-out from my local brew pub ). My problem is I only bottled 55 12-oz'ers for the wedding, put the rest in 2-liters ( hey, I like to drink my beer ), and last night my fiancée informed me that I would need 60 bottles because she miscounted. The beer is an ESB from extract, OG of 1.054 and FG of 1.012, using a Munton and Fison dry yeast. It was bottled 3 days ago.

My question is is it possible to rebottle from the 2-liters to the 12-oz bottles? I assuming I will need to re-prime the smaller bottles, and that enough yeast will still be present to carbonate the beer. But what effect will the dissolved CO2 have ? should I allow the beer to go flat first?

And I am responding because I am bored and can't find anything else in this issue to argue with.

Many modern taxonomists prefer to create an entirely new kingdom for all fungi and hence they are neither flora nor fauna.

The general concesus however, is to place fungi in the Plant Kingdom and they therefore become flora. Although some slime mold plasmodium do migrate impresively over a substrate, this does not change their taxonomic position as flora nor are they any more closly related to yeast than a mushroom.

Yeasts are somewhat unique in that they are single celled organisms with little or no propensity to form colonies. This is also true of most bacteria but they are miles away from each other taxonomically. Yeast is as evolutionarily removed from bacteria as far as humans are from yeast. The fundamental difference between bacteria and all the rest of us is that they lack a nucleus and all the genetic implications involved it that.

Bacteria are exceedingly primitive plants in current thinking although some would again put them in a kingdom of their own.

My reference to fauna invading the mash was in terms of flies or other animal types that could get it if not covered or small enough to get in under the cover.

From: WEIX@swmed.edu  
Subject: Alcohols

Hi all,  
IHTNPB (I Hate To Nit Pick But):  
Methanol=wood alcohol=denatured alcohol, but NOT rubbing alcohol.  
Rubbing alcohol is isopropanol(or 2-propanol).

Another thing,  
Korz writes us saying:  
>Jack writes:  
>>There is no doubt a multicultural flora ready to do a number on the  
mash  
but

>I've read that yeast are technically a "slime mold" and that they are  
>animals, which would make them fauna rather than flora. I would then  
>assume that non-slime molds would then also be fauna. However, what  
>are bacteria, flora or fauna? My guess would be, again, fauna. I have  
>seen "microflora" and I think I've used the word myself, but I'm playing  
>with this topic just for fun anyway (so don't take it too seriously).  
>Al.

To which I say (not that I am taking this seriously), IHTNPB, yeast?,  
slime  
molds? I think not. Yeast are unicellular fungi, and although some yeast  
can grow into multinucleate organisms complete with psuedohyphae and  
other  
technical words, they cannot move, aggregate, grow a stalk, or do any of  
the  
other nifty things that slime molds can do. Slime molds, however, make  
bad  
beer, so I would call it even. Also, to relegate fungi to the animal  
(fauna) kingdom or to the plant (flora) kingdom seems to me to be  
unnecessarily restrictive. I believe that the correct scientific term  
for  
anything that is smaller than a mouse and that does not nurse its young  
is the  
word "bug" (from the greek, I believe).

>the extra effort for ales, esp if you are using domestic 2 row pale or

Well, despite the fact that I haven't done an all-grain Weizen, I would like to propose that perhaps it's a good protein rest that is essential for a brew with a large percentage of wheat and not necessarily a decoction mash that's essential. Indeed, the decoctions will help convert the starches in wheat, especially raw wheat, but I've tasted quite a few very good weizens made with temperature-controlled (step) mashes.

On a semi-related topic: mashing technique nomenclature. There's a lot of conflicting information in the books and magazines regarding the following point. The point is that:

"step-infusion mashes == temperature-controlled mashes."

What I mean here by temperature-controlled, is stovetop mashing, where the burners are used to raise the mash from protein rest to saccharification rest to mashout. \*I believe\* that step-infusion mashing is NOT the same, rather it is a method whereby hot water is \*infused\* into the mash to raise its temperature. Do I have this nomenclature right? I've read conflicting views on this.

This would imply that there are basically four methods of mashing (the last having multiple variations):

1. single-infusion -- add a measured amount of water at a calculated temperature to bring a measured amount of grain to saccharification temperature. Mashout is often not done and the hot sparge water is what effectively ends the conversion.
2. step-infusion -- add a measured amount of water at a calculated temp to bring a measured amount of grain to protein rest temperature. Add another infusion of hot water to bring the mash to saccharification temp. Finally, add boiling water to get the mash to mashout temp.
3. temperature-controlled -- dough-in (cool water) or mash-in (protein rest temperature) with the full mash volume of water. Add direct heat to raise the temperature to other rests.
4. decoction -- dough-in or mash-in with the full mash volume and then remove parts of the mash to a kettle in which this "mash fraction," which is called a decoction, is heated to boiling and then returned to the rest of the mash to raise it's temperature. There are several variations to this (double (two decoctions), triple (three decoctions), etc.) in which some of the decoctions are replaced by infusions or the entire mash is moved to a kettle and then direct heat is used in place of one or more decoctions. It is interesting to mention that decoction mashing can be done WITHOUT A THERMOMETER, given enough experience, which I've read is the reason that it was invented (they did not HAVE thermometers at the

time).

Subject: Substitutions and Bulk Malt Extract

Question #1)

I am planning to make a porter whost recipe calls for 5# of dark malt extract.

I have 3.3# of dark and 1.7# of light. I have heard that their is a way I can use the light in place of dark if I add roasted barley, black patent, or chocolate malt. Is this wise? Which should I use if it is? How much? On that note, is there any rule o' thumb for substitutions like this?

Question #2)

I was at the local health food store (People's Food Coop, Ann Arbor) yesterday and I noticed that they had bulk "barley malt" they sold by the pound. Is this type of stuff ever suitable for brewing? Anyone ever try? It is about \$1.50/lb so it seems it would be a cheap experiment to brew something with it? Any suggestions?

^^^^  
This had better be boiled and cooled water -- \*everything\* must be  
sanitized  
(sterilized would be even better -- I use a pressure cooker).

> add your "mini wort" to your starter.  
> The additional pint of cold water helps to bring the mixture's temp.

>"in the know" of what a fine beer should taste like.

Yes... I did, at that place with three names (something Bakery,  
something Restaurant and Widmer Brewery (although it is technically  
next door)). I don't have my tasting notes here, but I remember it  
was very good. I recall it had an OG of 1066 and did have a noticeable  
alcoholic component to the flavor. It was really the first American-  
made Bock I've tasted which I feel deserved to be called a Bock.  
Most I've had don't have that alcoholic component. If you like  
Widmer Bock, you might as well take any remaining Henry's and MDG  
out of your fridge and store it warm for rinsing kegs... you'll need  
the room for some of the great bottled beers in the PNW!

Tim writes:

>I have two hop plants, (out of three planted last March),  
>and I am wondering when to collect the flowers. There

Ideally, and if you have the patience, harvest each cone  
as it becomes ripe. Ripe cones are noticeably lighter, drier  
and "fluffier" than un-ripe. If it begins to turn yellow  
at the tips, then it's over-ripe. Note that you will still

have to dry them before storing them away. I don't have my notes here, but last year, I believe my hops lost 90% of their weight during drying -- I used a food dessicator, but I think it was too hot (too rough on them).

\*\*\*\*\*

I wrote that yeast are animals. Apparently, two or three additional kingdoms have been created in addition to plants and animals. Yeast appear now to be neither plants nor animals.

I  
>picked up some viable yeasties?

Yes it's possible, but you need to give it a day or two to start. You may have picked up some viable yeasties, but dry yeast is quite a bit faster starting than the small amount of SNPA yeast (which by the way bears a striking resemblance to Wyeast #1056), so the SNPA yeast contribution was probably imperceptable.

>had any problem with off-tastes in young beers (even barleywines).  
>Note also that I use a blowoff, which loses some hop bitterness,  
>and that I do not use high-alpha american hops.

First off, I virtually always use some flavor hops in the last 15 minutes of the boil, often 20 to 40% of the IBUs in the last 15 minutes.

Secondly, I use Jackie Rager's formulas, but add 10% since I use a hop boiling bag and another 10% if I use whole hops in stead of pellets. I have not had my beers tested for actual IBUs, but my taste buds seem to confirm that my numbers are right. My boil hops are usually in for 60 to 90 minutes.

>Many (Most?) breweries (PU and Traquiar I know for sure)  
>boil the bittering hops 4+ hours. As long as you have an handle  
>(from expreience) on how much hop bitterness to expect, I see no  
>reason to boil the bittering hops for an extended period of time.

I'm quite certain that most breweries don't boil that long, let alone boil their hops that long. I've read that the maximum utilization one can expect from hops is 30% of the alpha acids and according to various hop utilization tables I've seen, anything more than 60 minutes does not increase hop utilization significantly.

From: hartman@varian.CSB.Varian.COM (John Hartman)  
Subject: Re: Counterflow Questions

In HBD #1195 Jim Grady <grady@hpangrt.an.hp.com> asks:

> 1. Some have mentioned that they sanitize their counterflow chillers by running boiling water through them. How do you get the boiling water in the chiller without scalding yourself?

I'd like to point out a technique I've been using with my counterflow chiller for about the last 8 batches. It improves sanitation while reducing the work involved.

I must say first of all that one needs a hot water pump. About 5 minutes before the end of the boil I setup the counterflow chiller: To do this I place a pick up tube in the boiler and attach its output to the input of my hot water pump. The output of the hot water pump is then attached to the input of my counterflow chiller. It's important (for priming purposes) to have the pump upstream of the counterflow. Otherwise there's too much dead-volume and priming becomes a nightmare. Leaving the counter-flowing water turned off (sic) I start the system from the output-side of the chiller. Once started I direct the output back into the boiler. Within 15 seconds this tepid wort reaches a temperature of 180F, since it's not being chilled. I leave the system pumping this way for 5-10 min. During this interval the entire chiller is sanitized. Any pathogens originally in the chiller are quickly killed either in place or as they are carried to the boiling vat.

At this point I turn the burner off and the counter-flowing water on. Within a minute the effluent drops to pitching temp and I then direct it to the waiting fermentor. The nice thing is the system only needs to be plumbed once--for both sanitizing and chilling. This saves a lot of time and minimizes the hassle of sanitizing the chiller.

From: LIFE'S TOO SHORT TO DRINK CHEAP BEER <UNDERWOOD@INTEL7.intel.com>  
Subject: Hot yeast

Hey all,

First..I made my first all grain a month ago. I'm pleased with the results...no it wasn't harder but it took a while longer to clean up. Anyway, the plunge has been took. Now. I saved the leftover yeast slurry in a (hopefully) clean sanitized Mason Jar. It went into my beer fridge and nicely settled out into several layers of color. Well my electric bill decided the beer fridge had to be shut off. Now a month later, I have this mason jar in a hot fridge in a hot garage (New Mexico is HOT in July) full of hoy yeast. Are they still good? The top has bowed up quite a bit. Should I throw it away and buy more or if I can use it....what now?

Thanks in advance

From: jimmy@netcom.com (Jimmy Patrick)  
Subject: Beer (the magazine)

I saw the recent article about All About Beer by (sorry, I forgot.)  
I just received the premiere issue of a magazine called "Beer the  
magazine

" It is put out by Bill Owens, founder of Buffalo Bill's in Hayward and  
publisher of American Brewer magazine. The book is about beer, not  
specifi-  
cally brewing. But, it may be of interest to some of you. I talked to  
Bill  
about 8 months ago and he mentioned a Wine Spectator (ie tabloid, high-  
gloss)  
format. The magazine looks way better than I could have imagined.

Some articles:

Hot&Wet - Chili Beer

Wheat Beers - Feature article & reviews

Beerspective - A column by (you guessed it) M. Jackson

Interview with Alan Eames (the Beer King)

Easy Homebrew - Easy Steps to Better brew

etc. etc.

The magazine is fat and contains many articles. It might be worth  
a look but again, it is aimed for consumers. I have no financial interest  
in the magazine but I thought you all might be interested. E-mail me  
for more info.

From: John Mare <cjohnm@ccit.arizona.edu>  
Subject: RE: Yeast = animals?

The perception that bacteria are "plants", and protozoa are "animals" is an old one, no longer held to be useful or valid. While no single biological classification is accepted by all, a currently popular one is the so-called "Five Kingdom System". The imbibers of beer are in the "Animalia", the hops and barley are in the "Plantae", the yeasts are in the "Fungi", the unwanted (but sometimes necessary) bacteria are in the "Monera", and the protozoa (often in the water until boiled) are in the family "Protista". Another name for the "Monera" is "Prokaryotae", the kingdom in which the bacteria reside. All monerans are unicellular, and have no no organized nucleus, in contrast to the multicellular members of the "Plantae". As you can see there is little sense in persisting with the idea that bacteria are plants!

The term "microflora" has been and still is widely used to describe populations of bacteria, but this usage too is falling away, to be replaced by the more neutral "microbiota". I hope this helps!

Can anyone report the collective review of the grind-off between the Maltmill and the PhilMill which occurred at the AHA Conference Jamboree last Tuesday night ? Has anyone analyzed the grind from the Glatt Malt Mill, specifically, do the deep grooves in the rollers tear the husks apart too greatly ?

For those lucky enough to have some of the Chile Extract given away by The Beverage People during the conference, could you please post the results of its use.

Regarding yeast starters beginning with a petri dish. At the Yeast Culturing class given by Siebel at the conference last Saturday, they tell commercial brewers to increase volume by no more than 5 times per step so that the yeast would get accustomed to eating various sugars as they'll be found in the wort. They did concede that homebrewers with low volumes of well-aerated wort could get by with step increases greater x 5. I go from 5 ml to 50 to 500 then finally to 1500. Diacytl or excessive unfermentables don't seem to be a problem. They also recommended starter gravities around 1048 unless the target beer is high gravity.

Subject: Help No Hops

I've been brewing hopped extract kits for years. Under the encouragement of HBD and Prodigy BB, I started using un-hopped kits, and DME to make great all-malt brews (for an extract brewer). The problem is, in my haste I left out the hops from my latest brew, I added Irish Moss to the boil and forgot the hops (thought it seemed too easy). I'm now two days into the primary and guess I'm destined to dry-hop the entire 5 gal batch.

I used two cans of M&F light to make up 5 gal. I have never dry-hopped before. I have 2 ozs. each of Cascade and Chinook. Can anyone suggest the procedure and amount for me? Oh, pellet hops is the type I have.

Enjoy reading all the great information here on the Digest. Thanks for any and all techniques to remedy this oversight.

Item #1 Another opinion on ALL\_ABOUT\_BEER:  
I recently picked up a couple of issues of ALL\_ABOUT\_BEER recently and found the magazine a worthwhile read for a variety of reasons. It is not however (in my opinion) going to replace the other beer and brewing publications I read.

Micheal Jackson's article are always a great read. When NEW\_BREWER (otherwise a good mag) did an article on "women in the brewery" and it was about what wimpy/pale/fruity beers you should make for ladies, ALL\_ABOUT BEER was doing a series (not just one article) on women in the brewing industry from distributors/ importers to owner/operator/brewers. Kudos to ALL\_ABOUT\_BEER. Shame on you NEW\_BREWER.

Item #2 Wyeast 1007, (German)  
>Dave Smucker, Brewing beer -- not making jelly!

>I brewed up a batch of German Dusseldorf style Alt over the >weekend with about 20 % German wheat malt and Wyeast 1007, >(German) and got the strongest fermentation I have ever seen.

This is the usual experince I (and other club members, Just Brew It.) have had with this strain. If you pitch it at the rate you should, it will crawl out of the fermenter at the slightest provocation. We should have such problems with all the yeast we use. The warmer temps you mention will only agravate the "problem??".

Item #3 HBD #1197. Subject: Steve and Tina Daniels  
chuckm@pbn73.cv.com asks about Steve and Tina.  
I have met the Daniels Duo. Several times: Foam Rangers meetings, AHA stuff, contests. They are great people and talented brewers. They also do a mean job remodeling houses (all in their spare time..... HA). In Foam Rangers circles, Steve is known as "Negative Man" due a now legendary episode where he dumped a whole batch of wort (and started over) just because he forgot to rest the mash at 120 deg F. Hard to argue with their track record in contests.

My impression of their contest strategy is that they have adjusted recipes to directly respond to judges commnts and thus systematically hone their beers to "perfection". At least until the beers are very good indeed. Please look at LAST YEAR's zymurgy listing the AHA national winners and their recipes. I believe you will find 3 Steve and Tina recipes. Look at them carefully. They are in 3 different categories (of course). To the casual inspection, at least 2 of them appear virtually identical and the 3rd one very similar. What does this tell you??

- A.) The same beer can win in more than one category at the national level.
- B.) Some style descriptions are not very useful in helping

judges distinguish among similar styles.

C.) The most important parts of the brewing process are not captured in a recipe.

D.) Some brewers don't want to give away all their secrets or don't worry if published recipes allow you to duplicate a beer.

I don't honestly know the answer. It may be none of the above. Looking at these recipes as a brewer of 15 years, I don't see how they can be too helpful to novice brewers who want to follow in the footsteps of true winners like Steve and Tina.

Item #4 Temperature control

I will soon be fermenting in a modified refrigerator due to relocating in the Houston area and I am wondering about fermentation temperature control. Has anyone tried immersing the thermostat sensor in the fermenting liquid. I would assume that you would want to put the sensor in a narrow tube with a closed bottom to prevent direct contact with the liquid but to still get a good temperature reading. I would also assume that the tube would be glass, stainless steel or plastic that could be adequately sanitized. Any ideas, drawbacks?? Is this already standard practice and I am reinventing the wheel?

Beer is food.

**Subject: Recipe Postings**

A recent posting pointed out a problem (to me anyway) with the Cat's Meow.  
It's not really a problem with the Cat's Meow, rather with those who post recipes. Someone posted a recipe awhile back which made it into the Cat's Meow. Later, the poster comes back to HBD and admits it wasn't that good a beer.

Why post untried recipes? It's not fair to other brewers to have to flush 5 gallons of beer representing \$20-40 worth of ingredients down the drain when they repeat your mistakes.

Recipe postings are great and so is the idea behind the Cat's Meow, but please, wait until you've tasted the beer and can comment on it at the very least. Even posting a recipe and saying it was underhopped or too malty, or whatever is better than saying, I haven't tried this yet especially when you have to come back a few months later and say it was a complete flop.

From: rgarvin@btg.com (Rick Garvin(761-6630))  
Subject: Old Ale

Well, I finally got a ribbon at the AHA Nationals. It was nice being there and it was a bit of a surprise. Of the three beers that I entered (Old Ale, Barley Wine, and Imperial Stout) the Old Ale was the least good. The recipe, which follows, was high on the IBU side. This was meant to be a strong Pale Ale.

You say "Wow! Are the only beers you brew strongly alcoholic? Do you have a need for lots of VERY strong beer?" Actually, I do not feel that anything but strong beers can be done justice with the format that AHA uses for their national. The time between bottling date and Best of Show judging is at least 4 months! Most beer styles have passed their peaks by then.

My experience judging American Pale Ales enforces my opinion. All of these beers lacked fresh hop aroma. Many had cooked vegetable aromas and flavors. None was superb. The American Wheat that was awarded First Place was the only beer without faults. In the second round I expect beers to compete on superlatives, not who has the least faults. I believe that all of the problem that we tasted were age related. The good beers in this style that we had in the Washington, DC regional "The Spirit of Free Beer" had the fresh beer character that is the trademark of this style.

Maybe the lesson here is enter the regionals with the American Pale Ales. This style needs the faster turn around. Not to mention cheaper entry fees and better prizes.

My congratulations to Thom Tomlison for a well run second round and BOS.

And now, for some beer:

Garvin's Old Ale  
#159  
Rick Garvin  
Arlington, Virginia  
all-grain recipe

Recipe for 7 gallons:

14 pounds British Pale Ale malt  
1 pound 40 Lovibond Crystal malt

4 ounces Mt. Hood hop pellets, 3.7% AA. Boil 70 minutes.  
1 ounce Mt Hood hop pellets, 3.7% AA. Boil 10 minutes.  
1 ounce BC Goldings hop pellets, 5.0% AA. End of boil.

1 tablespoon Irish Moss for last 15 minutes.

16 ounces thick slurry Sierra Nevada strain yeast (Old Dominion Ale)  
3/4 cup corn sugar to prime.

Original specific gravity: 1064

Terminal specific gravity: 1014  
Brewing date: 4/19/93  
Primary fermentation: 1 week, 65 degrees  
Secondary fermentation and lagering: 1 week, 65 degrees  
Bottling date: 5/3/93

Brewer's specifics:

Single temperature infusion mash:

Dough in malt with 1.33 qts/lb water (5 gallons) water at 165F for a  
sacharification rest 154F-152F for 60 minutes. Sparge to collect 9  
gallons.

Boil sweet wort for 30 minutes before adding hops. Chill and pitch.

From: LLAPV@utxdp.dp.utexas.edu  
Subject: chili beer

Howdy, y'all!

I see that discussion is beginning of the use of chili peppers in beer again, & by coincidence, I tried my own Serrano beer last night. I was brewing a batch of Czech(oslovakian) Pilsner back in June, when the last discussion of chilis was going on. I decided to try it out, but I only wanted a few bottles. To do this, I tried the Ed's Cave Creek Chili Beer method, which is adding a serrano to the bottled product. I had had Ed's before, & found it overwhelmingly spicy. According to one HBD'er, whose name befalls me, Ed's maxed out in spiciness after 60 days. I'm sure that what I had was at least that old, so I figured that if I drank it early enough, it would be pleasant enough. That was very true! I bottled it 17 days ago, and the beer was spicy, but nowhere near overwhelming. The beer flavor was not obliterated by the pepper, but the two were well balanced. A successful experiment.

Some technical notes: I had originally intended to use jalapenos, but discovered that they were, for the most part, too fat to fit into the bottle. Serranos are much thinner. According to the Scoville method of measuring spiciness in chilis, serranos are hotter than jalapenos, but not much, so I figured they were the way to go. They were more expensive, but it came out to 3.5 cents a pepper, so it wasn't like I was going to go broke. I reviewed suggestions posted in the HBD about how to make sure the chilis were clean enough to introduce into the beer. Since I didn't like any of them, I decided to just wash them off in good old hot water. I dropped one in each bottle, poured the primed beer over it, & capped it off as normal. I noticed that the bottle I had last night did not gush, as chili beers often do, plus it didn't have any tastes that one might associate with bacterial infection; therefore, I would assume that the serranos were clean enough at bottling time. Something to think about.

I also used some chipotles (smoked jalapenos) in a couple of bottles instead of serranos. I intend to try one this weekend. I'll have a review early next week.

Since chili peppers are, technically, fruit, I was wondering if this method would work for other fruits. Has anyone out there bottled fruit with their

beer instead of adding it at an earlier stage? I'd like to know. I want  
to  
make a mango beer & a prickly pear beer, but don't want lots of it.

Happy brewing,

Alan, Austin

>  
Hmmm... Every starter I ever did was in the 1.045 - 1.050 range. It  
just didn't seem quite logical to make a starter at 1.020 and pitch the  
yeast grown therein into a 1.045+ wort. I would think it would be better  
to subject a small number of cells to the initial osmotic stress of  
adapting  
to a given wort than a much larger number of cells to a smaller osmotic  
shock. One might suspect that stressing a large number of cells might  
lead  
to some off-flavour components. On the face of it, it would appear that  
the people at Siebel concur. What sort of starter gravity do they  
recommend  
for a high gravity beer?

Subject: Botched Batch....

I messed up. I started a batch (had a good boil going, added my malt extract, bittering hops after ten minutes) and then realized that my flight outta town was not at 1pm, but 11:10 am, and that I hadn't packed or dropped my son off at my mother-in-laws yet and it was 9:15 with an hour drive to the airport. So....I turned off the heat, removed the pot and covered it and put it in the basement. My question is "what is the best course of action now?" Do I start it up with another boil (it was on the stove for only 20 minutes) or do I just add the next bunch of hops (ie. dry hop) and the yeast and hope for the best??? I realize this post/experience makes me sound kind of stupid, but, I can deal with that, some answers/suggestions would be appreciated.

One more thing, I did this tuesday the 3rd, and today's the 5th and I'm back.

Geotex@engin.umich.edu writes:

>I am planning to make a porter whose recipe calls for 5# of dark malt extract. I have 3.3 # of dark and 1.7# of light.....I have heard that I can use light in place of dark...?

I always buy light malt extract when I make an extract beer because you can always darken it but its difficult to lighten when you start with only dark or amber extract. For a porter I would recommend using black patent or chocolate malt (possibly about a 1/4lb or the former and 1/2 to 1lb of the latter, depending on your preference. IMHO, I would not use much roast since that is more characteristic of stouts. Again, you could crush or not crush the grain depending on your preference for color and steep it in water up to about 180 F. Sparge this with hot water and add it to your wort.

BTW, in reference to "All About Beer", it is now produced in Durham, NC the former beer capital of the Research Triangle !! The magazine appears to be quite well done, both colorful and interesting, though not for the technically oriented. There is even an article on introducing people to homebrewing.

A section called Beer Talk has 5 noted experts and one quest expert rate 5 different beers. The experts include Fred Eckhardt, the ubiquitous Michael Jackson, Charlie Papazian, James Robertson and George Saxon. But the quest expert really showed herself to be a beer connoisseur. Not only does she have an uncanny ability to detect subtle flavors and aromas in beer, she makes great Indian Food. She happens to be my wife (;^)!!

All disclaimers apply.

Subject: **Barreling Beer**

Previously, I asked for Brewers' experiences concerning "barreling" beer in wooden casks. With that, I received no responses. Maybe I need to be more specific with my barreling concerns.

I have a 5 gallon wooden barrel (together with spigot) capable of holding fluids. I plan to use my carboy as a primary fermenter (for a nutbrown ale).

When its time to transfer to bottles - I instead want to transfer to the wooden barrel. After the beer has conditioned in the barrel for about a month, I'm going to slam the spigot into the barrel and drink (along with 5 gallons worth of friends).

My concern is - Will a standard-fluid-capable-wooden-barrel be able to withstand the pressures that the beer will produce (during the conditioning process) over this period of a month?

Thanks in advance.

Subject: dunkleweizen & dual brews

IN the last digest:

<From: "Andy Phillips, Long Ashton, Bristol, UK" <phillipsa@afrc.ac.uk>  
<Subject: Recipe for Dunkelweizen needed

<

1. What grain should I use, and how much, to get the colour right? I can get hold of chocolate, black patent and crystal malt, and roast barley. I could probably roast my own malt to give an amber malt. I can't buy Cara or (mainland) European speciality grains. My best guess is crystal plus some chocolate.

60 - 70% wheat malt, pils for the balance except use lots of Caramel/crystal and a small amount of chocolate. Stay away for Black at all costs. You might try the Hugh Baird Caramel malts, I believe you can get them in 40, 60 and 80 lovi.

<2. Hops? Hallertauer?

excellent choice, keep IBUs below 18.

<3. Yeast?

Mailorder a culture of Weihenstephan #68 (apparently this is the real number not 66??). Several yeast suppliers have this including the Yeast lab folks, the Yeast Culture Kit folks and apparently the newest Wyeast weizen. Most bottled versions are useless to culture from.

Weizens

that "throw a good sediment" are usually krausened with lager yeast.

<4. Temperature? 67F.

Good.

Subject: Multiple Styles from single mash/boil

Does anyone have suggestions for other mixed-batch recipes, from a single mash/sparge/boil?

Sure, how about a barley wine and a small beer from the second runnings. Or, brew a 1.060 batch, hop it highly, split into two fermenters, dilute one down to 1.040 and call it a bitter, ferment the other and call it an IPA.

\*\*\*\*\*

<From: chiz@atmel.com (Robert Chizmadia)  
Subject: rebottling

2 litres into 12 oz.... Sounds like a lot of work and potential for really flat and/or oxidized beer. If you must do this, fill a keg with CO2, pour the beer into the keg, close and purge the keg with more CO2, shake and purge the escaping CO2 until flat (or close). Grow healthy krausen beer (10% of volume to be added into), mix krausen beer at high krausen and bottle. The secondary fermentation from the krausen beer \*may\* be able to absorb enough O2 to prevent oxidation. Allow 10 days to condition prior to dispense.

Good brewing,

Subject: decoction/weizens/mash techniques

<From: korz@iepubj.att.com  
Subject: Decoction a must?/Mashing techniques

<Jim (as well as one other poster) writes:  
>Decoction is a must for all grain weizens, and is very beneficial for  
>many styles of lagers, pils and bocks in particular. It is not worth  
>the extra effort for ales, esp if you are using domestic 2 row pale or

<Well, despite the fact that I haven't done an all-grain Weizen, I would  
<like to propose that perhaps it's a good protein rest that is essential  
<for a brew with a large percentage of wheat and not necessarily a  
<decoction mash that's essential. Indeed, the decoctions will help  
<convert the starches in wheat, especially raw wheat, but I've tasted  
<quite a few very good weizens made with temperature-controlled (step)  
<mashes

If one is using a upward step mash program (the politically correct term)  
,  
you can produce a good wiezen with a wheat content up to 50%. Depending  
on your lauter tun, I would never ever recommend going above this level  
of wheat without a decoction. this is especially true when using  
domestic  
wheat malt with protein levels around 15! A good protein rest is  
essential  
in both decoction and step mashing. Now an authentic Bavarian weien must  
be of at least 51% wheat malt, and this includes dilution by krausen beer  
if you choose this carbonation method. So if you are adding 10% helles  
krausen beer you must account for the dilution effects of the percentage  
of wheat in your beer. I brew weizens of 65-70% wheat malt and a  
decoction  
is really important. remember the taller your lauter tun, the more grain  
compaction that can occur resulting in more time consuming lauters. I  
use a  
tun that is twice as wide as the depth of grain bed.

Al continues:

<1. single-infusion -- add a measured amount of water at a calculated  
temperature to bring a measured amount of grain to saccharification  
temperature. Mashout is often not done and the hot sparge water is what  
effectively ends the conversion.

Correct. The dominant technique in many american ale houses that do not  
employ a fired mash tun (kinda the english methods)

2. step-infusion -- add a measured amount of water at a calculated temp  
to bring a measured amount of grain to protein rest temperature. Add  
another infusion of hot water to bring the mash to saccharification temp.  
Finally, add boiling water to get the mash to mashout temp.

Correct. A typical technique in homebrewing and in breweries that do not  
have a fired mash tun but want more control over the saacharafication  
temps. Requires proper mineral balance to maintain proper pH. Usually  
not an issue due to the "buffering" effects of the malt. A little gypsum  
will suffice.

3. temperature-controlled -- dough-in (cool water) or mash-in (protein  
rest temperature) with the full mash volume of water. Add direct heat to

raise the temperature to other rests.

Correct. "Upward step mash program". My preferred technique with regular ales.

4. decoction -- dough-in or mash-in with the full mash volume and then remove parts of the mash to a kettle in which this "mash fraction," which is called a decoction, is heated to boiling and then returned to the rest of the mash to raise it's temperature. There are several variations to this (double (two decoctions), triple (three decoctions), etc.) in which some of the decoctions are replaced by infusions or the entire mash is moved to a kettle and then direct heat is used in place of one or more decoctions. It is interesting to mention that decoction mashing can be done WITHOUT A THERMOMETER, given enough experience, which I've read is the reason that it was invented (they did not HAVE thermometers at the time).

Almost correct. The "mash fraction" that is boiled is also raised to a saacharafication rest temp, usually 147-158 or both, and after conversion, is then denatured through boiling. This rest is often ommitted by home brewers and may result in lost efficiency. Note that in a weizen decoction program, the main mash sits at protein rest temps for over an hour while the mash fraction is raised, held, then boiled.

Al continues:

<Yes... I did, at that place with three names (something Bakery, something Restaurant and Widmer Brewery (although it is technically next door)). I don't have my tasting notes here, but I remember it was very good. I recall it had an OG of 1066 and did have a noticable alcoholic component to the flavor. It was really the first American-made Bock I've tasted which I feel deserved to be called a Bock.

NOT! It is an ALE!!! All of Widmers products are made with the same Alt bier yeast. None is a lager, one of my major beefs with the incredibly successful Widmer brewery. Even that "HefeWeizen" is the same alt yeast, super thick and cloudy, echhh. BTW, there are some really good bocks (lagers) made by: Gordon Biersch, Sudwerks, Baltimore Brewing, Old Dominion brewing and Stoudts to name a few.

Good brewing,  
Jim Busch

Subject: Brewing Techniques, errors

In re: Brewing Techniques issue 2:

Anyone else catch the mistakes in this issue? Dave Miller claims that hefeweizens are made with *S. Delbrukii*, NOT! It is *S. Cerveasae*, see Eric Warners book, *Brewing Wheat Beers*. Also, the styles column claimed that Reinheitsgebot brewers cannot add minerals to the brew. NOT! They cant add non natural occuring things in water like acids. Since calcium is in the water, they can and many do add gypsum to the mash and/or kettle.  $CaCl_2$  is also OK. Raw acid is not, hence the use of Lacto to drop pH.

I also think Dave Miller is really really anal on cleaning his wort chiller. Hot boiling water, with hot caustics and a rinse with hot water works. The important point was cleaning with caustics to remove the grim, then sanitizing with iodophor or boiling water. I know of very few breweries that go to the extreme of an acid rinse between caustic and sanitation. Nothing wrong, just really excessive.

Subject: More on the Glatt Malt Mill

Patrick Sobalvarro called Glatt Machining, and learned some more information about their mill. With his permission I'm forwarding this information to the HBD. Based on this information I mailed them a check this morning.

/Don

-----  
Originally-From: pgs@ai.mit.edu (Patrick Sobalvarro)

The number [at Glatt Machining] is indeed (509) 529-2084.

I talked to the guy who designed the mill, and he sounded very conscientious. Here are some of the things he told me:

The reason it's easy to turn the handle is that the drive is geared so you have some mechanical advantage (neither of the two other inexpensive mills available are geared).

The rollers are 4 inches long, steel, and grooved lengthwise.

It takes about ten minutes to grind 10 pounds of malt, in his experience, if the mill is not motorized. They designed it with the idea of motorizing it easily, and connecting a drill to it is supposed to be pretty straightforward.

Both ends of one roller are adjustable, on what sounded like a sort of eccentric cam with set-screws. There is an engraved plate with a scale on it so you can repeat your adjustment.

The bearings are injection-molded Delrin (a hard plastic designed for use in bearings).

The construction is metal, the hopper is big, and there are two mounting holes for attaching the mill to a table.

The current cost is \$80 + \$5 shipping, when it's sold directly.

They can ship COD, or wait for your check or money order.

I'm sending him a check tonight.

Subject: weizen pointers

I've brewed a few weizens on and off. I also read Eric Warner's excellent "German Wheat Beers" and recommend it highly. These points have been made in hbd at various times, but again:

- Warner argues for a grain bill of 70:30 wheat malt to barley malt. That ratio is important to producing the desired beer.

- Warner argues for using a decoction mash. In addition to the usual reasons for doing a decoction, it appears that the decoction mash helps release into the wort flavor precursors for the desired weizen flavor. One could do an infusion mash, but I don't think the desired weizen character would result to the same degree.

- You need the right yeast. One doesn't need *S. delbrückii*, just an ale yeast with the right flavoring properties. It appears that Martin Schiller and Paul Farnsworth are both sources of a good weizen yeast, and that wyeast is test-marketing a new yeast.

From: "Palmer.John" <palmer#d#john@ssdgwy.mdc.com>  
Subject: Hops Schedule Equations

Today's homebrewer likes to dabble with different styles of beer, and to try duplicating prize winning recipes. A hops schedule is usually included as a part of these recipes as is the Wort Gravity and Final Gravity of the brew. There are occasions where this information is not included or where a homebrewer may not have a good feel for what the final brew would taste like. The International Bitterness Unit (IBU) is a better way to define the Hop character of a beer. The IBU take into account the wort gravity and the amount of time each hop addition is boiled. This allows the homebrewer to develop a hop flavor profile in the beer and plan for different hops to make up the overall character of the beer.

Several months ago, I wrote an Excel Spreadsheet based on Jackie Rager's work in Zymurgy, that allowed me to get a better idea of what a certain recipe's hop additions meant to the final level of bitterness in the finished beer. As a starting homebrewer, I had little idea of what XX IBUs/HBUs meant to what I perceived as taste. By sampling various beers from around the world, and pulling the bitterness data from Micheal Jackson's, \*Pocket Guide to Beer\*, I was able to determine what I liked in terms of hop level. Next, the question was, "If I want to make (someone's) recipe, how bitter will that be?" By using Rager's equations, I could determine the IBUs and get a better idea of how I might what to tinker with it.

Much the same idea was presented in a recent issue of \*Brewing Techniques\*; but some of the equations seemed different. So, I called Karl King in Milwaukee to ask him about that. He's a nice guy, and had done his homework. We had both discovered the several mathematical errors in Jackie's article and had the same questions about Wort Gravity adjustments. Rager had stated in Zymurgy that if the Wort OG is less than 1.05 then the Gravity adjustment is Zero. This returns a Gravity of 1.00 to the IBU equation. Karl King had determined that it should be (1 point whatever), the OG; and I agreed. In addition, the Hop Utilization data presented by Rager was added to by King, and he used two linear regressions to describe that data in his article in Brewing Techniques. Karl got the additional utilization data points from the public library archives in Milwaukee, which seems like a good source, when you think about it.

So, below I am listing the equations first presented by Rager, and later revised by Karl King and myself. I was originally going to UUencode my Excel Spreadsheet, but when decoded, it produced an unreadable (corrupted) GIF, so forget that.

**\*The International Bitterness Unit\***

The IBU is based upon utilization of the hop oils, specifically the Alpha Acids. The alpha acids are released into the wort during the boil and also into the beer during Dry Hopping. Unfortunately, the diffusion rate is e.

utilization rate, data is not available for Dry Hopping, so any contributions

to the total IBUs, however small, from Dry Hopping will not be discussed here.

The equations expressed below take into account the change in Utilization rate

with time, and make use of the influence of wort gravity to that rate.

**NOTE:**

The 7462 constant is for US units; for grams and liters, use a constant of 1000.

An IBU can be expressed by the equation:

$$IBU = Wt * \%util * \%alpha * 7462 / Vol\ ttl / GA$$

where Wt is the amount of Hops in ounces, Percents are decimals, Volume is the total recipe volume, and GA is the Adjusted Gravity.

**\*The Adjusted Gravity\***

The OG needs to be adjusted if it is greater than or equal to 1.05. Rager gives the example that if the OG for a 5 gallon recipe is 1.048, but he's only

boiling 2.5 gallons then his apparent gravity is 1.096, or twice the OG. (That's twice the .048 part) Therefore, the 1.05 condition needs to be met for

partial boils. This is done with the following equations. (VT is total vol,

VB is Boil vol, GB is Boil Gravity)

$GB = ((VT/VB) * (OG - 1)) + 1$  ie. multiplying the degrees of extract by the volume ratio.

Then, if GB is greater than 1.05,  $GA = 1 + (5 * (GB - 1.05))$

Otherwise,  $GA = GB$ .

**\*The Utilization Rate\* (from Karl King)**

If the boiling time is less than 23 minutes, then  $\%U = (0.64 * time) - 2.62$

Otherwise,  $\%U = (0.4 * time) + 3$

**\*Doing it Backwards\***

What if you say to yourself, I would like most of the hop character from Northern Brewer, Some from Fuggles, and some from Saaz? Well the IBU equation

can be worked backwards for the amount of Hops that need to be boiled for a given time.

$Wt = (\% \text{ of total character}) * (\text{Target total IBUs}) * VT / \%U / \% \text{ alpha} / 7462$

Where the % of the total hop IBUs is expressed as a percent. Ex. 60% of  
50  
IBUs total from Northern Brewer would be  $0.6 * 50 * VT$  etc. The time  
boiled is  
expressed as the percent utilization from the equations above.  
I hope this will be useful to all of you as well as correct the mistakes  
in  
Zymurgy.

Subject: Secondary Fermentation Questions

I have several novice-type questions about Secondary Fermentation.  
Background: All-malt unhopped extract brewing, adding hop pellets,  
bottled  
H2O.

1. Is racking to a secondary fermenter only/mostly used for Ale yeasts,  
Lager Yeasts, or both (ie. yeast is not the criteria)? When (and other  
adverbs) do I need to rack and secondary ferment?

2. According to Dave Miller, he racks when the bubbles slow down to 1/  
30  
seconds (I think). What span of time has passed (typically) 3 days, a  
week?

3. Okay, approx 3 days - a week has passed in the primary fermenter  
(white  
bucket) and I am racking to a glass carboy (6 gal). At this time I would  
be  
adding my dry Hops. Do I need a Blow-Off Tube? Do I need the Brew-Cap?

4. After secondary ferm'g of 2 weeks, I will rack to my bottling pail and  
prime. Is oxygen damage my main concern, or is lambic still a problem?

From: Jonathan G Knight <KNIGHTJ@AC.GRIN.EDU>  
Subject: hop boiling times

I would compare the effects of differently timed hop additions to the use of herbs and spices in certain dishes. For example, I discovered a while ago that reserving a large portion of the chile powder/cumin/etc. until the end of cooking a pot of chili, the presence of these spices was dramatically enhanced. The dish is not really "hotter," although people will tell you it is; it is really the aromatic presence of the spices which can be overwhelming.

Similarly, if you've ever used wine as an ingredient in spaghetti sauce, you know that if added at the beginning of the simmer, there will be a certain something in the end product, but the winey-ness will not be obvious. On the other hand, if you add it towards the end, the wine will be more detectable as wine. Or if you make a quick-cooking (20 min or so) tomato sauce for pasta with wine in it, the presence of the wine will be more pronounced than if simmered in a sauce for a few hours. Or, if you wanted a pronounced basil note in a sauce, the way to get it would be to add the basil toward the end of the simmer.

When making beer, I have found that some of my more pleasing efforts have had the benefit of mutiple hoppings, for example, 60, 30, 15, 0. I'm not into calculating IBU's (yet?), I'm just "cooking" when I make beer - but I'd say the principle is the same: hops are to malt, etc., what herbs are to "main ingredients" in cooking (meat, legumes, whatever).

Depending upon what type of pump it is, it could easily be oxidizing your  
wort.

From: tmgierma@raphael.acpub.duke.edu (Todd Gierman)  
Subject: Sour Mash Brewing

With all the discussion concerning the overnight mash, I'd like to raise the issue of the sour mash. As you may know, the sour mash method ala Papazian is somewhat similar, the difference being that the mash is inoculated with about 1/2 pound of raw grain at 135-140 degrees F. The mash is then left to sit overnight 15-24 hours, depending on the degree of sourness desired. A week and a half ago, I found myself contemplating the merits of this procedure as I was attempting to produce a slightly sour Belgian witbier. I was troubled by the overnight mash: would I end up with an extremely attenuated beer, which I guess is somewhat desirable for the style, by allowing excessive conversion? would the bugs even grow at such a high temperature, this is pretty high for your garden variety bacillus? Okay, so I worried and decided to hedge my bet - do the complete mash and lauter, then add bugs that were cultured several days in advance from the grain and let it go 12-13 hours. I figured that the actively growing bugs would push the souring time ahead. I examined the cultures from the grain under the microscope. All kinds of stuff gets started from the grains - mainly wild yeast and bacilli, but also some little round guys all strung together (cocci). It seemed like there was a lot more in there than I had wanted. I worried some more and hedged some more - I started a culture using sourdough starter, at least I had had some previous experience with it. So there I was at 1 a.m. as the wort cooled, "sourdough or grains? sourdough or grains? Okay, grains it is." I pitched the culture from the grains and went to bed. In the morning, I was sourly disappointed to see no activity and no souring. Why, Charlie P. had me anticipating little fuzzies growing all over my wort. I wondered whether the high temperature had inhibited growth (I had cooled to 115 F before pitching).

So, I figured what the hell and added the sourdough culture and let it go 6 hours more. Eventually, a bacterial scum accumulated on top, but I never got an impressive souring (I could only wait so long).

It turns out that sourdough starter requires a symbiotic relationship between a wild yeast (Candida) and a lactobacillus (sanfrancisco, no less), and perhaps it comes as no surprise, the sourdough and grain cultures looked surprisingly similar under the scope. Now, maybe, my experience indicates that it's not surprising that little if any spoilage occurs with other people's overnight mashes - it's difficult to get it when you're trying. I suspect that the high temperature of the mash is not all that conducive to the growth of lactobacillus. It is true that there are species of lactobacilli that do well above 45C, but the sour mash guidelines are, I believe, roughly 10 C above this. Besides, are these

stray bugs

the ones I want spoiling my beer? Traditionally, *Lactobacillus brevis* is used in the brewing industry to sour beers, or causes spoilage (also *Pediococcus cervesiae* and *Lactobacillus pastorianis* (a no longer valid name). It works well at lower temperatures (ideally 15C). This seems to be the bug that one finds in a bottle of Berliner Kindl Weissbier, at least

it won't grow very well above room temperature. Anyway, maybe the sourness

will come through once the sugars have been fermented. Does anyone else have a sour mash theory or experience? Has anyone added lactic acid or citric acid to sour a beer? What are the odds that I could successfully utilize the *Lactobacillus* culture from the Berliner Kindl?

Thanks.

From: dipalma@banshee.sw.stratus.com (James Dipalma)  
Subject: RE dunkelweizen recipes

Hi All,

In HBD#1197, Andy Phillips asks:

>I'd like to have a go a making a dunkelweizen soon. I have  
>a few questions about recipe formulation:  
>1. What grain should I use, and how much, to get the colour  
> right?

A dunkelweizen is supposed to have a soft, understated maltiness. I use 1/2 pound of chocolate malt, added at mashout. IMHO, roasted barley or black patent would lend a sharp, biting sort of flavor. Since a weizen is supposed to be lightly hopped, I'd also avoid crystal, the beer may come out too sweet.

I also use a pound of 8L-10L Munich malt, which contributes some color and maltiness.

From the guidelines for the 1991 AHA Nationals:

d) German-style Dunkelweizen "Chocolate-like maltiness evident."

>2. Hops? Hallertauer?

Hallertauer is fine, though I personally prefer Tettnang. Keep the hopping levels low, 15 IBUs or so. Speaking from experience, the combination of extreme cloviness and high hoppiness is quite unpleasant. I'd also recommend adding all the hops at once at the beginning of the boil, late additions are inappropriate for this style. You don't want a lot of hop flavor masking the more subtle phenolics found in a weizen, i.e., banana, vanilla, etc.

>3. Yeast? I know of no source of liquid cultures of wheat beer yeasts  
> in the UK. I can buy several HefeWeizens, which of these do you  
> think would make the best starter: Thurn und Taxis HefeWeizen  
> or Roggen, or Erdinger DunkelWeizen? The last of these seems  
> to throw a good sediment, so this is my first choice. Are all  
> HefeWeizens bottle conditioned, or are some pasteurized?

I use the Weihenstephan #66 strain, which does a beautiful job of producing the clovy, spicy character one expects in a weizen. I don't know about availability in the UK.

Andy, you might have a problem getting a good fermentation strain from commercial dunkelweizens. These beers are generally bottle conditioned with a lager yeast. I don't know offhand of any specific commercial brand that has the fermentation strain in the bottle. Anyone else know?

>4. Temperature? Unfortunately, I have no control over this,  
> so I may have to wait for autumn before I start. The temperature  
> in Bristol today is a sizzling 67F.

Please forgive me, I have to laugh at the notion that 67F in August is "sizzling". Here in New England, it was in the 90s and humid for most of July, which did not prevent me from brewing three batches of weizen. The W66 strain is supposed to be fermented at standard ale temperatures, though mine were fermented at 70F-72F, and came out fine.

One more note. If you can get the Belgian wheat malt from DeWolf-Cosyns malting, do it. This malt is plumper and contains far less protein than any German or American wheat malts I have used in the past. The resultant high extraction and ease of lautering make this a very nice malt with which to work.

Cheers,  
Jim

Date: Fri, 6 AUG 93 11:34:19 EST  
From: DEROSEGA%ML%WPAFB@MLGATE.ML.WPAFB.AF.MIL  
Subject: Water and carbonation

A batch of stout I made in February (extract + specialty grains) started out by having "perfect" carbonation and head retention, but after aging in the bottles it became overcarbonated to the point of pouring nearly all foam about 2 months ago. When I opened a bottle last night, which was first chilled, I let it sit on the counter for about 5-10 minutes before pouring, and foam slowly rose to the top and slightly poured over. Pouring as slowly as I could still gave me about a 4" head in a 12 oz slant-sided glass, which I had vigorously rinsed in hot tap water to remove any rinse agent residue from my dishwasher. The beer tastes fine, so infection does not seem to be the culprit. This leads me to a question for those who know more about water than I. I used my city tap water for the brew, which contains a lot of lime and other minerals (Fairborn, OH). Is there a relation between high mineral content of water and increased carbonation as a function of time? Could the "yuck" in my water serve as nucleation sites for bubbles?

Thanks for sharing your observations,  
Guy DeRose

Jonathan> interested in more discussion and/or recipes which are a  
Jonathan> nice match for this yeast.

The "Alt" yeast is #1338 (or something like that), Wyeast calls it European Ale. Wyeast 1007 is called German Ale, and I believe is Wyeast's original ale yeast. Byron Burch mentions in the special Yeast issue of Zymurgy that this is a "true top-fermenting" yeast. I recently brewed a cherry beer with this yeast, fermentation was quite vigorous and pushed a lot of sticky yeast up through the high krauesen foam, resulting in a tan/brown cap. This yeast would seem quite suitable for the practice of skimming the yeast at high krauesen for pitching into the next batch.

One thing I did notice with Weast 1007 -- I pitched when quite warm (80+ F), and after a day of strong fermentation I noticed a pronounced banana aroma from the fermenter. When I racked this beer at about a week the gravity sample had a definite banana ester character. I don't know first-hand how this yeast bahaves at more appropriate fermentation temperatures -- I think that Byron's article reports it to be a good general-purpose Ale yeast, fairly clean but with a bit more complexity than Sierra Nevada's yeast -- but if you're in an area where the homebrewers suffer from Summer heatwave-induced warm ferments, be aware that this yeast will give you some banana component. I'm pretty happy with the yeast-fruity background in this beer, so you might consider warm fermenting with 1007 when doing fruit beers.

From: WILSON.TROY@FORUM.VA.GOV  
Subject: HBD Garbage

Greetings fellow HBDers! I've been reading the HBD for over 3 years now and am finally putting in 2 cents. Sadly, however, it has little to do with the beloved art of brewing. I find myself having to respond to a post from lyons%adc2@swlvx2.msd.ray.com in HBD 1197 (whoever this person is). This individual provided the following input to a post by Mr. Geoff Reeves:

>Is this a joke? I can't stop laughing! Actually we shouldn't be laughing  
>about the mathematically ignorant. In case that this is not a joke,  
>please review your concepts of dimensional analysis or seek help.

And continues with:

>Did you get a high school diploma?

In my opinion, these comments are insulting, inflammatory, childish, etc. and have absolutely \*NO\* place in this forum. Whoever you are, you provided no input to the digest with your post. By using this forum as a platform to insult others you do serious damage to the HBD. How many long time readers (and experienced brewers) will see your post as the last straw and no longer subscribe? I recall the last time such nonsense occurred, many long time HBDers dropped out because it just wasn't worth tolerating. Further, how many new brewers have now been frightened into \*not\* asking beginner questions for fear of being ridiculed? As right, wrong or indifferent as a post may be, there is no justification for attempting to humiliate the poster. I believe that Mr. Reeves is due a public apology for these comments, and I hope other HBDers will join me in this call.

Hopefully my next post will be on a maltier subject...

From: sc@vcc.com (Steve Casselman)  
Subject: I want a new factor!

Having read the latest about pts-gal/lb I keep thinking I would like to have a factor that when multiplied by the number of lbs of grain I used would give me the lbs of extract I would need to get the same OG. This would be ratio of weight of the grain bill over the weight of the dissolved solids in the wort (or vice-versa). This would be dimension-less and would tell me how much grain I dissolved during my mash, a kind of efficiency. My question is this derivable from pts-gal/lb and would it be useful? I believe it would be a useful number for recreating grain rescpes with extracts.

From: Mark Garetz <mgaretz@hoptech.com>  
Subject: Hop Utilization

John Palmer writes:

>\*The Utilization Rate\* (from Karl King)  
>If the boiling time is less than 23 minutes, then %U = (0.64 \* time) -  
2.62  
>Otherwise, %U = (0.4 \* time) + 3

I haven't run a lot of values through this formula, but it's obvious that it's not right. For example, a 60 minute boil gives you (0.4\*60)+3 or 27% utilization. That's way too high. To quote Gail Nickerson in a recent conversation I had with her, "The big brewers will tell you they get 25% utilization, but they don't get it. They actually get between 18 and 22%." BTW, this is for a 90 minute boil.

The formula also will give a linear slope (for values above 23 minutes anyway) and that's not right either. The slope is not first order either, but looks more like this:

```
*
  *
   *
    *
     *
```

Forgive my "ascii" representation, but the idea is that it almost looks first order, but there is a "limiting factor" (suspected to be caused by the dropping pH of the wort) somewhere at the top end that causes the slope to be less steep than a true first order slope. Reference is an article by D.R. Maule in Vol. 72, 1966 of the Journal of the Institute of Brewing.

It's also clear from this article and others that, despite Rager's table and even my own version of it presented here, boil times of greater than 60 minutes do have an impact on the utilization (the tables assume anything greater than 50 minutes is the same).

Mark

Subject: Rats! Mistake in Last Equation

In the last issue of HBD, I wrote:

*\*Doing it Backwards\**

What if you say to yourself, I would like most of the hop charactor from Northern Brewer, Some from Fuggles, and some from Saaz? Well the IBU equation can be worked backwards for the amount of Hops that need to be boiled for a given time.

$$Wt = (\% \text{ of total charactor}) * (\text{Target total IBUs}) * VT / \%U / \% \text{ alpha} / 7462$$

Where the % of the total hop IBUs is expressed as a percent. Ex. 60% of 50 IBUs total from Northern Brewer would be  $0.6 * 50 * VT$  etc. The time boiled is expressed as the percent utilization from the equations above. I hope this will be useful to all of you as well as correct the mistakes in Zymurgy.

DID YOU NOTICE I FORGOT GA?! AARGH! (kick, kick, kick)  
Anyway, it should be:

$$Wt = (\% \text{ of ttl}) * (\text{ttl IBUs}) * GA * VT / \%U / \%A / 7462$$
  
Ok that should do it,  
JP Entropy is always increasing...

>Thanks to all of those individuals who let me know that Briess and  
>Northwestern malt extracts are one and the same, the only difference  
being >the packaging. Now I have a real problem on my hands, namely  
figuring out >what the Hell is going on with my brew!!!

Rest assured that your brewing is fine and there is indeed a problem  
with your Briess malt extract. I routinely use Briess malt extract  
(and some grain adjuncts) to brew 5 gallon test batches to evaluate  
new yeast strains for Brewers Resource and have not had a problem  
until recently. About six weeks ago I brewed a Brown Ale and  
Continental Lager both of which tasted sour (lactic acid) out of the  
primary fermenter. This nasty flavor has remained in my brew. As it  
turns out several other homebrewers have called Brewers Resource and  
complained of a similar problem. One person picked up this off flavor  
in the wort prior to fermenting. We believe that there is a bad batch  
of DME floating around. Brewers Resource has notified Breiss of this  
problem and demanded compensation. Most unsuspecting homebrewers  
however are probably stuck with this substandard product and are  
attributing this off flavor to some systematic error. Good luck in  
trying to get your 60 lbs replaced.

So much for evaluating some new yeast strains now I'm stuck with some  
sour beer which I must doctor in some way to make it drinkable. I  
added a few tablespoons of Hersheys chocolate syrup to the brown ale  
(Bosco beer) and my softball team sucked that five gallons down in no  
time. I'm still pondering what to do with the lager maybe some  
fruit; I've yet to taste the lager since I racked it into the  
secondary so we'll see.

The real question is do you have DME left and what to do with it?  
Maybe you can use it as a substitute for a sour mash and make a  
lambic-like beer. Some other HBD brewers may have some other creative  
ideas.

P.S. In case you all-grain snobs are wondering, yes I do brew all  
grain (40 gallons) but moving to a studio apartment in Manhattan a  
couple of years ago forced me into extract brewing and you know what I  
liked it! I continue to use extract brews for testing yeasts since I  
can brew 2 different five gallon batches at once and can do it in  
about 3 hours without any help. Plus it gives us some variety to  
what's on tap.

From: Mike Zulauf <zulauf@orbit.Colorado.EDU>  
Subject: cooler as a mash tun

Hello fellow homebrewers!

After doing several partial mash beers, three batches using my own design of a wort chiller, and two full boils, I now feel ready to proceed into the world of all-grain brewing.

The only real questions I have concern the mash tun. I am planning on using some type of cooler. I would prefer to use one of the cylindrical

ones, as I feel that I could obtain a deeper grain bed, and it would be easier to fit a false bottom, etc. What types and sizes have people used, and how well do they work? Are there any problems with using a cooler designed to store cold liquids with hot materials? (ie melting, off flavors from the plastic, etc.) What size will be required for mashing say 20 lbs of grain? Anything else I should know?

All responses appreciated,

Mike Zulauf

Date: Mon, 9 Aug 1993 15:21:34 +0400 (EET-DST)  
From: NIKKANEN@ntcclu.ntc.nokia.com (Kari Nikkanen, design engineer)  
Subject: Bitter rye ale

I posted a question to r.c.b in june, asking if anyone knew any beers that are brewed using rye malts, and also mentioned that I had brewed one rye ale myself. As an answer for those who asked me about the recipe, here it comes:

Kari's Bitter Rye Ale

Ingredients (for 10 litres = 2.6 gallons):

4 pounds Finnish sahti malt mixture  
(= 85% pilsner malt and 15% crystal malt)  
7 ounces Finnish rye (kalja) malt  
1/2 pound British crystal malt  
1 ounce Northern Brewer hops (60 min boil)  
1/4 ounce Fuggles hops (30 min boil)  
1/4 ounce Fuggles hops (10 min boil)  
1/3 cup priming sugar

yeast from a Tellford kit (not really recommended,  
I'll use liquid yeast next time)

Procedure: 1.5 hours mash at 140-145 , sparge water  
temperature about 175 F. Total boiling time 75 minutes.  
Yeast was dehydrated 2-3 hours before pitching. O.G was  
about 1040-42. Primary fermentation 4 days and secondary 7  
days.

Comments: There are some things I'll change when I brew my  
next rye ale. First, I'll do a temperature controlled mash  
with starch conversion at about 150-155 deg F. I won't use  
more than 3-4 ounces rye malt, because the rye malt I use is  
very dark and quite bitter, so 7 ounces is simply too much.  
The hops I used were not exactly fresh, and didn't have any  
alpha rating, so I think 1/2 ounce of fresh Northern Brewer  
will be enough next time. When this beer was only few weeks  
old, it was far too bitter and sharp, and the bitterness of  
rye malt was (too) clearly distinguishable. So I let it age.  
Now, after 7 months it's much smoother, but a bit thin. It  
has a nice amber colour and a smooth long lasting head, and  
even my wife says it's quite drinkable, so with these  
suggestions to improve it, I finally dare to post this  
recipe.

Cheers!/Kari

Subject: *S. delbrukii* or *S. cerevisiae*? Also notes on *S. uvarum*, *S.*

*carlsbergensis*, *S. pastorianus*.

Re: Jim Busch and BT errors.

I am a recent arrival to HBD.

*Saccharomyces delbrukii* or *S. cerevisiae*?? I personally believe both are technically incorrect. From the best that I have been able to find in the mycological taxonomy literature, the true name of this organism is *Torulospora delbrukii*, this is how the American Type Culture Collection lists it which sparked my interest and pursuit of this subject. An incorrect but often used synonym is *Saccharomyces*. Both genera are in the family *Saccharomycetaceae* and subfamily *Saccharomycetoideae*. The vegetative morphology of both genera is identical. However, the genera differ in their mode of conjugation and the morphology of sporulation (fide Barnett, Payne and Yarrow, 1979, *A Guide to Identifying and Classifying Yeast*. Cambridge University Press, New York. (fide = "on the authority of")). I feel German Wheat Beer by Eric Warner had excellent coverage of the biochemistry of weissbier yeast as it pertains to the final product, but failed to give the yeasts the proper taxonomic treatment. Yeasts from single cell cultures as those used in fermentation do not undergo their sexual cycle and as such a brewer would not be able to distinguish *T. delbrukii* from *S. cerevisiae*. INDUSTRIAL USERS OF MICROBES, BREWERS INCLUDED, FREQUENTLY TEND TO IGNORE TAXONOMICAL NOMENCLATURE BECAUSE THEY ARE MOST INTERESTED IN THE BIOCHEMICAL PROPERTIES IMPORTANT TO THEIR PROCESS (Beer! in this case).

An interesting, but just as esoteric discovery I have made suggests that a better name for *S. carlsbergensis* (syn. *S. uvarum*) is *S. pastorianus*. *Saccharomyces* speciation based on biochemistry has resulted in much confusion. Therefore, about every ten years major reordering of the genus occurs. One Italian study showed that in a university's industrial yeast collection, 144 out of 1014 isolates had mutated to another species when nutritional biochemistry was used for speciation. The result was that in *The Yeasts a Taxonomic Study-III* (Kreger van-Riji (Ed.), 1984) twenty one species were lumped into *S. cerevisiae*. A review article (Vaughan Martini and Martini, 1989, *A proposal for correct nomenclature of the domesticated species of the genus Saccharomyces*; in *Biotechnology Applications in Beverage Production*) cited two studies using a molecular genetic technique, DNA/DNA reassociation, which showed that the III and V (3rd and 5th) chromosomes of *S. cerevisiae* and *S. carlsbergensis* were significantly different and a greater than 80% homology exists between *S. carlsbergensis* and *S. pastorianus*. As *S. pastorianus* is the older name it takes precedence (I am assuming and need to verify before staking a reputation on this statement). To oenologists *S. pastorianus* is an agent of wine fermentation in cold climates.

AS BREWERS SMALL OR LARGE OUR CONCERN IS THE BIOCHEMISTRY OF THE YEAST AS IT PERTAINS TO THE FINAL PRODUCT. DON'T let the taxonomy get you down, but don't slam somebody else's taxonomy when basing an opinion from a single source either. From extensive experience wading through the taxonomy of fungi more than one name can be correct depending on the resource used for identification, and names are never static. FOR A BREWER MORE INFORMATION IS OBTAINED FROM AN ISOLATE'S DESIGNATION IN AN INDUSTRIAL CULTURE COLLECTION SUCH AS "WEIHENSTEPHAN #68" THAN WHEN ONE WORRIES ABOUT

ITS TAXONOMIC POSITION IN THE MYCOLOGICAL NOMENCLATURE. A rose by any other name...

I really apologize for this long entry, but felt things were so different from the current popular literature that explanations and citations were needed.

Tom Weicht

**Subject: Stainless Steel disconnects**

I recently acquired some stainless steel disconnects (ball-lock) for my cornelius keging system. The are much smoother then the plastic disconnects and, as far as i can tell, nearly indestructable. I have a plastic one that I cracked (still usable though). I highly recommend the stainless steel disconnects.

plastic disc: about \$3.20  
stainless: about \$8.50

FYI for you keggers out there.

Subject: supplying beer at a wedding / beer flavors for late october

I'm getting married in late october of this year and i'd like to supply at least some if not all of the beer at my wedding. With this in mind, I have a few questions:

- 1) In today's sue-your-neighbor environment, what kind of legal issues, insurance, etc. do i need to worry about if i serve my home-brewed beer at my wedding (on a private estate that is not owned by our families)? This is in the state of Massachusetts.
- 2) If it isn't much a legal hassle/worry, I'd like to think about brewing some stuff up now. I'd like to brew one heavier brew, appropriate for the season, and perhaps one lighter beer, that would please the occasional beer drinker. Suggestions? I'm most comfortable w/ extract brewing, partial-mashes, and full mashes, in that order.

I haven't heard of picking up a beer scrip at the pharmacy. Of course, we're not in prohibition now.

In any case, my mother's doctor advised her to start drinking beer. In her case it was because she was fairly underweight and the beer would help the problem because of its high carbos.

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Weihenstephan #68

I have had some email over the number and taxonomy of the weizen strain, Weihenstephan #68. It is indeed 68, and as far as can be determined it is indeed a *S. Cervesae*, and not a *Delbreuckii*:

<From Daniel\_F\_McConnell@mailgw.surg.med.umich.edu  
<*S. delbreuckii* is indeed an appropriate synonym for *Torulaspora delbreuckii*,  
but according to Kreger-van Rij (1984) so are about 36 others! Of the 59  
*Torulaspora delbreuckii* strains studied by Kreger-van Rij for this classification, NONE of them were isolated from beer of any type (rather: raw  
came sugar, sheep milk, grape juice, dates, cucumber brine, sour figs... ..).  
Thus I have my doubts that these yeasts make good beer.

Thanks Dan,  
Jim Busch

Subject: Question about dry hopping

Hello there:

I have a question concerning dry hopping. This is my first shot at this, so please bear with me:

I am in the process of making a Belgian Ale (just pitched it this morning :- ) ), and the recipe calls for dry hopping w/2 oz. Fuggles hops. I understand that dry hopping involves adding hops to the wort after transferring it to a secondary fermenter.

My problem is that I have a limited amount of brewing equipment, and no \$\$\$ to expand right now. I have been using a primary fermenter, and then once the SG has stabilized, transferred to a second carboy that has a spicket attached to the bottom for bottling (this carboy does not have a lid).

Anyway, I'm somewhat confused on the logistics of dry hopping, given this equipment. From what I can gather, dry hopping usually involves transferring the wort to a secondary fermenter, adding the additional hops for a few days, and then transferring to something else for bottling. I guess that I could transfer the wort to my 2nd carboy and add the hops, but w/o a lid I don't want to leave it sit around for any period of time exposed to the air. I guess I could always transfer it back to the primary fermenter, but then I'd have to transfer it again for bottling. The other option that I see is to transfer the wort to the 2nd carboy once the SG has stabilized, add the hops, let it sit for an hour or two, and then bottle.

Does anyone have any suggestions? I am a novice brewer (although I'm Armenian I'm not Papazian!!), so please excuse any real obvious errors in my brewing technique, etc. I could also skip the dry hopping altogether, but I'd like trying new things. But, if no dry hopping is preferable to the above option of dry hopping for a short time, I'd like to know that as well. Also, if dry hopping is done, and the wort is not filtered again, won't these hops get into the bottles?? Thanks in advance for any help.

Subject: questions

Greetings All:

While setting up a brew session this past weekend, I came up with a few questions that I was hoping the good people of the net would help me with.

First--

I was going to start a batch of yeast in anticipation of brewing later in the week. When I went to get my petri dish with the culture on it out of the fridge, I noticed that the entire surface of the dish was covered with a green growth of mold :-(. I had to start from a new slant with a different strain than I had intended to use. Anyone have any suggestions on how to improve my techniques in handling cultures so that this type of contamination does not happen again.

Second--

I purchased some plugs of Irish moss from a garden supply store about a year ago. These are incredible growers; going from <1" plugs when originally planted to > 18" clusters in just 1 year. They make a great ground cover with a thick compact mass of growth about 1 1/2" tall. A neat addition to the landscape. Now on to the question-- Anyone have any experience using fresh IM for brewing? Do I need to dry it or can it be used right from the ground? Any precautions to prevent contamination?

Third--

While watching "Mary Poppins" for the ten thousandth time (can you say parent of a three year old? ;-)), I noticed a line that goes "and doesn't smell like barley water". My first thought was that this must be an objectionable perfume but after thinking about it for a few minutes I realized that this must be a reference to some type of alcoholic beverage. Anyone knowledgeable in early 20th century London slang have any idea as to whether this refers to our favorite malt beverage or the other venerable potion made from barley malt (for those that can not figure out the obscure reference, I am talking about 'the good stuff' Scotch whiskey)..

Thanks for the help---

Keep brewing-

**Subject: A Draft Chili Beer?**

I've followed with interest the occasional thread on chili beers, and, since I've enjoyed a few Cave Creek bottles, I'd like to put up a batch for a party about 10 weeks off. However, I prefer to (Cornelius) keg my beers, and I'm wondering a bit about just how much of what variet(ies) of peppers to use! I can certainly add 48 peppers to the keg, but I think that might be a gross overkill, besides adding that much more chance of contamination...

What about a chili extract in alcohol? Would enough of the actives (capsaicins?) be dissolved? Or adding \*a few\* cut up/open chilis to the keg? As far as contamination is concerned, has anyone tried blanching the peppers in boiling water before adding to the bottles?

Too many questions, not enough time to experiment! Hopefully the collective wisdom of the Digest can shed some light...

From: npyle@n33.stortek.com  
Subject: Propane vs NG / Used Cow stuff

I have just acquired a 10 gallon stainless steel cream can from an old dairy. This thing is tapered at the top, but I think it will be fine for a kettle, which is what I wanted it for. I fitted it with a nice 1/4 turn gas valve for draining. Now I need a way to heat it. (I currently use a Bruheat as a boiler but I'd like to speed it up and increase my boiler capacity).

I know all the talk about "Cajun Cooker"s and "King Kooker"s, etc. but I'm a cheapskate. Also, I like to tinker and I have a water heater element, designed for Natural Gas. I want to use propane because that is the easiest fuel to get into my garage. I've been told propane has more potential BTUs and therefore needs more oxygen. I think I verified this by firing up this NG element with propane. The flame was high, about 6 inches, and yellow. Also, there was a lot of soot forming as it burned. I opened the air inlet all the way and it helped a little, but it still didn't burn anywhere near clean. I think I need to decrease the aperture (jet) that the gas passes through so that I will need less oxygen. Does this sound correct? Anyone else do this successfully? How? I'd appreciate any advice on this.

As an aside, old dairy equipment can be used in homebrewing in many areas: boilers, tuns, even fermenters. Most of it is stainless so look for it. I got a 10 gallon SS vessel for \$50, with a lid. Try to find that price in a yuppie cooking catalog!

Cheers,  
norm

Subject: NO wax nor flames from the "GREAT WHITE NORTH" -- just ICE.

Practical jokers aside, this forum should nor degenerate into a free place for verbal fisticuffs. I enjoy a practical joke - even if it leads to an earfull. However, like it or not, others do not. Lets keep it clean please. Not everyone has equal brewing skills nor other skills. Many are reading this forum to learn from others. If anyone really wants to help someone with their brewing problem/ math skills then contact the "needy one" by private e-mail. Be a good samaritan and save us some time and bandwidth.

The icepack seems to be flowing south of the 49th parallel. Several weeks ago while in a drought of home-brewed beer, I broke down and bought a couple of 12-packs of so-called ice beer. It was on sale for 12.?? (Canadian dollars) per 12 pack. Remember we also pay province and federal tax (7% +7%) on this to help fund our "free" medical system and other social nets. Now to get back on subject -- this ice beer was quite smooth, and everyone who drank it at my home in a "blind test" liked it. The complicating factor was that the beer was free. Nevertheless, this "ice beer" is certainly smoother in my opinion that many other Canadian beers.

Now that I have bottled four different batches of beer, I can forget this commercial stuff and start drinking "real beer". After all, winter is comming - -- there will be snow here in less than 3 months. Right now there are flooded basements due to all the rain, but my sump pump is helping to keep mine dry.

As Charlie P. has written "Relax, have a homebrew"

>  
I don't know if I want to weigh in on any answer that implies I'm an "elderly gentleman", but... although my mom didn't carry me during prohibition, and didn't need a prescription, her doctor did recommend she drink beer during the period she was nursing. The idea, as I recall, was that beer encouraged "let-down", in other words, it helped her relax and increased milk flow to her handsome baby child. It is possible, I suppose, that children of mothers who breastfed while drinking beer turn into beer snobs; I don't have enough data.

From: FARMERM@mcl.saic.com

Subject: Prescription for Brew (ref. Domenick Venezia)

In response to Domenick Venezia's question about a prescription for beer. Yes, My wife's grandmother, who lives in South America, was prescribed a dark beer w/ a raw egg everyday. The dark beer in South America is different, however. They refer to it as "malta" and has no alcohol in it, its just used for cooking. What the purpose of this is, I'm sorry I can't say.

Speaking of weird stories from prohibition:

I spoke with my grandfather last year about the strange things that went on at that time. There is one incident he mentioned that really sticks in my mind. He said that during prohibition, people would line up at hardware stores and buy denatured alcohol and then go to the grocery store to buy several loaves of bread. They would take the alcohol and pour it from one end the loaf of bread to the other. After filtering it through a few times, it was good enough to drink. Mmm Mmm.

Happy, Happy

Beer, Beer

From: CW06GST <CW06GST@SJUMUSIC.STJOHNS.EDU>  
Subject: Honey Priming Thanks

A couple of months ago I had asked about using honey as a priming agent. Thanks to those of you who responded to my post and prevented me from making glass grenades.

As it turns out, using honey as a primer works very well, and follows the same guidelines as any other agent.

I used 7/8 of a cup of Golden Blossom (tm) honey, and had good carbonation in about ten days. The bubbles were a little different than if using corn sugar or DME. It was a lot like champagne bubbles or a sparkling mead. In any event it was an interesteing effect and it tasted quite good.

Here is a copy of the recipe:

3.3 lbs Munton & Fison light malt extract  
3.3 lbs Munton & Fison wheat extract (1/2 malt, 1/2 wheat)  
3 lbs clover honey (generic supermarket brand)  
2 oz. styrian goldings hops (plug) for boil-60 min  
1 oz same for last 2 min  
2 pkgs Cooper's dry yeast (rehydrated)  
7/8 cup honey for priming

I had no idea what this beer was going to turn out like, but it made what I would consider a very fine IPA. Original gravity was 1.048. Final gravity was 1.008.

Thanks agian for all the help!

Subject: Decoction/Brewing Techniques errors/Secondary Questions

Jim writes (quoting me):

>>4. decoction -- dough-in or mash-in with the full mash volume and then  
>>remove parts of the mash to a kettle in which this "mash fraction," which  
>>is called a decoction, is heated to boiling and then returned to the rest  
>>of the mash to raise it's temperature. There are several variations to  
>>this (double (two decoctions), triple (three decoctions), etc.) in which  
>>some of the decoctions are replaced by infusions or the entire mash is  
>>moved to a kettle and then direct heat is used in place of one or more  
>>decoctions. It is interesting to mention that decoction mashing can  
>>be done WITHOUT A THERMOMETER, given enough experience, which I've read  
>>is the reason that it was invented (they did not HAVE thermometers at the  
>>time).

>Almost correct. The "mash fraction" that is boiled is also raised to a  
>saacharafication rest temp, usually 147-158 or both, and after conversion,  
>is then denatured through boiling. This rest is often ommitted by home  
>brewers and may result in lost efficiency. Note that in a weizen decoction  
>program, the main mash sits at protein rest temps for over an hour while the  
>mash fraction is raised, held, then boiled.

Oops. You're right. On the other hand, the way you worded it, may be unclear to those unfamiliar. Permit me to paraphrase Jim:

The "mash fraction" is moved to a kettle and it's temperature raised to 147-158 for a saccharification rest. It is then heated again to boiling before being returned to the main mash.

\*\*\*\*\*

In Marybeth Raines' article on Sanitation, it's a real shame that she failed to mention iodophor and a recently new sanitizing agent, marketed under the name "One Step," which is peroxide-based and comes in powder form. I would have been very interested in her recommended contact times for iodophor and OneStep. I haven't forgotten that I promised to take all the info I've collected from HBD and personal correspondence regarding sanitation for homebrewers and post it. I still intend to do this, but the arrival of "One Step" has thrown an monkeywrench in the cogs and delayed my posting.

Jim writes:

>Anyone else catch the mistakes in this issue? Dave Miller claims  
>that hefeweizens are made with S. Delbrukii, NOT! It is S. Cerveasae,  
>see Eric Warners book, Brewing Wheat Beers.

also

Tony writes (from Eric's book):

> - You need the right yeast. One doesn't need s. delbruckii, just an  
>ale yeast with the right flavoring properties.

I've read that S. Delbrukii is used for German Weizens in numerous books and magazines. Eric Warner's book is the only one which reportedly contradicts this. Despite Eric's proven knowledge of German Wheat beers, the data seems quite heavily stacked against him. Comments?

One piece of data from me in Eric's defense: the Troubleshooting Issue of Zymurgy lists wheat malt as a source for phenolic (clove-like) character. Perhaps this is the true source of the clove-like character in German Weizens or maybe it's a combination of this and the yeast. This is getting complicated no? I've yet to find the time to read "German Wheat,"

so I'm afraid I can only go on pieces of info as posted by Jim and Tony.

\*\*\*\*\*

John writes:

>1. Is racking to a secondary fermenter only/mostly used for Ale yeasts, >Lager Yeasts, or both (ie. yeast is not the criteria)? When (and other >adverbs) do I need to rack and secondary ferment?

In my opinion, it's not the yeast that you use (some use lager yeasts at ale temperatures), but rather the time that the beer will stay in the primary. If you will be bottling/kegging within two to three weeks of pitching, I feel that going to a secondary is an unnecessary sanitation risk. If you're adding fruit or making a lager (at, say 45F), then I think that a secondary would be a good idea.

>2. According to Dave Miller, he racks when the bubbles slow down to 1/30 >seconds (I think). What span of time has passed (typically) 3 days, a >week?

It depends on the temperature, how much oxygen you gave the yeast, the strain of yeast and the amount of nutrients in the wort (worts with a high percentage of sucrose or corn sugar will have less nutrients). As reported recently, Wyeast 1007 (German Ale) is really a quick yeast. Many dry yeasts are very quick fermenters. I've used a yeast that I've cultured from an Orval bottle that regularly takes two months to ferment out 1055 wort. Temperatures in the low- to mid-60s will give you slower ferments, whereas temps in the high-70s can ferment-out the beer in a day.

If you don't give the yeast a good supply of oxygen, they can take much longer to complete fermentation.

>3. Okay, approx 3 days - a week has passed in the primary fermenter (white >bucket) and I am racking to a glass carboy (6 gal). At this time I would be >adding my dry Hops. Do I need a Blow-Off Tube? Do I need the Brew-Cap?

If you are not adding any fermentables (like fruit) and you have waited till the fermentation has mostly subsided, then you don't need a blowoff tube. A BrewCap(tm) could be used (I'm not sure about 6-gallon carboys) if you want to bottom-crop yeast from the secondary, but you don't \* need\* anything other than an airlock.

>4. After secondary ferm'g of 2 weeks, I will rack to my bottling pail and >prime. Is oxygen damage my main concern, or is lambic still a problem?

A small amount of oxygen should not be a problem, but you should still try to minimize aeration as much as you can. I don't understand your "is lambic still a problem?" (Personally, if all my beers tasted like

lambieks, I would consider it a mixed blessing!) Do you mean "can I still infect my beer?" The answer to this question is most definately yes. Assuming you did not infect the beer with attenuative wild yeast or bacteria earlier in your process, there will be some unfermentable sugars/dextrins in your beer. These can still be consumed by some wild yeasts and bacteria. Granted, at this point in the process, they will add less perceptable flavors/aromas to your beer than if you infected at pitching time (when there were a lot more sugars and less alcohol and a higher pH), but you can still have problems with gushers.

Al.

From: R\_GELINAS@UNHH.UNH.EDU (Russ Gelinias)  
Subject: hops, 1007

Wyeast 1007 is not their "alt" yeast. It is called "German Ale". Their alt yeast has a different number (1338?). I haven't used 1007 in a couple of years, and the porter made with it is what I remember, possibly because it came as a surprise that it worked so well. If I were to use it again, I'd probably try for a dry, hoppy, very pale ale, sort of a pilsner-ale.

Speaking of hops, try putting a freshly picked hops cone into a bottle of beer. Instant dry hop aroma, and even some noticeable bitterness if the beer is one of those "super-premium-extra-light-draft" US brews. A bottle works better than a glass; the cone gets sloshed around as the bottle is tipped, and the neck concentrates the aroma. Try it.

Subject: Decoction Mashing

Message Creation Date was at 9-AUG-1993 15:29:00

I've been reading the recent threads on decoction mashing which is convenient in that we will be trying our first decoction mash on our Dopplebock this weekend. I've read Noonan and Warner and I was wondering if any of you HBDers that have tried decoction mashing have any other practical tips that will help us ensure success on our first attempt.

TIA  
Tom Cannon

Subject: The 7th Annual Great Taste of the Midwest Beer Festival

ANNOUNCING....

The 7th Annual Great Taste of the Midwest Beer Festival

WHEN: Saturday, Aug 21 1993, 1-6 pm  
WHERE: Olin Terrace, Madison, Wisconsin  
COST: \$13 in advance, \$15 at the door

Sample over 60 different beers fresh from the brewery! Tempt your palate and educate your taste buds with ales, lagers, pilsners, stouts and more. All served by over 30 Midwest brewpubs, micros and regional breweries.

Festival tickets include a commemorative beer glass and UNLIMITED beer samples

Tickets are available by phone (608-256-1100) with MC/VISA

Proceeds benefit Community Radio - WORT

Organized by The Madison Homebrewers and Tasters Guild.

Participating breweies in this year's beer festival:

August Schell Brewing Co.  
Broad Ripple Brewing Co.  
Capital Brewing Co.  
Cherryland Brewing Co.  
Chicago Brewing Co.  
Detroit & Mackinac Brewing Co.  
Dubuque Brewing & Bottling Co.  
Fitzpatrick Brewing Co.  
Frankenmith Brewing Co.  
Golden Prairie brewing Co.  
Goose Island Brewing Co.  
James Page Brewing Co.  
J.D. Nicks Brewpub  
Joe's Brewing Co.  
Joseph Huber Brewing Co.  
Kalamazoo Brewing Co.  
Lakefront Brewing Co.  
Lienenkugels Brewing Co.  
Melbourne's Brewing Co.  
Midcoast Brewing Co.  
Millrose Brewing Co.  
Minnesota Brewing Co.  
Pavichevich Brewing Co.  
Pete's Brewing Co.  
R.J. Ginseng Beer Co.  
Spanish Peaks Brewing Co.  
Sprecher Brewing Co.  
Stevens Point Brewing Co.  
St. Louis Brewing Co.  
Summit Brewing Co.  
Water Street Brewing Co.  
Woodstock Brewing Co.

IMPORTANT NOTES:

1) We sold out shortly after opening last year. So, if you come from out of town, buy your tickets in advance! We don't want to have to turn away people who have driven long distances but we will have to if we are full.

2) The festival is at Olin TERRACE not Olin PARK (also in Madison). Olin Terrace is right downtown at Wilson St. and Martin Luther King Jr. Blvd. It is just two blocks from the State Capital Dome and thus easy to find.

3) As mentioned above the ticket cost covers a beer glass with this year's logo and all the beer you want to sample. There is no messing with beer tickets or any charge for additional tickets etc. The only additional cost would be if you purchased brewery merchandise or food from our food vendors (recommended if you are sampling over 60 beers!)

4) The date listed for our event in "Brewing Technology" is completely wrong. I believe it is the date we used 3 years ago which is backed up by their calling it the 4th and not the 7th also. We at the club have no idea where they got that date and wish to apologize for any inconvenience that may ensue.

5) What great call letters for the community radio station that proceeds are donated to, WORT, eh!

From: Drew Lynch <drew@chronologic.com>  
**Subject: Cold Plates**

I recently acquired an 18"x24" Cornelius 3 line cold plate. It's pretty grungy, so I filled it with TSP solution and let it soak for a while. Should this be enough, or is there some other, more potent, cleaner I could use? I don't think it would be possible to feed any sort of brush through it.

Also, this thing is more than I need. I would be open to trading it for some combination of smaller cold plate(s) and cornelius kegs. Email or call me if you are interested.

Subject: chipotle

Howdy,

In HBD #1198, I reported on my serrano beer being a success. Saturday afternoon, my brother & I popped open the two bottles of chipotle beer we set up. Bad mistake. Do not put a chipotle into your bottle of beer. It will make a nasty concoction that is undrinkable, unpleasant, & all around unlikable.

As I reported on the serranos, the beer tasted fine, the pepper came through nicely but not overpowering, & all in all it was a success. We also added one chipotle each to two bottles of the same pilsner. Twenty days later, we tried them. Both beers had changed from the nice golden color to brown, one looking like an American bock, the other not quite as dark. Both were flat, even though they gushed when opened. The lighter colored of the two was so spicy that it could not be drunk (we think there was a crack in the pepper, allowing the seeds direct contact with the beer). We were unable to determine quality of taste of this bottle. The darker one was not too spicy. However, it was sweetish in taste, & not in a pleasant sense. The smokiness came out, but again, it just didn't work. It was as if it was a completely different beer from the original, which was a nice, well balanced pilsner. All in all a bad idea.

I did discover that beers bottled with chili peppers do need to be consumed rather quickly. The first serrano bottle I tried was 17 days after bottling, & was spiced just right. I tried a second one last night, 21 days after bottling, & it was pushing the limits on the spiciness scale for me. A friend who also enjoys spicy foods agreed with me. This is something to keep in mind if you are planning the bottling method of chili beer.

So, to sum it up: Don't consider chipotles. Serranos may be washed in water, dropped into the bottle & the primed beer racked onto them. Drink within 3 weeks, unless you have a particularly hardy palate.

BTW, I'm taking a trip to Bastrop, TX in September. Anyone know of any good brewpubs, breweries, expensive bottled beer bars, hop farms, barley farms, yeast labs, glassworks or beer coaster factories worth visiting near there?

Happy brewing,

Alan, Austin

From: Bob Regent <b\_regent@holonet.net>  
Subject: RE: I need a new factor!

Steve Casselman asked about the ratio of weight of grains vs the weight of dissolved extract. This is typically known as the extraction potential (%)

. This is the way that the data is presented from the maltster, they dont represent the data way that most homebrewers are used to. (pts/lbs/gallon)

My program, Brewer's Calculator, comes with the extraction potentials for most

malts using both the extraction percentage and pt/lb/gallon methods. It also allows you to enter your own data using either technique, and automatically converts the other. (cheap plug, sorry)

To convert from one to the other is easy.

Extract X .461 = pt/lb/gallon - 1

For example, if your grain has an extract potential of 76%, then

$76 \times .461 = 35$  or (1.035)

This may or may not be usefull in recreating grain recipes using extracts.

You must remember that Syrup extracts contain only about 76% solids and DME is

97.6 so you would have to take that into considerations when formulating.

I've got bad news. The irish moss you have is not the irish moss used in  
brewing. The irish moss clarifying agent is from a marine alga (seaweed)

.

>Third--

>While watching "Mary Poppins" for the ten thousandth time (can you say

One possibility: Malted barley infused with warm water was used as  
a tonic. With all those wonderful enzymes coursing through it, it's sure  
to cure what ails you. I can try asking my dad, since his dad published  
the books in the first place.

From: Lee=A.=Menegoni@nectech.com  
Subject: Wheat beer yeast

Re: Wheat beer yeast. The strain of yeast DOES matter to the end product.  
This summer HBD contributor Jim DiPalma has brewed some good wheat beers using a strain of Weinstephen yeast but they lacked the clovey character. He then got the "correct" yeast and his brews were excellent with clovey and fruity tones. Given his meticulous brewing technique and similarity in recipe the differences were clearly the product of the yeast used.

RE: Prescription beer. My high school Spanish teacher told us they would feed their young child beer, which they had warmed to remove alcohol and CO2, while traveling in South America since the water supply was unreliable.  
The beer was rich in carbohydrates too. I have heard that another reason to "prescribe" alcohol was to circumvent prohibition.

Date: Tue, 10 Aug 93 08:01:15 PDT  
From: tima@wv.MENTORG.COM (Tim Anderson)  
Subject: Prescription Beer

My grandmother loves to tell me the story of how Grandpa's homebrew saved my uncle's life. She always tells it in a conspiratorial tone, when my parents aren't around. Which is pretty cute, since I'm in my mid forties.

My grandparents were Nebraska farmers during prohibition, and like lots of folks during that time, they were brewers of the best kind of beer: available. Their third child, Charles, had serious digestive problems as an infant. He was unable to keep anything down, including his mother's milk. He was dangerously thin and his parents were resigned to losing him. One day as Grandpa was walking him around the room trying to give some comfort, he took a drink of beer. Baby Charles smacked his lips, apparently in response to the smell of the beer. Grandpa dipped his finger and put it into the baby's mouth. He sucked eagerly. The expected reaction didn't occur, so he got a little more. After several serious dips from the ol' beer stein he nursed and didn't lose it. He binged for a couple of weeks, was fat and healthy and they took him off the beer without ill effect.

I offer no theories, I just tell 'em the way I hear 'em. I'd love to add that Uncle Chuck continues to have his beer with a milk chaser, but it just ain't so, and I've resolved to keep my stories mostly honest. But I have noticed that whenever he's drinking beer, he tends to get awfully friendly with his wife, and she tends to give him those "drop dead" kinds of looks.

>Anyone have any  
>suggestions on how to improve my techniques in handling cultures so that  
>this type of contamination does not happen again.

I'm not sure your techniques are to blame, I've never had any success  
with long-term storage of cultures on petri dishes. The top and bottom  
halves do not form an airtight seal. After streaking the plates, I seal  
them with electrician's tape, and store them in a warm place. Two or  
three

days later, the colonies are sufficiently grown to harvest them, I then  
innoculate several slants. After one or two days at room temperature, I  
store the slants in the refridgerator, they're good for several months.

I have noticed that even when I reseal the plates with the tape, within  
a week or so fuzzy growths appear that look like mold. From this, I  
concluded that long term storage on petri dishes was not a good idea, and  
have been using the above procedure with good results.

Disclaimer: I'm a software engineer, not a microbiologist (hence the  
use  
of the decidedly non-technical term "fuzzy growths"), so would welcome  
comments by others more knowledgable.

Also in HBD#1200, Thomas G. Moore writes:

>In Eric Warner's German Wheat Beer book he mentions milling  
>malted barley wet as to keep the husks intact. This will help com-  
>bat stuck run-offs during lautering. Has anyone used this method  
>with wheat beer decoctions?

I tried this exactly once, the first batch of weizen I brewed after  
reading Warner's book.

I sprinkled the barley gently with water, and kept turning it until  
it was all lightly moistened. I ran it through an adjustable Maltmill,  
which does an excellent job of keeping husks intact in any event. This  
procedure \*does\* work, at least in terms of minimizing husk damage. It  
appeared as though each kernel had been gently opened - the water  
definitely  
helped reduce tearing of husks. The problem was cleaning the mill  
afterwards - the grooves in the rollers filled with the "paste" that  
resulted from flour and water, which dried quickly and became rock-hard.  
It was a major chore to clean up the rollers afterward, so I never tried  
this again. I get a good quality crush with the MM, and use a staggered  
protein rest and decoction mashing when brewing weizens, so I haven't had  
any problems with cloudy or stuck runoffs.

If you use a corona, I think this would be worth a try. It does reduce

husk damage, which is one of the corona's biggest drawbacks, and cleanup shouldn't be a problem with a mill that doesn't have grooved rollers.

Also in HBD#1200, Al Korz writes:

>One piece of data from me in Eric's defense: the Troubleshooting Issue of  
>Zymurgy lists wheat malt as a source for phenolic (clove-like) character.  
>Perhaps this is the true source of the clove-like character in German  
>Weizens or maybe it's a combination of this and the yeast.

Working from memory here, don't have Warner's book in front of me, but he writes that an important precursor to the 4-vinyl guaiacol phenolic, which is responsible for the clove-like flavor, is free ferulic acid. He goes on to state that ester bonds bind ferulic acid to pentasanes in the grain (can't recall if he meant wheat or barley), and recommends an acid rest at 110F to produce ferulic acid in it's free form.

That said, I've had an interesting time brewing weizens this summer. I obtained a Weihenstephan #68 culture early in May, and brewed a couple of batches, dutifully following Warner's procedures. While the beers were OK, neither had the desired clove character.

I did some investigation, as it turned out, the strain I had obtained was quite old. I found out that the strain was the original 1991 vintage, which apparently "pooped out". Commercial weizen brewers have experienced the same problem with this strain. It was quietly replaced in 1992 by those who distribute this yeast with a strain that has displayed considerably longer staying power. Since then, I have brewed three other batches of weizen, two dunkels and a pale, with the 1992 vintage, same recipes, same procedures. These brews are \*wonderful\*, hit-me-over-the-head clovey, well balanced with banana, with hints of vanilla, nutmeg, cinnamon - everything I love about weizens.

So, the moral is: IT'S THE YEAST.

Cheers,  
Jim

The "Irish Moss" you bought at a garden supply store is not the same as  
the  
Irish Moss used as a kettle coagulant in home brewing. The Irish Moss  
that  
we use is actually a marine red algae (*Chondrus Crispus*, if I am  
remembering  
correctly from my marine biology days).

>However, I prefer  
>to (Cornelius) keg my beers, and I'm wondering a bit about just  
>how much of what variet(ies) of peppers to use!  
>[...]  
>What about a chili extract in alcohol?

Have you considered using hot pepper sauce? A couple years ago someone on the HBD suggested using Tabasco Sauce (any hot sauce based only on peppers would do, so experiment to determine which varieties you like best). You can determine the amount to add by adding one drop at a time to a pint of beer, stirring and tasting after each addition, until you determine how many drops/pint give you the desired degree of hotness. Then multiply this by the number of pints of beer that you want to make to determine how many drops to add to your keg (perhaps subtracting 10% to be safe).

I haven't tried this, but it would seem to be more predictable than adding whole peppers (and more repeatable, too).

Subject: Water and carbonation

In HBD 11999, Guy DeRose (DEROSEGA%ML%WPAFB@MLGATE.ML.WPAFB.AF.MIL)  
writes:

>A batch of stout I made in February (extract + specialty grains) started  
out  
by having "perfect" carbonation and head retention, but after aging in  
the  
bottles it became overcarbonated...The beer tastes fine, so infection  
does  
not seem to be the culprit... Is there a  
relation between high mineral content of water and increased carbonation  
as a  
function of time? Could the "yuck" in my water  
erve as nucleation sites for bubbles?<

I think that the most salient question is: what was the starting and  
finishing gravity of the brew in question? Ofttimes, "gushing" is caused  
by  
incomplete fermentation or infection (which you feel you have ruled out)  
,  
which is not always detectable via tasting. What is the mineral content  
of  
your water? All the Burton-on-Trent brews (Double Diamond and Bass, to  
name  
a couple) are made with extremely high mineral content water. Write back  
to  
us about the O.G. & F.G. & exact recipe, including priming agent &  
dosage.

Date: Tue, 10 Aug 93 10:49 CDT  
From: "Michael Barre" <MBARRE@NOMVS.LSUMC.EDU>  
Subject: Second batch of beer

Thanks to the advice given by Mark, Al, and Tom over this forum, my second batch of beer is good! I made a Pale Ale using Northwestern Gold extract, Wyeast (American Ale), Cluster hop pellets (the homebrew store's suggestion), and Ozone spring water.

Hot break: After the water/malt had heated for 25 minutes, it began changing from very cloudy to egg-drop-soupy. After 45 minutes it reached a fast boil and I then added 3/4'ths (1.5 oz.) of the hops.

Aroma hops: After another 30 minutes, I added the last 0.5 oz. and removed the pot to the ice-water-filled-sink.

Cold break: After 45 minutes I poured the wort into a settling bucket (w/out straining), leaving 1/8'th inch of hop residue in the pot. A couple of minutes later I poured the wort into the carboy with 3 gallons of jug-aerated water, leaving behind more residue.

Liquid Yeast: It smelled good. Rehydrated dried yeast does not. I pitched the yeast into the 75F wort. 12 hours later no yeast activity was apparent. After 24 hours, the beer was swimming and foaming like crazy. Fermentation continued for 5 days. I then racked to a secondary, losing the siphon once because I didn't realize that the curve of the siphon tube in the carboy put the racking tip almost 4 inches up off the bottom.

Irish Moss: I rehydrated about 2 teaspoons of I.M. and added it to the secondary before racking, resulting in globs-of-goop all in the beer, which congregated at the top and bottom after 4 days.

Racking tip: I then siphoned the beer into the bottling bucket using the racking tip in the trub and discarding the first cup or two of beer.

Bottled Beer: Clear and tasty!

Thanks.

Subject: New Sanitizing Agent ?

Has anyone experimented with hydrogen peroxide as a sanitation agent ?

I'm not clear on the mechanics of the substance, but, besides reacting with organic matter, it also super-oxidizes the solution it is added to.

I have heard of hydrogen peroxide being used as a food additive, also. The theory is that the environment humans evolved in was far more rich with oxygen than it is now, especially in city environments - and that this subtle but detectable oxygen deprivation leads to anaerobic bacteria populations increasing within one's body ... resulting in more opportunities for infection, lethargy, et caet.

Specific infections I've heard it mentioned in connection with include herpes and warts ( both anaerobic viruses ), as well as AIDS. I'm not saying that it's a panacea, just noting that there is research on this topic here in the Bay Area.

( I've been trying this - neither hydrogen nor oxygen are poisonous, and hydrogen peroxide is recommended by dentists after oral surgery, as a dilute mouth rinse - and a wart on one finger \*does\* appear to be in remission. Just a data point. I'm using three droppers-full, twice a day, in a glass of Tang, each time. )

In connection with brewing, could it not also be used to oxygenate the wort ? Just a wild idea, but it makes intuitive sense to me ...

Further experimentation is indicated ...

A carboy by definition, I should think, has some sort of lid, doesn't it? At any rate, what is generally referred to as a carboy is a glass bottle (usually 5-7 gallons); there are things I might call a "carboy" in a pinch that are made out of plastic. Are you referring to a plastic bucket? If you can spend the limited \$\$ necessary to pick up a glass carboy (around \$10-12 max.) you would be doing yourself a service -- unless you have a very sterile area to keep your open secondary in. An open primary, maybe, with very vigorous yeast growth, but a secondary is pretty scary.

Assuming that you have something safe to put your beer in for a secondary, simply place loose hops in a cheesecloth bag, tie it closed and stuff it in the secondary. For simplicity's sake, don't bother sterilizing rocks or marbles and stuffing them in the bag -- an utter waste of time, in my book. If you want a real hoppy flavor, use very aromatic hops, use lots of them and leave them in for weeks. When you bottle, simply rack over into that dubious secondary with the spigot; the hops will stay in the bag.

Putting hops in for a couple of hours is likely a waste of time and effort; for that result you could simply add hops at the end of the boil, or run the hot wort over fresh hops on the way to the fermenter.

But for now, leave them out!

AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAaHHHHHH!!!!

Stop! Irish moss is NOT MOSS! The stuff used in brewing is produced  
from seaweed (kelp, probably). It's also not from Ireland. Leave your  
moss on the ground and keep it out of the beer!

Speaking (as you were) of kids' movies, we watched Darby O'Gill and the  
Little People the other night. Those old guys could really suck down  
the Guinness.

(Not the little people; they drank whiskey -- just goes to show what  
distilled beverages will do to you.)

**Subject: banned brews**

A small article in Monday's USA Today caught my attention. Montpelier, Vermont:

"The state is cracking down on strong beers, banning restaurants and stores from buying more, Dept. of Liquor Control officials say. Included are malt beverages with higher than 6% alcohol by volume - such as Sierra Nevada or Anchor."

I was wondering if any of the digest subscribers in VT could throw some light on this situation. Have there been incidents of rowdy Bigfoot Barley Wine drinkers getting out of control? Or is this just another example of government of the people, government of the people, government of the people?

Just curious,

From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>  
Subject: New Factor

The "new factor" Steve Casselman is looking for is the weight-percent yield of extract. It is the fraction of the weight of a mash or kettle ingredient which appears as extract in the wort. A 100% yield will give 46.3 points/lb/gal @ 60F, so some typical examples of %-yield are:

Dry Malt Extract at 45 pt/lb/gal =  $45.0/46.3 = 0.97$  (97%)

2-Row Malted Barley at 34 pt/lb/gal =  $34.0/46.3 = 0.734$  (73.4%)

The tables published in Dave Miller's book and in Zymurgy can be converted to %-yield using this factor. Noonan's "Brewing Lager Beer" has good table of %-yield from a number of extract sources, which can be converted to pt/lb/gal, if desired. Professionals generally use %-yield, and the typical lab analysis of a sample of malt or other grain will give extract figures in this form.

So, to make 5 gallons of beer of SG 1.048, with an expected yield of 73.4%, the amount of grain needed is  $(48 \times 5) / (0.734 \times 46.3) = 7.06$  lb. To convert this weight to an equivalent amount of dry malt extract, you need  $7.06 \times (0.734 / 0.97) = 5.34$  lb.

From: John Mare <cjohnm@ccit.arizona.edu>  
Subject: RE: Yeast contaminant: Irish moss: Barley water

Steve asks about yeast culturing techniques, growing Irish moss, and drinking barley water. About your agar contamination problem: It is hard to comment not being familiar with your technique. A few comments may be helpful. Work in a still (draught-free) place, use a flame (eg. propane torch) and a platinum loop (ex microbiology kit at a hobby shop). Start from a clean liquid culture and after flaming the loop streak the surface of your agar quickly and replace lid. Keep at room temperature for a few days until colonies are visible, place in plastic bag (eg. sandwich bag) and refrigerate. When making starters pick individual colonies with a sterile but cooled loop (dip into clear area of agar plate). DON'T flood agar plate as has been suggested recently. This is a sure way to pick up the odd contaminant which may find its way into you surface culture. "Irish moss" as used in fining during the boil is carageenan, a seaweed found among other places off the coast of Ireland Scotland and Wales. The weed is harvested, dried and flaked or pelleted for use as a fining agent. The "Irish moss" you are growing is another creature unless you have a spot of ocean at your disposal! One of the bane's of my early years growing up in the "British Way" was having to endure "barley water" which my mother prepared because "it was good for you!" This was simply a mild barley broth, strained, and served cold when we were well, and hot with added "Marmite" (yeast extract) when we were ailing! In the Mary Poppins context which you quote there may be a another more spirituous dimension!

Interesting. Red Hook Brewing Company is currently making a  
Summer Rye, which is quite pale. It's an interesting beer  
and although I was at the brewery and got a tour of the new,  
\*automated\* keggling line, I did not get to talk to the brewmaster.  
So, I did not get the percentage of rye in this beer or what the  
other base malts might be. Judging from the flavor, I would  
say that there may be a considerable percentage of wheat in  
this beer. Could someone from Seattle look into this?  
Domenick? Darryl?

\*\*\*\*\*  
Subject: I want a new formula

Alas, I've lost the original poster's name, and Kieran did post sort-of  
a formula for what the poster wanted, but I feel that just a couple of  
number is all that they really needed, so I'm posting my suggestions.

For substituting syrup for pale/pils malt, I recommend multiplying by 0.  
74  
and for substituting dry malt extract for pale/pils malt, multiply by 0.  
67.

I used 28 pts/lb/gal for the grain, 38 pts/lb/gal for the malt extract  
syrup  
and 42 pts/lb/gal for the dried malt extract.

Actually, everything is dependent on the efficiency of the extraction  
that  
the author of the recipe achieved and on the brand of syrup/DME you use.  
A much more accurate way to duplicate all-grain recipes using extract is  
to look at the OG of the recipe and figure out how much extract you need  
to hit this target. What I do is use the crystal and roasted malts/  
grains  
as they are listed in the recipe and then subtract their contribution  
from  
the OG. Here's an example:

5 gallons of Pale Ale with an OG of 1055 that contains 3/4 lb  
of light crystal malt.

1. subtract away the water (1.000) leaving 0.055
2. let's say you know that you get 0.022 per pound per gallon from your  
crystal malt, so you do the math:

$$0.022\text{pts} * 0.75\text{lbs} / 5 \text{ gallons} = 0.0033\text{pts}$$

3. subtract the 0.0033 from the 0.055 target and you get about 0.057

4. let's say you know you get 0.040 per pound per gallon from Northwestern Gold Extract, so you decide you will use 6lbs in the 5 gallon batch and make up the difference with dry extract, so again you do the math:

$$0.040\text{pts} * 6\text{lbs} / 5 \text{ gallons} = 0.048\text{pts}$$

5. subtract the 0.048 from the 0.057 and you're left with 0.009pts

6. let's say you know you get 0.044 per pound per gallon from M&F DME, so you do the math:

$$0.009\text{pts} * 5\text{gallons} / 0.044\text{pts} = 1.02\text{lbs}$$

So you use 3/4 lb of crystal malt, 6 lbs of NW Gold and 1 lb of M&F DME.

If you have the room, add whole Fuggles (they float, so it will be easier to siphon out from under them) to your primary. Let them sit for 7 to 10 days and then bottle as usual. If you don't have the room, you can siphon the beer into your bottling bucket, rinse and re-sanitize your primary and siphon the beer back onto the hops in the primary.

--S (sorry, lost your whole name) writes:

>I was going to start a batch of yeast in anticipation of brewing later in the week. When I went to get my petri dish with the culture on it out of the fridge, I noticed that the entire surface of the dish was covered with a green growth of mold :-(. I had to start from a new slant with a different strain than I had intended to use. Anyone have any suggestions on how to improve my techniques in handling cultures so that this type of contamination does not happen again.

Molds are aerobic. Luckily, yeasts are anerobic. You can put your petri dish in a "Tupperware" container and then purge the container with CO2. If you don't have a tank of CO2 handy, you can pour a cup of beer into a pitcher, loosely cover the top and agitate (cheap beer will work for this) briskly. The agitation will cause the CO2 in the beer to come out of solution and you can then pour-off the CO2 (remember, it's heavier than air) into the "Tupperware" container. Work slowly, in a room with still air (turn off the a/c and let the air settle down) and you'll have enough CO2 left in the bottom of the container to displace the air that the molds are breathing. Just picture the CO2 as an invisible liquid, like the fog from a fog machine. Hey, if you have some dry ice available,

you can just plop a piece of it next to the petri dish in the tupperware (leave the top open a crack till the dry ice disappears or drill a hole and put in an airlock so the top doesn't blow off). Don't do this work in a damp basement where there's more molds in the air.

issues,

>

Well, I don't see any difference between serving homebrew or commercial  
brew - unless it is unusually potent or something like that - but you  
never

what what they'll dream up to stick you with.

> 2) If it isn't much a legal hassle/worry, I'd like to think about  
brewing

>some stuff up now. I'd like to brew one heavier brew, appropriate for  
>

I am getting married this Saturday and I'll have six kegs of homebrew at  
the

wedding. I brewed two kegs of weizen and two of a bitter that I planned  
on serving during the day time. Both of those brews were on the light  
side

(O.G. 1.042 or so) so that people won't get schnockered on two glasses. I  
also plan on having one keg of commercial light beer (which, as my brew-  
partner is fond of saying, is for those who don't like beer) and one case  
of non-alcoholic beer. Although that sounds like a lot of beer we have  
260

people coming. That averages about 1 pint (or two 8 oz glasses) per  
person

which I think is a sane amount. Of course, there is no guarantee that  
one

person won't get drunk and I can't police 260 people. So as an added  
level

of control we have hired a bartender to police the kegs and keep an eye  
on

things. It's not a perfect system but we hoped it would be a nice  
compromise

between people having responsible fun and not letting it get out of hand.  
Estimating that only half the people coming will actually drink beer,  
that

still comes out to two pints per person. Consuming that much beer over a  
four hour period and in addition to a meal should be within reason.

The extra two kegs are a heavier pale ale (still not too heavy though,  
maybe

1.050? I can't remember off hand). But I am only going to serve that  
beer

in the evening for people staying overnight - one keg at the rehearsal and  
one the day of the wedding. There should be about 40 people for each of  
those nights and, again, I think that is a sane amount.

Good luck on your event! I certainly would recommend getting a head  
start

on it. It's not so far away that you should be worrying about stability  
problems. I may have more insight into the wisdom of serving homebrew at

an event like that when I come back from our honeymoon.

From: akcs.rab@vpnet.chi.il.us (Alan Belke)  
Subject: Mini Keg System

This is my first posting to HBD so please be gentle. First I have an observation and then a question.

Since I have been receiving HBD I have noticed many times that a question doesn't seem to get answered. Then all of a sudden there is a post from the person who asked the question saying thanks for the help. What is the protocol here? Are answers supposed to be e-mailed or posted back to the digest? Since I am interested in the digest as a learning tool I, obviously, would prefer the dialog be done in the digest.

Now the question: Has anyone seen, used, or done anything with the mini keg system advertised by Brew Ha Ha. It looks very attractive to me since I brew fairly infrequently (4 times a year or less) and it would be nice to get out from under bottles.

Thanks,  
Al Belke

From: Jim Busch <busch@daacdev1.stx.com>  
Subject: Weihenstephan #68 & T. Delbrukki

In the last digest,  
<From: Tom.Weicht@arrc.ncsu.edu (respond to deb\_neher@ncsu.edu)  
<Subject: S. delbrukii or S. cerevisiae?

<I am a recent arrival to HBD.  
Welcome!

<Saccharomyces delbrukii or S. cerevisiae?? I personally  
<believe both are technically incorrect. From the best that I have  
<been able to find in the mycological taxonomy literature, the true  
<name of this organism is Torulospora delbrukii, this is how the  
<American Type Culture Collection lists it which sparked my interest  
<and pursuit of this subject. An incorrect but often used synonym is  
<Saccharomyces.

<AS BREWERS SMALL OR LARGE OUR CONCERN IS THE BIOCHEMISTRY OF  
<THE YEAST AS IT PERTAINS TO THE FINAL PRODUCT. DON'T let the  
<taxonomy get you down, but don't slam somebody else's taxonomy when  
<basing an opinion from a single source either.

I am not claiming to be an expert on yeast taxonomy, but I do have some  
sources. I also do not intend to provoke a flame fest, but here goes..  
In the ATCC, S. delbrukki is listed as a valid synonym for T. Delbrukki,  
but  
appears to have been isolated from sources other than beer, ie wine and  
tree sap. So , unless other references are available that I am unaware  
of, it appears that this organism is not involved in wort fermentation.

Referring to the Weihenstephan catalog , an english translation of the  
catalog, calls the yeast a top fermenting S. cerevisiae. No doubt that  
T. Del exists but unless further evidence is found, I will stick with  
the designation from the Weihenstephan laboratories.

Tom's comments regarding the importance of the biochemical properties  
of the strains in our beer production over the importance of the  
taxonomy is quite true. I am merely attempting to clarify what I have  
found to be a confusing aspect of the homebrewing literature.

Good brewing,  
Jim Busch

"Irish Moss" for beer is a kind of seaweed. I don't know what kind if  
"Irish Moss" you are growing, but it sounds like something entirely  
different. Does the plant grow in solid masses and have a single really  
small round leaf at the end of each "blade"? I've seen a groundcover  
like this called "Irish Moss".

From: dturner@sca.com (David Turner)  
Subject: Sanitizing swing-top bottles

Greetings,

I am preparing to bottle my third batch of HB, using swing-top ("Grolsch") bottles for the second time. The first time I used them, I replaced all the rubber gaskets, as they were several years old and suspect. I boiled them at bottling time, i.e., I sanitized them seperately from the bottles.

For this round of bottling, I know the bottles are clean (of grunge), and don't plan a TSP bath. A good washing, then a chlorine soak, then bottle.

My question: can I leave the rubber gaskets on the bottles during the chlorine soak? Will they absorb chlorine odor/taste? Will they deteriorate? Must I remove them first, and boil them seperately, as I did the first time? Was that more than one question?

Thanks for any/all advice...later...DT

From: Michael.Burgeson@Eng.Sun.COM (J. Michael Burgeson)  
Subject: water filter

I was in the plumbing supply store yesterday, and saw filter housings and cartridges on sale. I thought this would be the perfect opportunity to add a water filter to my brewery.

I intend to removing chlorine and particulate matter from my brewing water, so I was looking at activated carbon filter cartridges. But one carbon filter caught my eye because it also claimed to filter at the 0.5 micron level. Isn't 0.5 microns fine enough to remove most bacteria and micro-flora? Would someone who is microbiologically literate please comment?

Assuming the output side of the filter was sanitary, wouldn't water filtered at this level be safe to rinse sanitized brewing equipment, without worrying about introducing a contaminant? Or are there contaminants that would pass through this filter?

The rinse/don't rinse debate has gone on here for a long time, but I never heard of anyone using filtered water to rinse. It seems this would be a great time savings over pre-boiling rinse water, and you have the added benefit of being able to filter your brewing water. I hope I'm right 0.5 microns being fine enough to remove bacteria.

BTW, there were 2 different 0.5 micron, activated carbon cartridges on the shelf, and were priced at \$24 and \$40.

From: npyle@n33.stortek.com

Subject: Chiller conversion

I have just invested in a new brew kettle (described in a previous post) which is a 10 gallon cream can from a dairy. It is tapered toward the top and therein brings a small problem. My immersion chiller will not fit into this small(er) opening and I'd like to convert it to a counterflow chiller. It is about 35 feet of 3/8 inch copper tubing coiled to about a 1 foot diameter. Any suggestions?

Actually, one of my ideas was to convert to a chiller (I can't come up with a descriptive name) in which there is one coil sitting in a bucket of sorts. The bucket contains cold water, maybe ice water, and the coil contains the wort. The cooling liquid could, probably should be flowing in/out. The wort would be siphoned through the coil, cooling it. Stoelting makes something like this for several hundred dollars, which I refuse to pay. Anyone done this? Anything I should be aware of?

Thanks,  
norm

Subject: Chipotle

Alan of Austin says: "Do not put a chipotle into your bottle of beer."

My experience cooking with chipotles makes it obvious to me that 1  
chipotle  
per bottle (i.e., \*50\* or so per 5 gallon batch) is going to blow your  
head  
off (to use technical chile lingo). Chipotles are \*hot\* (underlined, in  
caps, bold face, etc.).

However, that should not prevent homebrewers from trying chipotles  
altogether. Rogue River Brewery, in Ashland OR, puts out a beer called  
"Mexicali Rogue" that is flavored with chipotle. Very good stuff.

Subject: Sam Adams Winter Lager

I know old Ed Koch has been taking a few lumps here and on other forums. But last year he made a Winter Lager that was out of this world IMHO.

Does anyone have a recipe for a similar brew? Bob Jones published a recipe for Boston Lager many months back, I tried it and it turned out great! But it's not Winter Lager.

Gotta get started now for those Holiday parties!  
Thanks for your help.

From: RBSWEENEY@memstvx1.memst.edu  
Subject: extraction rates

I put together the following list of maximum extraction rates for grains based on some information obtained from a few extremely charitable HBD subscribers and from Dave Miller's book Brewing the World's Great Beers. There are two numbers listed for a few of the grain due to source discrepancies (Miller's figures are in lower caps) and I was wondering if someone with more knowledge than myself about such matters would lend a hand and tell me the \*right\* number to use. Thanks.

Disclaimer: I haven't tried it either. But I'd be cautious. Tabasco in particular, and hot sauces in general, have vinegar as a major component.

The best commercial chile-pepper beers (Rogue Mexicali Rogue and a sample from Fort Collins that Paul Edwards delivered to the AHA in Portland, thanks, Paul!) are not merely hot but present the distinct flavor of peppers in a much more complex flavor profile than I believe Tabasco and other commercial hot sauces would provide.

From: bszymcz@ulysses@relay.nswc.navy.mil (Bill Szymczak)  
Subject: Re: Sanitation

In HBD1200 Al Korzonas writes:

>In Marybeth Raines' article on Sanitation, it's a real shame that she  
>failed to mention iodophor and a recently new sanitizing agent, marketed  
>under the name "One Step," which is peroxide-based and comes in powder  
>form. I would have been very interested in her recommended contact  
times  
>for iodophor and OneStep. (...stuff deleted)

While we're still giving out constructive criticism of Maribeth Raines' article in Brewing Techniques on Sanitation, there was something else in the article that I didn't understand. Namely, the difference between dry and moist heat as a sanitizer. For example, why does moist heat at 250 deg. F only require 15-30 minutes to sterilize while dry heat at 350 deg. F requires 60-180 minutes? I use dry heat to "sterilize" my racking canes which are copper, and have been baking for only 1/2 hour at 350 deg F. Do I need to raise the oven temperature to 400 or 450 degrees to sterilize in 1/2 hour? Overall, the article was good and I learned something new in the fractional sterilization process. It could have been better by perhaps explaining more of the why's of sterilization than simply the how to's and some references to the statistics posted would definitely have improved the article.

Also Steve Lichtenberg asked about storing petri dishes and received some answers in HBD1201. I've found that whenever mold starts growing in a petri dish it was always starting from the edge (in the two or three dishes that went bad on me). Since then I've been careful in resealing the dishes after taking a sample. After closing the dish (and actually before also) use a cotton ball soaked in a bleach solution or alcohol and wipe the rim of the dish. Pass the edge over a flame which helps dry the bleach (be careful if you use alcohol and/or a plastic petri dish) before resealing with parafilm. I stack the dishes upside down in ziploc bags in the refrigerator. I've resealed some plastic plates I purchased from the Yeast Culture Kit and they have survived for over a year now without any sign of mold. Actually, the plates which were resealed have outlasted two of the originally "clean" plates without any culture, supplied in the Kit. Five out of six of the other plates I prepared myself about 4 months ago are still free of contamination.

From: Montgomery\_John@lanmail.ncsc.navy.mil  
Subject: Recipe formulation

Hi all,  
As with all the other "first time posters", please be patient with me.  
I have questions about formulating my own recipes.

I have about 10 or 11 batches of All Grain brews under my belt (all puns intended) and have, to date, been following TCJoH and TCHoH recipes. I am interested in stepping out into the "great unknown" and developing my own recipes, but seem to be having a hard time finding guidelines for such.

Should I just "waste" 10 - 15 gallons of brew for each style until I get it just the way I want it or is there some publication that offers particulars of and suggestions for recipe formulation? Do I need to study articles for each of Hops, Malts, Adjuncts, Water, Yeasts, etc... and postulate from there?

Many, many thanks in advance.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Aeration

Last week I put together an aquarium pump type aerator for the weekend batch to see what all the excitement was about myself.

After following Miller's procedure, I found that the commencement of fermentation was, if anything, later than it would have been using my standard procedure of simply squirting the wort into the fermenter.

I usually get fermentation at 40F within 24 hours but this time it took about 48 hours.

Several things come to mind:

One being that I was a victim of enthusiastic promotion based on unsound, anecdotal experience and wishful thinking.

Miller claims to use the same type of system on a large scale commercial operation as described for home brewing. The only exception he takes is that some part (presumably the airstone or hoses) are stainless.

It is simply preposterous to believe that one can get enough oxygen into a large batch of beer using an aquarium pump and an airstone for 15 minutes.

What makes it preposterous is that this is the same system/time recommended for a 5 gallon batch. [I used a total of 30 minutes pumping in my batch because 15 seems totally inadequate]

The idea of getting fermentation started in "3 to 8 hours" was enough to tweek my interest but I believe I fell into another trap created by non-critical writing; viz., he failed to mention whether he was talking about ale or lager and the fermentation temperature.

I can only now presume that he was talking about ale yeast at room temp and my enthusiasm has fallen an order of magnitude.

To settle the issue, I have constructed a controlled experiment which is now in process and I will report back in a few days.

In the meantime, does anyone have any such experience as Miller reports at lager temperatures?

From: /R=HERLVX/R=AM/U=KLIGERMAN/FFN=KLIGERMAN/@mr.rtpnc.epa.gov  
Subject: bad cider, Belgian wyeast, hydrogen peroxide

A couple of items:

I tried posting this from America On-line but never saw it or a rejection notice.

We recently tried making an apple cider by adding frozen, non-preserved apple juice over the dregs of a great cider. After a number of months it finally cleared after adding pectinase. However, while siphoning, I detected a distinct acetic acid smell and taste. It obviously has turned to vinegar, 5 gallons worth. We bottled some and my wife tried to save tthe rest by adding sodium metasulfite then sugar and fresh yeast to the remaining gallons. My question is: what organisms are responsible and does anyone believe it can be saved-- it still has a good apple aroma buy little alcohol.

I also recently made a Belgian Ale using a recipe in the Belgian Ale book and Belgian Wyeast (can't remember the number). Anyway its beautifully clear in the secondary, smells good, but has a really strange flavor I can't describe. I doubt it is contaminated and I feel the flavor is due to the yeast strain. Will this dissipate with aging after bottling? Any suggestions?

Finally, Rich Childers posts about using hydrogen peroxide as a sanitizing agent. It can be used as a sanitizing agent although I would be careful with it. Strong solutions will oxidize tissue. Oxygen is not innocuous or a cure all. Most aerobic organisms evolved developing protection from oxygen, since oxygen, especially peroxides, produce free radicals. These are thought to be responsible for some endogenous cancers, tissue aging, mutation, chromsome damage, and cell death. I don't want to flame the West Coast but ascribing increased viral and bacterial infections to lower concentrations of oxygen in the environment seems to be, well Californian !!(:^0.

I have doubts about this. Hot sauces are not just pure chiles but  
contain vinegar and a bunch of other stuff. If you like that in  
your beer....

But, if you're looking for a way to get consistent heat in your beer,  
I think the best way is to use capsaicin extract. It is pure chile  
heat without any other flavor and is consistent in heat. Many  
salsa manufacturors use extremely mild chiles and then add capsaicin  
extract in order to bring the product up to whatever level of heat  
they want. You can get capsaicin extract from spice companies  
specializing in hot foods or 'oddball' stuff.

According to some brewers, your city water is mostly fine for brewing.  
You  
may have to adjust it slightly to make it friendly for brewing, but other  
then that, city water should be OK. We can all thank COORS for  
portraying  
the image that pure Rocky Mountain water is the key to making smooth  
beer.  
This isn't the case at all, but, many people believe it is.

>her brew that has been kegged? Will I lose my fizz? How/what does a  
>counterpressure filler work/do? Can I build my own? Inquiring minds.

Well, one day I needed my keg and it was almost empty, so i figured,  
what  
the heck, i'll bottle the balance of it. I sanitized by bottles in a  
bleach  
solution, sanitized the caps by boiling them, pulled my keg from the  
fridge,  
hooked up the CO2, and began filling bottles. Capped 'em. Chilled 'em.  
No problems with carbonation - it was a little bit under carbonated, but  
that  
was easily fixed by pouring the beer from about 6" away from the glass (a  
rough pour, in other words).

From: hpfcla.fc.hp.com!scr!sead.siemens.com!jm (Jeff Mizener)  
Subject: The Alcohols: rubbing, denatured, etc.

I read this post and it didn't sound right to me:

From: WEIX@swmed.edu  
Subject: Alcohols

Hi all,  
IHTNPB (I Hate To Nit Pick But):  
Methanol=wood alcohol=denatured alcohol, but NOT rubbing alcohol.  
Rubbing alcohol is isopropanol(or 2-propanol).

So I asked my local research pharmacist, who provided me with the following information:

=====  
==

Ethanol - CH<sub>3</sub>-CH<sub>2</sub>OH - The good stuff - Distilled or fermented from sugar (cane, grain, grapes) - If ingested: drunkenness

Methanol - CH<sub>3</sub>OH - Wood alcohol in common parlance - Distilled from wood pulp - If ingested: blindness, death

Isopropanol - CH<sub>3</sub>-CHOH-CH<sub>3</sub> - The usual contents of a bottle marked "Rubbing Alcohol" - Produced in petroleum cracking - If ingested: headache, nausea, death (less toxic than methanol)

Denatured Alcohol - Ethanol that has had an ingredient added to make it unfit for human consumption (and therefore exempt from taxation); there are many formulae, examples follow:

SDA 3A = 100 gallons ethanol + 5 gallons methanol  
SDA 28 = 100 gallons ethanol + 10 gallons benzene  
SDA 28A = 100 gallons ethanol + 1 gallon gasoline  
SDA 30 = 100 gallons ethanol + 10 gallons methanol

The list is endless. You can get your own formula approved by the Treasury Department (or as they say here in Tennessee, The Revenuers)

Hope this clears it up.

Kevin

Subject: Fermentation with no kreusen?

Hello Brewers...

Here's my problem, maybe someone can help.

For 3 years I have done partial mashes and have just switched to full mash (eg all grain, 3 batches). I mash in a picnic cooler with a slotted pipe manifold. I boil in a homemade Bruheat-like bucket.

Now, my problem....

During fermentation I do not appear to get a kreusen. If I do get one it comes and goes while I sleep because I never see it. However, full fermentation takes place and the resulting beer tastes ok but is much cloudier than I am used to. I have tried two different strains of wyeast ....European ale and american ale... with the same results. My yeast starter had a nice kreusen but nothing in the fermenter. Can anyone shed some light on what might be going wrong?

Thanks in advance,  
chuckm@pbn73.cv.com

From: John Mare <cjohnm@ccit.arizona.edu>

Subject: RE: Water sterilization by filtration

Mik asks about the efficacy of a 0.5 micron filter for sterilizing water. You are right in assuming that most bacteria would be removed by such a filter, BUT you also identified the problem with this approach, namely "assuming the output side of the filter is sanitary". Do you have a means of ensuring this? (not easy unless the whole setup is autoclavable or you have an ethylene oxide sterilizer handy!). Even then some of the smaller bacteria eg. mycoplasmas, chlamydia, etc. will pass a 0.5 micron filter. I have cultured the very hot water from my tap and have not found bacteria. I therefore use very hot tap water for rinsing, which is probably as safe as the more expensive and cumbersome use of filtered water. John Mare.

From: nexgen!bart@olivea.ATC.Olivetti.Com (Bart Thielges)  
Subject: keg -> bottle

[Robert Pulliam writes :]  
> Just another quickie... How does one go about bottling some of his/  
> her brew that has been kegged?

Robert :

I recently tried a simple minded method of rebottling. The background is that I haven't had good results from my keg and was worried about losing an entire batch. What I did was the following :

- 1) insure that keg was not pressurized. In my case, the keg was leaking so no pressure had built up.
- 2) Mix in a some boiled corn sugar water. Since the keg started with 2 1/2 gallons, I only used 1/3 cup of corn sugar.
- 3) Siphon some of the beer into bottles.
- 4) cap bottles. Repair keg. reseal keg.

The theory is that the 2nd priming will provide enough carbonation for the bottled beer and whatever was left in the keg. This is done at a potential risk of altering the flavor of what was originally an all malt brew. I've never seen anyone else describe this technique. There might be a reason why ;-). Since the keg was leaking, I felt that I should reprime anyway, and this made a good opportunity to experiment with rebottling.

Unfortunately, I can't report yet on the results. I did this just a few days ago. I'll try to remember to post the results next week. At the same time that I had originally 1/2 filled the keg, I put the other 2 1/5 gallons into bottles. Therefore, I have some "reference" bottles that were processed in the normal way for comparison. The rebottling was done about 3 days after I had "kegged" (into a leaking vessel !! ^\$\*^&%\*\$)

**Subject: Redhook Summer Rye**

I called the Redhook Brewery and spoke to Thomas Price, a very nice and helpfull guy. Sorry, Al, but there is no wheat malt in their Summer Rye. Here's the scoop:

10% flaked organic rye  
5% Munich  
85% 2-row barley (probably Briess)

Mt. Hood - bitter hops  
Mt. Hood - aroma hops  
Yakima Hersbrucker - aroma hops

I'm heading for the Trolleyman tonight to sample this brew.

Subject: chili beer with flavor

Howdy,

In HBD #1201, Don of Xerox & Jim Vahsen make suggestions for kegged chile beer. Don suggests Tabasco sauce, & Jim suggests habanero extract. I would suggest neither. Tabasco sauce is not just pureed peppers; it also has vinegar &, if memory serves me right, salt in it. Plus, it would add little to no real chili pepper flavor to the beer, which, to me, is half the point. Habaneros are so spicy, that you would have to use so little that, again, you would miss out on the chili pepper taste. In fact, one big complaint about habaneros in cooking is that no flavor comes through because the amount used is so small. If you're going for no flavor & straight spice, add some fresh habaneros to the carboy when you start the fermenting process. If you want a good, clean pepper taste as well, & something that's not overpowering, I would suggest adding whole fresh serranos or jalapenos, about 40-50, to the carboy about one week before kegging. I may be wrong, but that's how I would do it.

Happy brewing,

Alan, Austin

>I am preparing to bottle my third batch of HB, using swing-top  
>"Grolsch")bottles for the second time. The first time I used them, I  
>replaced all the rubber gaskets, as they were several years old and  
>suspect. I boiled them at bottling time, i.e., I sanitized them  
>seperately from the bottles. For this round of bottling, I know the  
>bottles are clean (of grunge), and don't plan a TSP bath. A good  
>washing, then a chlorine soak, then bottle. My question: can I leave  
>the rubber gaskets on the bottles during the chlorine soak? Will they  
>absorb chlorine odor/taste? Will they deteriorate? Must I remove  
>them first, and boil them seperately, as I did the first time? Was  
>that more than one question?

I have been bottling with Grolsch bottles (green) that I kept after  
drinking the contents and Grolsch "look alike" (brown) which I bought  
at the local brew shop. Several observations;

The grolsch bottles seem to have a better stainless steel tension wire.  
The brown grolsch look alike oxidize a bit in the dishwasher.

My younger brother claims that the beers he's sampled are better  
carbonated using the brown bottles versus the real grolsch green bottles.  
I'm still researching whether it's the brew or him talking ;)

I have done 4 brew batches using both green and brown bottles and have  
had good luck with cleaning them - rinse bottles after emptying brew;  
wash in the dishwasher with the other dishes (put them neck  
down thru the slots in the rack-not neck in the pin holders, in the top  
rack where the glasses go); store in boxes and sanitize with a bleach  
solution (2-5oz./5 gal.) in a bottling bucket- 3 min. contact time just  
before bottling; and bottle wash them with a Phil's bottle washer-  
making sure to rinse the outside and cap too. No chlorine taste or  
smell- I would notice since the last two batches have been light  
lagers.

I have not noticed deterioration-although I have lost a couple of gaskets  
in the dish washer. I have replaced those. Still using the original  
gaskets that came with the bottles and they have been thru 4 brewings  
and 7 washings.

Also, in cases where I have left a half opened brew in the refrig., the  
remainder of the contents was carbonated and was very drinkable 5  
days later.

Item Subject: D:/MEMO/2NDARY.TXT  
From: "Robert K. Toutkoushian" <TOUTKOUS@vx.cis.umn.edu>  
Subject: Question about dry hopping

>From what I can gather, dry hopping usually involves transferring the wort to a secondary fermenter, adding the additional hops for a few days, and then transferring to something else for bottling. I guess that I could transfer the wort to my 2nd carboy and add the hops, but w/o a lid I don't want to leave it sit around for any period of time exposed to the air. I guess I could always transfer it back to the primary fermenter, but then I'd have to transfer it again for bottling. The other option that I see is to transfer the wort to the 2nd carboy once the SG has stabilized, add the hops, let it sit for an hour or two, and then bottle.

Does anyone have any suggestions?....

Rob Toutkoushian

Rob,

Consider using only a primary fermentation and dry hopping after fermentation nearly ceases, usually after 4-5 days depending on your temperature. Dry hop directly into the carboy and let sit for another 1-2 weeks. This is all done with an air lock. I use hop pellets for dry hopping and they settle out real nice before transferring to my keg or mixing carboy for bottling. I have found that the dry hopping aroma affect is much better in the fermenter vs in the keg. Just make sure you don't dry hop too early while the fermentation is very active else you defeat the purpose as the CO2 seems to "scrub" out the hop essence.

I and many other brewers in our area don't do a secondary but we also do full boils, do a rapid chill down (15-20 min for 10 gal) and pitch a starter from liquid yeasts. I have cut my sediment in the fermenters by half by doing full boils.

George Fix describes the procedure in the 1992 AHA National Conference Proceedings. From memory, you seem to have the procedure about right, but I must defer to the proceedings for details.

>It was one whole day before I had a beer after returning from Portland!  
The  
>best beer I had in Portland was a beer called "Mirror Pond" from Deschutes.

I \*saw\* Mirror Pond, hand-pumped at the Red Door just down the street from Red Hook Ale Brewery in Seattle. Alas, they had just switched to a new keg and the beer was pouring cloudy, so they were not serving it while I was there. I'll make sure to seek it out next time!

\*\*\*\*\*

John writes:

>Does anyone have any comments or experiences using bottled spring water for  
>brewing. How does it compare and are there any obvious advantages or  
>disadvantages (other than cost).

If your tapwater tastes good and is not too hard, there's no reason to resort to using bottled water. If your water is just too hard for some styles, then you can blend it with distilled water (also available from your bottled water people). You should be able to get an analysis of the bottled water so you can see what it has and doesn't have in terms of minerals. There was an issue of Zymurgy that had a few articles on water which despite a few minor errors was quite good. You can use the main article in that issue to adjust your water to the style of beer you wish to brew. Note that you will have to account for whatever minerals are already in your water.

\*\*\*\*\*

Michael writes:

>second batch of beer is good! I made a Pale Ale using Northwestern

> Aroma hops: After another 30 minutes, I added the last 0.5 oz. and

A 30 minute boil will boil-off any aromatics your hops might have added. Actually, since you used Clusters, you are probably lucky you did. Clusters

are not considered an aroma hop, but everyone's taste is different. If you want hop flavor, add some hops with 15 minutes left in the boil (anything longer will boil off the flavoring). If you want hop aroma, add some hops with 1-5 minutes left in the boil or you can dryhop. Dryhopping gives you a lot more aroma per ounce of hops than adding the same amount to the boiling wort. I recommend using hops that are generally regarded as aroma hops for the flavor and the aroma. The classic Pilsner hop is Saaz, but Tettnanger is a relatively close approximation. For German-style aroma hops, Hallertauer Mittelfruh (the best, but in very scarce supply), other types Hallertauer ("Tradition" I believe is one), Hersbrucker, Mt. Hood and Liberty (the last two being American varieties intended to duplicate Hallertauer Mittelfruh). English-style aroma hops include East Kent Goldings (my personal favorite), Fuggles (a little rougher), Willamette (an American Fuggle relative) and Styrian Goldings (actually Fuggles, but grown in Slovenia). The classic American-style hop is the Cascade, with it's faint grapefruit aroma, it has become the signature of the nose in several American microbrewed beers, such as Sierra Nevada Pale Ale.

Some say that all boiling hops are equal, but I disagree. Some of the higher-alpha hops (Chinook, for example), even in the boil, will give a harsh bitterness. It appears to me that with some lower-alpha hops you can't overbitter with them! Two that I've found with which it is next to impossible to make an undrinkably bitter beer are East Kent Goldings and Cascades. I've already posted about Thom Thomlinson's 135 IBU IPA, which was made with Cascades: super-bitter, but very drinkable -- YUM!

\*\*\*\*\*

Jeff writes:

>First of all, this is a bizarre recipe, given that Belgian Ales (in all >their utter complexity and diversity) are known for a near-total lack of >hop aroma. So, forget it this time.

Lest we forget Orval, with it's wonderful E.K.Goldings/Hallertauer aroma, \*when\* \*fresh\*. True, however, hoppy-nosed beers are very rare among Belgian brewers.

\*\*\*\*\*

I wrote:

From: weintrau@vs2.uh.cwru.edu  
Subject: Grain to Extract Conversion

I am about to create my first all-grain beer with a friend who has made quite a few all grain beers before. He has, however, left the recipe to me.  
I would very much like to duplicate a favorite Stout recipe of mine, but I do not know how to make the conversion between an extract recipe and a grain recipe.

Here is the Stout recipe I want to convert, mostly taken from CP's Toad Spit Stout:

Grendel's Stout

3/4 lb crushed british crystal  
6 oz. crushed black patent malt  
6 oz. crushed roasted barley  
3 lbs Muntion and Fison dried dark malt extract  
4 lbs Mountmellick Famous Irish Stout hopped extract  
3 oz. Northern Brewers Hops (3 \* 7.0 = 21 AAU) (boil)  
1 oz. Fuggles hops (4.3 AAU) (aroma)  
1 tsp irish moss  
1 pkg Burton Salts  
1 pkg EDME Ale Yeast

(Ingredients for 5 gallons)

Water was brought to a boil with all of the grains in a grain bag, steeping.  
The grains were removed a bit before the boil began. At the start of boil, the extracts were added.  
The Northern Brewers was added at three different points in the hour long boil with the last ounce added 20 min before the end of the boil. The fuggles was added over the last five minutes.

OG 1.052  
FG 1.022

I would also like to switch to a liquid yeast but would like to keep the relatively low attenuation of the EDME.

If you have any suggestions, please let me know by direct e-mail, as I may not have time to look through the HBD between now and when we brew on Saturday.

Thanks in advance...

Subject: factor, schmactor

I don't use the "pts/lb/gal" method of calculating efficiency. Never have, never will. It's a totally unfriendly method and I wouldn't be at all surprised if it was devised by some long-dead, neo-prohibitionist math teacher who is having the last laugh.

I prefer the method of "% Efficiency". I like it so much that I wrote a program called the Beer Recipe Formulator and rendered it unto the masses so that they could revel in it's perfection as I do. It runs on MS-DOS 3.2 or higher and requires 640K and a monochrome monitor. The software is available via ftp at mthvax. If you don't know what ftp means (I know I don't) and you have a computer with a modem, you can download it from a number of sites:

HBU BBS (708) 705-7263  
Maltose Falcons BBS (818) 342-0530

to name a few. The version on HBU BBS has the most recent data files. The latest version release is 1.1 but 2.0 is coming soon to a theatre near you.

Did I hear someone say "shameless plug"? You betcha.

Did I hear someone else say "shareware"? Yup.

From: G.A.Cooper@qmw.ac.uk (Geoff Cooper)  
Subject: Re: murphy's in a can

dab@cc.bellcore.com (dave ballard) writes

>hey now- at a place called the hog sty bay cafe on grand cayman i  
ordered  
>murphy's stout and got a can that looked identical to a guinness pub  
>draught can! it was tall and skinny and had directions about chilling,  
>opening, etc. there was also a little logo thingy that proclaimed the  
>can to be murphy's "draughtflow system" with a patent pending.  
>  
>has anyone else seen these cans? it tasted fine, although i detected a  
>little more "canny" taste than guinness. is this the same doohicky that  
>guniss uses or did murphy's invent/copy one of there own?

There are 3 different dohicky systems now patented and used in the UK for  
draught beer in a can. The Guinness system has been described here  
before.

The "draughtflow" system is owned by Whitbread and, for example, is used  
by  
them in Boddingtons. I don't know the commercial relationship 'twixt  
Murphy's  
and Whitbreads.

The draughtflow system has a larger capsule containing pressurised N2.  
The  
'lid' of the capsule contains a tiny hole (in the middle) which is  
closed,  
whilst the can remains under pressure, by the end of a 'peg' protruding  
from  
the centre of the 'base' of the capsule (the 'base' being the opposite  
side  
to the 'lid'). As the can is opened, its pressure drops, the N2 in the  
capsule  
expands thus flexing the lid away from the peg and thereby opening the  
tiny  
hole through which most of the N2 now passes. Hey presto!

If this is the system in Murphy's, there is an interesting demonstration  
you  
might attempt. The nature of the system is such that not all the N2  
escapes  
and the capsule is still under slight pressure. Identify which is the lid  
by  
locating the hole. Using a suitable implement (eg the edge of a coin)  
gently  
prise the lid off the body of the capsule. With a 'pop' the lid will fly  
across the room. OF COURSE be careful about 'flying object'

And if you are the type that hasn't any common sense and sue at the drop  
of  
hat, don't do it, or don't bother suing - the UK civil laws are  
different  
from the US. :-)

From: dejonge@tekserv.geof.ruu.nl (Marc de Jonge)  
Subject: Culturing yeast from bottled beers

Recently I came across some interesting statistics of the 1990 and 1991 open championships for amateur brewers, organised by "de Roerstok" in tilburg. They have published a booklet with a lot of information on the homebrew entered in this competition. Since questions pop up every now and again about culturing yeast from bottles, I will summarize a nice table from this (without permission, so destroy this before you read it):

The #1 field indicates the total number of entries, #2 is the number that scored over 6.4 (assuming that these are successful attempts), the score is the average score on a scale of 0[Yech]-10[Yum] for the 'over 6.4' beers (Not quite sure if Yech and Yum are SI units or Imperial)

| Beer/brewer#1     | #2   | Score |
|-------------------|------|-------|
| Achouffe          | 3 2  | 7.5   |
| Arcener tarwe     | 2 1  | 6.5   |
| Brugs Tarwe9      | 2 2  | 7.1   |
| Brugse Tripel     | 2 2  | 7.4   |
| Chimay            | 16 7 | 7.7   |
| Christoffell      | 1 1  | 6.8   |
| Corsendonk        | 3 2  | 8.0   |
| Dentergems Wit    | 2 2  | 6.9   |
| Dommelsch         | 3 1  | 6.6   |
| Drie Ringen2      | 1 1  | 6.5   |
| Duvel             | 2 1  | 6.6   |
| Erdinger Weisse   | 2 2  | 6.9   |
| HertogJan Tripel7 | 3 3  | 7.6   |
| Hoegaarden        | 9 4  | 7.5   |
| La Trappe         | 4 3  | 7.7   |
| Lowenbrau weiss   | 1 1  | 7.0   |
| MacChouffe        | 1 1  | 8.5   |
| Oerbier           | 1 1  | 7.7   |
| Rochefort         | 1 1  | 6.6   |
| Schneider         | 1 1  | 8.6   |
| Verboden Vrucht   | 3 3  | 6.9   |
| Westmalle         | 9 6  | 6.9   |
| West Vleteren     | 5 4  | 7.6   |
| Wieckse witte     | 1 1  | 7.3   |

Note 1: The fact that a certain yeast gives a good score does not mean that it is the original brewing yeast of the beer. For some of the above I'm almost certain that a bottling strain has been cultured; but then, if it tastes good who cares ?  
Note 2: Of the top 12 of 1991 only two beers were brewed with cultured yeast (Chimay and West Vleteren).

Subject: Re: water filters -- a data point

I have been using a T-10 carbon filter on the cold water line in my kitchen for 3 years now. I replace the filter every 6 months or so. I extract/adjunct brew and sanitize with bleach. I rinse and brew with water out of the tap that has been filtered. I have yet to have an infection. I boil about 2 gallons and top up to five with water out of the tap. Searching about madly for a piece of wood upon which to knock, I say that there has never been a problem with this method.

The reasoning is that the water coming into the filter and surrounding the filter on the inlet side is sanitized. I flush the filter out by letting the water run for a minute before using it for anything critical, and bacteria never have a chance to take hold.

I got mine from American Brewmaster and paid less for it (and it's a big under-sink filter) than something cheaper-looking at the hardware super-store.

Cheers, Jeff Mizener

From: G.A.Cooper@gmw.ac.uk (Geoff Cooper)  
Subject: *S. cerevisiae* & *S. delbrueckii*

There's been a little discussion about the 'correct' name of this yeast. I know little about the technicalities, but I can add a few more 'facts'. (I like facts 'cos they can cause such good arguments)

When I first saw reference to *S. delbrueckii* (yes I first came across it on HBD), I checked my catalogue from the AFRC National Collection of Yeast Cultures (NCYC) and found that no such yeast was listed, so I was a bit confused. My confusion was relieved when I located a couple of yeasts that had been originally deposited under the name *S. delbrueckii*, but now were classified with a different name.

I found *S. cerevisiae* strain number 92, deposited in 1933 by A.C. Chapman, original deposit name *S. delbrueckii*, NCTC 3964. (NCTC = National Collection of Type Cultures, Collindale). There was no ATCC number. So I concluded that the *S. delbrueckii* were really just strains of *S. cerevisiae*, but that (home) brewers used the term *S. delbrueckii* as a convenient 'handle' by which they could refer to a particular strain (or strains).

I also found *Torulasporea delbrueckii* (perfect form of *Candida colliculosa*) with 10 strains listed, all of which had been originally deposited under a different name (I was amused by *S. inconspicuous*. NRRL Y-7435). One of these, number 408, had been deposited as *S. delbrueckii* var *mongolicus*.

I think I shall stick with my first assumption, which corresponds nearest to that of Jim Busch. Perhaps because it gives me a warmer feeling :-). That is, *S. delbrueckii* might not be the correct name, but when we use it, we refer to those yeasts, now considered strains of *S. cerevisiae* that have particular properties of interest to us; namely they make good wheat beer.

OK. So that contains a few more facts; what's the truth?

Geoff (who cares about the truth if it makes good beer) Cooper

Subject: Petes

> I saw this recipe in the cats meow 2. Can anyone suggest how  
> I would convert this to an extract recipe.

Pete's Wicked Clone

Source: Richard Stern (rstern@col.hp.com)  
10/16/92

Ingredients:

8-9 pounds, pale malt  
1 pound, crystal malt  
1/4 pound, chocolate malt mash at 155F  
1/2 ounce, Cascade (60 min boil)  
1/4 ounce, Chinook (60 min boil)  
1/2 ounce, Cascade (10 min finish)  
Wyeast #1056

Procedure:

Mash malts at 155 F. Add 1/2 ounce Cascade and 1/4 ounce of Chinook  
for  
boil. Use 1/2 ounce Cascade to finish.

Comments:

I've requested a recipe for Pete's Wicked Ale, but nobody sent one, so  
I  
guess I'm going to have to wing it. This recipe is based on the  
GABF  
program, which says " Pete's has: pale, crystal and chocolate malts,  
and  
Chinook and Cascade hops. OG: 14P" (Isn't that 1.056?)

Pete's is pretty malty with a low hop bitterness and aroma. I think  
the  
malt combination should be ok, as long as I get enough body from  
the  
155F mash temperature.

Subject: Re: Mini Kegs and Briess DME

Subject: Mini Kegs

I bought, use, and like the 5 liter mini kegs. Some stores sell imported commercial beer in these kegs. These can be reused if you have a tapper like the one that comes with the Brew Ha Ha offer and DO NOT use the method recommended with the purchase.

I too had foaming problems until the found the secret of the tapper. Once the pressure gets low, add only a little bit more of CO2 and then turn the CO2 back to the off position; in other words, don't keep the CO2 pressure on -- after a few seconds, turn it off and proceed.

Subject: Q: Briess DME

After reading Dr. Raines's posting on HBD concerning contaminated Briess DME, I wonder if there is a way to identify "bad" lots. I recently purchased from Brewers Resource 25 lbs of Briess, Brewers Gold DME. I first brewed with it only a few days ago, but I brewed a Trippel with 10 lbs of the Briess.

I would really hate to find out in four months that I brewed with the contaminated lot.

>little more "canny" taste than guinness. is this the same doohicky that  
>guniss uses or did murphy's invent/copy one of there own?

Yup, sure have seen 'em and I have perhaps 1 or 2 left in my closet. When I went to Ireland last year (Oct '92), I grabbed a couple of 4-packs to bring home w/ me. When I first sampled it, i thought it was better then guinness in a can. Pretty much the same design as guinness, as far as i can tell.

I've had guinness in a can that one can buy in the states. the ones i brought back from ireland, imo, we better tasting then the cans bought in the states.  
unscientific datapoint, fwiw! :-).

**Subject: To Secondary or not to Secondary**

In HBD1202 John in Boise writes that he and many brewers in his area do not use a secondary fermentation.

I know this has been discussed several times, but I thought I would throw in my \$.02. For quite a while I did not do a secondary fermentation: I fermented in primary for about a week, then bottled. The result was beer that primed very quickly, but seemed to have a slight but harsh flavor undertone. The bottles also had a fair amount of yeast sediment. I came to wonder if the harse undertone was a result of yeast autolysis.

I then tried shifting to doing a one-week primary fermentation, followed by a one-week secondary fermentation. The secondary step is actually more of a rest to allow yeast to settle and thus be separated from the brew. After bottling, the result is brew that primes more slowly, but throws less yeast sediment. That harse undertone also appears to be gone, and the beer is noticeably smoother.

My conclusion: the settling of yeast that occurs in secondary produces a smoother brew than a single-step fermentation gives. You can make a drinkable beer faster using just a primary, but I amusing a secondary settling step from now on....

Well, while we're being 'constructive', I'll add my 2 cents.

I sent her email about not mentioning B-Brite, which I had acquired  
from my local homebrew shop and later realized was not labelled with  
a 'dosage' recommendation.

She replied that she didnt know the 'dosage', but would call the  
manufacturer. She did, and replied to me in about 2 hours via email.

From: LLAPV@utxdp.dp.utexas.edu  
Subject: chipotle

Howdy,

In HBD #1202, Tom mentions how chipotles may be too spicy for beer. This was not the problem with the beer I discussed in #1201. One of the two bottles was too spicy; the other was quite tolerable in terms of spiciness. My warning is against putting the chipotle pepper directly into the bottle with the beer. The results were inconsistent & made an otherwise good beer undrinkable. Chipotles themselves, in terms of overall chili pepper spiciness, are about mid-spicy, according to the measuring technique known as the Scoville units. Bell peppers rank low, like around 10, jalapenos (& by extention, chipotles) are around 2500-5000, serranos around 5000-7000, and habaneros around 3 billion (my figures may be a little off). Please don't get me wrong; chipotles will hurt you if you just pop one into your mouth. I'm just saying that if the spiciness of serranos can be controlled, then the spiciness of chipotles can be controled.

Mexicali Rogue sounds like good stuff. Any idea how the make it?

Happy brewing,

Alan, Austin (where there's a Tex-Mex restaraunt on every corner)

Subject: Grolsch bottles

Mr Cox and Bill were talking about Grolsch bottles and sanitation of them along with a few other things.

I have been using a mixture of Grolsch, Fischer Amber and regular bottles with about every batch. I use the Grolsch and Fischer bottles for myself and the regular bottles go to friends. :-)

Anyways, all I do is soak all the bottles in the tub with a good amount of bleach for an hour, rinse them, and bottle. Nothing fancy. I haven't had a problem yet (10+ batches). Also, keep in mind, the bottles I get are from a Package Store that my roommate works at so I'd consider these worst case type of bottles.

As far as carbonation goes, I notice 0% difference from bottle to bottle. I keep all my bottle together in the dark, so I wouldn't expect a difference. There might be a difference if you had all the bottles exposed to light I guess.

The bottles are great to use if you can find them. It beats the heck out of capping.

>writes that there is a difference in the pre and post 1992  
>versions of this yeast. How do I know which one I get?

I've received a few similar inquiries via private email, so I thought I'd post and reassure all concerned.

The information I have is that the yeast that did not perform well is no longer commercially distributed. After about one year, it simply stopped producing spicy, phenolic flavor characteristics, so it was replaced with another strain quite some time ago.

I obtained the older, non-performing strain from the yeast bank of a local homebrew club, where it had apparently been stocked for a long time. What added to the confusion was that a member of this club, who is a mutual acquaintance of Jim Busch and myself, had a weizen yeast that he listed as "W66". The two different numbers, in addition to the disparate performance, contributed to the false perception that there were two different strains in circulation.

I've exchanged email with Jim on this issue, and he's assured me that the strain currently being distributed as Weihenstephan #68 is displaying considerably greater staying power than it's predecessor. Having brewed a few batches with it, I can personally vouch that this is a great weizen yeast, and recommend it without reservation.

Cheers,  
Jim

> my enthusiasm has fallen an order of magnitude.

I use the aquarium pump idea in conjunction with my normal methods of aeration. I've tried this for numerous batches of ale and one batch of lager. My normal aeration method is to splash the beer while siphoning it into my carboy and periodically stopping the siphon and shaking the carboy vigorously. I noticed a slight improvement in lag times for all of the batches.

Lag time is controlled by a lot of variables. Pitching volume (and what stage the pitched yeast are in) probably has a greater effect on lag time than the aquarium pump.

BTW, I would expect that Miller was almost certainly talking about ale yeast in his 3-8 hours figure.

Subject: Re: Water, Chiles

> ...city water should be OK. We can all thank COORS for portraying  
> the image that pure Rocky Mountain water is the key to making smooth  
beer.  
> This isn't the case at all, but, many people believe it is.

Certainly the water is only a small part of what goes into a fine beer,  
but the importance of a good water source (especially for large  
commercial breweries) can't be underestimated. I think one of the  
reasons that the Pacific Northwest and Colorado have become large  
brewing centers *is* for the water -- it simplifies things greatly if  
you can just use the city supply. Water here in Fort Collins is great  
right out of the tap; I don't have to pre-boil or add minerals or  
anything.

Some slight drift here...

> Habaneros are so spicy, that you would have to use so little that,  
> again, you would miss out on the chili pepper taste. In fact, one big  
> complaint about habaneros in cooking is that no flavor comes through  
> because the amount used is so small.

And it's a crying shame, too. Habaneros (also known as Scotch Bonnets)  
have a wonderfully fragrant, sweet aroma that complements food, and  
probably beer, very well. Does anyone know of "de-capsiacin-ized"  
habaneros or habanero essence without the fierce burn? Where's the  
chile-pepper mailing list? Why is there a rec.food.sourdough but no  
rec.food.chiles? Thank goodness we have HBD and rec.crafts.brewing.

From: tims@ssl.Berkeley.Edu

Subject: recipe formulation - relax!

To the person who was worried about "wasting" 10 - 15 gallons as they "perfected" a recipe: My plan for formulating a recipe is to find one of a similar style, either all-grain or extract based, and copy its proportions of pounds of grain or pounds of extract to hops (IBU's). Add any other ingredients in the proportions you think, being on the gentle side (better to underdo than overdo). I have used this philosophy for perhaps 15 batches, and have always had very drinkable results. I don't worry that "it doesn't taste exactly like Bass," because I don't care that much - if it is a well-made beer, they taste great.

As always, R,DW, HAHB! Cheers,

Tim Sasseen

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: The Tumbleweed Report (Part 4)

Having covered the equipment we're using at Tumbleweed, now I'm really going to bare my soul concerning the brewing procedures, ingredients, and recipe decisions we faced. I find this part particularly interesting because here is where we found it necessary to scrap ideas that had been cast in stone for us as homebrewers. All sorts of factors caused us to rethink basic procedures. Clearly, our main concerns were the change in scale and the economics of trying to make money. It's funny how money (or the lack thereof) can influence decisions!

Ingredients and Materials:

The biggest question was whether we were going to continue with the extract beers Tumbleweed was brewing with and brewing, in all honesty, rather poorly. Should we go all-grain? Or bear down on producing a decent extract beer?

Since I've been brewng all-grain beers for 12 years, I thought long and hard about the feasibility of all-grain brewing in 40 or 60 gallon batches.

To go that route we would have had to design an awfully big insulated mash tun. We would have had to worry about the ever changing mineral content of the town water we were using. We had to worry about where to store and grind the grain in an already overcrowded space. As if this wasn't daunting enough, we would be looking at 12 hour brewing days. With my teaching duties at ASU and the demands of operating BrewCo, I frankly didn't have that kind of time.

So we decided to brew with extracts. Since this was, in some sense a "cheat", we figured we'd cut no corners on the rest of the process. We would use pure yeast cultures, fresh hops, specialty grain infusions, and filter our water.

Extracts were appealing because (1) storage was easy (we already had a walk-in cooler), (2) it cut our brewing day down to 6-8 hours, and (3) we could count on a certain stability in the malt product and didn't have to worry about the variability in the quality of grain and the headache of wrestling with our water. We had enough to worry about already so far as redesigning the equipment and getting used to brewing on a larger scale was concerned. Later, after we got all these factors under control, we figured we could consider the move to all-grain.

The decision to brew with extracts still bothers me. I could see myself making excuses (like I'm doing now) to my brewing buddies and my newly acquired peers in the commercial brewing world. But this was no time to be dogmatic. Instead we had to be realistic about the physical brewing environment and the market we were trying to crack. I've had enough bad all-grain beers to know that the decision to go all-grain was not going to ensure a high quality product. And I've had enough outstanding extract

beers to know that it *\*is\** possible to brew a decent beer using extracts. Technique is everything. We inherited some pretty sorry ingredients when Burton and I signed on. The extracts were old and stale. The hops were pelletized and God knows how well they were stored before we got them. Still we brewed with what we had and the difference between what we brewed and what was brewed before was noticed by all. The quality improved even more once we started getting fresh malt, fresher hops, and instituted the hop back.

Regarding our market, we had to be realistic about what the common drinking public was going to expect from us. We figured they wanted a beer that was a huge cut above Budmiller. No problem. But I didn't really expect them to come in and be disappointed if they weren't drinking beers comparable to a Pilsner Urquell, a Sam Smith's Oatmeal Stout, or a Liberty Ale.

Neither did we expect, nor have we found, very many beer drinkers that are going to get down to the level of criticism that we have come to expect from ourselves and our fellow homebrewers. So, what the hell, we resigned ourselves to the conclusion that the extracts, though unlikely to produce that godalmighty awesome beer we all dream about, would allow us to turn out a fairly reliable, quality beer that would be as good or better than anything the average guy ever drank out of a bottle and would impress 99% of the people who walked through our door.

And they have. Most of the homebrewers who come into Tumbleweed are surprised to learn they're drinking an extract beer.

We started out using Premier's 100% malt extract. It comes to us in 5 gallon pails and is as clean as a whistle. So far we've found that it doesn't attenuate below 1.012. The color is not as light as Alexander's, which we've just began experimenting with. The Alexander's is very light in color and attenuates to below 1.010.

Our present feeling is to use the Alexander's on our lighter beers and stay with the Premier for our heavier ales when we want the higher terminal gravities. We like the idea of using two extracts because this gives us some diversity in the different beers we brew. We're also playing with Briess at the moment but the results aren't in as yet. If we find that they all produce clean beers then we'll play around with mixing them together for single batches to add even more complexity to the malt side of the flavor profiles.

Of course, these aren't just straight extract beers. We only buy light malt extract and depend on specialty grain infusions/steepings as the water comes to a boil to add grain character to the beer. Nothing new here. 1000's of homebrewers have been doing this for years.

(To be continued)

^^^^^^^^ ^^^^^^^

Given that the Red Hook Brewery is within 175 miles of Great Western's Vancouver, WA plant (and in the same state), this seems bizarre if not completely unlikely. As far as I've been able to determine over the years, virtually every west coast brewery gets their base malt fm GW. Even if the quality of their malt wasn't the question, surely shipping rates would be.

From: birkelan@adtaz.sps.mot.com (Joel Birkeland)  
Subject: Tannic verses

I was wondering if anyone out there can give me some advice about treating my water for brewing. Our water here in Phoenix is very hard and very alkaline, (pH ~ 8). As I recall, the hardness number is about 250 (ppm?) and the alkalinity is about 170.

I tried my first partial mash a few weeks ago, tasted the results last night, and it is OK, but had noticeable tannic astringency. I recall hearing that the pH of the sparge water has a strong effect on tannin extraction during sparging.

For the record, I kept the sparge water at or below 168 deg F, and I had to cut the sparging short because another user needed the kitchen resources.  
The initial runnings were > 1.080, final > 1.020.

TIA for your help.

Subject: Re: Recipe Formulation

John Montgomery writes in HBD 1202

>Should I just "waste" 10 - 15 gallons of brew for each style until I get it just the way I want it or is there some publication that offers particulars of and suggestions for recipe formulation?

If beer be the is drinkable it is never a waste (obvious but worth mentioning!). The 1991 Special Styles issue of Zymurgy has a wealth of information concerning styles. The Cat's Meow here on the net also has literally hundreds of recipes classified by style, although not as tightly classified as the Zymurgy issue. Most issues of Zymurgy also have the style guidelines describing the characteristics of a style for competition entry.

There are also many books which have specific recipes included, the Winners Circle comes to mind offhand, but there are several.

As a final tidbit there are also computer programs which can help you formulate recipes to duplicate styles. My program, the Brewer's Workshop, has the style definitions from Zymurgy built in and calculates gravity, bitterness and color so you can match those characteristics of a particular style. Please note that there are other programs that do the same thing, I am not trying to make this a commercial. People tend to get very touchy on the net when they smell advertising.

I would recommend starting with the styles issue and working from there. There were also two good articles in the first issue of Brewing Techniques, one by Darryl Richman on recipe formulation and another article on recipe formulation using a spreadsheet. Hope this gets you started in the right direction. Prosit!

From: gbaldw@zaphod.usin.com (Gordon Baldwin)  
Subject: Irish Moss revisited

Going back to an earlier discussion about using higher ammounts of Irish Moss, I have a data point. I brewed last weekend and I upped my IM rate from 1 teaspoon to 1 Tablespoon per 5 gallon batch. After racking to the secondary the beer is already a lot clearer. The interesting thing was the sediment in the bottom of the primary. I use a plastic bucket for the primary and ususlly the sludge in the bottom is a slurry of hop particles and other small particle precipitate. Kind of a loose mud consistancy. With the higher rate of IM it had more the consistancy of large flake oatmeal. It had large chunks of what I think is protien. I will be interested in the difference in body. I won't be able to do a direct comparison as my kegs should be arriving today and the bottles are going to the recycler. Unless there is someone in the Olympia WA area that wants 4 cases of well used bottles (I am keeping a couple cases)

Norm,

I did this, and you can have it if you want it. I am building a true counterflow chiller tonight. I had to run huge amounts of water through the damn thing to get sufficient cooling, and that's not PC out here in drought land. I put 50' of 3/8" od? copper tubing in a 5 gallon bucket, and attached garden hose fittings to the bucket as well. When I tried to attach a hose to the outflow to use the water in the garden, the top of the bucket kept popping off, if I used enough cold water flow to chill the wort enough.

From: lanbrew@aol.com

Subject: Kegged Chili-Beer

I have done quite a few chili-beers in the past, including one on draft.

Here's how:

I used 5 ounces of serrano and jalapeno peppers in the last 15 minutes of the

boil. The peppers were halved and seeded. Since the batch size was 10 gallons, the heat and flavor from the chilis was very subtle. My partner bottled his half and I kegged mine.

Desiring more chili character, I decided to "dry-chili" the brew. Using a

muslin hop bag and a generic zip-tie, I contained approx. 1 ounce of dry whole peppers and 1 ounce of serrano peppers (fresh) halved and seeded. I boiled the whole works for about 5 minutes to sanitize and threw it into the

keg. The beer had already been carbonated and was chilled.

Within three days the brew went from mild to hot, with incredible complexity

and depth. I opened the keg and removed the bag 'o' chili, re-sealed the keg

and purged the O2.

Afterward, I noticed two things:

1) The beer did not become tainted one bit in the four months I had it on

tap, so the process, although unorthodox, resulted in no obvious flaws.

2) Within a week of "dry-chiling" the beer fell brilliantly clear. Hmm.

. .

Overall, a very good experience and I'll try it again.

Lanny

From: "John R. Calen - Contacting Systems - E.F., N.Y" <calen@vnet.IBM.COM>

**Subject: Hot pepper sauce**

I've been following the recent thread about hot pepper sauce in brews.

Please forgive me if this has been posted before. The hot pepper sauce itself is fermented. This is what I remember from a documentary about Tabasco Sauce.

The red peppers, presumably red chiles, are macerated and comprise the mash. They ferment in wood barrels under a layer of salt which is about an inch thick.

Particulars are a trade secret, as such I don't know them. The yeast, any additives, i.e. sugar, and type of wood I'd have to guess.

This all happens on an island in Louisiana, so I'd assume that it's a rather warm ferment.

The stuff sits for about three years, after which the salt is removed, the barrel emptied and the mash is infused with vinegar. The whole magilla is then pressed and bottled.

If you've got some gallon bottles around, a bunch of peppers, and lots of patience, why not give it a shot? (How's mine? What, are you kidding?)

>to use. Thanks.

<snip>

>MALT EXTRACT (DRY) 45 ?  
>MALT EXTRACT (SYRUP) 35 ?

<snip>

The snag is that each manufacturer's extracts have very different numbers.  
I've found less variability in dry extracts, but syrups I've used go all the way from 35 up to 40.

LAGER 2-ROW35 1.7  
LAGER 6-ROW31 1.7

PALE ALE 36 3  
PILS 2-ROW 35 1.2

Again, potential varies by maltster and the condition of the malt when you get it. Are there a lot of different malts available to us homebrewers?  
You bet: DeWolf-Cosyns, Crisp Maris Otter, Ayinger, Briess, Great Western, Minnesota Malting, Gambrinus, Munton & Fison, Golden Promise (not just yet, but I'm working on it -- it's the malt used by Caledonian Brewing Co. to make what's marketed in the US as McAndrew's Scotch Ale), Canada Malting.  
..  
just to name a few.

Since we're on the subject of malt, I'd like to mention that Klages is no longer grown commercially. It's replacement is Harrington. After a few years, barley tends to lose it's disease resistance and the growers switch to a new strain. Currently, like I said, it's Harrington. If your retailer is really selling you Klages, then it's very, very old. Alas, even the wholesalers don't really understand this too well and some still contend that they are wholesaling Klages, so it may not be your retailer's fault, then again, shouldn't he/she know these kinds of things? On the bright side, there's no doubt on the pronunciation of Harrington ;^).

Subject: First Batch

Hello to everyone. I am new here and have read a couple of issues of the HBD and I plan on checking out back issues.

This is very timely for me, as I plan on starting my first batch of homebrew this weekend. Are there any suggestions that anyone would like to

make to me regarding this first attempt?

I have read the Papazian book, have assembled my supplies and equipment, and read the book. I feel like I am ready.

I will be making a Nut Brown Ale with a Muntons kit.

I've noticed some discussion here and at rec.craft.homebrew about chilling

the wort. Should I be concerned about this? (Although I have made mental plans to accomplish it if I have to.)

Any advice that anyone has will be welcomed.

I am excited, and I'm trying hard to relax, not worry and look forward to having a homebrew.

Subject: Tabasco pepper question

Hi!

As a fan of \*hot\* food, I've been enjoying the discussion about using chili peppers in beer. I love Tabasco(R) sauce, and I was wondering if anyone knew what kind of pepper is used to make it? The ingredient list is as follows: Vinegar, Red Pepper and Salt. I'd like to use those peppers to make a chili beer. I have access to the official Tabasco(R) cookbook, but it doesn't identify the pepper type either. :- ( Any ideas? kj.

Press Release:

The Northeast Florida Society of Brewers, in conjunction with The Hogtown Brewer of Gainesville, FL and The Home Brewery of Brooksville, FL, announces it's 1st Annual First Coast Brewer's Challenge, an AHA sanctioned homebrew competition open to all home brewers. Entry deadline is October 29, 1993, with final judging to be held on November 7, 1993. Beer styles for this competition are Pale Ale and Stout. Fee is \$6.00 per entry. First prize will include \$50.00 in beer related merchandize, second prize will include \$20.00 in merchandize. Three bottles of beer will be required for each entry.

For information, contest rules and entry forms, contact Bob Gammie (904) 241-8879 (RobertG211@aol.com), Chuck Cummins (904) 292-2166, or Joe Bryant (904) 399-3367 (Prodigy BPNS42A) or write to: Brewer's Challenge, 354 Magnolia Street, Atlantic Beach, FL 32233.

and Drew Lynch responded

>Norm,  
> I did this, and you can have it if you want it. I am building a  
>true counterflow chiller tonight. I had to run huge amounts of water  
>through the damn thing to get sufficient cooling, and that's not PC  
>out here in drought land. I put 50' of 3/8" od? copper tubing in a 5  
>gallon bucket, and attached garden hose fittings to the bucket as  
>well. When I tried to attach a hose to the outflow to use the water  
>in the garden, the top of the bucket kept popping off, if I used  
>enough cold water flow to chill the wort enough.

A slight modification of Drew's idea can work very well.  
First, I needed an immersion in ice chiller not because of a small  
kettle opening but because our tap water in the summer is 80 deg.  
F. What I use (in the summer) is a large plastic bucket (they sell  
them at the Price Club for storing toys for about \$7 and hold about  
20 gallons). Drill a hole near the bottom so that a flexible  
siphon hose can fit snugly (without leaking too much). This hose  
will be connected inside the tub to the copper coil carrying the  
wort and outside to your carboy. Fill the tub with a few gallons  
of water and you'll need about 5 gallons of ice (about 45 pounds)  
to chill 5 gallons of boiling wort to about 60 deg F. With a  
little more ice and stirring the ice water in the tub you can  
get your wort down to 50 degrees F in 15 - 20 minutes (for lagers).  
One problem with this procedure is the amount of ice needed. You  
could use less if you first chilled the wort using an immersion (in  
hot wort) chiller using tap water and then running it through the  
immersion in ice chiller. (I've done this for my last two batches  
and also noticed Rick Garvin has done this when he described his  
award winning old ale recipe). Another  
problem with this setup is starting the siphon through the copper  
coil. I found it was too difficult to begin by simply sucking,  
which is why I attach the flexible hose coming out of the tub to  
a small copper racking cane which fits snugly into one of the holes  
on the carboy cap. Through the other hole I use a hand pump to  
begin the siphon. (Of course you wouldn't have this problem if you  
had a spigot at the bottom of your kettle.)

Hope this helps.

We're getting off the subject of homebrewing, but since someone may want  
to  
brew some tabasco beer...

Tabasco(tm) sauce is made using tabasco peppers. There are at least two  
varieties, but I'm not sure which variety is used to make the sauce. The  
Tabasco Country Store (a mailorder catalog from the Tabasco sauce people)  
sells

a "kit" for growing the peppers. I've also seen the seeds in the Tomato  
Grower's Supply Co. catalog (and a catalog from a California supplier:  
the

Redwood City Seed Company or something like that). I've grown them here  
in New

York state, and they are \*very\* hot.

We are moving into a new house with a well and water softener. The water tastes \*slightly\* salty, (but it maybe that's because I was expecting it to taste salty), and is clean and clear and free of any bacteria (at least from our lab test).

A few questions:

1. Where is the best place to get a water hardness analysis?
2. Given the above info, is there a target for hardness?  
I understand that different beer styles usually call for different mineral content.
3. Are there better methods for water softening than the standard salt method (sodium/calcium exchange)?

I'm an extract brewer (for now), if that helps.

Thanks,

From: Robin Garr <76702.764@CompuServe.COM>  
Subject: Mexicali Rogue/chipotles

In HB1203, Alan in Austin (where there's a Tex-Mex restaurant on every corner) asks about the procedure Rogue Brewery uses to make its chipotle-flavored Mexicali Rogue Ale.

I asked the Rogue folks that question at last year's GABF and didn't get a totally forthcoming answer, but the short of it is, they "dry pepper" with chipotles in the secondary. How many? "Not too many." How long? "Not very long." It really is great stuff, and goes ever so well with Tex-Mex and other spicy stuff. It's starting to turn up here and there around the U.S. in 22-ounce bottles. I found some at Carlo Russo's World of Wine & Spirits in Fort Lee, N.J., the other day.

Say hello to Evita's Salsitas for me, Alan. I love that place ...

Subject: Malta & "Malzbier"

Date: Mon, 9 Aug 1993 14:11:48 -0400 (EDT)  
From: FARMERM@mcl.saic.com  
Subject: Prescription for Brew (ref. Domenick Venezia)

In response to Domenick Venezia's question about a prescription for beer. Yes, My wife's grandmother, who lives in South America, was prescribed a dark beer w/ a raw egg everyday. The dark beer in South America is different, however. The refer to it as "malta" and has no alcohol in it, its just used for cooking. What the purpose of this is, I'm sorry I can't say.

I grew up in Puerto Rico, where "malta" was a popular drink for children, in the way that root beer is here. I never heard of it being used in cooking, though. I'm not sure what the brewing process is, but malta is available here in the Boston area at major supermarkets (like Star Market) in the section where they sell Hispanic foods. I think the ingredients on the variety I bought recently were barley, hops, molasses, and water.

I've had it recently, and it's really quite sweet, with just a little hop bitterness and no hop nose. The molasses and malt tastes can be readily distinguished. It is dark brown or black, with a lot of body, and forms a brown head that was not retained very long in the brand I tried. It's drinkable, if you're in the mood for something very sweet.

When I was growing up, malta was brewed by a number of major brewers who distributed in Puerto Rico. Two Puerto Rican breweries were "India" and "Corona" (distinct, to my knowledge, from the Mexican brewer of the same name); they both sold undistinguished (and indistinguishable) pilseners, and also Malta India and Malta Corona. But some non-local brewers sold a malta product, as well. In particular, I remember that Rheingold sold a "Malta Rheingold," and there may have been a "Malta Amstel," although I'm not sure; but it must be admitted that there was no "Malta Miller" or "Malta Budweiser" (although both of these beers were popular on the island).

Sometimes children would mix malta with milk when drinking it. Some people would even go so far as to mix this already very sweet and heavy drink with sweetened condensed milk (I swear I did not make this up). What I find interesting is that, while malta was popular with some adults, none of the brewers on the island ever seemed to realize that this might mean that there would be a market for a darker, sweeter, heavier beer for adults, in addition to the watery pilseners that they sold.

Close to ten years ago, I did have such a beer that was in fact brewed in Latin America. I was doing some consulting in Sao Paulo, where two of the more popular brands of beer were called "Antarctica" and "Brahma." It seemed that most of the beer sold by these brewers was (the ubiquitous and undistinguished) pilsener, but they also sold a black beer that they called "Malzbier," pronounced as it would be in German. These "Malzbiers" were typically sold in 22-ounce bottles, and, if memory serves, tasted sort of like a highly sweetened Doppelbock. The popular claim was that "Malzbier" was rich in vitamins and minerals, and thus this beer was recommended to pregnant

women (I suppose fetal alcohol syndrome wasn't so well-documented then as it is now). People would often mix a sort of black and tan from a bottle of "Malzbier" and a pilsener, but I never saw an attempt to keep the layers separate, as seems to be the practice when mixing a stout and an ale.

There is a Brazilian beer sold in the United States that is a similar to these beers -- it's called "Xingu," and I'm sure that a lot of people reading the HBD will be familiar with it. However, it is a little different, in that it isn't nearly as sweet as I remember "Malzbier" being.

Which brings up a question -- was "Malzbier" indeed what I suspect, a local mutant style derived from Doppelbock by sweetening or possibly brewing with an unattenuative yeast, or is such an extremely sweet black beer known in other parts of the world? I'd be interested in hearing about similar styles.

-P.

I brew all grain English style ales here in Tucson which has almost  
identical water to Phoenix - it's wonderful for ales! When I sparge  
I add one teaspoon of lactic acid to reduce the PH for sparging. I  
just can't seem to remember what it drops the PH to at the moment but  
I used the info I got from Miller's book. I noticed that when I  
started using lactic acid to reduce my PH for sparging that any tannic  
astringency was now gone and the most importantly my extraction rate  
improved. Remember not to over sparge because you can still extract  
tannins even if you adjust the PH.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: Lite, Aeration

>From: "Manning, Martin P" <manning#m#\_martin\_p@mcst.ae.ge.com>

>I was just this morning thinking that no one had responded to the  
posting by  
Elizabeth Gold requesting information on amateur-brewed light beer.  
Today Dick  
Dunn did the unthinkable - he asked WHY?

I suspect most of us who did respond, did so via email for obvious  
reasons.

However, I see no reason not to share my two cents with the Digest so  
here is  
what I told her, more or less.....

>Subject: Light Beer for zymurgy

First of all, please do not dismiss this as a joke. It is serious and  
in the  
final analysis, more or less what the commercial brewers do.

To make a "lite" beer, one makes ones favorite beer and at bottling  
time,  
simply add an appropriate amount of "brewing water", prime and bottle or  
keg  
and carbonate as usual.

"Brewing water" is defined as boiled and cooled or otherwise de-  
oxygenated  
and sterile water.

To make a "lite" beer to style, it should be a Pilsner type beer but in  
the  
generic notion of a lite beer, i.e., lower calories, lower alcohol and  
easy  
drinkability, any beer can be used.

I have used as high as a 50:50 ratio of beer to water to produce very  
nice  
"lawn mower" beer. I would suggest starting at one gallon in a five  
gallon  
batch and working up to one's liking.

As outrageous as this seems to homebrewers, there obviously are people  
out  
there who like lite and we might as well know how to make it. I would  
also  
point out that "lightened" homebrew, if made from a good beer, will out-  
taste  
the commercial stuff by a mile.  
.....

I then pointed out that I developed this process in conjunction with my  
experiments with NA and included my NA process for her edification.

>From: Jason Goldman <jason@gibson.sde.hp.com>

>Lag time is controlled by a lot of variables. Pitching volume (and what stage the pitched yeast are in) probably has a greater effect on lag time than the aquarium pump.

That is why I designed my experiment to include only one variable; viz. aeration. Should be ready for Monday's Digest.

>BTW, I would expect that Miller was almost certainly talking about ale yeast in his 3-8 hours figure.

Gotta be as I have not heard anyone yet make any such claims for lager since posting my comments.

>From: birkelan@adtaz.sps.mot.com (Joel Birkeland)

>Subject: Tannic Verses [cute]

>I was wondering if anyone out there can give me some advice about treating my water for brewing. Our water here in Phoenix is very hard and very alkaline, (pH ~ 8). As I recall, the hardness number is about 250 (ppm?) and the alkalinity is about 170.

>I tried my first partial mash a few weeks ago, tasted the results last night, and it is OK, but had noticeable tannic astringency. I recall hearing that the pH of the sparge water has a strong effect on tannin extraction during sparging.

I think we need to turn the Ayatola loose on those who continue to scare people about the pH of the sparge water.

You may indeed have a problem but you can not assume this unless you actually do a mash. My water also has a pH of around 8 but as soon as I dough in the malt, it drops below 6.

As you are making extract beer and sparging adjuncts grains this could present different problems but it's worth looking into anyway.

In any case, mix some malt into your water and check the pH before and after before concluding that you need to do something about.

In an all grain beer, the mash can buffer out the high pH of a lot of sparge water without increasing the pH of the runoff more than a few tenths of a point.

The important thing is to run through your whole process before messing with the water.

>For the record, I kept the sparge water at or below 168 deg F, and I had to cut the sparging short because another user needed the kitchen resources.

The initial runnings were > 1.080, final > 1.020.

You threw away a lot of beer.

>From: pacasey@lexmark.com (Patrick Casey)  
>Subject: fermenting a lager

>Is there any way to ferment a lager without using a refridgerator and one of the fancy thermostats? For example, what's wrong with shoving the carboy into the normal fridge?

Nothing. Other than the fact that most people can't spare the space in the kitchen fridge for the time it take to make a lager. If you have a spare and a carboy fits, you'er in business.

From: WEIX@swmed.edu  
Subject: Yeast FAQ

Hi to all in HBD land. I have received several requests both to post the information that I collected on yeast and to make a Yeast FAQ. I will have to divide the information into several chunks to post to the HBD. Almost all of this data was plagerized from somewhere by me or others; however, I have not knowingly used any copyrighted stuff. (I was very careful \*not\* to check anything for a copyright ;-).) I have altered the focus of some documents to more accurately reflect what I feel to be the interests of the \*home\* brewer. Some of the information is very basic; some, more technical. I have tried to give a basic introduction to what yeast are, how they affect beer taste, and the proper handling of yeast.

Some portions of the following were taken from the Wyeast information circular mailed to me by David Adams; the sections pertaining to yeast culturing are adapted from an upcoming book by Dr. Fix. Dr. Fix also provided the section on the proper method of yeast rehydration. The information on the "reputations" of the many yeast strains was collected from the HBD over the years by Doug O'Brien. Many thanks to David Adams, Dr. George Fix, and Doug O'Brien for providing me with almost all the materials used to write this summary. Others are thanked for their contributions where appropriate. My name is Patrick Weix, and I am a graduate student in the Genetics and Development program at UT Southwestern at Dallas. I hope you find this document useful. I would appreciate any comments and criticisms of a constructive nature before I submit this to the homebrew archives at [sierra.stanford.edu](http://sierra.stanford.edu).

This document is composed of rampant hearsay and rumor. Any attempts to pin anything on me or my co-conspirators will be resisted. If all else fails I will call your boss and ask him why you are reading the HBD at work instead of grinding out the Fitzsimmons contract. What do they pay you for anyway? Don't you have anything better to do?...

From: WEIX@swmed.edu  
Subject:

## SECTION II: Yeast Profiles

### Part 1: Dry Ale Yeast

Ales (*Saccharomyces cerevisiae*)

#### Coopers Ale Yeast

Good to very good reputation. The Coopers is quite fruity fermented at 65F. It's not phenolic at all and all the flavour is a very clean fruitiness.

#### Glenbrew Special Ale Yeast

Specially designed for use in "all malt" beers. Contains a special enzyme to obtain extremely low terminal gravities.

#### Doric Ale Yeast

Ok to very good reputation.

#### Edme Ale Yeast

Starts quick. Produces some fruity esters. Attenuative. Good reputation

#### Lallemand Nottingham Yeast

This yeast is remarkable for its high degree of flocculation. It settles out very quickly and firmly. Very good reputation. Very fast to create a krausen and needed blowoff tube 6 hours after pitching hydrated yeast. Quick fermentation at 62F. It's very clean and only very slightly fruity in the keg, but tastes/smells nutty in the bottled version. Nottingham appears to be relatively attenuative (more so than the Coopers).

#### Lallemand Windsor Yeast

Produces a beer which is clean and well balanced. This yeast produces an ale which is estery to both palate and nose with a slight fresh yeast flavour. Very good reputation. Not a quick as the Nottingham. Not attenuative. Definite banana smell at racking.

#### Munton-Fison Ale Yeast

Starts quick. Produces some fruity esters. Attenuative. Phenolic taste. Fair to good reputation.

#### Red Star Ale Yeast

This brand had a very bad reputation in the past, and for a while production was suspended. A different strain (AHY 43391) was selected by the company and is now being sold as Red Star Ale Yeast. The new strain is much improved! Reports from Dr. Fix, a brewer's yeast consultant, suggest that this is an excellent general purpose ale yeast with a clean taste. Apparent attenuation 76-78%.

#### Whitbread Ale Yeast

Fast starter. Distribution switch[ed][ing] to Crosby and Baker with [evidently] a change in the yeast. Very good reputation despite past quality problems.

## Part 2: Liquid Ale Yeast

-----

Date: Fri, 13 Aug 1993 13:17:45 -0500 (CDT)  
From: WEIX@swmed.edu  
Subject:

Part 2: Liquid Ale Yeast

WYeast 1007 German Ale Yeast

Ferments dry and crisp leaving a complex yet mild flavour. Produces an extremely rocky head and ferments well down to 55 deg. F (12 deg. C). Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg. F (17 deg. C). A good balance of sweetness and tartness, with a pronounced green-apple note. A very pleasing yeast.

WYeast 1024 Belgian Ale Yeast

Banana estery flavour. With both clove-like phenolics and alcohol spice, the Belgian will tell you right away that it's no ordinary yeast. Tartness often develops over time. Ferment warm or with inadequate aeration and you're likely to get a bubblegum-like note. Intended for abbey beers, and works very well for that. And, depending on the wort composition, \*lots\* of banana notes.

WYeast 1028 London Ale Yeast

Rich mineral profile, bold woody slight diacetyl production. Medium flocculation. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C). Complex, woody, tart, with strong mineral notes, this one will bite you horribly if you over-hop or if your water is high in carbonates. If you avoid that Scylla and Charybdis, it produces ales of marvellous complexity and sophistication. Most of the time you'll wish you'd used 1098 or 1056. Had best results in porters. Over-hopping is especially bad, but if you throttle the hops back, the results are indeed marvellous. Used this yeast in a Kolsch once, and it was \*fantastic\* The wood and mineral notes fused with the Hallertauer hops (which were used with some restraint), and a couple of months of cool ageing brought out some green apple in the aroma as well as the palette. It tasted a good bit hoppier than it really was, and overall was well-balanced and smooth.

WYeast 1056 American/Chico Ale Yeast

Ferments dry, finishes soft, smooth and clean, and is very well balanced. Flocculation is low to medium. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C). The cleanest of the bunch, but mutation-prone. This is Sierra Nevada's yeast. Probably the best available all-around yeast, this strain can be used for anything, without embarrassment.

WYeast 1084 Irish Ale Yeast

Slight residual diacetyl is great for stouts. It is clean smooth, soft and full bodied. Medium flocculation and apparent attenuation of 71-75%. Optimum fermentation temperature: 68 deg. F (20 deg. C). Soft, round, malty; the least attenuative of the Wyeast line. Very nice for any cold-weather ale, at its best in stouts and Scots

bitters.

WYeast 1098 British Ale Yeast

Ale yeast from Whitbread. Ferments dry and crisp, slightly tart and well balanced. Ferments well down to 55 deg. F (12 deg. C). Medium flocculation, apparent attenuation 73-75%. Optimum fermentation temperature: 70 deg. F (21 deg. C). Tart, crisp, clean. Great in pale ales and bitters, good in porters.

WYeast 1338 European Ale Yeast

Ale yeast from Wissenschaftliche in Munich. A full bodied complex strain finishes very malty. Produces a dense rocky head during fermentation. High flocculation, apparent attenuation 67-71%. Optimum fermentation temperature: 70 deg. F (21 deg. C). It's clean and malty, especially well suited to Altbier.

Yeast Lab A01 Australian Ale Yeast

This all purpose strain produces a very complex woody and flavourful beer. Australian origin. Medium attenuation, medium flocculation. Great for Brown Ales and Porters.

Yeast Lab A02 American Ale Yeast

This clean strain produces a very fruity aroma, with soft and smooth flavour when fermented cool. Medium attenuation and low flocculation. This is an all purpose ale yeast.

Yeast Lab A03 London Ale Yeast

Classic Pale Ale strain, very dry. A powdery yeast with a hint of diacetyl and rich mineral profile, crisp and clean. Medium attenuation and medium flocculation.

Yeast Lab A04 British Ale Yeast

This strain produces a great light bodied ale, excellent for Pale Ales and Brown Ales, with a complex estery flavour. Ferments dry with a sharp finish. Medium attenuation and medium flocculation.

Yeast Lab A05 Irish Ale Yeast

This top fermenting strain is ideal for Stouts and Porters. Slightly acidic, with a hint of butterscotch in the finish, soft and full bodied. Medium attenuation, high flocculation.

Yeast Lab A06 Dusseldorf Ale Yeast

German Altbier yeast strain finishes with full body, complex flavour and spicy sweetness. Medium attenuation, high flocculation.

Yeast Lab A07 Canadian Ale Yeast

This strain produces a light bodied, clean and flavourful beer, very fruity when fermented cool. High attenuation, medium flocculation. Good for light and cream ales.

Yeast Lab A08 Trappist Ale Yeast

This is a typical Trappist strain, producing a malty flavour with a balance of fruity, phenolic overtones when fermented warm. Alcohol tolerant, high attenuation and high flocculation.

Part 3: Lager Yeast (*Saccharomyces uvarum*)

Dry Lager Yeast:(generally not recommend--tend to be inconsistent)

Liquid Lager Yeast: Much preferred over dry types!

WYeast 2007 Pilsen Lager Yeast

Our original Lager Yeast Strain. Specific for pilsner style beers. Known as many things, we call it Pilsen. Ferments dry, crisp, clean and light. Medium flocculation. Apparent attenuation from 71-75%. Optimum fermentation temperature: 52 deg. F (11 deg. C).

WYeast 2035 American Lager Yeast

American Lager Yeast. Unlike American pilsner styles. It is bold, complex and woody. Produces slight diacetyl. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C).

WYeast 2042 Danish Lager Yeast

Danish Yeast Strain. Rich, yet crisp and dry. Soft, light profile which accentuates hop characteristics. Flocculation is low, apparent attenuation is 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

WYeast 2112 California Lager Yeast

Warm fermenting bottom cropping strain, ferments well to 62 deg. F (17 deg. C) while keeping lager characteristics. Malty profile, highly flocculant, clears brilliantly. Apparent attenuation 72-76%.

WYeast 2124 Bohemian Lager Yeast

The traditional saaz yeast from Czechoslovakia. Ferments clean and malty, rich residual maltiness in high gravity pilsners, medium flocculation, apparent attenuation 69-73%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

WYeast 2206 Bavarian Lager Yeast

Lager yeast strain used by many German breweries. Rich flavour, full bodied, malty and clean. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

WYeast 2308 Munich Lager Yeast

Lager yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American home brewers. Sometimes unstable, but smooth soft well rounded and full bodied. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg.F (10 deg. C).

Yeast Lab L31 Pilsner Lager Yeast

This classic strain produces a light lager in both flavour and body, fermenting dry and clean. High attenuation and medium flocculation.

Yeast Lab L32 Bavarian Lager Yeast

Use this classic strain for medium bodied lagers and bocks, as well as Vienna and Marzen styles, rich in flavour with a clean, malty sweetness. Medium attenuation and medium flocculation.

Yeast Lab L33 Munich Lager Yeast

Wissenschaftliche strain for medium bodied lagers and bocks, subtle and complex flavours, smooth and soft, a hint of sulphur when fresh. Medium attenuation and medium flocculation.

Yeast Lab L34 St. Louis Lager Yeast

This strain produces a round, very crisp and clean fruity flavour, with medium body. High attenuation and medium flocculation. Good for American style lagers.

Yeast Lab L35 California Lager Yeast

A California common beer strain, malty with a sweet woody flavour and subtle fruitiness. Medium attenuation and high flocculation.

Part 4: Weissen, mead, and barleywine styles.

*Saccharomyces delbrueckii*, *S. cerevisiae*

WYeast 3056 Bavarian Weissen Yeast

A 50/50 blend of *S. cerevisiae* and *delbrueckii* to produce a south German style wheat beer with cloying sweetness when the beer is fresh. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 56 deg. F (13 deg. C). Problematical to get the right flavour, often just produces bland beer, without the lactic flavour.

Yeast Lab W51 Bavarian Weizen

This strain produces a classic German style wheat beer, with moderately high, spicy phenolic overtones reminiscent of cloves. Medium attenuation, moderately flocculent. Evidently much more consistent than WYeast at producing a true Weizen flavour.

The following are available from Brewtek at (800) 8BREWTE:  
(P.S. I swiped the following descriptions of the net myself (PW).)

CL-90 Belgian Wheat -- A top fermenting yeast which produces a soft, bread like flavor and leaves a sweet, mildly estery finish.

CL-92 German Wheat -- A true, top fermenting Weizenbier yeast, Spicy, clovy and estery. High attenuative.

CL-94 American Wheat - Offers a smooth, slightly sweet wheat beer, with a full, clean, underattenuated malt flavor.

Mead Yeast

Yeast Lab M61 Dry Mead

Very alcohol tolerant, ferments dry, fruity and clean, yet leaves noticeable honey flavour and aroma.

Yeast Lab M62 Sweet Mead

This strain has reduced alcohol tolerance, therefore produces a very fruity, sweet mead with tremendous honey

aromas.

#### Wine Yeast

Lallemand Lalvin Wine Yeast

S. Bayanus. Good reputation.

Red Star Pasteur Champagne Yeast

Very attenuative. Good for mead. Good reputation.

WYeast 3021 Prise de mousse Champagne Yeast

Institute Pasteur champagne yeast race bayanus. Crisp and dry, ideal for sparkling and still red, white and fruit wines. Also can be used for Barley wines. Optimum fermentation temperature: 58 deg. F (14 deg. C).

WYeast 3028 Wine Yeast

French wine yeast ideally suited for red and white wines which mature rapidly. Enhances the fruity characteristics of most wines. Optimum fermentation temperature: 72 deg. F (22 deg. C).

#### Malo-lactic Bacteria

Leuconostoc oenos

WYeast 4007 Wine Yeast

Malo-lactic culture blend isolated from western Oregon wineries. Includes strains Ey2d and Erla. Excellent for high acid wines and low pH. Softens wines by converting harsh malic acid to milder lactic acid. Can be added to juice any time after the onset of yeast fermentation when sulphur dioxide is less than 15 ppm.

### SECTION III: YEAST MANAGEMENT

#### Part 1: Hydration Procedure For Dry Yeast

- a. Use 14 grams of dry yeast (usually 2 packets) per 5 gallons of brew.  
\*\*\*Rigorously\*\*\* sterilize everything used in the hydration procedure.
- b. Add the dry yeast to 1/2 cup of water at 90F (32C). Leave for 15 mins.
- c. Combine the hydrated yeast with 1-2 gallons of wort that is as close to  
the wort to be fermented as possible. You can take samples from the  
main wort at the end of the mash/sparge and rapidly boil and cool it.
- d. Aerate the starter as much as possible under sanitary conditions.
- e. Don't forget to properly oxygenate the main wort once it is \*chilled\*  
(Shaking hot wort is dangerous, but even worse it can cause oxidation  
and give your beer funny flavors.)
- f. Pitch the starter into the main wort once the latter has been chilled to  
the recommended fermentation temperature (65-68F or 18-20C). Yeast  
with good viability will result in minimal lags. (The longest experienced in  
test brews using the new Red Star Ale Yeast was 2 hrs.)

An alternative but slightly sub-optimal method is to cool the yeast-in-water  
mix from "b" to room temperature. Once the wort has been chilled and aerated  
(shaking the carboy works well), pitch the yeast. Stir or invert the carboy to  
disperse the yeast. Put in the blow-off tube or fermentation lock.

The two most essential things are to:

1. Sanitize everything in sight.
2. Aerate your wort to insure rapid initial yeast growth--your best defence  
against secondary infection.

-----  
-----

#### Part 2: Propagation of Yeast Strains

or  
How to have your very own yeast ranch!

##### A. General Comments

There is no single item as important as the selection of a yeast strain,  
or  
if appropriate strains, to be used in commercial brewing. The same  
applies to

homebrewing. Sensory characteristics -- taste and smell -- will normally determine the type of yeast that is appropriate to any particular beer formulation. This section contains the necessary procedures for achieving self-sufficiency in pitching yeast. The part treated in this section is often called the Hansen pure culture system. The heart of this system is the so-called "yeast slant". It is a test tube containing a solidified media sloped at an angle. Often Petri dishes are used, but the media is level, and hence the term "slant" is not always appropriate. In any case, yeast cells are streaked on the surface of the solid media. When refrigerated, these slants will keep at least 3-4 months before they have to be recultured. Yeast are taken from the slants, and built up so there is enough to pitch a full batch. The system also contains procedures for doing the exact opposite, i.e., adding yeast to slants for storage and future use.

## B. Equipment

The equipment needs for operating a pure culture system with slants are rather modest. The following are the major items.

1. Refrigerator. This is needed for slant and media storage.
2. Autoclave or pressure cooker. This will be needed to sterilize equipment and media for yeast work. A pressure cooker will do, but it should have a pressure gauge attached so that the conditions during sterilization can be controlled.
3. Media. The preferred media for slants is malt extract and agar. These can be obtained from any scientific outlet. Food grade agar is also available from some oriental markets. The flaked form is easier to work with.
4. Misc. A number of minor items will also be needed. These include inoculation loops, glassware, petri dishes, and test tubes.

## C. Propagation of Yeast

This process consists of transferring some of the yeast on slants to a small flask or jar containing wort, then building this up until there is

enough to pitch a full brew. the most delicate steps are the initial ones.

Experience has shown that the best results are obtained by using full strength hopped wort for propagating yeast. The ideal situation is when the

wort used in propagation is identical to the wort that will be used in brewing.

Practical experience has also shown that it is best to pitch yeast freshly

harvested from slants at the maximum acceptable rate. Anticipating the results in the next section, this for lager yeast amounts to pitching 1 volume of yeast \*SOLIDS\* for each 250 volumes of wort. Thus, we need  $5\text{gal}/250 = 0.02\text{gal} \cdot 128\text{oz}/\text{gal} = 2.5\text{oz}$  of yeast solids for a 5 gallon batch.

Using the estimation that yeast solids are 1/10 the total volume of a yeast culture, that means that one needs about 25oz or a little more than 3 cups culture. For ale yeast all of these numbers are reduced by a factor of two, so (3/2) to 2 cups of an ale yeast culture would be sufficient.

In the procedure described below new wort is added just after the end of the period of high kraeusen, and in particular after the foam starts

to recede. The reason for this is to keep the yeast in the aerobic exponential growth mode. This will insure a steady buildup of yeast cells, and thereby minimize the number of wort charges that are required. The importance of taking great care when adding fresh wort can not be overemphasized. To avoid infections not only is it

necessary

to properly sanitize equipment, but it also important to sterilize necks

of vessels and jars by flame or 200 proof alcohol solutions. The easiest

way to flame a jar at home is with a lighter (esp. the ones for pipe-smokers!). Be extremely careful, and don't use both alcohol and a lighter.

The first four steps described below are done under the cleanest conditions

possible using 1000 ml. starter jars. At the end of step (iv) there will

invariably be more than enough yeast in each starter jar to pitch a 25 liter

brew (about 6gal); i.e., there will be at least 1/10 liter of yeast solids as

can be checked by visual inspection. These numbers are based on the requirements of lager yeast. As will be seen below there will be no harm in

producing too much yeast in this procedure since at the end only the correct

amount will be added to the fermenter.

(i) Preparations:

a. Carefully inspect all the slants that are to be propagated. Those which have unusual growth patterns and/or discoloration should be discarded. The ideal is thin white yeast layer on top of the solid media.

b. Autoclave the starter jars and the rubber stoppers for the airlocks for 5 mins. at 15 psi. Alternatively, use your favorite chemical sanitizing agent.

c. Add 250 ml. (about 8 oz) of wort to each starter jar. Wipe their necks with a 200 proof alcohol solution. After this add the airlocks.

d. Pasteurize the wort by adding the starter jars to a water bath at 60 C (140 F), and hold this temperature for 20 mins. Cool to 18 C (75 F).

e. In a clean room with no air movement (turn off fans and air conditioning

for at least 15 min to give the dust a chance to settle) and then place starter jars, yeast slants, inoculation loops, and a 200 proof alcohol

solution in a clean, quiet spot (i.e. lock the door after first  
insuring  
that Fido, Fluffy, and Junior are on the other side of it :-) !).

End of HOMEBREW Digest #1204, 08/16/93  
\*\*\*\*\*

-----

Date: Fri, 13 Aug 1993 13:18:19 -0500 (CDT)  
From: WEIX@swmed.edu  
Subject:

(ii) Inoculation:

a. For each jar, start by sterilizing its neck. Then sterilize ("flame") the inoculation loop. Open a slant, quench the loop in clean agar ("sizzle") and use the loop to remove some yeast. Remove the airlock and then add the yeast to the starter jar. Replace the airlock, and then start work on the next jar.

(iii) Initial Buildup:

a. Place the starter jars in a location where 68F (18C can be held). Aerate twice daily by vigorously shaking jars. 1L Erlenmeyer flasks are excellent for this purpose because they permit vigorous swirling without getting the wort up by the neck and opening.

b. A widely used practice is to discard any starter that is not active within 48 hours. Certainly if some of the starters are active within this period, then the inactive ones should be discarded. In any case, any starter not active within 72 hours should definitely be discarded even if this means they are all discarded.

(iv) Second Wort Charge

a. When the foam has receded prepare 250ml. of fresh sterile and aerated wort for each starter.

b. The new wort is to be added to each starter, and this should be done as cleanly as possible.

c. Before pouring the wort into the starters, it is very important to swab the necks of the starter jar and the wort jar with a 200 proof alcohol solution to prevent contamination or flame them with a lighter.

d. It is also desirable to reduce the temperature to a point closer to the temperature that will be used in production if that is lower than 18 C. For example, with lagers fermented at 10 C, this is usually taken to be 14-15 C.

e. The starters should be aerated at the start and then again after 12 hours. New activity should be seen before 24 hrs. Those which are not active within 36-48 hours should be discarded.

f. Increase the volume of wort until you have sufficient volume to pitch.

(v) Pitching the Yeast

a. At this time you should have a jar with about 500ml (a little more than 2 cups) of yeast for a 5gal ale batch. I would suggest pitching before the krausen (foam) totally dies down so that the yeast are still in rapid growth phase. The total volume will vary with batch size, yeast type, and your personal experience/whim. Remember to keep yeast notes along with your beer notes so that you can learn from experience!

b. Clean the outside of the jar with 200 proof alcohol or weak bleach and allow to dry.

c. It is not advised that you pitch the old wort and yeast into the fermenter because the media has been exposed to air and oxidized, etc, etc. Therefore, pour off or siphon off the old media, leaving the yeast on the bottom of the flask. Pour this slurry into the primary or resuspend this slurry in sterile water and add immediately to the wort. A short exposure to water will not harm the yeast, although they should not be exposed to it for long periods or they will lyse.

#### D. Preparation of New Slants

Two steps are needed in the preparation of new slants. The first consists of adding the proper media to test tubes or petri dishes. Once prepared the slants will store well for a very long time when refrigerated, so many can be prepared at one time. The second step consists of inoculating the slants with yeast.

For the homebrewer who cannot afford several refrigerators: Please be advised that your refrigerator is a haven for bacteria, mold, and wild yeast. Anyone wishing to store sterile slants in their refrigerator is advised to 1. Wipe down the slants before storage with ethanol or your favorite sanitizing solution. 2. Seal the slants with parafilm or electrical tape. 3. Keep the slants in a ziplock bag. 4. Wipe down the bag with ethanol or your favorite sanitizing solution before opening.

#### Preparation of Media:

- (i) The media consists of dry malt extract and agar. As a general rule 4 tablespoons of malt extract and 1 tablespoon of agar per cup of water will yield 16-18 slants.
- (ii) Bring the water to a boil, and then stir in the malt extract. Boil for 10 mins.
- (iii) Remove from heat, and then start stirring in the agar. This will take some effort, but this usually indicates that

a good solidification will ultimately be achieved. If your slants "sweat" too much, increase the amount of agar you use. Although commercial/scientific agar will vary little, I cannot answer for "food grade" supplies.

Gelatin is easier to dissolve, but it sometimes does not always give a proper solidification.

(iv) When the agar is dissolved, the malt/agar solution should be added to the test tubes, filling each to approximately a third of their volume. Add the screw cap, but do not fully tighten.

(v) Autoclave the tubes at 15 psi for 5 mins.

(vi) Tighten the caps on the tubes, and place them at a 30 degree angle. Allow them to solidify at room temperature. Solidification should become apparent within a few hours. Tubes which are not solid after 24 hrs. should be discarded.

(vii) Refrigerate until needed.

Note: Petri dishes can not be autoclaved, and so alternate procedures are needed for them. A common practice is to autoclave the malt/ agar solution in

small jars. The agar solution is then poured into the petri dishes. Let the

agar cool until the jars are hot but touchable. If the agar is too hot it will warp the plates. Swirl it gently to mix but avoid bubbles. It is also a

good idea to leave petri dishes prepared in this way at 25-30 C for 1-2 weeks

to make sure bacteria or molds are not present. Let the poured plates dry overnight in a clean quiet room. Wipe them down, seal them, and bag them, but

leave them at room temperature for 1 week. The bad bugs, if they are there,

will be visually apparent at the end of that period and the contaminated plates discarded. While Petri dishes are more trouble than test tubes, they

do offer the distinct advantage of having more surface area and being easier

to store. After the trial period the dishes should be refrigerated.

#### Inoculation of Slants:

(i) Collection a small portion of the yeast to be added to the slants. It goes without saying that one should strictly follow the standard sterilization procedures of all items used to collect this yeast.

(iii) With one hand sterilize the inoculation loop (flame or alcohol solution). With the other hand open the cap of a slant.

(iv) Dip the loop into the yeast solution, and remove a small amount.

(v) Slowly insert the loop into the tube avoiding contact with either the sides or neck of the tube. Streak the yeast over the solid. Only a thin layer is wanted, and one should try to use as much of the surface area as possible.

(vi) Slowly remove the loop avoiding contact with tube walls or neck. Add the screw cap back on the tube and tighten.

(vii) When finished store the tubes at 25 C for one week. Visually inspect all tubes at this time both for yeast growth, and also for any irregularities. Discard those which are not satisfactory.

(viii) Store the remainder at 2-8 C. After 3-4 mos. of storage, unused tubes should either be discarded or recultured; i.e., propagated by the procedures in Section III.2.c and then put on fresh slants. The best idea is to put production yeast on slants on a regular basis so that reculturing is not necessary.

Note: The larger surface area afforded by Petri dishes can be used to advantage in the above procedure. In particular, it useful to streak out yeast in parallel lines which make angles with each other. This allows for a better examination of growth patterns. Petri dishes should be sealed after the 1 week trial period with electrician's tape and refrigerated.

neither  
> tried nor even tasted?  
>  
> This is not the sort of responsible journalism that would keep  
Zymurgy  
> at the fore of the homebrewing industry.

I think this is uncalled for. Many of us will agree that the AHA has not  
done a very good job of appealing to the more advanced brewers. I think  
we should be welcoming the change in the AHA that is evident by the  
editor  
of Zymurgy requesting technical info from us the HBD community. It is  
quite apparent that there is some technical brewing knowledge right here  
and it is a welcome change to see the powers that be asking for input  
from us, even if it is on a "light beer style" question (eechhh).

It is also naive to believe that any publication would have the time or  
resources to actually taste or verify the recipes that are given by  
people who are supposed to be knowledgeable in the subject matter.

Good brewing,  
Jim Busch

Thank you for your help. I'm posting these responses so all can enjoy. Sorry for the spacing. I guess my initial estimate of 3-4 lbs of fruit is way too low.

Subject: RE: HBD 1203 (blackberry mead)

Date: Fri, 13 Aug 93 8:25:32 EDT

**Subject: Blackberry Mead Responses**

Hi Drew,

You are about to embark on a homebrewing experience that will leave you forever changed. I brewed a black raspberry mead last season that was probably the best stuff (beer or mead) that I have ever made. The recipe was patterned after Papazians "Purple Haze Hendrix Mead" which was posted in some past Zymurgy issue (I'm working without my references here). Pap says in comments following this recipe that this is one of his all-time favorites and I would have to second that opinion. This season my parents and girlfriend gladly helped to pick about 32 lbs of fresh black raspberries at the local U-pick-um farm with the understanding that they will all be supplied with the resulting nectar. BTW it was an incredible year for raspberries here in Ohio. My recipe goes something like this:

**Black Raspberry Melomel**

8-12 lbs of good quality honey (I like raw orange-blossom)  
10-15 lbs of very ripe black raspberries (picked fresh then frozen for a days before brewing)  
2.5 tsp pectic enzyme  
1.25 tsp good yeast energizer (I like the stuff that is primarily urea but also contains a bunch of B-vitamins and various amino acids)

**Optional:**

1-2 oz fresh ginger (grated or finely sliced)  
1 oz dried lemongrass

(the reason most of the ingredients have a range of quantities is that I varied the recipe a bit this year)

**Procedure:**

- Bring 2 gal of good brewing water to a boil and add honey
- Boil honey must for 10-15 min (you can skim the scum if you want to, but I'm not convinced it makes a difference)
- Add raspberries, ginger, and lemongrass, stir and turn off heat
- Cover and let steep (read pasteurize) 20 min
- Cool, dilute to 5 gal and add pectic enzyme and yeast nutrient
- Aerate VERY well and pitch your favorite mead yeast ->If you dont have a favorite, I can recomend "Lalvin S. Cerevisiae (an eppernay type) as an excellent choice.
- Wait patiently

**Notes:**

1. I use two stage fermentation with the racking of the mead coming when the CO2 is down to about 1 bubble every 15-30s (usually about 1 wk.)
2. I have used the Lalvin yeast on my last six or so batches of mead and I am very pleased with the speed with wich it starts and finishes. It

also flocculates well and besides all that it leaves a nice clean slightly sweet finish. I have been ready to bottle after only about a month of fermentation (counting both stages) since I started using this yeast. BTW I think the yeast energizer is critical to this as well.

3. The above recipe is pretty general. I used essentially the same program to make both strawberry and mullberry melomels as well this summer.

Let me know if you have other questions.

Hi Drew,  
Your request for a Blackberry mead recipe caught my eye in the HBD. Being from Seattle, I know that the blackberries are ready to pick this weekend, so if you get any recipes, could you forward them to me?

TIA,

Dave

Subject: Blackberry Mead Responses

> Does anyone have a good recipe for Blackberry Mead?

Not a specific recipe, but based on the variations I've done: Use around 2 lb fruit per gallon to get a strong fruit character. Use around 2 lb honey per gallon. (I normally use a full gallon of honey--which is a bit under 12 lb--in a 5 gallon batch.) You can use a fairly strong honey with berries like this.

That's it--berries, honey, water, and a suitable yeast. My current favorite yeast for melomels is "Prise de Mousse".

Crush the berries; you don't actually need to extract the juice. Use a plastic-pail primary fermenter. Assuming you get a good fast start to fermentation, I'd skim out all the berry-crud and rack it after about a week. That should be enough to ferment out most of the berry sugar. If you leave the berries in much longer, you'll get too much astringent character.

You might consider a mixture of berries--say blackberry+raspberry. Depending on the type of blackberries and what the growing season was like, blackberries can be rather bland. (This surprised me.)

Frozen fruit works just fine; in fact the freezing helps break up the berries and release the juice. However, given your location and the season, I'm guessing you have plenty of fresh fruit.

Subject: Yeast FAQ part 2 of 7 (read this after intro then continue in seq.)

## SECTION I: Yeast Characteristics

Yeast are unicellular fungi. All brewing yeast belong to the genus *Saccharomyces*. Ale yeast are *S. cerevisiae*, and lager yeast are *S. uvarum* (formerly *carlsbergerensis*). Weizen yeasts are usually 50/50 mixtures of *cerevisiae* and "*delbrueckii*" (*delbrueckii* may or may not be an accepted taxonomic class, however its use as a label appears widespread, and it is used herein for simplicity). You may ask, "If all these yeast are the same species, why all the fuss?" The fuss has to do with strain variation. Just as all dogs are the same species, yet no one will ever mistake a basset hound for a doberman (at least not twice :-). Using different strains can add fun and spice to brewing, especially if you have an idea of the differences. I originally put together this guide to catalogue the different affects of different strains. This information is in Section II.

Some yeast strains are more active and vigorous than others. Lager strains in particular do not show as much activity on the surface as many of the ale strains. Most packages provide an adequate quantity of yeast to complete fermentation with varying amounts of lag time depending on strain, freshness, handling, and temperature. If you find it too slow, make a starter as recommended on the package or as listed in Section III. In any event, a closed fermenter with an airlock is recommended.

### Temperature

The slow onset of visible signs of fermentation can be improved by starting fermentation at 75 deg. F (24 deg. C) until activity is evident, then moving to your desired fermentation temperature. A few degrees does make a significant difference without adversely affecting flavor.

The normal temperatures for ale yeast range from 60-75 deg. F (16-24 deg. C). A few strains ferment well down to 55 deg. F (13 deg. C). 68 deg. F (20 deg. C) is a good average. Lager strains normally ferment from 32-75 deg. F (0-24 deg. C). 50-55 deg. F (10-12 deg. C) is customary for primary fermentation. A slow steady reduction to the desired temperature for secondary fermentation typically works well.

The fermentation rate is directly related to temperature. The lower the temperature, the slower fermentation commences. Fluctuations in temperature such as cooling and warming from night to day can adversely affect yeast performance.

#### Attenuation

Attenuation refers to the percentage of sugar converted to alcohol. Apparent attenuation of yeast normally ranges from 67-77%. The attenuation is determined by the composition of the wort or juice and the yeast strain used. Each yeast strain ferments different sugars to varying degrees, resulting in higher or lower final gravities. This will affect the residual sweetness and body.

Really, it's slightly more complex than that (isn't everything ?-). There's

"apparent attenuation" and "real attenuation". The difference comes about

because alcohol has a specific gravity less than 1 (about .8). Real attenuation is the percent of sugars converted to alcohol. So, if you had a

10% (by weight) sugar solution (about 1.040), and got 100% real attenuation,

the resulting specific gravity would be about 0.991 (corresponding to about

5% alcohol by weight). The apparent attenuation of this brew would be 122%!

George Fix published a set of equations relating apparent and real attenuation and alcohol content last year. To wit:

A = alcohol content of finished beer in % by wt.

RE = real extract of finished beer in deg. Plato

Since A and RE are generally not known to us, additional approximations are

needed. The following are due to Balling, and have proven to be reasonable.

Let OE and be defined as follows:

OE = original extract (measured deg. Plato of wort)

AE = apparent extract (measured deg. Plato of finished beer).

Then,

$RE = 0.1808 * OE + 0.8192 * AE$ , and

$A = (OE - RE) / (2.0665 - .010665 * OE)$ .

The "tricky part" here is the expression of the sugar content in degrees

Plato. This is a fancy term for % sugar by weight, and corresponds \* roughly\*

to "degrees gravity" divided by 4. That is, a 1.040 wort has an extract of

10 degrees Plato. He goes on to calculate an example: To take a specific

case, first note that from Plato tables an OG of 1.045 is equivalent to OE =

11.25 deg. Plato, while a FG of 1.010 is equivalent to AE = 2.5 deg. Plato.

Therefore,  $RE = 0.1808 * 11.25 + 0.8192 * 2.5 = 4.08$  deg. Plato, and  $A =$

$(11.25 - 4.08) / (2.0665 - .010665 * 11.25) = 3.68$  % wt. The apparent attenuation is 75%

(from 1.040 to 1.010), the real attenuation is  $(11.25 - 4.08)/11.25 = 64\%$ .

N.B. Most attenuation figures are given in terms of \*apparent\* attenuation.

(Thanks to Chris Pencis quoting Stuart Thomas quoting George Fix).

### Flocculation

Flocculation refers to the tendency of yeast to clump together and settle out of suspension. The degree and type of flocculation varies for different yeast. Some strains clump into very large flocculate. Some flocculate very little giving a more granular consistency. Most yeast strains clump and flocculate to a moderate degree.

### pH Ranges

Typical pH range for yeast fermentations begins at about 5.1 and optimally 4.8. During the course of fermentation the pH reduces to typically 3.9-4.1 and as low as 3.1 in some wines.

### Alcohol Tolerances

The alcohol tolerance for most brewing yeast is as least to 8%. Barley wines to 12% can be produced by most ale strains. Pitching rates need to be increased proportionally to higher gravities. Alternately, Champagne and Wine yeast can be used for high gravities sometimes reaching alcohols to 18%.

### Smells and Tastes

Although the principle tastes present in a beer are the result of the malts and hops used, the strain of yeast used can also add important flavors, good and/or bad. Yeast that add little in the way of extra flavors are usually described as having a "clean" taste. These yeast are especially useful for beginners because they permit experimentation with different ingredients without worrying about yeast influence. Yeast produce three main classes of metabolic by-products that affect beer taste: phenols, esters, and diacetyl. Phenols can give a "spicy" or "clove-like" taste. Esters can lend a "fruity" taste to beer. Diacetyls can give beer a "butterscotch" or sometimes a "woody" taste. The desirability of any one of these components depends largely on the style of beer being brewed. In addition, there are certain by-products in these families that are more noxious than the others. A lot depends on the individual palette and the effect you're aiming for.

A final note: some yeast, especially lager yeast during lagering, can produce a "rotten egg" smell. This is the result of hydrogen sulfite production.

Although the scent of this bubbling out of the air-lock is enough to make the strongest homebrewmeister blanch, fear not! The good news is that this will usually pass, leaving the beer unaffected. Relax, etc.

My original guess that their 2-row was Briess was based on the stacks of  
Briess Malt sacks glimpsed through the brewery's window. A phone call  
to Thomas Price clarified the matter. Redhook gets their wheat malt  
from Briess and as Jeff correctly surmised they get virtually everything  
else from Great Western.

Yikes! This is a TOUGH room.

From: Philip J Difalco <sxupjd@anubis.fnma.COM>  
Subject: Grolsch bottles & Carbonation

I also use Grolsch bottles (using usual anal sanitation precautions), and have had no problems with any of my batches.

However, concerning carbonation, I did notice that the few beers that I put into the fridge, for a little over a weeks time, experienced less carbonation than the ones I stored in my basement. The gaskets are relatively new (as the bottles are not even 5 months old)

.

I was thing that the colder fridge temperatures may have caused the gaskets to contract enough to make an imperfect seal letting gas escape from the beer (to outside the bottle), thusly reducing the beer's carbonation (factor).

From: Bill Flowers <waflovers@qnx.com>  
Subject: Hard, high pH water treatment for new masher

I've started mashing and I think I might have a problem: my water supply has a high pH (8.0-8.2) and is quite hard (250 ppm). Its perfect for the fish I keep (rift valley cichlids), but I'm not sure what to do with it for brewing. Before I started mashing I never concerned myself with it, but now I'm mashing and wanting to make pale ales and pilsners instead of stouts and Munich dunkels, so it is now a concern. I've got a call into the lab to get the water analysis details, but I won't have them until Monday.

I've also got access to lower pH, softer (but still not soft) water here at the office. I'll get the details of it on Monday too.

I've read Miller on water treatment, and it just left me more confused than ever. Why can't he just say: "Do this if you have this water, do that if you have some other water"?

What I want is a recipe or flow chart (or hand holding) on what to do with my mash and sparge water. Can anyone help me? Or at least put Miller's explanation in terms I might understand.

**Subject: cleaning swinger**  
Full-Name: Mark S. Hart

Just a data point.

I have always used the brown and green swing top/Grolsch bottles. Being a procrastinating lazy sort here's the easiest way I've found to clean them with out a single mishap to date.

Rinse the bottles after emptying and stick em in the dish washer with the dinner stuff. Save these bottles (usually only 5 or 6) until you have enough to bottle the next batch. When your ready to bottle the next batch wash all the bottles again and toss 1 or 2 ounces of bleach into the washer. The washer will recycle the bleach water solution a few times before beginning the rinse cylcle. Bottle when washer stops and every thing is dry. I usually don't use any soap on the second washing. Scoff all you want but I've done my last 7 or 8 batches this way with no worries or infections. Initially I was concerned about the bleach deteriorating my washers seals so I now dilute the 1 or 2 ounces of bleach in a gallon of water and dump the whole mess in the washer. So far everything is O'tay. I also have noted that the green bottles are superior in quality to the brown.

See Ya, M. S. Hart

Have I  
> finally gone off the perverbial 'deep end'?

Nope, you've not gone off the deep end. I've used this technique (based on 2nd hand information which was supposed to have come from the now retired, former senior biochemist for John Courage) on my Barley Wine, and it tastes fantastic! Before pitching the ale yeast, I put 1L of wort in a sanitized mason jar into the fridge. About 3 days into the primary fermetation, I removed the wort from the fridge in the morning to warm up. That evening I mixed it with 1L of boiled and cooled water (to get the gravity down to something more reasonable for a "starter") and pitched some champagne yeast. When that was well started I added it to the fermenting barley wine.

For a beer like this where you want to get the typical ale flavor (esters) as well as the higher alcohol content, I highly recommend the technique.

Date: Fri, 13 Aug 1993 22:40:57 -0400 (EDT)  
From: Jim Griggers <brew@devine.ColumbiaSC.NCR.COM>  
Subject: Shipping live yeast

I bought a "Yeast Culture Kit" from ~~\_\_\_\_\_~~ when I was at the AHA Conference in Portland. I had been thinking of buying one for some time, and their "special show price" of \$29.90 seemed great.

"Save \$10 since the regular price is \$34.95 and you save the \$5 shipping."  
"

I was told the slants would be inoculated on Monday after they got back to California. They would check for viability, and send them out by UPS. (Conference was July 27 - July 29)

I called ~~\_\_\_\_\_~~ Thursday, August 12 to check on the yeast. I was told it was shipped out Monday, August 9, by surface, which I assumed was by UPS.

The yeast arrived Friday in a plain manila envelope in the US Mail. My mail box is a standard flat-black metal rural box that spends 75% of its time in direct sunlight. Today is fairly cool (90F) and mostly cloudy. The temperature inside the box was around 105F. I guess I am lucky in that: 1) I was home, 2) I checked the mail early, and 3) today has mostly overcast skies.

To quote their catalog: "IMPORTANT NOTE: Due to the delicate nature of live yeast and the temperature extremes in many parts of our country, we STRONGLY recommend 2nd Day Air delivery of your yeast culturing kits. (2nd-Day Air delivery is the only way we can guarantee your live yeast cultures to be viable upon receipt)." They charge \$6.00 for this BTW.

I was disappointed. I know they saved money shipping it by US Mail (\$0.52 stamp), but why put the "IMPORTANT NOTE" in their catalog if it does not matter? I know the owner will make good on the yeast if it turns out to be fried, but that is not the point. I had delayed brewing because I didn't have any more yeast and I wasn't going to get more Wyeast since I had this yeast on order. (I drive 80 miles, each way, to Charlotte, NC to buy yeast, so I usually stockpile.) If the yeast turns out bad, then it would be another two weeks before I could expect a replacement.

I guess I am asking the yeast experts out there what they think about the above conditions in the handling of yeast. What is affected by high temperatures of yeast on a slant, other than possibly lower viability? Can elevated storage temperature cause undesired fermentation characteristics?

I am NOT knocking the shop owner or ~~\_\_\_\_\_~~, but I am questioning their choice of shipping. I have heard nothing but praise about their operation.

The kit I bought is supposed to be the best on the market. The yeast I received may be in perfect condition. I am simply asking for information regarding yeast handling, since I am certainly not an expert on this subject.  
Thanks.

-Jim Griggers    [jdg@devine.columbiasc.ncr.com](mailto:jdg@devine.columbiasc.ncr.com)  
West Columbia, South Carolina

PS. Since I have not tested or used the yeast in question, I feel that it would be unfair to name the shop.

From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)  
Subject: RE: fermenting a lager

Patrick asks in HBD 1203 about \*fermenting\* a lager by placing the carboy in a referigerator without using an AirStat(tm) or other thermostat. His concern was temperature fluctuations.

The problem isn't so much with temperature fluctuations as with the mean temperature, Patrick. To ferment, you're looking for temperatures in the 45 - 55 F range. This is too warm for most referigerators. They're expecting to keep things in the 32 - 40F range. Note that this is ideal for lagering, but not for the fermentation. In fact, I have an AirStat(tm) and the main problem I have with it is that it only goes down to 40F. Why? Well, who sets their air conditioner below 40 degrees? So, I use the AirStat(tm) to control in the fermentation and serving range, and just use the built-in referigerator thermostat when lagering. There's a guy in our local brew club who uses a thermostat he got from Granger -- it controls over the whole range we want, and costs about the same as the AirStat(tm). You don't get the fancy LCD display though. If you have a Granger catalog, you might check it out.

Hope this helps...

From: r.wize@genie.geis.com

Subject: Missing Head

I have made some decent all grain beer lately but have noticed a significant difference in the way they hold a head. I have been very careful to pour the beers in the same type cleansed glassware so the only variable I can turn to is the grains. What makes this unique I believe is that the beers which do not hold a head are Wheat beers. My pale ales keep a head for a good 5 minutes while my wheat beers lose their head within 2 minutes. Two comparable grain brews were;

|            |        |      |
|------------|--------|------|
| Wheat Pale |        |      |
| Brit Pale  | 08lbs  |      |
| Klages     | 6lbs   | 1lb  |
| Wheat      | 3.5lbs | .5lb |
| Crystal    | .5lb   | .5lb |

Is there something I don't understand here? I always thought wheat beers would have longer lasting heads and that is why you add a little wheat to most recipes.

Date: Mon, 16 Aug 93 08:51 CDT  
From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: WORT AERATION

WORT AERATION PRIOR TO PITCHING

Jack Schmidling  
Aug 14, 1993

There has been a great deal of enthusiastic reporting on the use of aquarium air pumps to aerate wort prior to pitching yeast and many rather preposterous claims of shortened time to the onset of fermentation resulting from the use of same. As the author's experience on one batch did not support any such claims, a controlled experiment was designed to determine the validity of said claims.

The experiment described herein compares the air pump aerator with several other less exotic methods along with an un-aerated control batch.

The wort used was withheld from a batch of Pilsner style beer with a gravity of 1.050. It was re-boiled several days after the original batch was pitched so that it could be pitched with controlled amounts of krausen from the new batch. The re-boiling was to re-establish an anaerobic environment along with re-sterilizing the wort.

Prior to pitching, the wort was divided into (4) 500 ml samples in sterile, one quart mason jars and aerated in various ways as follows:

#1 Control... No aeration. Just gently poured from kettle into jar.

#2 Siphon Simulation... Poured into jar from a height of 12 inches in a narrow stream to simulate what one would get simply by siphoning and letting the stream fall into a fermenter.

#3 Pumped from kettle through nozzle to "squirt" into jar. This is the system normally used by the author to transfer from kettle to fermenter.

#4 Aerated with aquarium pump and fine mist airstone. Pump was run until foam volume equaled wort volume then shut off till the foam collapsed. This was repeated 5 times for a total on-time of (2) minutes. The time was based on a very conservative scale down from Miller's suggested time of 15 minutes for a 5 gallon batch. It represents about 5 times the amount of air per unit wort volume recommended by Miller. (\*1)

The wort was cooled to a temperature of 70F before being aerated. All four samples were pitched with 50 ml of working krausen. This active wort was taken as a single sample and thoroughly mixed prior to dividing into 4 individual portions to assure a homogeneous and identical yeast in each test.

The yeast used was Pilsener Urquel recultured from a slant obtained from Paul Farnsworth. (\*2)

After pitching, the four test batches were placed in a refrigerator at 40F and checked every four hours for signs of incipient fermentation.

RESULTS.....

No sign of fermentation was detected until the 72 hr check. At this time, a small island of bubbles was just visible in the center of all four samples.

To accelerate the conclusion of the experiment, the samples were removed from the refrigerator and allowed to rise to room temperature (75 F). They were monitored until the entire surface of the fermenters were covered with foam. This occurred about 9 hours later on all four samples.

.....

ALE YEAST

To take the experiment one step further, a similar but abbreviated experiment was conducted with ale yeast.

Two 500 ml samples of a similar wort were treated as follows:

#5 Control... No aeration

#6 Shook jar vigorously until foam volume equaled wort volume. This was allowed to settle and repeated (5) times.

Both samples were pitched with 0.4 grams of granulated EDME ale yeast, poured directly on top of the wort.

They were maintained at a temperature 75 F and monitored regularly until the onset of fermentation. This occurred at 4.5 hrs in both samples. The tops of both fermenters were covered with foam at 10 hrs total elapsed time.

CONCLUSION...

The experiment seems to confirm the author's previous experience and points to the conclusion that the method of aeration used has no correlation with or effect on the time to onset of fermentation. Contrary to frequently stated anecdotal experience, the un-aerated control samples started fermenting as soon and with the same vigor as the variously aerated samples. This was true both in the case of cold temperature lager yeast and room temperature ale yeast.

This experiment was not intended to test any other aspects of the brewing process that may be affected by wort aeration. Much has been written on the subject and the present author's intent was only to study the effects of aeration on the onset of fermentation.

Subject: Lager yeast at warm Temp.

I am preparing to brew up a pilsner from Charlie P's book. I have purchased Wyeast American Lager yeast.

I realize that that I will not obtain a true pilsener without a lagering operation, but at this time, I don't have the means to keep the fermentation cool. (I had hoped I would by now).

So the big question is: Should I go ahead and brew this batch at a warm temp. (70+) with the lager yeast? More specifically, will I get a complete fermentation from lager yeast at the warm temp?

Charlie P. says that the lager yeast will do okay at room temp, but I wanted to see if anyone had any bad (or good) experiences with this type of situation. (Or, if anyone had any suggestions)

You can e-mail me to save bandwidth.

Thanks for the input,  
Alex

Subject: Re: Recipe formulation

John Montgomery asks about formulating his own recipes. He says he has 10 or 11 all grainers behind him and wants to strike out creating his own recipes.

This brings up an interesting point to me. I wonder how many people with this much experience have done this little experimenting. I have brewed a total of 16 batches, the last 5 or 6 being all-grainers. I have been trying new things with recipes since the second batch. Now, maybe I'm taking more creative credit than I'm due, because I usually start with a recipe. I then adjust it for my setup, ingredients on hand, ingredients available at the local HB shop, my whims, etc. Doing this, I've only really screwed up one batch due to poor recipe formulation, and I used it for boiling brats, etc. so it wasn't a total loss.

The biggest variability I found was with hops. Once I found Rager's formulas in the Zymurgy hops special addition, this went away. Of course, yeast is a big contributor, but with some common sense, you probably can't pick a yeast that will ruin a brew. The grain affects final flavor in a big way too, but again, you won't ruin a batch by picking an American 2-row rather than a Belgian 2-row. It will be different, and you may prefer one over the other (I bet I know which one!) but it won't be bad.

With John's experience, he should be experimenting a lot, IMHO. Maybe I screw around too much but then I'm not out to win contests. I'm only out to brew a beer I really like. For me that means variety, and variety means experimentation, which is a major reason I homebrew. I guess I've rambled enough about this. Comments?

Subject: Yeast FAQ corrections

First off, 3 cheers to Patrick for the effort in compiling all that yeast information!

I have a few additions and corrections, however:

- > Lallemand Nottingham Yeast
- > This yeast is remarkable for its high degree of flocculation. It settles out very quickly and firmly.
- > Very good reputation. Very fast to create a krausen and needed blowoff tube 6 hours after pitching hydrated yeast. Quick fermentation at 62F. It's very clean and only very slightly fruity in the keg, but tastes/smells nutty in the bottled version. Nottingham appears to be relatively attenuative (more so than the Coopers).
- >
- > Lallemand Windsor Yeast
- > Produces a beer which is clean and well balanced.
- > This yeast produces an ale which is estery to both palate and nose with a slight fresh yeast flavour. Very good reputation. Not a quick as the Nottingham. Not attenuative. Definite banana smell at racking.

According to two fellow Brewers of South Suburbia, Dick and Steve, the Windsor is more powdery (doesn't flocculate as well) as the Nottingham and thus tends to be more attenuative.

- >
- > Munton-Fison Ale Yeast
- > Starts quick. Produces some fruity esters. Attenuative.
- > Phenolic taste. Fair to good reputation.

I believe I was the one who reported the intense phenolic nose and flavor with M&F "Muntona" yeast. It appears, however, that they have gone to a new strain and a recent batch I made had none of the phenolics I reported earlier. I've read that improper rehydration (rehydration in wort rather than water) can lead to off flavors, so maybe that was the problem I had with the Muntona yeast.

>WYeast

First off, it's Wyeast and it's sort of a pun, since Wyeast is the Native American name for Mt. Hood which is not far from Wyeast Labs.

Also, a frequently asked question is "how do you pronounce Wyeast?" Well, it's pronounced like "WHY-yeast."

- > WYeast 1007 German Ale Yeast
- > Ferments dry and crisp leaving a complex yet mild flavour. Produces an extremely rocky head and ferments well down to 55 deg. F (12 deg. C). Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg. F (17 deg. C). A good balance of sweetness and tartness, with a pronounced green-apple note. A very pleasing yeast.

I did not get a green-apple note when I used this yeast. Perhaps it was just tasted young and it was actually acetaldehyde which is often found in young beers but later fades unless the beer is filtered (like Budweiser).

> WYeast 1028 London Ale Yeast  
> Rich mineral profile, bold woody slight diacetyl  
> production. Medium flocculation. Apparent attenuation  
> 73-77%. Optimum fermentation temperature: 68 deg. F (20  
> deg. C). Complex, woody, tart, with strong mineral  
> notes, this one will bite you horribly if you over-hop or  
> if your water is high in carbonates. If you avoid that  
> Scylla and Charybdis, it produces ales of marvellous  
> complexity and sophistication. Most of the time you'll  
> wish you'd used 1098 or 1056. Had best results in  
> porters. Over-hopping is especially bad, but if you  
> throttle the hops back, the results are indeed  
> marvellous. Used this yeast in a Kolsch once, and it was  
> \*fantastic\* The wood and mineral notes fused with the  
> Hallertauer hops (which were used with some restraint),  
> and a couple of months of cool ageing brought out some  
> green apple in the aroma as well as the palette. It  
> tasted a good bit hoppier than it really was, and overall  
> was well-balanced and smooth.

This is one of my two favorites (1056 being the other) and I've brewed some very high IBU ales with it without the overhopping problems reported here. Just 40 datapoints or so. Also, I'd like to mention that this yeast was used for the 1992 B.O.S.S. Challenge 1st place Barleywine, brewed by none other than Brian and Linda North.

> WYeast 2007 Pilsen Lager Yeast  
> Our original Lager Yeast Strain. Specific for pilsner  
> style beers. Known as many things, we call it Pilsen.  
> Ferments dry, crisp, clean and light. Medium  
> flocculation. Apparent attenuation from 71-75%. Optimum  
> fermentation temperature: 52 deg. F (11 deg. C).

It is worth mentioning that this yeast strain is reportedly used quite a bit in St. Louis, if you know what I mean ;^).

> WYeast 2035 American Lager Yeast  
> American Lager Yeast. Unlike American pilsner styles.  
> It is bold, complex and woody. Produces slight diacetyl.  
> Medium flocculation, apparent attenuation 73-77%.  
> Optimum fermentation temperature: 50 deg. F (10 deg. C).

This yeast allegedly is the one used by August Schell in new Ulm, MN.

> WYeast 2112 California Lager Yeast  
> Warm fermenting bottom cropping strain, ferments well to  
> 62 deg. F (17 deg. C) while keeping lager  
> characteristics. Malty profile, highly flocculant,  
> clears brilliantly. Apparent attenuation 72-76%.

Allegedly, the Anchor steam yeast.

> WYeast 2124 Bohemian Lager Yeast  
> The traditional saaz yeast from Czechoslovakia. Ferments  
> clean and malty, rich residual maltiness in high gravity  
> pilsners, medium flocculation, apparent attenuation  
> 69-73%. Optimum fermentation temperature: 48 deg. F (9

> deg. C).

Allegedly, one of the four (?) Pilsner Urquell yeasts.

> WYeast 2308 Munich Lager Yeast  
> Lager yeast from Wissenschaftliche in Munich #308. One  
> of the first pure yeast available to American home  
> brewers. Sometimes unstable, but smooth soft well rounded  
> and full bodied. Medium flocculation, apparent  
> attenuation 73-77%. Optimum fermentation temperature: 50  
> deg.F (10 deg. C).

I'd like to mention that I got an intense off aroma (like home perm solution) with this yeast fermented at 45-50F, but it miraculously disappeared after four months aging in the bottle at 40F.

> WYeast 3056 Bavarian Weissen Yeast  
> A 50/50 blend of *S. cerevisiae* and *delbrueckii* to produce  
> a south German style wheat beer with cloying sweetness  
> when the beer is fresh. Medium flocculation, apparent  
> attenuation 73-77%. Optimum fermentation temperature: 56  
> deg. F (13 deg. C). Problematical to get the right  
> flavour, often just produces bland beer, without the  
> lactic flavour.

No, no, no. Lactic sourness is the requisite characteristic of a \*Berliner\* weiss, not a Bavarian weizen -- Bavarian weizens are characterized by clove-like aromas/flavors and often some mild banana esters. What the original poster probably meant was: "Problematic to get the right flavor, often just produces relatively unattenuated beer, without the clove-like aroma/flavor." I have been thinking that perhaps it's the freshness of the Wyeast #3056 that makes the difference in whether you get the clove-like aroma/flavor or not. Any other data points?

> Red Star Pasteur Champagne Yeast  
> Very attenuative. Good for mead. Good reputation.

Popular yeast for Imperial Stouts and Barleywines due to it's high tolerance for alcohol. Some use it by itself, others pitch Pasteur after their chosen beer yeast poops out.

>Part 1: Hydration Procedure For Dry Yeast

>  
>a. Use 14 grams of dry yeast (usually 2 packets) per 5 gallons of brew.  
> \*\*\*Rigorously\*\*\* sterilize everything used in the hydration procedure.  
>  
>b. Add the dry yeast to 1/2 cup of water at 90F (32C). Leave for 15 mins.

According to the Lallemand newsletter, the proper temperature for rehydration is 104F to 110F. Also, you may want to mention that this should be boiled and cooled water, so chlorine is boiled off and so the water is sanitized. You would be surprised at how literally some people take directions!

>know what the problem is with doing this. Please, someone, set me  
straight.  
>I'd like to get the facts.

I think the most important reason is to avoid aerating the hot wort. It  
would be okay to instead \*gently\* pour or (even better) siphon the hot  
wort  
into the cold water. Once the temperature of the wort has dropped to  
below  
80F (that's the commonly agreed upon temperature) you should then aerate  
the heck out of the wort, but not while it's still hot. Before I built  
a wort chiller, I used to gently lower blocks of boiled-then-frozen water  
into the kettle and then topped up the fermenter with boiled-cooled  
water.  
I noticed a BIG difference in the flavor and stability of my beer. I  
think  
you will too.

OOPS!

It was actually Al Korzonas, from Sheaf & Vine Brewing Supply, that called the manufacturer and emailed me the proper dosage (1 tbsp/gal) for B-Brite.

Sorry, Al

And THANKS!

jim

-----

11) Coil this using your favorite round object as a form. I used my old 5 gallon brewpot. Zip tie the coils together.

I attached 3/8" id plastic tubing to each end of the chiller. For the "in" end, I attached a 3/8" od copper racking cane. I hose clamped a copper Chore Boy scrubber to the end of the racking cane, to filter out hop particles.

To sanitize, I siphon iodophor solution through the chiller into the carboy. To start the siphon, put a female garden hose to 3/8" hose barb fitting on the "out" end and attach it to a water source, Place the "racking cane" into a bucket filled with sanitizer. Then run the water until all the air is removed from the system, disconnect the water source, and place the "out end" lower than the "in end" immersed in sanitizer. I use this same method to start the siphon from the hot wort (remember not to blow bubbles into the hot wort though).

This design works very well. I was able to drop boiling wort to within 5 degrees F of the tap water temperature. I found three drawbacks: 1) The flow is very slow. It took about 20 minutes to siphon 5 gallons through the system. 2) a fair amount of wort is left in the tubing then the siphon quits. 3) a fair amount of wort is left amongst the hops in the bottom of the brew kettle. I have a small food grade pump which I may attach to the outflow of the chiller next time I use it, which should solve #1 & #2 and help #3.

I may also add another, bare copper coil between the outflow of the CF chiller and the carboy. This coil will be immersed in a small ice bucket. This will minimize the amount of ice needed, and get that final, desirable drop in temperature.

From: nexgen!bart@olivea.ATC.Olivetti.Com (Bart Thielges)  
Subject: re-priming results

As promised, here are the results from my attempt to recarbonate a partial batch of ale. This is a follow up to last week's response to Robert Pulliam's question about rebottling beer that has already been kegged. I can now comment on the results.

First, some history of the batch. It was brewed from a Boot's "mild" kit combined with 4lbs of unhopped amber extract. The following dates refer to time relative to the initial priming/kegging/bottling :

day 0 - batch is combined with 1/2 cup corn sugar and mixed in a 5 gallon cornelius keg. 2.5 gallons are then siphoned off into bottles.

day 2 - After noticing that the keg does not build up any pressure, I finally figure out an error that I made in reassembly. The error is corrected, but I am even more suspicious of the viability of the kegged beer. 1/3 cup of corn sugar in boiling water is added to re-prime the beer. About 1 gallon is siphoned off into bottles, leaving about 1.5 gallons in the 5 gallon keg. The relief valve at the top of the keg is left open overnight to allow air to be replaced with CO2.

day 12 The kegged beer is sampled. The keg starts with about 20psi and is relieved to about 5psi for dispensing. It is iced down from the cellar temperature of 70F to 50F. It tastes fine.

day 15 The kegged beer is iced down and sampled again. Now it has developed a harsh unpleasant bitter taste. Making the assumption that the lowered pressure has somehow activated a "bad" mode of yeast growth, I repressurize to 20psi.

day 16 The taste test. (see below)

The taste test involved comparing the three different sub-batches. Batch A is the originally bottled beer from day 0. Batch B is the beer rebottled on day 2. Batch C is what remained in the keg. Here's the comments from the tasters :

Batch Taster 1 Taster 2

- - - - -

A Tastes good. mature Tastes fine, full bodied

B Good, but a little "green" Like batch A except much more carbonation and a little thinner.

C Like batch B, but flat too bitter, a bit flat

So, one conclusion is that the re-priming technique seems to work well at the expense of losing some of the body. If it were re-primed with DME, perhaps the body could be preserved. In retrospect, 1/3 cup of corn sugar was too much for the repriming.

However, I am somewhat baffled about why the beer turned harshly bitter between days 12 and 15. This is the second time a kegged

batch turned out with this bitter taste. The first keg started out bitter even when filled to 5 gallons. It did however, have a long ride in the back of a car soon before tapping.

These bitter kegged beers are somewhat disappointing. So far, I have yet to get a good batch of beer from a keg. My bottled beers do not exhibit this problem. Does anyone have any guesses as to why my kegged batches are turning bitter ? Surely 100s of homebrewers using cornelius kegs can't be wrong.

Until I can figure out what is going wrong, Mr. Cornelius Keg is on probation.

From: Victor Stevko (Human Genome Center, LBL) <stevko@genome.lbl.gov>  
Subject: hydrogen peroxide

DO NOT DRINK Hydrogen Peroxide! Gee whiz - look at your logic: hydrogen and oxygen aren't poisonous, you say. Sodium and chlorine ARE, yet table salt, sodium chloride, is an essential nutrient. Besides, even granting your (incorrect) logic, oxygen IS poisonous. Oxygen damages your body. Vitamin C is supposed to do its job by being an anti-oxidant - any connections? Your body does a great deal of work trying to keep oxygen, which, yes, is essential, from damaging you beyond repair. Honest- I did

a thesis on a related matter.

The super-oxidation of solutions you refer to IS the chemical reaction you are looking for - it breaks down proteins, lipids (fats), cell walls, etc.

That's how it kills bacteria as an antiseptic

Data point: Viruses don't respire aerobically or otherwise. An anaerobic

virus is a meaningless term.

Data point: Warts come and go, often spontaneously.

In beer, hydrogen peroxide will kill your yeast. Remember, it's supposed to stop infections?

Data point: There is a POISON label on that bottle oof peroxide. Why might it be there?

Mr. Childers, I am sorry to be so vehement, but I fear you are doing yourself harm. Stop drinking hydrogen peroxide, and do deep breathing exercises, if you want more oxygen. Call the researchers you refer to, and ask them about this, if you must. But do the research before the experimentation with your health and life - please.

Subject: Strike temperature

Until recently, I mashed using a Bruheat boiler (a brewing bucket fitted with thermostat and element), but I became dissatisfied with the poor control of temperature, hot spots near the element etc. I've now bought an insulated mash tun (actually a picnic chest with tap and slotted pipe sparge manifold).

This is probably an FAQ, but can someone tell me the specific heat capacity of crushed malt, so that I can heat my strike liquor to the right temperature (65C)? Dave Line's books don't seem to take the mass of grains into account when calculating strike temperature. Alternatively, could you tell me what mass of grains you use and at what temperature, the volume of water and strike temperature, and the final mash temperature, so that I can work it out for myself.

Thanks

Andy Phillips

From: neal.ridgeway@mms.raleigh.nc.us  
Subject: ICE-BREWED BEER

A friend of mine just returned home from Canada and he told me of a new slogan being used by the Canadian breweries. He said they were now selling "Ice Brewed" beers! I asked him if he didn't mean "Cold Filtered" and he assured me that it wasn't cold filtered or ice filtered but "Ice Brewed". He told me he like Labatt's the best, but also like Molson's, Carling Black Label, and others.

Is this something new in brewing like "Dry Beer" was or are we talking about the old process of Lagering?

Also - Like JS, I have used an aquarium pump to try to aerate my new batches of ale. For me it just never did as well as my old reliable 18 inch stainless steel 3/8 inch tube with the 4 1/16 inch holes drilled 2 inches from the top. With my SS Keg/Boiler sitting at approx 3 feet of the ground, approx 2 feet of 3/8" ID vinyl tubing connecting the spigot of the boiler to the SS tubing, when I open the spigot and start pouring 65-70 degree wort into my primary, the air rushing through the holes in the SS tubing COMPLETELY aerates the wort. When finished there is a good 12 inches of foam protruding out of the fermenter.

Hoppy trails to U.

From: ghultin@sfu.ca  
Subject: water, beer in BC, homebrew data

I enthusiastically second the kind of info Bill Flowers called for regarding water alterations. I have never fooled with my water, but it would be nice to see some more straightforward talk and less scientific language (which is difficult for me, a non-science type to understand).

Beer in BC. There are several microbreweries in BC. Don't be fooled by the name however, my experience (limited) with Seattle micros suggests that BC micros are smaller versions of the big brewers. Sure, Okanagan Spring, Whistler Breweries make good beer, but they do not have a diverse range of product, tending to stick with what sells in our relatively small canadian market. Don't even bother with Granville Island beers, they aren't worth it. If you've tried Canadian you've had these supposed micro beers. (actually, it's not that bad, but the general drift of meaning is there).

I do recommend Horseshoe Bay breweries. But Best for Last, go to Spinnakers Brewpub in Victoria. It is close to downtown, just the other side of the blue lift bridge, and they have wonderful brew, and a wonderful variety. Swann's Brewpub is also a good choice in Victoria. I tend to favour Spinnakers, but that's personal choice for you.

Finally, I would be most interested in any collected database of homebrew oriented information. If this collection does get made, are there any plans to share/post/distribute it? I would enjoy a copy.

geoff.

From: carlson@61.267.ENET.dec.com  
Subject: FWD: It was foamy with a mature flavor ...

LONDON (UPI) -- Divers exploring the wreck of a Royal Navy ship that sank near the Isle of Skye off Scotland during World War II have recovered a small treasure -- 48 bottles of beer, unopened and unspoiled after 50 years on the sea bed, officials at the Whitbread brewery said Tuesday.

The divers, members of the Hartlepool Diving Club, were exploring Royal Navy mine-layer HMS Port Napier when they discovered the cache of Whitbread beer in the ship's galley. When they brought the bottles to the surface, they sampled the brew and found it still drinkable.

``It was foamy with a mature flavor and you could still taste the beer,'' said Tony Brumwell, one of the divers.

The divers handed over some of the beer to Whitbread's Castle Eden brewery for testing.

``Beer is not meant to last a long time but our brewers are interested in analyzing it to test its condition and alcoholic content,``

said Whitbread Regional Director Jim Kerr.

A fire broke out on the HMS Port Napier in 1942 as it started out on a mine-laying mission. It sank in 80 feet of water. The navy later salvaged the mines from the vessel but the ship remains on the sea bed and is a favorite for exploration by divers.

From: "John R. Calen - Contacting Systems - E.F., N.Y" <calen@vnet.IBM.COM>  
Subject: RE:Grolsch Bottles and Carbonation

Philip J. Difalco suggests that contracting gaskets from the cold of his refrigerator may lead to reduced carbonation in his beer.

I disagree.

Assuming that the conditioning is finished, the "problem" is more likely the vapor pressure of the brew. The apparent carbonation is a function of temperature and atmospheric pressure.

Basically, beer with a given content of Carbon Dioxide in solution, will bubble more vigorously when it's warm than when it's cold. (Also on a rainy day vs. a sunny one. But that difference is slight.)

It's very likely that the one which is 40 degrees F or so cooler than the other will appear less carbonated.

Getting the thing nice and chilly is a good way to help offset the effects of an overcarbonated brew. In fact, I've got a batch right now that will gush if merely cooled, but is manageable once chilled. (Though it still needs decanting. Hey, I thought it was done!)

Regards,  
John Calen

Subject: reLYeast culture kits & shipping

In the last digest,

<Date: Fri, 13 Aug 1993 22:40:57 -0400 (EDT)  
From: Jim Griggers <brew@devine.ColumbiaSC.NCR.COM>  
Subject: Shipping live yeast

<I bought a "Yeast Culture Kit" from ~~\_\*deleted\*\_~~ when I was at the AHA Conference in Portland. I had been thinking of buying one for some time, and their "special show price" of \$29.90 seemed great.

<The yeast arrived Friday in a plain manila envelope in the US Mail. My mail box is a standard flat-black metal rural box that spends 75% of its time in direct sunlight. Today is fairly cool (90F) and mostly cloudy. The temperature inside the box was around 105F. I guess I am lucky in that: 1) I was home, 2) I checked the mail early, and 3) today has mostly overcast skies.

I exchanged email with Jim, and just wanted to clarify that the kit in question was **\*NOT\*** from the Yeast Culture Kit Company. I was a bit concerned of this, thinking that there is a supplier that is not following the preferred methods of shipping. When shipping yeasts in the hot hot summer, it is most definitely a good practice to fork over the 6 bucks and get fast delivery. The yeast may be fine, it may not. A small test ferment is in order to ascertain the condition of the yeast.

Good brewing,  
Jim Busch

From: Mike Zulauf <zulauf@orbit.Colorado.EDU>  
Subject: withholding grains until after conversion

Hi everybody!

Now that I have my Gott insulated mash/lauter tun all set and ready to go, I have a couple quick questions.

I have heard from numerous different sources of the benefits of leaving any crystal malt of the mash until after conversion. This supposedly keeps the complex sugars in the crystal malt from being reduced to simpler, more fermentable ones, and has the effect of yielding a maltier tasting beer.

My first question is, how many people do something like this? Does it work?

Also, what other grains would benefit from this treatment? I've heard rumbles that dextrine malts might as well, but I would like a little more reassurance before I try it.

Thanks,  
Mike

From: "Phillip Seitz" <p00644@psilink.com>  
Subject: Visiting Los Angeles

I will be in the Los Angeles area (mostly mid-town and Orange Co.) from this Saturday, August 21 through Thursday, August 26, and will likely have a lot of evening time to burn. Can anybody recommend any beer-related venues where I should spend my time?

More to the point, are there any brewers out there who'd like to meet up? A Maltose Falcons meeting?

Please send any suggestions to me via direct e-mail, and TIA!

From: Stephen Brent Peters <sp2q+@andrew.cmu.edu>  
Subject: top fermenting infection?

Last may I used the last of my malt extract to make a smoke lager. I made the mistake of using yeast that hadn't seen fresh wort in six months and the fermentation took off very slowly and never picked up much speed. It fermented over a month in the fridge with no sign of stopping, and being an impatient person I took it out so it would finish up faster. It didn't. Even the heat wave didn't finish it off.

Finally two weeks ago I tasted it. Sour. Infected. Tasted terrible. So, two days ago I finally get around to dumping it out. After the first few inches of beer gurgled out of the carboy I noticed the beer aroma had improved. I poured myself a glass, and sure enough the bad flavor was gone! What's happening here? Shouldn't the whole batch be as bad as the stuff on top? Has anyone else ever experienced anything like this?

Subject: yeast FAQ comments/Zymurgy Bashing/more yeast comments

Patrick writes:

> a. Place the starter jars in a location where 68F (18C can be held).  
Aerate  
> twice daily by vigorously shaking jars. 1L Erlenmeyer flasks are  
excellent  
> for this purpose because they permit vigorous swirling without getting the  
wort up by the neck and opening.

Yes, but I've read that although fermentation may be done at lower temps, 80F is a better temperature for starters. Remember, you're trying to increase your yeast bulk here, not make beer. Also, 1L Erlenmeyer flasks are extremely expensive from most places, unless you buy in bulk. If you're interested in a source for inexpensive 250ml, 500ml and 1L Pyrex Erlenmeyers in single-quantities, email me.

Another interesting point is that if you use a glass airlock, you can put that in your pressure cooker or autoclave (this is definately NOT recommended with a polystyrene airlock!). Jack Schmidling gave me a great tip that I use when I make starters on the stovetop: put an empty glass airlock on the flask and let the boiling wort's steam sanitize and FILL the airlock too! Again, don't try this with a plastic airlock (YUCK!).

> d. It is also desirable to reduce the temperature to a point closer  
> to the temperature that will be used in production if that is  
> lower than 18 C. For example, with lagers fermented at 10 C, this  
> is usually taken to be 14-15 C.

Yes and this should be done slowly. You should \*slowly\* lower the temperature of the starter to the temperature of the wort into which you will be pitching. A few degrees difference is okay, 10 degrees may increase your lag time, 20+ degrees may shock your yeast so they are never quite the same.

> a. At this time you should have a jar with about 500ml (a little more  
than 2

beer  
> notes so that you can learn from experience!

This goes against what I've found to be true. Pitching \*just after\* the krausen dies down is just about ideal. Quoting Mike Sharp:

MS> what I really wanted to address was the 'you should pitch at high  
MS> krausen' myth. Research has showed that you actually want to  
MS> pitch just after the cells have entered their stationary phase.  
MS> (thats the stage after high krausen when the yeast begins to

MS> flocculate). The reason for this relates to the glycogen level  
MS> (think of it as the cell's gas tank) in the cell. During high  
MS> kraeusen the cells are rather depleted of glycogen and are less  
MS> able to multiply. This results in slow starts, a possible  
MS> increase in sulfur dioxide levels, and a host of other problems.  
MS>  
MS> The reference I have at hand for all of this is:  
MS> Impact of Yeast-Handling Procedures on Beer Flavor Development

> sterile water and add immediately to the wort. A short exposure to  
water  
> will not harm the yeast, although they should not be exposed to it for  
long  
> periods or they will lyse.

I don't think the spent starter liquid should be oxidized or was exposed  
to  
air. If you've had activity in the starter, the air in the flask has  
been  
displaced by CO2 created by the yeast. It's not a big deal if you pour  
it  
off or pitch it. The main reason for pouring it off is if you want to  
make more yeast but you don't have room in your flask. You can then  
pour off the liquid and add fresh, sterile wort.

>(v) Autoclave the tubes at 15 psi for 5 mins.

Actually, 15-20 minutes is recommended.

>(vi) Tighten the caps on the tubes, and place them at a  
> 30 degree angle. Allow them to solidify at room temperature.  
> Solidification should become apparent within a few hours.  
> Tubes which are not solid after 24 hrs. should be discarded.

You should let the tubes cool quite a bit in the autoclave/pressure  
cooker  
before you tighten the caps. If you tighten them when they are too hot,  
they will implode. I let everything cool overnight in the pressure  
cooker.

>Note: Petri dishes can not be autoclaved, and so alternate procedures  
are  
>needed for them. A common practice is to autoclave the malt/ agar  
solution in

No, no, no. You mean disposable, polystyrene petri dishes cannot be  
autoclaved. Polypropylene and glass petri dishes can be autoclaved. I,  
personally, don't like to use disposable anything, so I've found a source  
for glass petri dishes. Email me for a single-quantity source.

Gosh, I hope I don't sound too negative about Patrick's posts -- they  
were

a lot of work and, he has said that they are collected from various sources. These sources are not always 100% on target and therefore some minor errors are inevitable. Again I must tip my (HopUnion) hat to Patrick for a well-done piece of work.

\*\*\*\*\*

Subject: re:Zymurgy bashing

I'm with Jim Busch on this topic -- Zymurgy and the AHA in general have been making efforts to improve and I, for one, am glad to see that they are soliciting more input from us.

\*\*\*\*\*

More from Patrick:

> Yeast are unicellular fungi. All brewing yeast belong to the genus  
> Saccharomyces.

Ahem, since I occasionally brew Pure-culture Lambieks, I take great exception with this statement. There are a great many different genus of yeast that play a role in Lambieks, for example, Brettanomyces. See J.X. Guinard's book Lambic for a detailed discussion of all the different microbiota that work in concert to make this most complex of beers.

From: CCAMDEN@delphi.com

**Subject: Your favorite supplier?**

OK, my first batch is busy bubbling away. (Is it normal to go in and just look at it every so often?) And I am already looking forward to the next time.

My local homebrew store is really just a health food store with a corner devoted to brewing and wine making. However, not only is their stock limited, but I question how old some of the stuff is. So I have been calling a few mail order suppliers and requesting catalogs. In a few days I will get 5 or 6 and then I will have to decide who to use.

So, help me out. Who is your favorite mail order supplier? Which one seems to do the best job? I welcome any and all opinions.

Email replys welcomed. (I'm sure this would be old hat to most.)

Thanks, Cary Camden

From: Davin Slade <10692851@eng2.eng.monash.edu.au>  
Subject: Boiling

I am only new to the brewing idea so please forgive my ignorance.  
When people talk about boiling is this to produce the syrup that you  
can buy in the can from the homebrew shop. ie to make your own taste.

If so i assume you add the yeast later after it as cooled to the  
temperature for brewing.

Subject: my own hops

Howdy !

It's time to harvest hops down here in Germany, so I took a look and found some very good looking plants in close vicinity to my parents' house. I have two resulting questions:

1) it's most probable that these are "wild" hops. Are these useable for homebrewing anyway ?

2) if I can use these hops - how can I measure the amount of alpha-acid so I know how much to use of them for my next batch ?

Thanks in advance for any response !

Matt

From: Tom.Weicht@arrc.ncsu.edu  
Subject: C. cerevisiae taxonomy?

Respond to: deb\_neher@ncsu.edu

Re: S. cerevisiae and taxonomy, 1 of 2 (The most important IMO)

I originally had this posting over 8K. If I can post more than 8K per day, the other will follow today. Other wise, the other will follow tomorrow. There are more direct answers to others posting on this subject in 2 of 2.

The main point I wanted to make in my first posting was that in industrial/commercial culture collections taxonomy is often perverted for a variety of reasons, and as a result, caution should be used when accepting a classification as RIGHT or dismissing a classification as WRONG. The requirements for proof of a species may be beyond what is possible for every isolate used in fermentation when the current genetic status of commercial yeast cultures make this difficult at best, and impossible based on traditional taxonomic approaches. The fermentation sciences do not hold to the same naming convention as other practical sciences using mycological taxonomy. This could ultimately result in few vegetatively propagated isolates which have been in the industry for a long time, but incorrectly classified as *S. cerevisiae*. The fungi unlike other organisms can be correctly classified under more than one latin binomial. The ideal latin binomial for a fungus is the one reflecting the sex reproductive stage or teleomorph. However, a fungus (or fungal culture) which does not readily show this stage, but also, has an asexual reproductive stage or anamorph will have a latin binomial related to this stage, these are the Fungi Imperfecti. Therefore, in order to resolve controversy over a yeast's teleomorphic identity, in the case of the Saccharomycetaceae, the asci and ascospores would have to be produced. However, many commercial isolates have lost their ability to sporulate. This is the result of polyploidy (multiple genomes; greater than 2x the haploid or diploid) and aneuploidy (a genome which is not an even multiple of the haploid). This genomic status is important to the fermenting and baking industries because of the genetic stability and minimal susceptibility to mutation multiple genomes confer on an isolate. Laboratory isolates of species of the Saccharomycetaceae are often relatively stable haploids and diploids. Because of asporogenous ambiguities many authors address the species "*S. cerevisiae* (sensu lato or s.l.)" = "*S. cerevisiae* (in the broad sense)" suggesting that it may be a complex of organisms which deserve other classifications. Therefore, best source for understanding the asporogenic brewing yeasts will be the tools of molecular genetic: mapping, probing (genomes, mitochondria and ribosomes), restriction fragment length polymorphism, and random polymerase chain reaction patterns (PCR fingerprints). Fungal genomes are large and the necessary technologies are just becoming widespread enough so that probably much information will be available in the next few years. Currently, most research seems to be with laboratory isolates.

Based on classical taxonomy, the anamorph of yeasts used in brewing may be best, or most confidently, classified as *Candida* (*cerevisiae*??). The precedence established in the *Sylloge Fungorum* by Saccardo, has the hierarchy of characteristics used to classify the Fungi Imperfecti as follows: Conidia (spores or buds) take precedence over mycelial structures. A description of the genus

from Barnett and Hunter, Illustrated Genera of Imperfect Fungi reads: Mycelium not extensive; conidia (blastospores) hyaline, 1-celled, ovoid to fusoid, forming short chains by budding. Because of Saccardo's precedence to spores, I am ignoring mycelium in the description. The ontogeny of blastospores is identical to budding. The down side of this classification is that it is uninformative. This genus is basically a trash can. *Candida* has members which are both basidiosporogenous and ascosporeogenous.

When addressing a fungus in standard communications, most other sciences use a name which applies to the morphological stage which dominates process. For instance, if a vineyard were inoculated with *Botrytis cinerea*, it would be called *Botrytis* (anamorph) and not *Sclerotinia* (teleomorph). Even in brewing, when addressing the organisms which occur in a lambic, *Brettanomyces* (anamorph) is used over *Dekkera* (teleomorph). That the teleomorph *Saccharomyces* is used over an anamorphic classification in commercial industries could be the result of several circumstances. First, as stated earlier, the genus *Candida* is uninformative while *Saccharomyces* is more informative because it is a narrower description. In the above examples where anamorphs are used over the teleomorph, the anamorphs are very narrow and relate directly to one teleomorphic genus and are therefore, very descriptive and informative. The other reason *Saccharomyces* may be used over an anamorphic name may relate to a historical precedence. Almost certainly the past fermentations would have contained asci and selection toward asporogenous cultures occurred because of man's selective pressure. Because of this previous association, *Saccharomyces* was linked intimately with the nomenclature surrounding the fermentation process and because changing the nomenclature denotes less information there has been no strong pressure to change.

However, to call an isolate *Saccharomyces* spp. when only an asporogenous cultures exists has it liabilities because there is the connotation of sexual relatedness which may be unavailable. Further, because of the economic potential of these organisms there is probably much information not in the public domain. To feel secure about a particular classification of a particular isolate used in brewing or to rule another one out is probably not wise. Older more established collections of asporogenous yeasts are potentially sources where a few incorrect classifications may be found because of the fluxes which occur in the taxonomy of the entire subfamily *Saccharomycetoideae*. There is no basis upon which to classify a yeast if it only buds. Modern molecular tools and researchers studying these yeasts will establish the new basis of classification by comparing their results with traditional taxonomy. I doubt any of us have access to the teleomorphs the fungi in question or can find the appropriate citations describing these asci and ascospores in the detail required to make an independent judgement, and proof if it exists in the literature is probably buried in an article with a title like "Authentication of ATCC Strains in the *Saccharomyces cerevisiae* Complex by PCR Fingerprinting". I suspect that as more isolates are studied with the tools of molecular genetics these organisms will be shuffled and reshuffled for years to come.

Not all isolates are asporogenous, many are only difficultly sporogenous and some are relatively easily sporogenous. If any body on the HBD has information on this relative to brewing cultures I would like to know.

Subject: Taxonomy Debate

REspond to: deb\_neher@ncsu.edu

Re: S. cerevisiae and taxonomy, The debate, 2 of 2.

I originally had this posting over 8K. I would have preferred some of this prefacing 1 of 2 and some of this as post script to 1 of 2.

I would like to start by saying that I appreciate the feed back from my original posting, and I like debate as a way to refine my ideas; PLEASE DON'T TAKE ANY OF THIS AS A PERSONAL ATTACK or AN OUT OF CONTROL FIRE-FIGHT; I plan to be polite. I revisited some of the ideas and expanded on a few others in my second posting on this subject; particularly some of the subtleties of mycological taxonomy and certain areas of conflict and incongruities which have shaped my thoughts and prejudices on this subject area. Unlike just about any other area there is the potential for a great amount of debate on taxonomy.

First off, I want to say after rereading my original posting, I feel much of the response coming from it originates from an over statement of my position:

"Saccharomyces delbrukii or S. cerevisiae?? I personally believe both are technically incorrect. From the best that I have been able to find in the mycological taxonomy literature, the true name of this organism is Torulospora delbrukii, this is how the American Type Culture Collection lists it which sparked my interest and pursuit of this subject."

A more appropriate stating would have been:

"Saccharomyces delbrukii or S. cerevisiae?? I personally believe both MAY BE technically incorrect. From the best that I have been able to find in the mycological taxonomy literature, the true name of this organism is Torulospora delbrukii, this is how the American Type Culture Collection lists it which sparked my interest and THOUGHTS ON this subject."

Admittedly all I have ever looked up on this subject was the description of the teleomorph (sexual reproductive stage). Like several of the other posters (responders) both public and private, all I have found from the standard data base literature search on the subject was the reference to wine, and although I was tempted to acquire the ATCC isolate, I remember refraining because this isolate had not come from a brewing source. I suspect that if there is a publication in support of Wyeast, it is probably in molecular genetics article on S. cerevisiae and will take time to ferret out, ie. Computer data based searches on the obvious are probably incomplete. I have not prioritized this subject high enough to have done this work yet.

By the way I was reexamining my latest Current Contents search and found this citation.

Author JL Huffman  
Title Authentication of ATCC Strains in the

Saccharomyces cerevisiae Complex by PCR  
Fingerprinting (Vol16, Pg 316, 1992)  
Source Experimental Mycology 17: 2 (JUN 1993)  
Page 155

(It looks like there may have been two sources?? This is how I sucked it up from the search.)

I could conclude that I fell into a Wyeast myth as some of the posting have suggested. Admittedly, I made the assumption that there was some truth in their classification. Although there are fraudulent products available to the HOMEBREWER, I assumed there was no profit motive in this and thus, no reason to deceive the HOMEBREWER. (Antidotal reports suggest that since Siebel lost the contract for the Witbread yeast one distributor still distributes a yeast under that name; this APPEARS to be FRAUDULENT.) In fact, wouldn't the market place be more receptive to classifying this yeast as the classic weisbier yeast? HOWEVER, to base a classification on a classification in Weihenstephan is to make the same assumption I made. The only difference is that Weihenstephan is more sentimentally favored over Wyeast. (See explanation about asporogenous classification in the previous posting). The next issue of The Yeasts a Taxonomic Study will probably be a good source to settle some of our current issues of debate, but as the current issue YTS III seems to already have been surpassed by the research in the area of classification it too will also become out dated quickly (see the second half of my first posting where *S. carlsbergensis*, may be better classified as *S. pastorianus*). IMO there will be a explosion in taxonomical rearrangement as more isolates are tested with the tools of molecular genetics.

Because of the asporogenous nature of some isolates classified as *S. cerevisiae* the current status of the species is that of a repository for many isolates which may not be proven true members of the species. ie. *S. cerevisiae* has become a taxonomic trash can to a limited extent. Essentially, this status diminishes the information that can be concluded based on classification alone. It maybe interesting to contact Wyeast and see if they would share their source for classifying their isolate and if it is related to the Weihenstephan #68. I will write them a letter when I have time again to write some thing, and I will share this response if I get one.

Again, if there is a source of information about which isolates are sporogenous please inform me. I would enjoy proving the taxonomic status of any questionable isolates, and I am happy to change my opinion about the isolates in question.

I should include a small biography to let readers know where I am coming from, but I written a lot and have taken more time than I have for my brewing hobby. I'm too lazy to say much more than: I have two degrees in Plant Pathology (under grad and masters) from UC Davis. I have had two mycology courses in my history, an undergrad and grad, one of which I have also TA'ed. The grad version was an eclectic mix of every taxonomical opinion ever sustained in the discipline for more than one author. I collect slime molds as pets (for real) and pursue *Chantharellus* and other edibles in the woods regularly. I have published one key, but to tomato diseases not fungi, although a small fungal/pathogen key is part of the whole.

From: "Rick (R.) Cavasin" <cav@bnr.ca>  
Subject: re:WORT AERATION

Jack,  
Just a little quibble with your experiment. I wonder if there isn't one confounding variable you've overlooked, namely, fermenter geometry. The surface area/wort volume ratio, and the amount of head space in the quart jar fermenters is radically different than what most people would encounter in normal sized homebrew batches, even for people doing open fermentations in buckets. (people using blowoff tubes would fill their carboys near full, resulting in small surface areas with almost no headspace). I wonder if the rate of diffusion of oxygen from the headspace into the wort doesn't compensate for the lack of aeration in your 'control' sample. If people were using half empty carboys as primary fermenters (which I've done actually, got tired of fiddling with blowoff tubes and such - just split the batch between two carboys for the primary, then rack back into one for secondary), the comparison would be more valid. In the case of your lager test, is a starter/wort ratio of 1/10 typical? (don't know, don't do lagers myself)

Cheers, Rick C.

> calculating strike temperature. Alternatively, could you tell me  
> what mass of grains you use and at what temperature, the volume of  
> water and strike temperature, and the final mash temperature, so  
> that I can work it out for myself.

It depends on the moisture content of the grain, but a good figure is  
.4 c/gram.

You will most likely need to experiment in any case when you run your  
numbers. For single step infusion using my gott cooler with slotted  
copper pipes and assuming grain at room temperature (68F), and  
further assuming 1qt of water per pound of grain my strike  
temperatures are:

| Strike Heat  | Mash Temp    |
|--------------|--------------|
| 160F (71.0C) | 148F (64.4C) |
| 162F (72.1C) | 150F (65.5C) |
| 164F (73.3C) | 152F (66.6C) |
| 167F (75.0C) | 154F (67.7C) |
| 169F (76.1C) | 156F (68.8C) |
| 172F (77.7C) | 158F (69.9C) |

When I do an upward step infusion I use 24oz of water per pound of  
grain with a strike heat of 146F (63.3C) and I get a mash temp around  
122F (50C). For the second step I add an addition 1/2 qt of boiling  
water 212F (100C) per pound of grain and my mash goes to 150F (65.5C).

I find it best to add strike water at few degrees higher than I really  
want. I then let it drop to the correct temperature in my mash tun  
before adding my grains. This works best for me. Your mileage may vary.

Subject: re: Welding Stainless

In HBD1206, Brian Vandewettering asks about welding stainless steel. A year or so ago I made a boiler out of a Sanke keg and welding a nipple into the bottom was required. I took the keg to a "professional" welding shop and inquired. The welders comments re stainless were:

1. It's considered a white metal and arc welding is very difficult if not impossible.
2. MIG welds (Metal Inert Gas) contain cadimum. Poisonous and could leach into your brew, the welder said MIG's are never put on surfaces to be in contact with food.
3. TIG welds (Tungsten Inert Gas) contains no toxic metals, will weld white metals, very strong and non-toxic. This is what I had put on my keg and it's been fine for over a year.

TIG welding is an art, apparantly, so it may cost a little more. My job (weld 3 little legs and a nipple, 2 holes cut with a plasma torch) ran about \$45(CANADIAN).

I just tried a fantastic microbrew last night. It is from Bar Harbor, Maine, my home state. They have three brews: Real Ale, Pale Ale, and Coal Porter (a stout) They were all good, and I suggest trying some if you are ever in the area. They also give tours of there brewery, so check that out as well.

>Subject: Shipping live yeast

>The yeast arrived Friday in a plain manila envelope in the US Mail. My  
mail  
box is a standard flat-black metal rural box that spends 75% of its time  
in  
direct sunlight..... (I drive 80 miles, each way, to Charlotte, NC to  
buy  
yeast, so I usually stockpile.)

One of the great advantages of culturing one's own yeast is that yeast  
purchases become a very rare event, dictated more by wanting to try  
something  
new than by the brewing schedule.

An obvious solution to the hot mailbox is to purchase culture yeast in  
cool  
weather.

Actually "buying" yeast could become a thing of the past. I haven't  
purchased any yeast since the last time I used EDME. They have all come  
via  
swaps with other homebrewers.

It occurs to me that yeast swapping could be very effectively supported  
by  
computer networks. If we can use them to find out the names of pubs in  
a  
town to be visited, we should be able to just as effectively find a free  
yeast culture we want.

ATTN: YEAST SWAP

I will start the ball rolling by offering a PU culture for a good  
European  
red wine culture.

>I am NOT knocking the shop owner or ~~\_\_\_\_\_~~, but I am questioning  
their  
choice of shipping.

I thought it was YOUR choice. Didn't they offer air as an option?

> 69-73%. Optimum fermentation temperature: 48 deg. F (9  
> deg. C).

<Allegedly, one of the four (?) Pilsner Urquell yeasts.

Two rumors I would like verified here....

The first is the blending of (4) different beers from (4) different yeasts by

PU. This was reported in an article I just read but do not recall where.

Nothing of this sort was reported by Daryl Richman from his visit to the brewery.

I was told by "someone" and it may have been the owner of Wyeast that they do

not have a yeast from PU. It is similar but not one of their yeasts.

The yeast I use was obtained by Paul Farnsworth from PU and in a conversation

with him, he mentioned nothing about (4) yeasts. I would not have started

using it if it was just one of four used. I will call him but would like

some backup facts/rumors first.

From: Kelly Jones <k-jones@ee.utah.edu>  
Subject: Heat Capacity of Malt / Infusion Calculations

In HBD #1206, Andy Phillips asks about the heat capacity of crushed malt, to be used for calculations of infusion mashes. I have found that the number 1350 (where water is about 4200) to work well for me. I believe the units are J/Kg/K, but this is not important. Alternately, one could use the dimensionless number 0.32 for the malt, where water is equal to one. Of course, this will vary somewhat depending on the type of malt used, the moisture content of the malt, etc. but this should be a good starting point.

For those not familiar with these calculations, I will present them here:

First, let  
Cpm= heat capacity of your malt, about 0.32  
Cpw= heat capacity of water, 1.0  
Mw = mass of water used  
Mm = mass of malt used  
Tw = temperature of strike water  
Tm = beginning temperature of malt (usually room temperature)  
Tf = final temperature of mixture (rest temp)

Masses and temperatures can be in any units, as long as you are consistent.

The basic formula, then, is

$$(1) \quad T_f = (C_{pm} * M_m * T_m + C_{pw} * M_w * T_w) / (C_{pm} * M_m + C_{pw} * M_w)$$

This can be rearranged in many ways to solve for the desired unknown. For example, if we want to know the quantity of water to add to result in a desired protein rest temperature, we can write

$$(2) \quad M_w = C_{pm} * M_m * (T_f - T_m) / (C_{pw} * (T_w - T_f)) \quad \text{or, using the numbers for } C_{pm} \& C_{pw},$$

$$(3) \quad M_w = .32 * M_m * (T_f - T_m) / (T_w - T_f)$$

SO, suppose you have 4Kg of malt at 25C, and you want to add some quantity of water at 54C to achieve a protein rest temperature of 50C:

$$M_w = .32 * 4 * (50 - 25) / (54 - 50) = 8 \text{Kg of water}$$

These formulas can also be used to calculate additional water quantities to raise the mash temp further. However, different variables must be used: Instead of Mm, we will substitute Mmash, the mass of the mash, equal to the total mass of malt and water used so far; for Tm, we will substitute Tmash; and for Cpm, we must use Cpmash, calculated as

$$C_{pmash} = (C_{pm} * M_m + C_{pw} * M_w) / (M_m + M_w)$$

Thus, the revised formula (2) is

$$M_w = C_{pmash} * M_{mash} * (T_f - T_{mash}) / (T_w - T_f)$$

continuing our example, we have Mmash = 4Kg + 8Kg = 12Kg, Cpmash =

$(.32*4+1*8)/(4+8) = .773$ . Suppose our mash temp is still at 50C, and we want to raise it to 66C for a saccharification rest using some quantity of water at 100C. Then

$M_w = .773*12*(66-50)/(100-50) = 3\text{Kg}$  of additional (boiling) water.

Some simplifying assumptions have been made here, but they seem to work out just fine. (So please don't get on my case about enthalpies of mixing, non-additive Cp's, etc.) You may need to play around with the value of Cpm to get these equations to work out better for you. Also remember that your mash tun will absorb some heat, resulting in a rest temperature slightly lower than that predicted here. You may want to shoot for a degree or so higher to compensate. Note that your boiling water temp may not be 100C.

Equation (1) may be rearranged, if instead it is desired to know, for example, what water temperature should be used to obtain a given temperature rest for a given volume of water ( if one is shooting for some specific mash thickness).

Hope this helps (or did it just confuse the hell out of you?),

Subject: re: Wort Aeration

A comment on Jack Schmedling's experiment on wort aeration and my own experience.

Jack very interesting experiment. Thanks for running it and posting results. I have two questions/concerns about the small scale of your experiments.

1) I'm curious about the geometry of your small fermenters. Specifically I'm wondering about the relative amount of wort exposed to air and thereby oxygen. Let's call the specific area exposed to air Aa: This is

$$Aa = \frac{\text{area exposed to air (sq in)}}{\text{volume of wort (cubic in)}}$$

For a cylindrical fermenter this number will be:

$$Aa = \frac{\pi * \text{radius}^2}{(\text{height\_of\_wort}) * \pi * \text{radius}^2}$$

or

$$Aa = 1 / \text{height\_of\_wort}$$

For my glass primary with wort say 20 inches deep in it Aa = 1/20in or 0.05/in. For a mason jar with 6 inches of wort in it Aa = 1/6in or 0.17/in. So all your small scale fermenters have access to a lot more oxygen than my 'full scale' primary fermenter.

2) It's my understanding that oxygen is important during the initial growth/reproductive phase of the yeast (help here from you microbiologists). If you pitched enough active yeast that they didn't need to reproduce (to reach the maximum number of colonies/ml), then the amount of oxygen present may be irrelevant.

Having made all these theoretical observations here is my practical experience: I siphon my cool wort into the primary through a aerating tube. The aerating tube is a 6 in long plastic tube w/ 1/32" holes drilled in the tube wall near one end. (This end is near the siphon hose not at the end the wort exits.) It works just like your sink aerator; air is drawn into the tube through the 1/32" holes and the wort exits as a frothy liquid. When the siphoning is done there is 2 to 6" of foam on top of the wort. I pitch an active starter solution. The volume of the starter solution (wort+yeast slurry) is 2 cups. I always see active fermentation within 12 hours, usually faster. (I don't get up every four hours to see if my beer is working--Jack you're dedicated.) This info is for ale yeast.

Followed this procedure last night. Pitched yeast at 11:00 pm by 8:00am this morning there was a full krausen. Bottom line: I agree with Jack at least for ales. One doesn't need the air pump system for ales, if you use a good active yeast starter and aerate wort going into the fermenter.

**Subject: Irish Ale Yeast**

The description of Wyeast's Irish Ale yeast recently posted says that is not very attenuative. I recently used it for an Imperial Stout (a variation of Miller's extract/mash recipe in Brewing the World's Great Beers). Although the OG was a bit lower than the OG in the recipe, the FG was also a bit lower than the recipe. The stout tasted quite alcoholic when bottled.

From: Bill Flowers <waflovers@qnx.com>  
Subject: Details re. Hard, high pH water treatment for new masher

OK, I got the water analyses for my home and my office. When I actually had numbers in my hand and re-read Miller's Complete Handbook chapter on water, I finally began to understand what I was dealing with and, maybe, what to do. I'm going to post a lot of details here and some conclusions so someone with more experience and knowlege can double check me. Apologies ahead of time for the length of this.

My home tap water is drawn from two wells. Unfortunately the regional lab doesn't do a complete analysis of the well water. All I got was readings of some characteristics for the last 7 months. The averages of the pertinent numbers are:

pH 7.8 sulphates (ppm) 68  
Total Alkalinity, as CaCO3 250 Total Hardness, as CaCO3 256

There were a few other numbers of no consequence as well.

I wouldn't know what to do with this water, but it doesn't sound great. Luckily I've got another water source.

The analysis of my office's water was another matter. I received max, min and average values for both the raw and treated water, and more information than I could enter into this message (now I know how much uranium is in the water I drink). The important things (I think) are:

Treated Water  
mg/L (ppm) unless otherwise stated

minmaxavg

-----  
pH 6.89.98.3  
Total Alkalinity, as CaCO3 17.0 48.0 25.8  
Total Hardness, as CaCO3 26.0 72.0 51.7

Chloride, Cl 3.58.05.3

Calcium, Ca 15.00 18.60 16.80  
Magnesium, Mg 1.94 2.43 2.28  
Potassium, K 0.728 0.820 0.776  
Sodium, Na 2.78 3.78 3.12  
Sulphate, SO4 19.60 30.50 24.00

Other values are in the parts per billions or Miller wasn't concerned with them

(or both) so why should I be. Who cares about immeasurably small traces of Vanadium when brewing anyway?

This water seems to be rather nice for brewing. It doesn't seem too far off of Miller's St. Louis water which he discusses in detail (actually better in some areas such as sulphate and sodium). Although the pH is sometimes high the buffering capacity (total alkalinity) seems low so the mash water pH should drop. In fact, the alkalinity might be too low and I may have to add calcium carbonate. It is always easier to add than to take away. Also, just as Miller does, I should probably acidify my sparge water.

At least, that's how I interpret these numbers. How do they look to the "experts"? How important is it to acidify the sparge water? What happens if I don't? All I could find was Miller's comment: "It is desirable to keep the pH of the runoff during sparging below 6.0."

poor  
>recipe formulation, and I used it for boiling brats, etc. so it wasn't a  
total  
>loss.

I have to second this question, how many people brew solely from  
someone else's recipe? I have brewed over 20 batches (14 or so that  
were all grain) and have never intentionally brewed directly from  
someone else's recipe (not even on that first extract batch). Granted  
I have made some mistakes, but I think that experimentation leads to a  
better understanding of the flavor contribution of different grains,  
hops, and processes. I have won some awards in competitions, but that  
is not my primary objective when formulating a recipe.

I do enjoy reading recipes and have learned a lot about matching style  
guidelines by reading other's recipes (esp. those in the volumes of  
the Classic Beer Style series). I look at recipes as guidelines (both  
in brewing and in cooking) but I never take a recipe and follow it to  
the letter (not even one of my own!). I too like a little variety in  
the beers I drink. I suppose that I may be tempted to replicate some  
of my previous beers if I ever get one that I feel is outstanding, but  
I suppose that I am just a likely to try it with a different yeast or  
different hops.

Formulating your own recipes really isn't hard, and there has been a  
lot of good information published in recent Zymurgys and in the HBD on  
how to hit target OGs and the like. When I look at a recipe, I first  
compare the OG, IBUS, color, etc. with the guidelines for the style,  
then look at my inventory (I keep 50-100# of assorted grains, and  
several pounds of assorted hops around the house at all times) and see  
what I have that can produce a beer in that style. I break out the  
calculator and my brewing notebook and get to work! Every brew is  
different, and I like to think that they are improving as I gain  
experience.

This is not intended to knock anyone that is uncomfortable breaking  
away from cookbook type brewing. I hope that it will serve to  
encourage others to experiment and post their results (or better yet,

send me some :-).

I just tried the 1028 strain on a couple of back to back english style  
ales. The first was a fairly low gravity Bitter that came out fairly  
nicely. It was not overly hopped, yet the hop bitterness came through  
nicely. I did note the woody and mineral flavor notes in this brew.  
The second brew was a fairly hoppy IPA and I wish that I had chosen a  
different yeast. I found that the attenuation was a bit much in the  
IPA, but it is still very young and may turn out fine in another month  
or so. The IPA currently has a nasty stale veggi character that I  
believe is due to using some old Cascades (they have been kept in the  
freezer since I bought them though) for dry hopping. I just replaced  
the blend of Cascades and Kent Goldings with some fresh Mt Hood in the  
keg and am hoping for the best.

>  
Right! Bavarian weizens should not have a dominant lactic sourness

(though I find that just a little makes them very refreshing)!

For some more data points, I have brewed a couple of Bavarian weizens with this strain. One had virtually no clove or banana aromas or flavors and really was a bit under attenuated. The second time I used it (pitched from the slurry in the secondary on the first batch) I got a wonderfully clovey/banana weizen character (this beer took 1st place in the 1993 HWBTA competition in the wheat beer category). I have also made a couple of Bavarian weizens with the bavarian wheat strain from the Yeast Culture Kit Co (don't remember the number but it is supposed to be the Weinstephen?sp? #66 I think) that had much more pronounced weizen character. I certainly believe that the 3056 is a bit unstable based on my experience and the experience of some others and I will probably never use it again. I am looking forward to trying the new bavarian wheat strain that Wyeast is currently testing.

From: Stephen Brent Peters <sp2q+@andrew.cmu.edu>  
Subject: yeast pitch experiment

With my last batch I wanted to pitch as much yeast as possible with spending as little time as possible playing with it. Here's what I did:

- 1) I boiled up enough hopped 1.020 wort to fill two 16 oz bottles, and one 32 oz bottle.
- 2) mixed a packet of wyeast belgian with one of the 16 oz bottles in the bottom of a very sanitized carboy.
- 3) the next day I added the entire 32 oz bottle to the carboy.
- 4) at 8am the next day (brew day) I added the last 16 oz bottle to the carboy
- 5) at 4pm that day I finally added the cooled wort to the carboy, areated by splashing it through the funnel/strainer combination. The wort was 1.063 gravity.
- 6) when I came home that night at 9pm the beer had an inch and a half of krausen on it. So, about five hours for a very vigorous takeoff.
- 7) by the next day the krausen had fallen and now only a week later it is almost ready to bottle. This is by far the fastest fermentation I have ever had with liquid yeast.

conclusions:

I had never used more than 16 oz of starter before because of the hassles pouring from bottle to bottle. I also used to have trouble pitching at high krausen (timing, timing) , but by using the carboy it is possible to get the yeast up to speed by adding more wort a few hours before the brewing will happen.

comments?

Subject: Use of Chilis in Beer

Hello everyone,

With all of the recent discussion going on about variations of Chili beer's and how to go about imparting chili flavoring to the beer, I just wanted to throw in my 2 cents worth.

First of all, let me begin by saying that I have not ever tried to brew a chili beer and I currently have no plans to attempt one (the chili beers I've tried, Mexacali Rogue and Cave Creek, just don't do much for me). That aside, I do consider myself an avid chili lover. As such, one of the first things one quickly learns is that individual chilis vary greatly in flavor and "heat" intensity. This holds not only for different varieties, but also within specific varieties. Unless you know the source of the chilis, it's difficult to judge this variation below using the chilis. You can come pretty close to grouping chilis based on "heat" if you pay attention to the aroma (from the oils in the skins) while roasting/peeling the chilis.

Also, when I mention "source" above, I really mean that you need to know the source. I've found that chilis vary dramatically even on different plants within my garden. Chilis can vary greatly (like any other crop) based upon micro-climate conditions, water, soil conditions, growing season, etc. If you get your chilis at a market or grocery store, odds are that you're getting a mix of chilis from various sources.

Hint for home growers: I've found that if you like really hot chilis, cut back on the watering once the blossom sets. Don't kill the plants, but cut back on the amount of water they receive. The chilis may be smaller, but they really seem to get hotter.

That said, I would have to agree (in principal) with Alan in Austin (HBD#1203) about warning against spicing beers directly using chilis in the bottle. The results, while perhaps good, would be inconsistent (bottle to bottle)

I would think that the technique of "dry peppering" or "dry-chiling" as mentioned by Lanny (HBD#1203) and Robin Garr (HBD#1204) would result in much better flavor control. Likewise, adding your chilis to the later stages of the boil could work too. The idea for consistency is to expose the entire

batch to the same chili mix. Of course, if you like the idea of not knowing what to expect, keep the mystery behind the beers and spice using individual chilis in the bottles!

Kevin

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: Aeration. What the pros say...

The latest in Jack's continuing vigil against the accursed momilies of brewing focuses on aeration.

He writes:

> There has been a great deal of enthusiastic reporting on the  
> use of aquarium air pumps to aerate wort prior to pitching  
> yeast and many rather preposterous claims of shortened time  
> to the onset of fermentation resulting from the use of same.

(snip, snip)

> The experiment seems to confirm the author's previous  
> experience and points to the conclusion that the method of  
> aeration used has no correlation with or effect on the time  
> to onset of fermentation. Contrary to frequently stated  
> anecdotal experience, the un-aerated control samples started  
> fermenting as soon and with the same vigor as the variously  
> aerated samples. This was true both in the case of cold  
> temperature lager yeast and room temperature ale yeast.

I'm not sure what Jack's claims are here. But I'll point out several points of interest that may affect his "scientific" experiment.

I shall cling to Jack's statement that his experiment "seems" to confirm his experience because his conclusions run counter to what the literature has long accepted as fact. Not wanting to allow another momily into the annals of brewing literature, I'll briefly point out that underaerated wort can have definite deleterious effects on the flavor of the beer (increased ester production, for one) and adverse effects on the speed of fermentation (read increased lag times and the resultant risk of contamination, prolonged fermentation times (speaking from experience here), and the production of several components that do not contribute to the flavor profile of what we normally call "beer").

But don't take my word for it. Here is what the pros say about the matter.

>From Malting and Brewing Science:

p.633

"To increase the oxygen content, air is often bubbled into the medium, but this has little or no effect if the bubbles escape rapidly. Small bubbles provide a larger surface area for oxygen transfer, while baffles built onto the walls of the vessel help to arrest the loss of bubbles. Shaking or swirling the medium has the effect of increasing the effective surface area of the liquid presented to the atmosphere. Furthermore, a vortex produced by an agitator has the same effect.

The rate at which oxygen passes from atmosphere into solution depends on:

(1) the degree to which the medium is saturated with oxygen, (2) the area of the interface between atmosphere and medium and (3) the ease with which oxygen passes through the interface. The rate is expressed by  $Kla(C^*-C_1)$  where

$K_1$  - The ease of passage with which oxygen passes through the interface.

$a$  - The area of interface.

$C^*$  - the oxygen concentration at which atmosphere and medium are in equilibrium.

$C_1$  - The actual concentration of oxygen in the medium.

They then measured oxygen absorption rates as follow:

| Vessel                            | Vol. of medium             | Air flow                               | $KlaC^*$  |
|-----------------------------------|----------------------------|----------------------------------------|-----------|
| (l/min)                           | (mM-O <sub>2</sub> /l/min) |                                        |           |
| 18 x 150 mm test tube             | 10 ml                      | Stationary                             | - 0.03    |
| Erlenmeyer flask 500 ml           | 20 ml                      | Stationary                             | - 0.32    |
| Erlenmeyer flask 500 ml           | 20 ml                      | Eccentric shaker (250 rev/min)         | - 1.1     |
| Indented Erlenmeyer flasks 500 ml | 20 ml                      | Eccentric shaker (250 rev/min)         | - 2-9.5   |
| 100 ml                            | 50 ml                      | Reciprocal shaker (80-100 strokes/min) | - .78-1.5 |
| 1000 ml                           | 200 ml                     | Reciprocal shaker (80-100 strokes/min) | - .22-.78 |
| Baffled Tank                      | 1460 ml                    | Stirred:                               |           |
|                                   | 3.5                        | 1750 rev/min                           | 5.8 3.6   |
|                                   | 1100                       | rev/min                                | 6.1 6.33  |

I interpret  $KlaC^*$  as being the amount of O<sub>2</sub> absorbed into the beer using the various processes above, though I could be wrong. It comes as no surprise that the different methods achieve different levels of oxygen absorption. It's interesting to note that the surface area of the samples exposed to the air makes a big difference in the rate of oxygen absorption.

Perhaps this lends credence to the theory that one of the best things you can do to aerate the wort is let it fan out over the sides of the vessel as one siphons into the fermenter.

From: Kinney Baughman <BAUGHMANKR@conrad.appstate.edu>  
Subject: Aeration. What the pros say... (part 2)

The authors of Malting and Brewing Science also make the following observations concerning the absorption of air into beer:

p. 634

"The role of oxygen in brewery fermentations has received study using fermenters of 30 brl capacity. Wort of SG 1.044 was pitched at .2 lb/brl at 64 degrees F and the degree of oxygenation prior to pitching was selected in the range 5-100% saturation. The weight of yeast crop was hyperbolically related to the initial oxygen concentration of the wort. Above about 20% oxygen saturation, little is achieved if the wort is completely saturated with air. Below this level, the yeast crop is greatly influenced by the initial level of oxygen and, with the strain of yeast used, it seemed likely that no growth of yeast would occur in the absence of oxygen...the rate of fermentation was related to oxygen saturation in a manner very similar to that shown (below)."

p.635

"It is now well established that different strains of brewing yeast have different requirements for molecular oxygen. Furthermore, most, if not all, of the molecular oxygen consumed by the brewing yeast is used for the production of unsaturated fatty acids and sterols, which are essential constituents of the yeast cell membrane...Where insufficient O2 is available for membrane synthesis, yeast cells fail to grow and loss of membrane integrity results in cell death. These changes are also associated with an increased production of esters...The concentration of oxygen at 100% air saturation is inversely proportional to the specific gravity; thus an air saturated wort of SG 1.040 contains 8.5 mg/l O2, whereas a wort of SG 1.070 contain 7.9 mg/l O2.

p.646

"The amount of yeast added to the wort at the time of pitching greatly influenced the speed of fermentation. (Surprise! Surprise! Surprise!-krb)

For instance top yeast pitched at 1 lb/brl into wort at 63 degrees F attenuated to 75% in 84 hr. At four times this pitching rate the same attenuation was reached in 44 hr."

p. 647

"The effects of rousing or agitating fermentation vessels include aeration and mixing. BOTH TEND TO HASTEN FERMENTATION (emphasis mine), aeration by supplementing the dissolved oxygen supplied by the wort, and mixing by bringing yeast in the head and yeast that has sedimented into suspension. The overall action is to increase yeast crops and speed fermentation.

p. 648

"Wort composition greatly influences the speed of fermentation, the extent of fermentation, the amount of yeast produced, and the quality of the beer produced. The wort constituents which play a major role include fermentable carbohydrates, assimilable nitrogenous compounds and accessory food factors. Amino acids normally limit growth...

p. 664

"With respect to the main fermentation, the control on the speed of attenuating to satisfactory gravities depends on (1) wort composition, especially the level of alpha-amino nitrogen and the spectrum of fermentable sugars, (2) DISSOLVED OXYGEN (emphasis mine), (3) temperature, (4) pressure, and (5) yeast concentration....With respect to the effect of these variables on flavor, it has been shown that dissolved oxygen content can be important. Reducing the level from 8 to 3 mg )2/l causes significant increases (2-4 fold) in the esters ethyl acetate (winey/lacquer like), isoamyl acetate (banana esters) and ethyl caproate. Acetaldehyde rises seven-fold. Level of zinc ions up to .08 mg/l may be necessary for satisfactory fermentations."

Sorry to take up so much space quoting scientific literature but I kept coming up with references that pointed to the importance of a well-oxygenated wort. Besides Jack's experiment, I have been interested in this topic of late because I have become aware that we have not been aerating our worts enough at Tumbleweed and it appears to be a factor in several of the flavor problems we've had.

From: "Bret D. Wortman" <wortman@centurylub.com>  
Subject: New (first!) Brewpub in Kansas City

I had the thrill of a lifetime this past weekend. Dining and drinking at a restaurant that hadn't officially opened yet.

To top it all of, the restaurant in question was Kansas City's first brewpub.

I won't dwell on the food (which was wonderful, especially the brewer's bread appetizers made from spent grains) but will get to the \*real\* reason for visiting The 75th Street Brewery at 75th and Wornall in the Waldo area.

The beer.

75th Street currently has three beers on tap that are brewed locally, with a fourth coming in September. "Cow Town Wheat" is a very light, very refreshing wheat ale. It's made from Kansas-grown wheat and Munich malts with Hallertauer and Saaz hops.

"Yardbird's Saxy Golden Ale" commemorates KC's contribution to jazz and bebop. A light, \*very\* smooth golden ale, this one uses Vienna and Munich malts with Cascade hops. A pint of this is probably the most refreshing thing the house serves.

"Possum Trot Brown Ale" is a nicely nutty, unmistakably malty classic brown ale. It uses cluster and cascade hops and I couldn't pry the malt combination from the Brew Master (who just \*loves\* showing off the setup to appreciative homebrewers -- maybe others will have more luck. ;-)

The September addition is called "Muddy Mo Stout" and is billed as a dry, Irish-style stout. It gives me a good excuse to make sure I go back next month. ;-)

In addition to these on-site brews, 75th Street also offers three guest beers. A hometown favorite, Boulevard, has contributed their "Bully! Porter" to this effort. Brewed by Brewmaster John McDonald, it's an outstanding porter. My limited beer vocabulary just ain't up to describing it any more than this.

Additionally, there's a pair of brews from Anchor Brewing Company. On KC tap, we have their "Liberty Ale". 75th Street is the only place in "Old where you can get this beer on tap. They also sent some of their "Old Foghorn" barleywine. \*Man\*, this stuff is absolutely \*indescribable\*. Again, you can't get it anywhere else in KC on tap, and it's a nice twist to the menu.

Anyone coming near KC, give me a holler and I'll help arrange a tour of

the place for you, or call them directly at 1-816-523-HOPS.

Okay, I'll say it. The service staff was unbelievably friendly. I don't think I \*ever\* saw someone standing around looking upset. Everyone was smiling. Even when things went wrong for us (hey, the place wasn't officially open yet, and it was "investor's party night"), everyone was pleasant and bent over backwards to make sure we were taken care of and happy. I can't recall the last time I was pampered like that.

My waiter's name was Ken. Ask for him. You won't regret it.

WortMan

Disclaimer: I have nothing to do with The 75th Street Brewery, save as a satisfied customer. I don't own any part of the company, nor do I work there. I know the brewmaster by first name, but he probably wouldn't remember me if I walked up to him in a crowded shopping mall, so who really cares? ;-)

Subject: hop harvest question

Greetings:

2 Questions re: hop harvest..

1. Do you need to dry the hops before use, or is the drying a method of preservation?
2. How do you tell when the hops are "ripe"?

FYI: I planted 3 different types of hops this year. The centennial are the only plant to grow buds so far ~ 30 buds. The hallertau plant grew the fastest & biggest, but no buds. The perle only grew about 6 ft. and stopped growing about 4 weeks ago.

regards,

Michael

This sounds very much like the water that I get at home, untreated, straight from the tap. Total hardness and alkalinity are in the 40-80 range. pH is typically 8. (I don't have the #'s with me so I can't quote values).

```
> Although the pH is sometimes high the

> Miller does, I should probably acidify my sparge water.
```

With such soft water, I never get an alkaline mash. Where most people have to do an acid rest, I do not. I frequently have to increase the mash pH as it is too acidic. Calcium carbonate works well for this. (Added to the mash)

I acidfy my sparge water using 1/4 teaspoon of acid blend in 5 gallons. That works well, dropping pH to mid 5's.

I've found this sort of water great to brew with. Adding desired minerals is much easier than taking them out!

Subject: Barley Water Response

Awhile back, someone requested information about a Victorian-era English drink called "barley water". I believe this was several weeks ago, and the reference was to some dialog in the movie "Mary Poppins".

I remembered seeing something about this drink in my historical references, but it took awhile to find it. I'll post the information here for general interest. The passage is from the book "Food and Drink in Britain" by C. Anne Wilson (Barnes & Noble, 1974):

It [barley water] had a long history as an invalid beverage. In the sixth centruy A.D., Anthimus had recommended a thin drink made of barley with pure warm water as beneficial for fever patients. The later medieval version in France had the name tisane (from the Greek ptisana for barley water), and it was sweetened with sugar and seasoned with licorice and sometimes also figs. Adapted for English use, it more often comprised barley boiled in water with licorice, herbs and raisins. It was still a licorice-flavored drink in the first part of the seventeenth century but soon afterwards was brought up to date by the substitution of lemon juice for licorice.

The author went on to mention that there was no longer a barley water tradition in the English-speaking world, but that a popular version called "horchata" was still enjoyed in Spain and parts of Latin America.

BTW, Wendy and I very much appreciated the favorable response to the Chicha & Chang presentation at the AHA Conference. It was a lot of fun to do, and we were gratified so many people were willing to expand their horizons beyond the "barley, hops, and yeast" tradition. Sorry the chicha arrived late (shipping problems), but at least a fair amount finally got consumed. Gak & Gerry were seen making a significant dent in the keg following the banquet Thursday night.

Date: Thu, 19 Aug 93 09:58:01 EDT  
From: Spencer.W.Thomas@med.umich.edu  
Subject: Boiling

We boil our wort for several reasons:

1. To sanitize it -- there are any number of "nasty" organisms that would just love to chomp on the sugars in unfermented wort. If you boil the wort (and any other water that goes into the fermenter), you reduce this risk.

2. To add hop bitterness -- because we started with "all grains", because we used unhopped extract, because we want a bitterer beer than the hopped extract will give us. Extraction of hop bitterness requires boiling for at least 30 minutes, and preferably an hour.

3. To add hop flavor and aroma -- hopped extracts usually have a low level of hop flavors and aromas. Boiling hops from 0 to 20 minutes adds these (the longer the boil, the lower the aroma, but you don't get appreciable flavor with less than 5-10 minutes).

4. When mashing grains to get part or all of the wort, the boil precipitates proteins that would otherwise cloud the beer and potentially produce unpleasant flavors. This requires 60-90 minutes, typically.

5. To reduce the volume and concentrate the wort -- again, when all-grain brewing, you typically get more liquid from the "mash" than you want to make beer, unless you're making a very light beer.

But, even if # 2-5 don't apply to you, a 15 minute boil to sanitize the wort is always called for.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: WORT AERATION

>From: "Rick (R.) Cavasin" <cav@bnr.ca>

>Just a little quibble with your experiment. I wonder if there isn't one confounding variable you've overlooked, namely, fermenter geometry.

That is one of the problems with any experiment. The number of variables is usually infinite. One nails down as many as possible and those deemed unrelated to the information being sought are eliminated. It is frequently a subjective choice but that is why the results are published to allow others to ponder.

I would suggest that the geometry of a mason jar is very similar to a typical fermenter. The fact that they were half full is a detail but of no consequence in the control sample which turns out to be the most important one in the final analysis.

>The surface area/wort volume ratio, and the amount of head space in the quart jar fermenters is radically different than what most people would encounter in normal...

That is true but it remains to be proven that reducing the headspace would effect on the final results.

It is my opinion that geometry differential increases the oxygenation of the sample using the airstone because it can be aerated longer before the space is filled. This would only serve to exaggerate the difference between it and the control and tend to favor it but the results speak for themselves.

> In the case of your lager test, is a starter/wort ratio of 1/10 typical?  
(don't know, don't do lagers myself)

The amount of starter is of no consequence. It is the amount of yeast in the starter that effects the lag time. The 72 hour lag time at 40 F would indicate that, if anything, there was too little yeast.

>From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>

> 1) I'm curious about the geometry of your small fermenters. Specifically I'm wondering about the relative amount of wort exposed to air and thereby oxygen. Let's call.....

> So all your small scale fermenters have access to a lot more oxygen than my 'full scale' primary fermenter.

A valid argument but in this case, it only applies to the control sample as it enhances the aeration of the others.

In order to prove YOUR point, you would have to show that the control sample had received enough oxygen to provide a normal fermentation by the minimal handling it received and/or through the mechanism of the fermenter geometry.

The experiment proves the former. I leave it to someone else to scale it up to prove the latter.

>Having made all these theoretical observations here is my practical experience: I siphon my cool wort into the primary through a aerating tube. The aerating tube is a 6 in long plastic tube w/ 1/32" holes drilled in the tube wall near one end. (This end is near the siphon hose not at the end the wort exits.) It works just like your sink aerator; air is drawn into the tube through the 1/32" holes and the wort exits as a frothy liquid. When the siphoning is done there is 2 to 6" of foam on top of the wort.

I think that you have made one of the points I was testing for in my experiment, vis., the aquarium aerator is an unnecessary complication of the home brewing process.

Having said that, I will point out that with your approach, you only get one shot at it. With the aerator, one can repeat the foam buildup ad infinitum but the bottom line is, does it really matter?

>From: Chris Williams  
>Subject: Cold plates and wort chilling

>With all the recent talk about cooling wort, I started wondering if you could use a cold plate to accomplish this. If the tubing inside the cold plate isn't SS you might get off flavors, or you might clog the thing up with hop particles, but is it a valid idea ? Any thoughts/experiences ?

The tubing in the ones I am familiar is ss but the problem is the diameter is so small you would need to pressurize or pump the wort through it. It would be tediously slow by gravity.

Subject: Proteins

My last brew (although wonderfully tasty) had problems with both head retention and chill haze. It was a pale ale, the first all-grain pale ale I've done. The other all-grainers I've done were darker and had no problem with either. Is this coincidence or do dark grains helps these problems somewhat?

It seems to me that large proteins in solution link together at low temperatures (that's how they keep warm!) and form the chill haze. I believe the solution for me is to add a protein rest to my mash cycle to help the proteinase enzymes break down these large proteins. Are there other solutions to this problem, i.e. a certain grain bill, etc. I'd rather not depend too much on finings.

I've read that head retention is a function of the proteins in solution as well, although I don't know the details. Would this problem be aided by a protein rest, too?

Cheers,

Subject: Re: Taxonomy

Tom...  
your latest taxonomy post may be a little too much

BTW, ATCC has no listing for "Torulospora delbrukii", though it does for "Torulospora delbrueckii"

I find this a little confusing, since I know the grandson of the delbru(umlaut)k in question and he has no c in his name.

ATCC searches can be reached by Gopher, with this gopher information  
+INFO: 1ATCC - The American Type Culture Collection  
1/Database-local/cultures/atcc merlot.welch.jhu.edu 70

the real wuestion seems to be should we use weihenstephan 68 or wyeast.

I (the empiricist) cloned out the wyeast bavarian culture as reported in HBD a year ago and found that only about 1% of the colonies had a variant morphology and created an estery beer. I use this exclusively now. This low percentage might explain why wyeast cultures are criticized as bland.

One other question: What source is there for the Weihenstephan 68 strain??

Subject: Strike Temperature / Withholding grains

Andy Phillips asks about specific heat capacity, strike temperature, etc. I have made the very same evolution in my brewery (Bruheat -> insulated mash/lauter tun w/ slotted pipe manifold) and am quite happy with it, Andy. The strike temperature problem is not much of a problem really. I add 1 qt. of 168F strike water for every pound of grain to hit around 152F initial mash temperature. For you, I'd recommend 1 litre of 75C strike water for every pound of grain to aim for around 67C initial mash temperature. If this is too high for you just lower the strike water temperature a degree or two. A lot of this depends on air temp, how much heat your mash tun absorbs, etc.

I've read that the enzymes in the grains are not too sensitive to short duration temperature extremes. The thing to do is measure your mash temperature after you have doughed in the grain, and adjust with cold or hot water accordingly. A few times doing this and you'll know what the strike temperature for your system should be.

Mike Zulauf uses a similar setup and wants to know about holding off specialty grains until after conversion. I recommend this with crystal, chocolate, black, and any other specialty grains. Crystal malt has already supposedly already undergone conversion at high temperatures so as to produce the unfermentable sugars. Another conversion is not necessary and could very well have the effect of further reduction of these sugars. Dark grains which are added for the color and flavor (not for the sugars) should never be added until mashout time, IMHO. The absolute worst brew I've ever made (the only one I've ever poured out more than I drank) was made with the dark grains in the mash. For some reason, conversion on that doomed brew took almost 3 hours and I'm sure that had a combined effect with the dark grains, but the bottom line was this brew had a harsh astringency which tasted like chewing on chocolate malt. Needless to say, I will never add dark grains until mashout again.

Cheers,

From: Domenick Venezia <venezia@zgi.com>  
Subject: Water treatments

Since Fuller's ESB is the best ale in the world (flame on dissenters), I have spent some time exploring the Burton-upon-Trent water. I went so far as to contact the Public Water District for Burton and the British National Rivers Authority. The PWD sent a comprehensive analysis of the Burton municipal water supply. The NRA sent me a slick pamphlet, and said that the famous brewing water neither originates from the Burton municipal water nor from the river Trent, but from shallow wells in the surrounding area. So I wrote to a number of brewers in the area asking for their water analysis and/or treatments. No responses expected for a few weeks.

Just to cover my butt, let me say that I realize Fuller's brewery is in Chiswick, London and not Burton-upon-Trent, but they do "burtonize" their water.

So in response to Geoff in #1206, and Bill Flowers in #1205, for whatever it is worth I submit the following information.

### Burton-upon-Trent Water Recipes

#### Target Ranges

|       |         |       |     |
|-------|---------|-------|-----|
| Ca++  | 260-352 | (306) | ppm |
| SO4-- | 630-820 | (725) | ppm |
| Mg++  | 24-60   | (42)  | ppm |
| Na+   | 54      | (54)  | ppm |
| Cl-   | 16-36   | (26)  | ppm |

#### Target Recipe for 5 Gallons

|       |         |         |            |
|-------|---------|---------|------------|
| Ca++  | 260 ppm | 0.81 g  | NaCl       |
| SO4-- | 740 ppm | 5.70 g  | MgSO4.7H2O |
| Mg++  | 30 ppm  | 21.10 g | CaSO4.2H2O |
| Na+   | 17 ppm  |         |            |
| Cl-   | 26 ppm  |         |            |

|       |         |         |            |
|-------|---------|---------|------------|
| Ca++  | 275 ppm | 1.00 g  | CaCl2.2H2O |
| SO4-- | 740 ppm | 5.70 g  | MgSO4.7H2O |
| Mg++  | 30 ppm  | 21.10 g | CaSO4.2H2O |
| Cl-   | 26 ppm  |         |            |

|       |         |         |            |
|-------|---------|---------|------------|
| Ca++  | 295 ppm | 1.25 g  | CaCl2.2H2O |
| SO4-- | 787 ppm | 6.00 g  | MgSO4.7H2O |
| Mg++  | 31 ppm  | 22.50 g | CaSO4.2H2O |
| Cl-   | 32 ppm  |         |            |

#### Common Names

NaCl Table Salt  
MgSO<sub>4</sub>.7H<sub>2</sub>O Epsom Salt  
CaCl<sub>2</sub>.2H<sub>2</sub>O Calcium chloride dihydrate

---

Until I hear back from a brewery or two and get a definitive answer,  
please note that the Burton target ranges are from Papazian.

Any errors are my own though I of course take no responsibility for their  
consequences.

If anyone is interested in what the municipal water of Burton-upon-Trent  
is like I can email a copy.

Domenick

From: ulrich@sfu.ca

Subject: "Not much of a beer drinker", "Evolution" of Beer

The other day, someone gave an overview of BC microbreweries and said not to even bother with Granville Island. Yesterday's Vancouver Courier (local free newspaper) contained an article that I found illuminating. I quote the second and third paragraphs.

"Granville Island Brewing Co. president Ian Tostenson says consumers will soon be able to buy GI draft suds in cans. To date, Granville Island products have only been available on tap and in bottles."

"'Sixty per cent of the beer consumed in B.C. is canned,' Tostenson says. 'I'm not much of a beer drinker, but when I do drink it, I want it in a can. It's the convenience factor.'"

Would you buy beer from this man?

On a lighter note, I recently saw a cartoon (Catman by Peter Perry in Terminal City, 8/11-24/93) hypothesizing about "the 'evolution' of beer". Extrapolating from Dry Beer ("developed after conventional marketing ideas dried up") and the current fad Ice Beer, he predicts Dry Ice Beer ("Beer vapors are inhaled. This is for those who are too cool to swallow or afraid of spilling regular beer in their trendy 4x4s."), followed by Ice T Beer ("After being opened, some cans start rapping and tell you you've won a pair of rap shorts.") and Mice Beer ("due to the increasing amount of mouse parts found in big brewery beer"), and eventually Dry Mouse Beer.

From: Oh Noo- Mr.Bill <coxco@dpmmai.enet.dec.com>  
Subject: Brewpots

GA writes about welding stainless steel, which brings up my question. I have been using a 20 cup brew pot which does not allow me all wort brewing, not to mention the mess.

I inquired about a buying a new brew pot from Brewers Warehouse in Seattle, WA. The following was quoted:

10 gal. stainless steel brew pot - \$149.00  
brass/copper ball valve,nipple,fitting - \$ 86.00  
cut to fit bottom screen to filter wort - \$ 60.00  
-----  
\$295.00

Given this is heavy gauge "restaurant gauge" stainless and they claim the pot is fabricated in house, is this worth the price or is this like "killing a fly with a shotgun"?

The only other pots that I have seen are these thin cheesy Taiwanese \$49.00 20 qt. pots in the local brew shop. I don't plan to do batches with a outdoor burner so this rules out a converted keg system. Good deal or bad? Alternatives?

Mr. Bill

From: Greg Demkowicz <71470.171@CompuServe.COM>  
Subject: RIMS

I've read what ever posts I could get on RIMS, however I haven't seen comments about the Rodney Morris system. Has anyone actually built his system, or tried adapting his design to 7.5 or 15.5 gal Keg? I'm sure grain compaction will be a problem with the keg geometry, but to what extent (I think Alan Gerhard? used a screen cylinder in the center, to reduce this affect)? Also, for minimal HSE, how should the warmed wort exiting the pump be directed, through a manifold over the mash, or directly into it?  
Thanks  
in advance for any assistance.

"Date: Tue, 17 Aug 93 12:38 CDT  
From: korz@iepubj.att.com  
Subject: yeast FAQ comments/Zymurgy Bashing/more yeast comments

">a. Place the starter jars in a location where 68F (18C can be held) ..  
.

"Yes, but I've read that although fermentation may be done at lower  
temps,  
80F is a better temperature for starters."

I've been culturing sourdough yeast recently, and the instructions  
indicate  
that the best temperature for culturing \*this\* yeast is 85 F.

They definitely indicate that 95 F would kill the yeast.

In general, I've found bread yeasts to be pretty closely parallel to ale  
yeasts in their operating parameters.

One would hypothesize that, much as there are complementary niches in the  
'beer' and 'bread' environments for relatively warm temperatures, there  
must also be bread yeasts which complement the colder lager yeasts,  
which,  
apparently, have not yet been discovered ( although Alaskan sourdough  
yeast  
might violate this presumption :-).

They also pointed towards the ( unlit ) oven as a good, unchanging warm  
place for yeast-culturing, and I've found this to be true. Mine climbs a  
little above 85 F over a day or so, and falls down to around 80 F if I  
leave the door open, so it's good to check it out, first, over a few  
days.

Any microbiologists ( or microbotanists, microzoologists, microflorists :  
- )  
in the crowd whom might care to comment on whether there is a general  
range  
of maximum temperatures over which all known yeasts die, and another  
general  
range of temperatures under which all yeasts become dormant [ excluding 0  
Kelvin :-] ?

Didn't someone just post a four-part yeast-culturing FAQ ? Is it in there  
?

From: Michel Vandenplas <mvd@maties.sun.ac.za>  
Subject: Summer Blues - contamination

Two members of our newly formed brewclub were describing a recurrent infection that they get during the summer months. The only advice that we could come up with was for them to throw it out and try again.

How do they prevent this from happening again? Apparently the infection shows up a few days after fermentation has started and appears as a white filmy layer on top of the fermenting wort. It feels oily and the beer is undrinkable, sorry no flavour descri

Any advice would be appreciated - or is this strictly a local problem?.

Regards

Michel

> tradition in the English-speaking world, but that a popular version  
called  
> "horchata" was still enjoyed in Spain and parts of Latin America.

I realize that Bill didn't say this but was quoting someone else.

However,

horchata (pronounced without the leading h sound) is a common drink from Mexico and is made from ground rice and cinnamon, and is pretty sweet. In the LA area you can generally get this instead of, say, a soft drink at a restaurant. It doesn't sound like it's got very much in common with barley water, however, in either ingredients or intended use.

Subject: wort aeration comment

Thanks to Kinney for his postings from Malting & Brewing Science. The literature establishes beyond doubt that wort aeration is an important factor in final beer quality and flavor. I wonder whether the usual homebrew rack and siphon to the carboy adds sufficient oxygen to the wort? It seems that the splash tube gadget is a step in the right direction. I have used an aquarium pump wort aerator since last Fall, and feel that this has contributed to shorter lag times and more vigorous fermentations. I also feel that aeration is especially important for stronger beers (SG above 1050 or so). Admittedly, I didn't do split test and control batches, but I leave that to Malting and Brewing Science. If I have a clean acid carboy available, because of its greater headspace, I'll rack the just-cooled hopped wort into it and start the aerator. Sometimes, the beer head foams up, in which case I'll leave the aerator on for 5 minutes and swirl the carboy. Every half-hour or so, I'll repeat the process. At other times, the foam head doesn't go all the way to the top, in which case I'll leave the aerator on for 3 to 6 hours. It seems to me that aerating the wort in this fashion is one of those things one can do -- like using a wort chiller or racking to secondary -- to try to make better beer.

From: "William A Kitch" <kitchwa@bongo.cc.utexas.edu>  
Subject: re: Wort Aeration

Thanks to Kenny Baughman for some good data. (I wish Dover would reprint Malting and Brewing Science (MBS) in paperback for \$35). I will attempt to summarize I've learned on this aeration thread. Y'all let me know if this makes sense.

- 1) Having enough dissolved oxygen (DO) in the wort is extremely important for a proper fermentation. Inadequate DO can lead to
  - a) Long lag times w/increased risk of infection
  - b) Long or stuck fermentation
  - c) Increased production of esters and acetaldehyde leading to off flavors.
- 2) A DO level of 20% of oxygen saturation seems to be adequate (MBS via Kenny B.)
- 3) 100% air saturation is about 20% oxygen saturation. (Lucky for us--or maybe it's not luck! Could it be Divine intervention?)
- 4) Observations of the lag time by several home brewers (Jack S, myself, et al) indicate that techniques such as shaking the fermenter, splashing wort on side of fermenter, syphoning through an aerating tube, indicate that these techniques provide adequate aeration. HOWEVER, no home brewer has measured DO, nor have any tests for unwanted byproducts (e.g. esters) been done either qualitative (tasting) or quantitative.
- 5) Clearly with the air pump method one can achieve 100% air saturation, just keep pumping.

My Conclusion: For 5 gallon sized batches with OG around 1.045 splashing, shaking, or siphoning through aeration tube will provide adequate oxygen in the wort.

**Subject: Topping off secondary**

On Wednesday (took the day off to brew my first all grain batch), a great mash, a nightmare sparge (suddenly, I was standing barefoot in 1/2 gallon of hot wort), and a vigorous boil, I ended up with about 4.5 gal of 1.054

wort. I should have topped off the primary, but somehow it slipped my mind. Can I top off the secondary with impunity? I have a week long dry hop coming up and I figure to just top off at that time. Any downside besides the dilution?

Thanks in advance. Use private email unless its of general interest.

"DO NOT DRINK Hydrogen Peroxide! ... Honest- I did a thesis on a related matter."

I won't dispute this, in general, but I'd like to note that hydrogen peroxide can also be used to increase the oxygen content of water one uses on house plants.

"Data point: Viruses don't respire aerobically or otherwise. An anaerobic virus is a meaningless term."

I freely admit that this is outside my realm of expertise.

"Data point: Warts come and go, often spontaneously."

I can only report what I have experienced.

"In beer, hydrogen peroxide will kill your yeast. Remember, it's supposed to stop infections?"

I'd guess this depends on the concentration. It seems possible to me that as the hydrogen peroxide dissolved into solution, it would become too weak to kill yeasts en masse, but still sufficient to oxygenate the solution, at which time it might influence yeast production to surpass that growth curve represented by the yeast population, had it not had hydrogen peroxide added.

"Data point: There is a POISON label on that bottle oof peroxide. Why might it be there? "

It's not. "Topical solution USP 3%". It's not data if you don't check.

"But do the reseearch before the experimentation with your health and life."

A reasonable request, but sometimes experimentation involves risk.

Others have pointed out the danger associated with free radicals, which are the latest culprits in the search for the cause of ageing, and have pointed me to some appropriate magazine articles. ( And I thank them. )

If it's any comfort, I donate blood about once a week, and they'd be the

first to let me know if there was anything wrong with my health. As it so happens, I seem to have a very healthy cell count and blood chemistry ..

Subject: Mash Out

Message Creation Date was at 20-AUG-1993 08:10:00

I've been a faithful HBD reader for about six months now and, though this must be a FAQ, I've seen nothing addressing the Mash Out Phase of all grain brewing. We've done about 20 all grain brews, and we always do the Mash Out either in the Mash Tun or by Sparging in the Lauter Tun with 170 deg water. I know what the Mash Out does for the grain (stop enzyme activity) but what does it do for the resultant beer? Is there a difference between mashing out in the mash tun and lautering with 170 deg water? Bottom line: What is being gained (or lost if we don't mash out)? TIA.

KB> production, for one) and adverse effects on the speed of fermentation  
KB> (read increased lag times and the resultant risk of contamination,  
KB> prolonged fermentation times...

Information I have heard indicates that you're \*both\* right. The scientific literature, with experiments presumably conducted much more rigorously than Jack's, says aeration is important. Jack's experiment, and anecdotal evidence from some homebrewers, indicates otherwise (at least as far as lag times are concerned).

According to Jeff Lebesch, the owner of New Belgium Brewing, he uses a stainless-steel airstone with pure O2 because he says you just can't get the amount of oxygen you need from air. That, coupled with the fact that an aquarium pump/airstone is probably not a very efficient way to transfer O2 to the wort, indicates that \*homebrewers, without special equipment\*, may not be able to get enough oxygen into the wort to make a difference.

So I submit that the question is not whether O2 is important for yeast, but whether homebrewers can oxygenate their wort sufficiently without resorting to difficult or expensive methods. I'm ignorant of any data that may prove or disprove this -- does anyone know the volume of air pushed by an aquarium pump, what the efficiency of gas transfer might be with an aquarium airstone, O2 vs other gases in air, etc.?

Personally, I've given up on aerating with an aquarium pump, as it seemed to make no difference in my beer and, since I had no in-line filter, I was worried about introducing airborne contaminants. YMMV.

From: Michael.Burgeson@Eng.Sun.COM (J. Michael Burgeson)  
Subject: Aeration

Thanks Kinney for siting some good sources on the topic of wort aeration! After reading Jack's article on his aquarium pump/lag time experiment (HBD #1206, "WORT AERATION"), I meant to respond, but have been too busy at work to gather information. So, I'm just going to post without my sources at hand.

I think its important that we remember, as Kinney pointed out, that poor lag time is not the only symptom of poor aeration. "Malting and Brewing Science" referred to higher ester production. An article by Dr. Fix in "Brewing Techniques" about diacetyl cited poor aeration as a possible cause of excess diacetyl production. I have also seen references to increased fusel alcohols, and other undesirable fermentation byproducts resulting from poor aeration.

The ideal level of dissolved oxygen in wort at pitching time is 8 mg/l. Coincidentally, this is approximately the maximum dissolved oxygen level you can obtain using air. This is why I have not started using oxygen to areate my wort; by simply saturatiing my wort with air, I am acheiving nearly the ideal dissolved oxygen level, without an expensive dissolved oxygen meter.

As far as Jack's experimental results, I think it would have been enlightening to measure the dissolved oxygen levels in his samples. Due to the small size of his samples, there is proportionally much more surface area exposed to the air during transfer than in a 5 gallon sample. I feel that the dissolved oxygen levels in his samples may have been closer to the same level than if 5 gallon samples were used. Also, how did they taste Jack?

One last point: 50ml of starter ("working kraeusen" in Jack's words), for a 500ml batch is an adequate amount of yeast. Most homebrewers under-pitch, since it is not practical to build up to a 2000ml starter for a 5 gallon batch. Personally, I usually pitch from a 500-1000ml starter. I know from working in a homebrew supply store tha many people pitch far less; ie. the 50ml straight from a Wyeast packet. The effects of improper aeration are multiplied when under-pitching.

I do not mean to slam Jack's experiment. It was a good controlled experiment, but I think it is incomplete without knowing the dissolved oxygen levels in the samples, and what the differences in the flavors were.

Irvine has no brewpubs itself. However, Dana Point (about 15 miles South) has Heritage Brewery, which is near the wharf area. I haven't been there, but I have tried some of their beers bottled and they are pretty good. Best recommendation however, is Goat Hill Tavern, in Costa Mesa. They have about 110 beers on tap, mostly microbrewery types, with a few big shops (Coors, Bud) thrown in for the huddled masses. If you have time, Manhattan Beach Brewery, on Manhattan Beach Blvd in Manhattan Beach, is really good, with pizza that is perfect. They are about 30-45 minutes north of Irvine on the 405 fwy (Dana Point is also on the 405, just south).

Subject: To blow-off or not to blow-off?

I have noted a number of beginning brewers and all-grain neophytes (like myself) in the HBD lately, and I have a question that may be of general interest to this group.

What is the feelings out there on whether to employ a blow-off fermentaion or not? Just using a 7 gal carboy and not worrying about boiling off enough to fit in a 5 gal carboy seems like a lot less stress, but I've always used a blow-off in my extract brews. And besides, all that brown tar just worries me.

Let's see public responses to this because I think it's of general interest.

Subject: Yeast FAQ Notice, CaCl2 info.

Hi HBD,

First off I would like to thank everyone for pointing out the errors/oversights in my Yeast FAQ. Most of the points were valid, and I appreciated the input from those with more experience than myself. I should

be posting the corrected version to the archives in about a week. If anyone

else has found errors or suspected errors, either with the technical info

or the yeast "flavor" data, please e-mail me.

To the gent looking for food-grade CaCl2: I doubt that you will find any.

The bottle at our lab reads, "Warning: Causes Irritation." This is not to

warn you off using it if you need to correct your water chemistry. I think

that the amounts used to alter the concentrations of Ca and Cl in water to be used for brewing

will not irritate you (are you using Miller's section on water ions for guidance?). Luckily, most lab grade products are more pure than food grade,

and you can get an analysis of any contaminant levels shipped with your purchase. A good general source for chemicals is SIGMA.

Ordering is (800) 325-3010

Customer Service is (800) 325-8070

Technical Service is (800) 325-5832.

I don't know what their policies are about shipping to the public, but the

numbers are toll-free. I don't own any stocks, let alone stock in SIGMA, etc. etc. Please check the contaminant levels, and buy the best grade

you

need.

Here is my info for those who want to reach me about the Yeast FAQ.

Or anything else.

From: tmgierma@raphael.acpub.duke.edu (Todd Gierman)  
Subject: yeast cultural hysteria

Well, well, well. After scanning through the ENCYCLOPEDIA MYCOLOGIA in HBD #1207, what can one say but: "well, well, well." Yes, it was excessive and uncalled for - more of an attempt to intimidate than educate, really. There's no point in attempting to unshroud Mr. Weicht's thesis from its thicket of scientific jargon and double-speak; for our purposes (homebrewing, remember?) the point is really moot. For anyone really interested in pursuing further information concerning yeast biochemistry, genetics and (yes) taxonomy, I suggest that you start with a wonderful little primer put together by one of this century's more noteworthy yeast experts, namely: The Life of Yeasts by H.J. Phaff, M.W. Miller and E.M. Mrak, 2nd edition, Harvard University Press, Cambridge, Mass., 1978. This is a marvelously thorough, yet simple overview of yeasts, including: historical aspects, morphology and vegetative reproduction, sporulation and life cycles, genetics, metabolic activities, industrial uses (well, you get the idea). Its straight forward approach makes it a pleasure to read for both scientist and non-scientist alike, I'm sure. Check your large, local university or public library.

On a more philosophical note, allow me to quote Phaff et al.,

Many controversies exist in viewpoints concerning biological taxonomy. Some investigators are "splitters," those inclined to establish many species on the basis of relatively minor differences, and others are "lumpers," wishing to reduce the number of species.

I propose for the purposes of this forum, that we consider ourselves "lumpers." It really doesn't matter what we call them, as long as everyone understands what is being talked about. It becomes increasingly meaningless in this forum to say it's this genus or that genus, etc, though for lambics (*Brettanomyces/Dekkera*) we must make an exception. The point is whether it has been used in brewing and what were the consequences. To this end, I propose dispensing with scientific names as much as possible and sticking with the common names, the ones that everyone understands and sees displayed in the local homebrew store. Let's go even further: instead of saying Wyeast #3056 or MeV 320 or whatever, why not, as has been previously requested, refer to them as Wyeast Munich or Bavarian, or Bohemian (use the number in parentheses) and eliminate cryptic references to its putative source (these may be inaccurate). I think this would be far more useful to those less familiar with the available cultures.

I have a second proposal that merges two suggestions brought up in the last

couple of issues: sharing yeast cultures via the network and  
Weihestephan

68. In the realm of scientific research, as many of you are aware, it is customary and considered "good form" to make all reagents available that have been communicated through publication. Within reason, these are freely made available gratis to any colleague who requests them. I think that there are many individuals out there who would be quite eager to obtain a culture of Weihestephan 68, myself included. This network offers

a wonderful means by which to distribute the culture, rather than wait until who knows when for its release. Certainly, someone out there has an

agar slant full of this stuff. Therefore, I am proposing a Weihestephan 68 chain letter, of a sort. It works like this: an individual with a reliable culture announces it in the HBD; all others interested in receiving a sample respond via private e-mail; each person responding denotes themselves as a culturer (one who has the ability to make agar slants and propagate the yeast) or a non-culturur (self-explanatory); the first individual (a culturur himself) selects two non-cultururs and one culturur to receive the yeast on slants via first class mail; once the designated culturur (recipient) receives his slant, the information is posted in the HBD and the process begins anew. Of course, non-cultururs have no further obligation other than to notify and thank the sender.

Once

three cultures are shipped, the culturur is relieved of any further obligation, unless colonies do not appear on the slant - then a new attempt

should be made. Slants should be streaked with more than one colony pick,

in case more than one strain is actually involved, and sent immediately even before the colonies appear, they may ship better this way. This process may take a while before everyone who wants the culture actually receives it, but, because it spreads the burden of culturing and shipping,

it should be fairly painless. So, is there anyone out there who will come

forward with Weihestephan 68? Put me down as a culturur.

Oh, yes, if you must flame me, flame me in the forum. Please don't waste my time with private e-mail flames. Thank you.

Date: Sat, 21 Aug 1993 20:22:14 -0600 (CDT)  
From: jim@n5ial.mythical.com (Jim Graham)  
Subject: a fantastic bock

Hey, this is a first...I actually have something other than a beginner's question to post here!

A few weeks ago, I set out to brew what would be my first true departure from kits and simple batches with a single tin of malt extract, dried malt extract or corn sugar, hops, and yeast. And to make it really worth the effort <grin>, I decided to (more or less) brew one of the recipes from TNCJoHB, that being Papazian's Dr. Bock (p. 203).

Now, I couldn't get the exact quantities that he suggested, but I wasn't particularly worried about that (I'm \*NOT\* one who follows recipes like they're cast in stone). I did have to decide between using lager yeast, and living with fermenting/aging at around 75 deg F, or just using ale yeast and not worrying about it. I chose the ale yeast (after a lot of debating the subject), based mainly on a comment in the book that said ``Don't be afraid to substitute ale yeast for lager yeast and vice-versa'' (p. 174).

Anyways, here's what it amounted to (for 5 gallons):

9 lb 6 oz (3 tins) of Superbrau amber malt extract syrup (\*)  
1/2 lb chocolate malt  
2 oz Hallertauer hop pellets (boiling)  
1/2 oz Hallertauer hop pellets (flavor)  
2 pkgs ale yeast (\*\*)  
approx. 3/4 cup corn sugar (for bottling)

(\*) Papazian calls for 8 lbs malt extract syrup  
(\*\*) Papazian calls for 1--2 pkgs lager yeast

Anyways, it's been in bottles now for just under 15 days, and even though just about everyone I talk to says to expect a bock to take a \*LONG\* time to age, it's already \*WONDERFUL\*!!! It's already the smoothest beer I've ever brewed, and I've done what I consider to be some really good beer. Scratch that...it's the smoothest beer/ale/whatever that I've ever tasted, period. I can't wait to see what this batch is like after a couple of months....what little of it is left, that is! :-)

The flavor is very smooth (creamy actually comes to mind as a better word), with a lot of malt flavor, and just a hint of a chocolate flavor from the chocolate malt. It has virtually no bitterness from the hops (other than to offset the sweetness of the malt...which, if I read things right, means I did something right! :-)). It pours very nicely, with about a 2 cm head, which holds up very nicely.

It does, however, pack a bit of a punch...much more so than any batch I've brewed to date. :-)) It's certainly a batch to be enjoyed in moderation (which helps it to last longer, too!).

Oh well, just thought I'd pass this success story along. Later,

From: LIFE'S TOO SHORT TO DRINK CHEAP BEER <UNDERWOOD@INTEL7.intel.com>  
Subject: More questions

I brewed my second all grain the other day and differed my procedure just a little. Now the questions. Usually I boil, siphon the wort into a plastic primary and let sit overnight to settle/cool. The next morning this gets racked into the carboy, yeast added, etc.

This batch I used an immersion chiller to cool and then straight into the carboy it went. The first method usually leaves about an inch of trub in the bottom of the bucket. With the chiller, I left a lot of stuff in suspension. Which is the better method?

Also with that previous batch I saved some of the slurry in a mason jar. Unfortunately the garage fridge got unplugged, now the lid is bowed. Is this yeast bad? I will have more slurry here in a day or two. Whats the proper method for saving this stuff?

Thanks for the help, Chuck

I tend to agree with Al on this one. I am a prodigious user of the Wyeast 1056 strain, albeit not their culture. I believe that Seibel has this strain catalogued as being from the Narraganset brewery and was used by them in their Porter. It has been reported in this sage journal as being the Sierra Nevada house strain. I get this yeast from the Washington, DC local Old Dominion Brewery by the quart. I find this yeast a great performer yet too bland for many styles. In my search for a characterful

yeast I have settled on the Wyeast 1028. I use the actual Wyeast strain.

I have found the Wyeast 1028 to have the complex woody character that is ascribed to it above. It does produce many other pleasant esters that remind me of cask Wadsworth's 6X. I have found it to be a strong attenuator. The Narragsanset/Sierra Nevada yeast is a VERY strong flocculator. Once it is done with the job it DROPS! The London Ale yeast is a bit more dusty so it hangs around and nibbles on them sugars a bit longer. This may be the character that seemed to accentuate hop bitterness. I have not found this yeast to be a big diacetyl producer. On the contrary, I find the Narraganset/Sierra Nevada culture to be a bigger diacetyl producer. Especially in higher gravity beers. As far "green apple" acetaldehyde, not in my experience.

An interesting behavior of the 1028 is its "top fermenting character." Very large colonies of yeast form on top of the krausen. These are the size of pie plates.

A recent experience with this yeast bears out my description. I made a batch of 1.052 Pale Ale with this yeast. The recipe follows. The woody character of the yeast (very apparent) combined with the MT Hood characteristic resinous character to produce a very pleasant beer. Plenty of character here for me.

American Pale Ale:

Through KitchenAid Grain Mill:  
22 lbs Great Western 2 row  
1 lb Dewolf-Cosyns Cara Munich 70 Lovibond

Hop Pellets:  
2 oz Perle 8.1% AA 60 minutes  
3 oz Perle 8.1% AA 30 minutes  
1 oz Mt Hood 3.9% AA 10 minutes  
1 oz Cascades 5% AA 5 minutes  
1 oz Mt Hood 3.9% AA 0 minutes

1 teaspoon Gypsum  
2 tablespoons Irish Moss

OG: 1.052  
FG: 1.009

Procedures:

Single step infusion mash at 152-150F with Gypsum. Sparge with 170-190F water to collect 15 gallons in 2 hours 30 minutes. Boil for 30 minutes before adding first hop addition. Add Irish moss for last 30 minutes. Use immersion chiller for 30 minutes while setting up "counter flow" chiller. Divide unfermented beer between 3 carboys with air locks (blow off tubes? Not this decade). Add 1/3 gallon yeast starter to each (1.040 OG starter) at 62F. Shake to aerate. Ferment in front of window AC. Krausen appears over night.

Cheers, Rick

From: "Andy Phillips, Long Ashton, Bristol, UK" <phillipsa@afrc.ac.uk>  
Subject: Mashing in picnic cooler

On Saturday, I mashed for the first time in my new mash tun - an insulated picnic cooler with slotted pipe sparge manifold - and was impressed with how much easier it was than with my old Bruheat. I prewarmed the tun to 80C, then mixed 5.3 kg (11.6 lb) of pale malt with 13 litres (2.9 Imperial gallons) water at 76C. The resulting mash started at 66C and dropped to 65C over 90 min. I stirred occasionally to redistribute any cold spots near the walls. I sparged to 6 (UK) galls at a gravity of 69 at 20C. My calculations suggest that I had almost 100% theoretical yield!! My highest with the Bruheat had been about 85, and usually about 20% of this was unfermentable, probably due to hot spots near the heating element, killing off the beta-amylase.

The other advantage is that the Bruheat can now be used to heat the sparge water (no more sparging with pans from the stove), and the runnings from the mash tun can be sent straight to the Bruheat for boiling. Assuming that the resulting beer tastes OK, I'm completely sold on the new system.

Andy

Subject: Computer Controlled Mashing

Has anyone on the net undertaken the process of automating their mash by using a closed loop control system.

ie: temp sensor --> computer --> solenoid --> gas burner --> brew pot --  
    ^ |  
    | |  
-----

I have used the BruHeat Boiler (hope I can mention the name) for some time with good results but got a nice little tingle from it the other day so am no longer keen on electrical heating elements. Instead I now have a 3 ring gas burner beneath a 40Gal SS keg which enables me to do larger batches which come up to temperature quicker. What I would like to do with this system is use the inner ring (or possibly a seperate element) as a pilot flame with a computer controlled solenoid that would switch gas on/off to the other rings to maintain the appropriate mash temp.

Ofcourse there are much easier (and cheaper) ways of managing a temperature controlled mash but a computererised system (at a reasonable price) provides IMO a great way of documenting and reproducing recipes!

What do people think? Are there other problems with this sort of system such as exactly where in the mash should you measure the temperature or should the mash be constantly mixed, etc?

Any info would be appreciated.

Cheers,

Murray.

Subject: Barley Water (Cont'd)

In the continuing "barley water" debate, Darryl writes:

> > The author went on to mention that there was no longer a barley  
>water tradition in the English-speaking world, but that a popular  
>version called "horchata" was still enjoyed in Spain and parts of  
>Latin America.

>I realize that Bill didn't say this but was quoting someone else.  
>However, horchata (pronounced without the leading h sound) is a common  
>drink from Mexico and is made from ground rice and cinnamon, and is  
>pretty sweet. In the LA area you can generally get this instead of,  
>say, a soft drink at a restaurant. It doesn't sound like it's got very  
>much in common with barley water, however, in either ingredients or  
>intended use.

I did a little more reading on the subject, and Darryl is correct.  
Modern-  
day horchata is rice-based. However, at one time, it apparently was  
barley-  
based. The term "horchata" comes from the Latin "hordeum", meaning  
"barley". It appears that rice supplanted barley as the grain of choice  
when the Moors introduced rice to Spain in the late middle ages.

There also appears to be another form of horchata, found mostly in  
Spain,  
made from chufa, or ground tiger nut - the underground tuber of a plant  
called "earth almond". One reference says this tuber was mentioned in  
the  
writings of Theophrastus as being harvested by the Egyptians and cooked  
in  
barley juice. Hence, the original "chufa horchata" appears to have  
derived  
from this ancient Egyptian tradition.

From: Allan Janus

Greetings, all - does anyone in the Washington DC area have any information on a new brewpub that's been a-building in Gaithersburg for a long, thirsty time? I recently moved nearby, and the sight of a brewpub gave me a very positive view of the local quality-of-life index. Now it's the middle of a mid-Atlantic August, my thirst is great, and the brewpub continues to hold its peace. Anyone know the brewer-founder, plans, opening date, etc?

From: Mark A Fryling <mfryling@magnus.acs.ohio-state.edu>  
Subject: preservatives??

Howdy,  
I have a question for those of you in the know concerning preservatives and their toxicity to yeast. Specifically, I recently bought some catawba and concord grape juice from one of the lake Erie wineries to use to make some pyment (grape mead). After purchasing however, I noticed that the juices are preserved with "benzoate of soda", which I presume means sodium benzoate. Questions, a) how persistent is this stuff; i.e. does it become non-toxic or un-reactive with time like sodium metabisulfite? and b) if it is persistent is there a threshold level below which my yeasty-beasties should be safe?

The juice is extremely sweet (not at all like Welch's) and I was thinking that I would use it at about 2.25L of juice and 6-8 lbs of honey per 3gal of finished pyment. One way of testing is to try a small (say 1gal) pilot batch, and I may do this regardless, but advance info would be helpful.

I have further interest in this subject because I would like to figure out another way to make hard cider and cyser this fall without the use of metabisulfite. Call me hypersensitive, but I still taste and smell the sulfur in the hard cider I made last year using campden tablets and then pitching Wyeast Irish Ale (1084?). The sulfur aroma is not real obvious, but I'd like to try to avoid it this year and still ferment with a yeast of known characteristics instead of leaving it up to the wild beasts.

TIA

From: Michael Howe <howe@gwl.com>  
Subject: SF area Breweries & Brewpubs

Hello HBD'ers,

I would like any/all information anyone might have about Breweries and Brewpubs in the San Francisco area. I know Anchor and Sierra Nevada are both out in that neck of the woods, but where? What about "Can't Miss" micros and brewpubs. I know the area is rich in drinking potential, thus I would like to maximize my opportunity.

Also, I would like to obtain the current brewpub list that was recently compiled. That could probably answer many of my questions. I would get it myself but I don't have FTP access. Could some kind soul forward that to me as well.

Feel free to mail to me directly to save precious HBD space...

Thanks in advance,

Michael Howe e-mail : howe@gwl.com

From: trl@photos.wustl.edu (Tom Leith MIR/ERL 362-6965)  
Subject: Mash Out

>I know what the Mash Out does for the grain (stop enzyme activity)  
>but what does it do for the resultant beer?

Provides for repeatability, mostly. ie: enzyme activity is stopped  
after x minutes, period.

>Is there a difference between mashing out in the mash tun  
>and lautering with 170 deg water?

Yes. You won't have enough mass of sparge water at 170 degrees  
to raise the entire grain-bed (with its water at, say, 150 degrees)  
up to the enzyme-stopping temperature. And you shouldn't use water  
much hotter than 170, for fear of tannins and other off-flavors being  
carried into your beer. This is an argument for mashing in a kettle  
on the stove, or going to decoction (did I spell that right?) as opposed  
to the straight infusion method.

>Bottom line: What is being gained (or lost if we don't mash out)? TIA.

Gained: a little time

Lost: repeatability

yer welcome

From: okra@genesis.nred.ma.us (dean goulding)  
Subject: no subject (file transmission)

FWIW - 2 tips that have helped me...

1 - I make a temporary burner liner for my gas stove from two layers of aluminum foil. Cut an asterisk shape the size of your burner element in the center of the first and fold under the hole in the stovetop for the burner element.

Leave plenty of excess to cover the enamel stovetop. Do the same with the second sheet, perpendicular to the first. This helps with the stains from burnt wort and the enamel distress from 1.5 hours of high heat. It also helps to have the stove spotless to start with.

2 - I sparge using the grainbag-in-a-bucket system. I've found that using two sections of newspaper taped around the bucket w/ masking tape makes an effective/recyclable insulation. Cut an indentation if you use a tap at the base.

Pet peeve: Let's remember that some of us call long distance to download the HBD. I'd rather read valuable brewing info than cute tagline drawings or excessive quotes from the previous HBD.

Question: For my last 2 batches, I've used Wyeast Chico/Ballantine (1056) yeast. This appears to be a bottom fermenting ale yeast. Isn't that an oxymoron (ie.jumbo shrimp, military intelligence)? Aren't yeast segregated as either top/ale or bottom/lager? Dr. Fix?

Thanks! Dean Goulding (okra@genesis.nred.ma.us)

Domenick> tar just worries me.

Domenick> Let's see public responses to this because I think it's of  
Domenick> general interest.

Domenick> Domenick Venezia  
Domenick> ZymoGenetics, Inc.  
Domenick> venezia@zgi.com

You may not see a public response to this, because I have never been  
able to successfully post to HBD. Maybe it will work this time, I  
will try.

Although I am not an all grain brewer yet (will be in a couple of  
weeks), it seems to me that once you have done your boil and have  
racked to a fermenter, it matters not at all how you got your wort.  
You will still have malt sugar, water, yeast and hops in a carboy. If  
you used a blowoff fermentation setup before and it worked and you  
liked it, keep using it. BTW, I use a blowoff hose and ferment in a  
SS soda keg. I get tons of krauesen and hop pellet residue in my air  
lock bucket. I really like the blowoff system.

"Date: Sat, 21 Aug 1993 15:15:59 -0500  
From: tmgierma@raphael.acpub.duke.edu (Todd Gierman)  
Subject: yeast cultural hysteria

"I have a second proposal that merges two suggestions brought up in the last couple of issues: sharing yeast cultures via the network ... This network offers a wonderful means by which to distribute the culture, rather than wait until who knows when for its release. Certainly, someone out there has an agar slant full of this stuff."

I like this idea, also, but it is not a new one. I was browsing through the bread FAQs I could find in gopherspace, over the past few days, and discovered that there is a very close parallel between bread yeast, and beer yeast, collectors. Bread yeast collectors also trade yeast samples ... sourdough is a fairly common variation, as it occurs, differently, all over the world.

Below is a method for preserving bread yeast and stabilizing them for mailing and long-term storage. I don't \*know\* that it will work for beer yeast, but I see no reason why not ... I don't think agar slants are a prerequisite to successful propagation of a genotype ... just a useful intermediate storage.

Here's another useful intermediate storage that may be much more stable.

The procedure, as described, lacks sanitary safeguards ... but I don't think this is an unsurmountable problem. A homemade glove box would do nicely. (-:

Aluminum foil might be preferred over wax paper, for sanitary reasons.

From: John Adams <j\_adams@hpfcjca.sde.hp.com>  
Subject: Brewpots

I just had a 6.5 gallon stainless steel brew pot made for me. The materials for a 14 gauge stainless (this is probably thicker than "restaurant gauge") amounted to \$75. The real "cost" involved is the actual construction. Getting someone with stainless cutting/welding experience and the right equipment is the trick.

My father-in-law is a supervisor at a beef plant where they do all of their own stainless work. My pot has a fitted lid, stainless handles fabricated from 1/2" rod (with walnut grips) and a 3/8" stainless threading pipe at the base.

All it cost me was a batch of beer!!!

> Warehouse in Seattle, WA. The following was quoted:  
> 10 gal. stainless steel brew pot - \$149.00  
> brass/copper ball valve,nipple,fitting - \$ 86.00  
> cut to fit bottom screen to filter wort - \$ 60.00  
-----  
\$295.00

The prices for the screen/valve seem a bit high but the price for the pot itself is reasonable (assuming you get a lid).

>Subject: Aeration. What the pros say...

>The latest in Jack's continuing vigil against the accursed momilies of brewing focuses on aeration.

>I'm not sure what Jack's claims are here. But I'll point out several points of interest that may affect his "scientific" experiment.

I am not sure what Kinney's point in this lengthy response is but I have several reasons to suppose it is something other than objectivity.

First of all, puting the word scientific in quotes is a rather unprofessional way of trivializing the time and effort I put into this.

Secondly, if he misunderstood the conclusion and objective of the experiment before posting this same stuff on r.c.b., he certainly is aware now, that it has nothing to do with what I was trying to learn. We thrashed it out on r.c.b. for over a week and to restate the original objections and ad hominems without changing a single word, reeks of demagoguery.

For those who may still be confused, the conclusion follows...

.....

CONCLUSION...

The experiment seems to confirm the author's previous experience and points to the conclusion that the method of aeration used has no correlation with or effect on the time to onset of fermentation. Contrary to frequently stated anecdotal experience, the un-aerated control samples started fermenting as soon and with the same vigor as the variously aerated samples. This was true both in the case of cold temperature lager yeast and room temperature ale yeast.

This experiment was not intended to test any other aspects of the brewing process that may be affected by wort aeration. Much has been written on the subject and the present author's intent was only to study the effects of aeration on the onset of fermentation.

.....

I will be happy to discuss aeration as related to lag time but, flavor profiles, final gravities and other aspects are not part of the study nor is the overall need for adequate aeration under question.

For the record, the incoming mail is in very close agreement with my conclusion. I have yet to hear from a single person who reports that lag time has dropped after switching to an aquarium aerator from whatever they were doing before.

It may seem like nitpicking to prove that aeration does not improve lag time if it is necessary anyway for good beer but nit picking is what science is all about.

If someone makes a statement that lists 10 reasons for doing something but one of them is wrong, the entire statement becomes suspect.

If aquarium aerators do not improve (reduce) lag time, it is time to stop saying they do, no matter how important aeration is for other reasons.

If they do, someone else will have to prove it, I tried and could not.

>Subject: Mash Out

> Is there a difference between mashing out in the mash tun and lautering with 170 deg water? Bottom line: What is being gained (or lost if we don't mash out)? TIA.

Lautering with 170 deg water is not the same as mashing out in the kettle because the mash temp never gets anywhere near 170 degs while sparging.

Bringing the entire mash up to 170 before sparging has the effect of increasing the mash temperature during the sparge. This possibly results in a more effective sparge, less possibility of stuck sparges and some chemical aspects that I will leave to the experts.

From: "Anthony Johnston" <anthony@chemsun.chem.umn.edu>  
Subject: Cream Stout

This past weekend I devoted some time to my OTHER hobby (namely, drinking good commercial beers) and happened upon some Watney's Cream Stout. This was one of the best beers I have ever tasted, and I would like to brew one similar (as similar as I can get) and would hope for some pointers from fellow HBD'ers. Here are my (possibly erroneous) understandings:

1) Cream stouts have lactose added to sweeten them. In the boil? At bottling? In between?

2) Stouts are traditionally made with darker adjunct grains added such as roasted barley, chocolate malt, black patent. As an extract brewer I would steep the grains before bringing my water to a boil. Now that I am hoping to move on to partial and all grain recipes, when does one add these adjuncts?

3) The Watney's I sampled seemed much lighter in body than other stouts I hve tried. Does anyone have any idea of an OG and FG for the style? Is it the same as the sweet stout in Papazian's general guide lines?

Any helpful information will be appreciated. If you e-mail me direct, I will edit the responses and post a summary on Cream Stout to the HBD. If you post to the HBD, then I will not summarize in the interest of conserving bandwidth.

Thanks,  
Anthony Johnston

From: Eric Wade <ericwade@CLASS.ORG>

**Subject: Source for pumps wanted**

I'd be interested any any sources and recommendations for pumps to move both wort and hot water. I'd like to be able to lift 175 df and above water to a hot liquor tank (HardSparger(tm), all in good fun Jack!) as well as run hot water and cleaning solutions through the pump and other parts of a system like a counter flow chiller. I am aware that the pump should pull (rather than push) the wort through the chiller to avoid HSA. It is difficult to tell (at least for this layman) which pumps can handle the high temperatures, are food grade quality, will deliver an appropriate throughput, will raise water the 6-8 feet (est), and are available for a reasonable price. I've got the Cole-Parmer catalog and think I've identified an appropriate pump. Still, I'd like the advice and recommendations of those who've gone this route already; is there something better, cheaper?. If you have a recommendation, please be as specific as you can regarding source, model number, catalog page number, price, etc. SF Bay Area sources also appreciated.

BTW, nice work on the yeast FAQ. It, and the followup comments are now part of my brewing library.

Cheers,

Eric <ericwade@class.org>

I will try to find my source for this and post, but from my memory, it's not anything to do with blending of four beer made from four yeasts, rather

PU was (or maybe still is) brewed with a mixed strain. Again, from memory,

someone, several years ago, got a hold of the PU production yeast and from

it they isolated four different yeasts, which they called A, B, C and D. I believe that they made test batches and the B and D strains were the most

Pilsner Urquell-like.

From: sc@vcc.com (Steve Casselman)  
Subject: Two Cents on Aeration.

So let me put in my two cents in on aeration. As far as I know there are two different kinds of fermentation, aerobic and anaerobic. During aerobic fermentation yeast take sugars and water and produce CO2 and water. Yeast can only reproduce during the aerobic growth stage. This means that a yeast cell produces another free roaming off spring. When the O2 runs out yeast go into anaerobic fermentation. During this time they consume sugars and water and produce CO2 and alcohols. At this time they stop reproducing and start budding which produces a long heavy chain of cells which start to drop due to their weight, this is called flocculation. The trick is to have enough yeast such that during anaerobic fermentation the yeast consume the sugars before they flocculate. This can be done by adding alot of single yeast cells or by having enough O2 in your wort for the yeast you add to reproduce to the right levels.

One of the experiments I have done in the past was to take pure water in a corney and force oxgenate it. I then added this to my chilled wort. While I never got levels right (the yeast didn't flocculate for a long time) my lag times went down dramatically.

Lately though I just try and ferment in a large plastic bucket with a loose fitting lid for the first week then rack to 15 Gal kegs. We resently made 30 gals of beer and put 20 gals into the "open" fermentor and ten in the keg. The keg had an air lock. After the primary fermentation we took a gravity reading the 20 gals came out at 1.012 while the keg fermentaion came in at 1.030.

From: korz@iepubj.att.com  
Subject: Pronunciation/Mashout

Sorry, but I've lost who asked for pronunciations of certain words, specifically, Maerzen and Saaz.

Alas, there is no FAQ on this, but perhaps someone would like to create one. I can contribute Maerzen and Saaz to it (note that if you have an a-umlaut, you can lose the "e" in Maerzen) oh, heck, I'll add a couple more:

Maerzen MARE-tzen

Saaz ZAATS

Kraeusen KROY-zen

Wort WERT

Trub TROOB

Gueuze GUE-ze (a tough one - Jackson says "rhymes with cursor" but remember that the English often understate their "r"s)

Willamette wil-LAM-met

Boone (Frank) BONE

Spaten SHPA-ten

Here's a new one on me:

I heard "lauter" pronounced "LOI-ter" at the AHA conference. Is this correct? Should it be spelled laeuter?

\*\*\*\*\*

Tom writes:

Is there a difference between mashing out in the mash tun and lautering with 170 deg water? Bottom line: What is being gained (or lost if we don't mash out)?

A more important reason for mashout (besides denaturing the enzymes as Tom mentioned) is to make the runoff more, well, runny (less viscous). Yes, 170F sparge water will raise the temperature eventually, but lautering will be slower than if you had gotten the whole mash up to 170F before trying to get the sugars away from the husks.

\*\*\*\*\*

Domenick writes:

What are the feelings out there on whether to employ a blow-off fermentation or not? Just using a 7 gal carboy and not worrying about boiling off enough to fit in a 5 gal carboy seems like a lot less stress, but I've always used a blow-off in my extract brews.

I did two blowoff/non-blowoff experiments using split batches, and the difference was very noticeable. The non-blowoff sub-batch was more bitter and astringent than the blowoff sub-batch. However, I have reason to believe (I've posted it in the past) that the blowoff method may reduce your head retention. I haven't done enough experiments to prove or disprove this, so it needs some more work. Has anyone else seen this

(blowoff - head retention) correlation?

Subject: Glatt Machining

Those of us who were fortunate enough to be at the AHA National in Portland this year got to see an impressive looking new malt mill made by the company named in the subject line. When I got home I immediately ordered one.

Well, that was the 3rd of August. Today, the 23rd, I got a telephone call from the owner of Glatt Machining. He called from Oregon - I live in New Hampshire - to tell me that he was behind in his orders and would have my mill out to me by the end of the week. He said that the response to his mill has been so good that he can't keep manufacturing fast enough.

He also asked me if I was on the internet. When I said that I had access to internet mail he asked me to tell "all those internet people" that he was running behind in filling orders, but would get them out as soon as he can. I figured that the internet people must be the HBD. Having done that, I've made good on my promise.

As far as the mill is concerned, it's an all metal construction, and has two grooved rollers. It's adjustable and the hopper holds about 2.5 lbs of grain. The real surprise is that it's only US\$80 per mill plus S&H. I was impressed.

Naturally, I have no commercial connection with Glatt Machining or anything like that, this is meant just as general info.

From: mustbkept@aol.com  
Subject: Recipe-Honey Creek Summer Wheat

Honey Creek Summer Wheat

Source: Kerwin Manuel (KerwinM@aol.com)

Ingredients:

7.0 lbs Wheat Malt Extract (60/40)  
1/2 lb Crystal Malt  
1/8 lb Chocolate or Black Patent (your preference)  
1.0 lb Clover Honey (my preference)  
1/2 tsp Gypsum (adjust +/- for your water)  
1.0 oz Tettnanger for 60min  
1/2 oz Hallertau Hersbrucker for 30min  
1/2 tsp Irish Moss for 10min  
1/2 oz Tettnanger-Secondary Dry Hop  
1/2 oz Hallertau -Secondary Dry Hop  
1-2 pkg Ale Yeast (Wiezen Yeast if you prefer)

Procedure:

Steep crystal and chocolate malts for 30 minutes in 1.5 gals of 150 degree F water. Sparge into brew pot and add malt extract, honey, gypsum and enough water to bring volume to 3 gallons. Bring to a boil and add 1 oz Tettnanger, continue boil & 30 minutes later add 1/2 oz of Hallertau, still boiling 20 minutes later (50 minutes into the boil) add 1/2 tsp of Irish Moss for final 10 minutes. Total boiling time is 60 min. Pour wort into primary fermenter filled with 2 gallons of cold water (splashing hot wort into cold water to aerate). Pitch yeast when temperature is within range, 70-80 degrees F. 5-7 days in the primary and after fermentation has slowed, transfer to the secondary fermenter. Add dry hops (bagged or free floating) to secondary (I prefer to use a bag..easier to clean-up) and complete fermentation for 4 weeks. 3/4 to 7/8 cup of corn sugar for priming and bottle. Carbonation should be ready after at least 5 days (I was anxious to try this batch!)

Comments:

Very smooth, good mouth feel. Slightly estery. Banana or fruit aroma? I'll use a real wheat yeast next time. Clear, copper color. OK head retention and color. Very crisp, clean hop bouquet/aroma. Slightly sweet, smooth going down. Alcoholic taste, too much? Small, delicate bubbles. All disclaimers apply...after all, I'm judging my own creation ! Actually, several friends (and a couple of strangers) have told me they really like this one. I apologize if this recipe seems too explicit for some of you experienced types...but I remember what it was like just starting out... recipes or instructions with only partial information...phooey !

Specifics:

Original Gravity: Sorry..didn't take any readings

Final Gravity:

Primary Ferment: 5-7 days

Secondary Ferment: 4 weeks

Type of Fermenter: Plastic

Temp of Ferment: 70-76 degrees F

In my report on the Pilsner Urquell brewery, I noted that they were using three yeasts identified as D, H, and W. I believe that Miller has reported four strains in use and Jackson, 5.

I was explicitly told that the beer from each yeast is kept separate until the yeast is cropped, and then the beer is blended by taste.

I have speculated on this before; I believe that there is only one strain in use, but it has a tendency to mutate. In order to avoid problems, the PU brewery grows up a pitching slurry and labels it with a letter (for example, 'A'). They brew beer from this yeast and attempt to maintain it as if it were a separate strain in the brewery during successive repitchings.

At some fixed interval, they grow up another batch of yeast ('B') and begin brewing with it, also. The 'A' yeast eventually mutates, or it becomes infected, and the brewers are able to detect it while it isn't very severe. They can blend off the results (cutting the flavor contribution to well under the taste threshold, perhaps a third to a fifth of the level at which they were able to detect it) and dispose of that batch of yeast. As this happens somewhat unpredictably, the distribution of letters assigned to successive yeast batches, and the number of batches in use, varies.

Well this isn't exactly a recommendation but maybe it could turn into a source...

Has anyone ever looked into using a dishwasher pump? (or maybe even a washing machine pump?) I would think that since it was designed to move hot water, soap, detergents and bleach (the washer anyways) around that it could probably handle wort/beer as well. A dishwasher pump has the added bonus of being meant for handling dishes someone will eat off of. (hopefully this means that it's not going to pass on nasties to our beer)

As far as availability, there are used appliance stores everywhere and most will sell salvaged parts.

Just thought I'd mention that mine arrived this past Friday, so they certainly are being shipped, however slowly. I was not in Portland, so this was my first look at the mill, and it does seem quite well-made.

I am in the midst of moving, so most of what I own is in boxes and I can't brew. But the Boston Wort Processors will be informally evaluating the Glatt and several other mills in our upcoming Klasic Klub Krush-off in about two weeks. I say "informally" because we aren't prepared, for example, to run the crushed grain through screens of graduated fineness, but we will take a close look at the crush and the quality of construction and ease of use of the mills.

Subject: Re: Source for pumps wanted

For my recently operational RIMS, I'm using a March Manufacturing seal-less magnetic drive pump, model MDX-1/2. The magnetic drive allows seal-less construction and prevents the fluid from contacting the mechanical hardware and lubricants. The materials in contact with the fluid are food-safe plastics, ceramic, and stainless steel and can withstand a reported 190 F. It has 1/2 inch barbed ports for plastic tubing hookups. It operates on household current at 1/50 HP and can move 5.5 gpm at zero head, and has a maximum head of 7 feet. A speed controller built according to Rodney Morris' schematic in the Zymurgy Gadgets special issue works fine.

For information about retailers near you, call March at 708-729-7062. All retailers in my area were selling this pump for about \$95. C&H Sales Company, however, sells it for \$49.50 via mail order. C&H can be reached at 800-325-9465. Their catalog has many reasonably-priced items that may be used in a RIMS.

Disclaimer: No connection with March or C&H; just a satisfied customer and

a new RIMS brewer!

>I like this idea, also, but it is not a new one.  
>(I) discovered that there is a very close parallel between bread yeast,  
and  
>beer yeast, collectors. Bread yeast collectors also trade yeast samples  
...  
>sourdough is a fairly common variation...  
>  
>Below is a method for preserving bread yeast and stabilizing them for  
mailing  
>and long-term storage. I don't \*know\* that it will work for beer yeast,  
but  
>I see no reason why not ... I don't think agar slants are a prerequisite  
to  
>successful propagation of a genotype ... just a useful intermediate  
storage.  
>  
>> How to dry and restart a culture

It is interesting, but if we ever do get this distribution of  
Weihenstephan  
68 off the ground, please, please, please, don't attempt to use this as a  
distribution method. It may work for bread, but it will certainly prove  
counterproductive in the propagation of any beer yeast (bread risings are  
only a couple of hours and you don't care what's there, fermentations  
last  
days, and you do). In this case agar slants are a prerequisite to the  
propagation of a pure culture, helping to maintain the integrity of the  
culture, and, thus, its stability. There will be a lot of angry HB'ers  
out  
there who expecting a wonderful weizen, end up with something between a  
lambic and pond scum instead. The agar slants allow for the examination  
and picking of individual colonies. Many of the nasties that can spoil  
hopped wort (e.g. lactobacillus) frequently fail to grow on the surface  
of  
agar, whereas they can be carried quite well in a dried mass of yeast.  
You  
will end up with a really nice microfloral garden if you propagate this  
way. When somebody indicates that a culture is available, we can take  
some  
time to establish a protocol for propagation (one that must be adhered to  
at all cost). The worst thing would be to ship people contaminated  
cultures.

I won't argue with the overall thesis but you have the reproductive part a little confused. Budding, i.e. vegetative propagation, is the ONLY way that beer yeast reproduce in the normal fermentation environment. The parent cell forms a bud which drops off at the appropriate moment to grow up and do likewise. I doubt that reproduction ever stops completely until fermentation is over but in any case, budding has nothing to do with flocculation.

CORRECTION....

The following statement fogs my point in the comments I last made on the objective of the experiment. It was not, however part of the original CONCLUSION.

>It may seem like nitpicking to prove that aeration does not improve lag time  
>if it is necessary anyway for good beer but nit picking is what science is  
>all about.

The objective of the experiment was to test the air pump/airstone and not aeration in general. The fact that the "non-aerated" control started at the same time is interesting but can be explained by other mechanisms.

The statement would be more correct if... artificially enhanced aeration does not seem to improve lag time in small batches...

**Subject: Blueberry Beer Recipe Request**

Hey:

Well it is getting to be brewing season for me again and I am raring to go. I have come into possession of 12.5 lbs of blueberries and am interested in making a blueberry beer. I have searched the archives using WAIS and looked in Cat's Meow and haven't found what I am looking for. The most common problem is that people give the recipe and then say "This really didn't have any discernable blueberry flavor or color." I am looking for an all-grain recipe, maybe a wheat beer, with pronounced flavor and color. I picked these berries myself and I don't want to waste

all that work. Some things I am particularly concerned about are 1)when to add the blubes, 2) How much to add, 3)how long to ferment them, 4) How to prepare them (ie blanching, pureeing, etc.) 5) What sort of hop rates are appropriate (I understand that too much hops doesn't go well). Anyway, all information would be appreciated....

Anthony writes:

>1) Cream stouts have lactose added to sweeten them. In the boil? At  
>bottling? In between?

I'm not sure if all cream stouts or all sweet stouts have lactose in them, but since I've recently done a semi-sweet (demi-sec?) stout that turned out quite nicely, I can offer a bit of advice. There are several things to keep in mind:

1. Lactose is unfermentable by conventional brewing yeast (it may be fermentable by other yeasts, but I don't know) but I strongly suspect that it is fermentable by Lactobacillus and/or Pediococcus bacterias, so be extra careful with sanitation or you'll get glass grenades.
2. You can add it in the boil or boil it in some water to sanitize and add it anytime up to bottling time, but I recommend adding it at bottling time because you can: add 4 ounces, taste, add 4 more ounces, taste again... You can adjust the sweetness to what you want it to be. Remember that the beer will taste a bit less sweet when it gains the acidity of carbonation.
3. Lactose is not very sweet. It appears that the larger the carbohydrate molecule, the less sweet it is. Lactose is a pretty big sugar and therefore not very sweet. You will need at least 8 ounces net weight in a 5 gallon batch to make a small difference.
4. How much? I had a relatively sweetish stout to begin with, having added a good 2# of various DeWolf-Cosyns crystal malts. I ended up adding 8 ounces (net weight) of Lactose to the 5 gallon batch and ended up with a not-too-sweet stout that was quite good. I wanted to avoid making a super-sweet stout since I had just returned from the Caribbean and down there they like their stouts so sweet (Dragon Stout, for example) you can pour them on pancakes!
5. Lactose sweetness is different from sweetness gained from malt. It is quite noticable and Brian North (a BJCP National judge) immediately pegged my beer as containing lactose. The obviousness of the lactose decreases as the beer ages.
6. Black and Brown malts give your beer quite a bit of acidity, so (unless

your water is high in Carbonates -- this is why Dublin is known for stouts and not known for it's pale ales) adding some Calcium Carbonate (a tablespoon or two for a 5 gallon batch) would help take away some of that dark grain sourness and help make the beer appear sweeter.

A1.

From: bobml@msd.measurex.com (Bob LaGesse)  
Subject: Any Thimbleberry Ale/Mead Recipes?

I just got back from two wondrous weeks of vacation in the Upper Peninsula of Michigan (i.e the Keewenaw). One of the "fruits" of this vacation was that I was able to pick ~10 lbs of thimbleberries while there (only grows wild, somewhat similar to raspberries in color and flavor only richer and slightly tarter, IMHO). I would be greatly appreciative of any recipes that anyone would be willing to share with me.

Thanks!

Subject: Job Posting

Pat Baker (of Crosby & Baker) has asked me to post the following:

\*\*\*\*\*

Crosby & Baker is currently looking for a person to manage the microbrewery & brewpub supply side of their business. Their current sales in this market segment are ~\$1 million/year.

They want someone with experience in marketing and distribution. Good people management skills are required. An MBA is desired, but not absolutely necessary.

The job location will be in Westport, MA, though travel will also be involved.

C&B has hired a consultant to review all submitted resumes. If you would like to be considered for the job or if you'd just like more information, contact Bob Sleeman, FAX # 508-994-9366.

Thank you.

Subject: CaCl2 source

>From Patrick Weix:

>To the gent looking for food-grade CaCl2: I doubt that you will find  
>any. Luckily, most lab grade products are more pure than food grade,  
>and you can get an analysis of any contaminant levels shipped with  
>your purchase. A good general source for chemicals is SIGMA.

Not for most of us. I called SIGMA and told them I was looking for  
pure stuff. For starters, they don't sell to individuals. Then I  
mentioned that this was to be used in brewing when asked if I wanted  
solid or solution.

\*\*The person I talked to about had a cow when she realized that this  
was a food-grade application.\*\*

She didn't have any idea where to get food-grade stuff. Maybe a  
pharmaceutical supply, but they wouldn't sell to individuals either.  
And she was really worked up about the food thing. Personally, I  
don't feel comfortable about non-food grade stuff. The 1% impurities  
could be a lot of heavy metals that don't purge themselves from  
your body and cause fun stuff like liver damage.

Anyway, I'm still looking for a source of FOOD-GRADE calcium  
chloride. There must be a commercial brewer's supply that carries the  
stuff, even if I have to buy a 20 lb sack (it doesn't go stale or  
anything!).

Subject: The word "lauter"

The word "lauter" comes from "laeuter" in German which means "to purify." The "ae" combination is used when your character set has no umlauts. And you heard it right at the AHA, it should be pronounced "LOY-ter". I think that the word is a victim of the English habit of just dropping the umlauts instead of using the "e" after the vowel.

From: Jim Cave <CAVE@PSC.ORG>  
Subject: WORT AERATION

The dialogue concerning Jack Schmidling's wort aeration experiment continues on the digest. I have E-mailed Jack directly concerning his experiment. However I feel that misconceptions continue regarding the experiment so I feel compelled to bring my concerns up on the digest.

In his experiment, Jack's hypothesis (not actually stated) is that one or more of the treatments differ in fermentation characteristics from the control. We must then disprove that hypothesis, by testing the null hypothesis, i.e., there are no differences between treatments. Note you can never "prove" a hypothesis, only disprove it.

I feel that Mr. Cavasin's criticism remains valid since Jack fails to adequately address the alternate hypothesis for his results: that is, he can't be certain that oxygen did not enter the wort (in all treatments) by simple diffusion. Put another way, the experiment does not closely mimic the situation in the brewery. Simple diffusion into the wort in all treatments is certain, considering the long lag time (72 hours for duration of the experiment) and the small sample volumes involved. This indicates a high surface area to volume ratio. The yeast in all treatments, as well as the control, could simply be responding to levels of oxygen achieved as a result of the simple diffusion from the head space in the jars (rather than any similarity in aeration of the samples as a result of treatment procedure). This would account for the similar lag times that were found. Therefore comparisons between treatments remain uncertain. BTW, the alternate hypothesis is the simpler hypothesis.

There are two ways to alter this experiment The first and most obvious is to make four full-scale batches (5-10 gallons?). The valid assumption can then be made that the experiment mimics the situation in the (home) brewery. The second way is to prevent any additional "contamination" of the treatments with oxygen after they have been set up. Erlenmyre flasks, completely filled with wort with the proper treatment (possibly handled under inert gas such as nitrogen) and fitted with blow-off tubes would be one way to go. Before running either experiment, one should go through the possible alternate hypotheses to see if there might be a reasonable doubt about any experimental outcome.

The criticism that the experimental environment does not mimic the natural situation is a very common criticism of experiments. Jack can take comfort in the company he has with numerous PhD and MSc students in science!

Cheers!

From: dd853@cleveland.Freenet.Edu (David Hyde)  
Subject: Tun size and cheapness

HBD was a great source of help for keggin info a year or so ago, so I'm back with more questions. With the time I save by kegging instead of bottling, I figure I can go all-grain and still not spend much more time than I used to. I'm acquiring stuff bit by bit to start and have run into problems finding a suitable mash tun. I'd planned on using a cylindrical "picnic cooler", but haven't been able to find the larger ones. Not true...I did find a large (10 gal?) one at an "exclusive" outdoor shop, but I didn't have the kind of money they wanted. I've found 5 gal ones at plenty of places, but that's the largest around here.

So...three questions:

1. Would a 5 gal cooler make an adequate mash/lauter tun for 5 gal batches with an average amount of grain?
2. If not, is there a relatively cheap source for large coolers?
3. Can a rectangular cooler make a suitable tun? I like the idea of a smaller grain surface area, but could sacrifice that for economy.

Understand, I'm deep in Southern Maryland, far from civilization :), but close to DC and Baltimore for supplies. By the way, I'm currently using a propane hot water heater element as a burner. They're pretty popular around here as crab cookers, and will boil something like 100 gal of water in 15 sec. At least that's how hot they feel leaning over one on a summer day :) (That's a joke, but they do work well.) They're cheap and easy to find around here, and I expect they would be elsewhere.

Thanks in advance.

From: neilm@juliet.ll.mit.edu ( Neil Mager )  
Subject: WORT AERATION & Sierra Nevada

America Online has an online, live Brewing discussion the 2nd Thursday of every month. Participants include knowledgeable folks from Sierra Nevada. I believe in July, the discussion turned to Wort aeration. One of the participants from SN said they like to achieve as high an oxygen saturation as they can - 100% if possible. They use something called a fishtail which is basically a pipe with a flattened end which they use to spray the wort into the fermenters.

From: arf@genesis.mcs.com (Jack Schmidling)  
Subject: PU, Honey, AERATION

>From: darrylri@microsoft.com  
>Subject: PU yeast

>In my report on the Pilsner Urquell brewery, I noted that they were using three yeasts identified as D, H, and W... I have speculated on this before; I believe that there is only one strain in use, but it has a tendency to mutate. In order to avoid problems, the PU brewery grows up a pitching slurry and labels it with a letter (for example, 'A'). They brew beer from this yeast and attempt to maintain it as if it were a separate strain in the brewery during successive repitchings.

I guess I missed this but if it was in the article, I probably mentally voided the information because it sort of cancels out in a practical sense. It would be futile for us to compare notes on "strains" considering that the brewery is pretty much throwing darts.

Thank you for clearing this up.

>Subject: Re: Cream Stout

>I'm not sure if all cream stouts or all sweet stouts have lactose in them, but since I've recently done a semi-sweet (demi-sec?) stout that turned out quite nicely, I can offer a bit of advice.

Having tasted this and several other sweet stouts at a CBS sponsored Stout Seminar, I rather liked the beer and made one up for a party.

However, not wanting to add another odd ingredient to my collection of never to use again stuff, I sweetened mine with honey and the result was just what I expected.

My thinking was that honey ferments very slowly in the first place and with ale yeast and in a cold fridge, it probably never will ferment out.

Prior to kegging the stout, I poured two cups of honey (boiled to sterilize) into the keg and filled and carbonated as usual.

If I were to do it again, I would only use one cup of honey as it is a bit too sweet for general consumption. The first few sips are a taste explosion

but a little goes a long way. It was made in May and I still have a couple gallons left and it is as sweet as the day I kegged it.

>From: Jim Cave <CAVE@PSC.ORG>  
>Subject: WORT AERATION

> The dialogue concerning Jack Schmidling's wort aeration experiment continues on the digest. I have E-mailed Jack directly concerning his experiment. However I feel that misconceptions continue regarding the experiment so I feel compelled to bring my concerns up on the digest.

My only concern is the misconception of the objective of the experiment but I did learn a great deal from the objective discussions both private and public and thank those who contributed.

I apologize for whatever share I may have had in the unpleasantness that developed but simply offer it as a warning of what happens when personal garbage is brought to a public forum. It is all too easy to attack the messenger and never get around to the message or so fog it that little else is accomplished.

>There are two ways to alter this experiment The first and most obvious is to make four full-scale batches (5-10 gallons?). The valid assumption can then be made that the experiment mimics the situation in the (home) brewery.

Considering the objective, viz., the wonders of the airstone, I guess I will fall back on anecdotal evidence. There are only two variables, airstone and whatever else one normally does to make good beer. Anyone who has been making good beer and tries the airstone, soon comes to a very practical resolution. If it improves things, he keeps doing it, if not he quits. The mail and posted comments indicate that most people quit. So much for science.

From: mlh@cygnus.ta52.lanl.gov (Michael L. Hall)  
Subject: Blueberry Beer

Dave (drose@husc.harvard.edu) asks for recommendations for blueberry beers.  
Since I made a blueberry beer recently, I thought I would respond. It had no blueberry color and very little blueberry flavor. My recommendations:

Make a *\*very light\** base beer. Mine was way too dark/heavy. A light wheat beer might be nice. Even then the color will probably not come through (but the flavor might). Blueberries tend to have a reddish color in solution, and I think that will be the best you can hope for.

Use lots of blueberries. I only used 5 lbs. of frozen blueberries in 5 gallons and it wasn't nearly enough. I would use about 2-3 lbs. per gallon.

Add fruit only to the secondary, so that flavors and aromas don't get scrubbed out by the vigorous fermentation. I did this, and it started a pretty good second fermentation due to the sugars in the blueberries.

Using hand-picked blueberries, I would pasteurize them first, by heating to 165 F for 20 minutes.

You may hate to do this, since you have nice fresh-picked blueberries and you would like the beer to have natural flavor, but you will probably be able to get a better blueberry flavor by using an extract. There are various ones on the market; some are probably better than others.

Actually, my final recommendation would be to use a different fruit. I don't think that blueberries have that strong of a flavor, and it gets swamped by all the beer flavors.

Making a good blueberry beer *\*can\** be done: I had a very good one put out by some microbrewery that I tried at a recent GABF (Great American Beer Festival). It had a straw color (not blue), but lots of blueberry flavor. My guess is that they used an extract.

Good luck, I hope it comes out well...

1993 Victoria Microbrewery Festival

Presented by the  
Campaign for Real Ale Society of British Columbia,  
Victoria Branch (CAMRA Victoria)

Victoria Conference Centre, Victoria, B.C.

12-8pm, October 23, 1993

Admission: \$5.00 per person, includes souvenir tasting glass  
and Festival programme.

Beer tickets: \$1.00 each, exchanged for a 4oz. taster.

Lots of different beers and ciders from registered breweries  
including:

Granville Island Brewing Horseshoe Bay Brewery  
Nelson Brewing Okanagan Spring Brewing  
Shaftebury Brewing Spinnakers Brewpub  
Swan's Brewpub Vancouver Island Brewing  
Whistler Brewing Big Rock Brewery  
Red Hook San Juan Brewing Co.  
Sleeman's Portland Brewing  
Merridale Cider Works Wyder's Cider

... and we're still working on it!

Prices are in Canadian funds. With the current exchange rate,  
it works out to a \$4.00 US admission fee and about 75 cents  
per taster. AHA home brew competition is on the morning of  
the Festival. Enquiries for both to:

From: CCAMDEN@delphi.com

Subject: Chlorine, Yeast and My Septic Tank

Hey Everyone;

While this is not a brewing question in the strictist sense, it is related. All the various discussions about sanitizing have got me wondering.

We just bought a house that has a septic tank, and that is a first for us.

We are sanitizing everything with a weak bleach solution. For most things,

I use 1 to 2 oz of bleach to 5 gallons of water. For a few things (cleaning

old bottles) the solution is stronger. Is all this bleach going down the drain going to harm whatever magic occurs in the septic tank? Could it be

offset by pouring the sediment from the first and secondary fermentations down the drain, too? (I think it was Heloise that had a hint once about putting yeast in your septic tank occasionally.) I have considered dumping

the bleach water in the washing machine as it is on a separate drain line from the septic tank. Do I need to (gasp) worry?

Thanks for any and all help. Answers by email or here in the HBD are appreciated.

Date: Wed, 25 Aug 1993 22:32:16 -0500  
From: tmgierma@raphael.acpub.duke.edu (Todd Gierman)  
Subject: yeast

I like Darryl Richman's line of reasoning concerning the question of the number of strains used by the Pilsner Urquell Brewery. It seems in line with what one might expect for conducting "low tech", low cost passage of a brewing strain. In support of this notion, an article by C. Rainbow of Bass Charrington Ltd. (c. 1970) indicates that it is common practice, at least in England, for brewers to limit the number of pitches (of a yeast culture) to five. He indicates that this is to limit contamination, which is inevitable in the brewing environment, and to avoid what brewers apparently refer to as "yeast weakness" (loss of desired properties coinciding with an increase of mutants in the population. So, it would seem likely that the folks at PU hedge their bets a little to avoid costly down time.

A quick comment on this posting:

>Date: Tue, 24 Aug 93 11:17 CDT  
>From: arf@genesis.mcs.com (Jack Schmidling)  
>Subject: AERATION  
>  
>  
> >From: sc@vcc.com (Steve Casselman)  
>  
> > When the O2 runs out yeast go into anaerobic fermentation. During  
> this time they consume sugars and water and produce CO2 and alcohols.  
> At this time they stop reproducing and start budding which produces  
> a long heavy chain of cells which start to drop due to their weight,  
> this is called flocculation.

This seems logical. I also thought so until further investigation has shown me that this isn't so. Actually, the yeast don't go into respiration mode until the amount of assimilable sugars runs out. Yeast are constantly in fermentation mode and the presence of glucose actually inhibits respiration even when oxygen is present. Jack's comment on the reproduction mode is essentially correct. Some yeast do reproduce via fission, but you probably won't find this kind in your beer, maybe your cider though. Also, I don't think that this description of flocculation is correct. Anyway, I'm not sure why one really needs to aerate, though apparently one does (?) I think George Fix has said that it is required for some process other than metabolism.

One final note, let's take a quick market survey concerning those desiring Weihenstephan, before we push this thing further. Who wants it? Can you culture? and what would be your mailing address. I will compile the results so that they can be e-mailed to the people who would be culturing it. This would save some time and trouble and we could, presumably, by-pass HBD postings.

Subject: BrewCaps (tm?): how and why?

Hello all,  
Could someone enlighten me on the purpose and use of the brew cap?  
All I know (well, suspect) is that it is used on a carboy, which is  
then turned upside down.  
If this is a really obvious question please email me privately.  
By the way, I've never seen one either, so a description might be  
useful.

Isn't the quest for knowledge a terrible thing!

Rob Thomas.

>3. Can a rectangular cooler make a suitable tun? I like  
>the idea of a smaller grain surface area, but could sacrifice  
>that for economy.

I use a coleman 48qt rectangular cooler with a slot-cut copper manifold,  
I think that I picked it up for <\$18 on sale....It works just fine for me.  
The  
drain spiggot is just the right size for 3/8" pipe.

Just use regular paper (Xerox or computer) and attach with a Glue Stick,  
the  
lable will stay on until you get it near any water.

It might.

The bleach might be diluted enough in the septic system that it will not harm the bacteria churning away in there..then again, it might not get diluted.

> I have considered dumping the bleach water in the washing machine  
> as it is on a separate drain line from the septic tank.

We have a utility sink on the same drywell as the septic tank. That's where I try and put my bleach water, just to keep it out of the septic system...

Subject: Re: BOTTLE LABELS

Gretchen,

I use a very basic UNIX program called 'pic' to draw my beer labels. It combines lines, squares, rectangles, circles, ellipses and text to make a decent beer bottle label. There are many other graphics software packages out that will do a much more sophisticated job.

As far as attaching them to the bottles, I used to use undiluted Elmer's white glue. I would brush it on to the outside 1/4" edge of the paper and slap it onto the bottle. I make up a different front label for each batch along with the bottling date. I have a "generic" back label for all batches. Thanks to a suggestion from this list, I switched to using a white glue/paste stick (FaberCastle "uhu stic"). This works just as well and is much easier to apply.

Both glues and labels come off easily after an hour of soaking in water.

From: Dennis\_Birch@vos.stratus.com  
Subject: septic systems

CCAMDEN@delphi.com (Cary Camden) asks about the dangers to his septic system from dumping his weak bleach sterilizing solution down the drain. I brewed quite steadily for two years at a house that was on a septic system (the house we're in now is on town water and sewer). I used about a tablespoon or two of bleach per 5 gallons to sanitize my carboys, and a stronger solution squirted into the bottles and rinsed before bottling. My thoughts were that the solution was so weak, and in such small quantity compared to the size of the holding tank that it should not make a difference. I had the tank pumped twice during those two years, and was told both times that there were no problems whatsoever with the system. The amount of clean water used in the brewing process for rinsing equipment off further dilutes this solution. I also washed my slurry down the drain after fermentation on the theory that the animals in it would be beneficial to the breakdown process. Not definitive proof, but a datapoint -- I was very comfortable with the ability of the septic system to handle these relatively small quantities of bleach.

Subject: 10 Gallon Picnic Coolers

David Hyde writes:

... stuff deleted...  
I'd planned on using a cylindrical "picnic cooler", but haven't been able to find the larger ones. Not true...I did find a large (10 gal?) one at an "exclusive" outdoor shop, but I didn't have the kind of money they wanted. I've found 5 gal ones at plenty of places, but that's the largest around here.

So...three questions:

1. Would a 5 gal cooler make an adequate mash/lauter tun for 5 gal batches with an average amount of grain?

Many people use them with great success, however an average batch will push the limits and give little room at the top. Some view the deeper grain bed as an advantage - but I like the extra room the 10gal cooler provides, plus it gives me room for brewing higher gravity ales at times.

2. If not, is there a relatively cheap source for large coolers?

I got mine at Wal Mart for around \$30-\$35. They actually had two sizes for the 10gal models. Both were made by Gott. One had a push-in top and the other had a screw-on top which could double as a stool. One modification I made was to remove the pushbutton spigot and drill the hole to fit a regulated spigot (available from most any homebrew supply).

With this setup I rarely loose more than one degree during a 90 minute mash period.

From: dmcMahon  
Full-Name: Daniel McMahon@pr  
Subject: Ingredients Substitutions  
To: homebrew@hpfcmi.fc.hp.com

I was recently given a recipe for an "excellent Belgian Trippel", but my local homebrew supply store doesn't have all the exact ingredients called for.

The two ingredients in question are: (1) Klages malt and (2) Liberty hops.

Not finding any comparative reference to Klages or Liberty in Papazian's book, I've decided to substitute Pale malt and Willamette (5.3%) hops respectively.

What are the special characteristics of Klages malt?  
Ditto for Liberty hops.

I've followed the ongoing discourse concerning experimentation with recipes. I'm not concerned about deviating from a proven recipe, I am curious about the specific properties of the two ingredients I am substituting for.

Any comments/suggestions? Thanks!

Subject: Mailing Strains

Hello:

I came in late on this Weihenstephan discussion, so I don't really know what it is all about. However, I thought it worth mentioning that there is a cheaper alternative to agar slants for mailing strains, and it works just as well. We routinely send out laboratory strains on filter paper. Basically, you just put a drop of culture on a ~1 cm square piece of filter paper (probably any absorbent paper would do) and wrap the square in a piece of sterile foil. Then pop it into an envelope and send it off. When it gets to the other side, they drop the paper on a rich media plate, incubate for a day or so, and the yeast grow up. Then you streak for singles on another plate and you're set. I haven't rigorously determined the viability of cells dried on paper, but they are very stable. It works.

I can think of two possible disadvantages to this system. First, we use autoclaved paper and foil, and a surprising number of households STILL lack an autoclave. However, while commercial paper is probably not sterile, I imagine it is pretty close; the yeast are going to far outnumber anything else, and when you streak for singles you will get what you want. The foil you could always steam, but probably it would also be close enough to sterile for most peoples purposes. The second drawback is that this method requires that you are set up to culture, and to streak for singles in particular. However, while this isn't absolutely necessary in the case of slants, it is certainly advisable. Anyway, just thought I'd throw it out there.

From: Spencer.W.Thomas@med.umich.edu  
Subject: Re: Tun size and cheepness

2. I found my 10gal "Gott" cooler at Buildre's Square for \$40. They've got them again this year (it's a summer item).

1. Depends on how much beer and how strong you want to make it. You could manage up to about 1.050, but not very far above that. As an extreme example, I was able to make only 3 gallons of a 1.090 Scotch Ale in a 7 gallon picnic cooler.

3. Yes. I did my first batch in such a cooler, using a slotted copper pipe manifold for sparging. Make sure you get one with a drain hole, though, as siphoning doesn't work very well (speaking from experience). I can send you a "plan" for the sparging manifold, if you are interested.

Subject: RE: Tun size

Hi All,

In HBD#1212 David Hyde asks:

>1. Would a 5 gal cooler make an adequate mash/lauter tun for  
>5 gal batches with an average amount of grain?

Sure, I've been able to fit ~12 pounds of grain in a 5 gallon tun. That much grain capacity is adequate for 5 gallon batches of all but very high gravity beers. If you want to brew a high gravity beer and 12 pounds of grain won't get you to the target gravity, you can always just sparge less and make a smaller batch. Last winter, I brewed a 4 gallon batch of bock, OG 1.076, in a 5 gallon tun by draining the tun, re-filling it, then sparged just 2 gallons.

>2. If not, is there a relatively cheap source for large  
>coolers?

I bought a 10 gallon Igloo at the local TruValue for \$29, the 5 gallon coolers were less expensive.

>3. Can a rectangular cooler make a suitable tun?

Yes, lots of people on this forum use rectangular picnic coolers. There are fairly comprehensive instructions in the HBD archives.

Cheers,  
Jim

Subject: Easily removed labels

>From BRANNAGJB@A1.GVLTEC.EDU

> Does anyone out there know of any clever ways that I can label my beer  
and  
> mead bottles? I'd like to design them on my computer, but they need to  
be  
> easy to remove (peel or soak) so I wont add more to the headache of  
preparing  
> bottles for the next batch.

I used to use sticky-back (peel off) paper for my labels, but they were  
really hard to remove.

There are a couple of methods you could use:

1) Get some gummed laser printer paper. A homebrew shop here in Northern  
Virginia sells gummed paper that will feed in most types of laser  
printers. It works well for me. Just wet the label with a little  
water and stick it on. Soaks off in warm water.

Brew America in Vienna, Virginia is the only place I've seen that  
carries  
the gummed paper. I think that they will do mail order. Their number  
is  
(703) 938-4805. I don't remember the price.

Standard disclaimer applies.

2) Use regular laser printer paper for your labels, wet the back with  
milk,  
and stick them to the bottle.

Sometimes the milk soaks into the paper too much and the label gets  
too  
wrinkly and the milk attached labels seem to take a little longer to  
soak  
off than the gummed labels.

There are a couple of companies listed in some of the beer-related  
magazines  
that specialize in multi-color labels, but they tend to be expensive.

For the artistically-impaired, gummed preprinted labels are available  
from  
most homebrew shops. Not a whole lot of variety though.

From: Spencer.W.Thomas@med.umich.edu  
Subject: pico-Brewery

Disclaimer: the owners of pico-Brewing Systems are friends of mine. I have no financial interest in the company or the system.

That said, I've used the system a few times, and it's a really nice system. There are still a few quirks, but it's one of the easiest breweries I've ever used. Last weekend, we made 15 gallons of Porter in a brewing demo at the Michigan Renaissance Festival, under slightly adverse conditions (only water supply is a garden hose, no sink, just a drain in the "floor" that kept backing up on us.) We arrived a little after 11am, and finished brewing about 3:30. (The clean-up then took another hour and a half because of the problems mentioned above.)

It was almost effortless -- We started by running some water into the hot water kettle and firing up the burner to heat it to mash-in temperature. Then we measured the (26 lbs) of grain into the mash kettle. After a little while, we pumped hot water into the mash tun, then heated the mash slightly to our mash temperature. Then we transferred the pump to the mash tun and started recirculating. This really helps maintain a constant/uniform mash temperature without stirring. Tasting the outflow, it appeared we had complete conversion after about 20 minutes, but we kept the mash going for a little over an hour (partly because we were explaining how brewing beer worked to all the people stopping by the booth, as well as telling them we couldn't sell or give them any samples).

Towards the end of the mash, we started heating more water for sparging. Moved the pump back to the hot water kettle, ran a hose from the outlet of the mash kettle to the boiling kettle, and opened the valve to start sparging. Because of the constant recirculation during mashing, the wort came out "clear" (I put this in quotes, because it was a pretty black Porter). We adjusted the valves on the mash kettle and the hot water kettle to the same flow rate, and sparged almost to the top of the boiling kettle (under which we turned on the heat after running a bit of wort in).

As the wort boiled down, we periodically sparged a little more from the mash tun into it. At the end of the boil, we put in the immersion cooler, hooked the pump to the boil kettle, started running water through the cooler, and recirculated wort past it to chill it. When it was cool (about 1/2 hour?) we pumped the wort from the kettle into our carboys with lots of splashing and foaming.

Cleaning up was pretty easy, as easy as it can be when you're wrestling 15 gallon containers, and trying to keep from overflowing the drain, which kept backing up (finally fixed this by wrapping a rubber glove around the hose and sticking it down the drain).

Good points:

- \* With the pump, and a good stand, you don't have to ever lift hot water or wort.
- \* Recirculation during mash and cooling means no stirring.
- \* Temperature wells in the pots make temperature control easy.
- \* Strainer screens in mash and boiling pot work very well.
- \* Easy to make 10 gallons, pretty easy to make 15, possible to make upwards of 20 (by also boiling in the hot water kettle).
- \* It's designed by home-brewers, for home-brewers. They're constantly refining and improving the design.

\* Good solid construction.

Problems:

- \* We had a slight problem with grain bed compaction during the mash recirculation. But we had 26 lbs of grain in there, too.
- \* Hop pellets can clog the pump if you stop it for a while. This only happened when I was rinsing the boiling kettle. Blowing through the hose from the outflow cleared it.
- \* There's a pretty large "dead" volume under the filter screens. This is probably most serious in the mash tun. I'd say it's more than a gallon.
- \* The price!

A note: one of my brewing companions, an experienced brewer, had never used the system before. He decided, based on that experience, that he wanted to buy one.

From: npyle@n33.stortek.com  
Subject: Coolers / GABF/ etc.

Dave Hyde asks about rectangular cooler mash tuns. This is what I use, Dave, and am very happy with it. Its very easy to make a manifold for this thing (mine looks like a fork from the top). The larger surface area to depth ratio doesn't seem to be a problem, although I suppose it could cause marginally lower yields (as the liquid flows through, it passes by less pieces of grain and therefore pulls through less sugar). Anyway, you can get them in various sizes, from 24 quart to 48 quart, and cheap! Go for it.

The Great American Beer Festival is planned for October 8 and 9 this year in Denver. I think it is at Currigan Hall downtown. Is anyone involved in the planning of the GABF a participant in this forum? I'd like to know if there are any provisions for designated drivers? I don't recall any in the past, but logic tells me there must be some plan for this. It would be extremely irresponsible for them to plan an event which will undoubtedly produce a large number of intoxicated people, and not to have a way for them to get home safely. Anyone know? The reason I ask is that my DD from the last few years (my wife) will be out of town that weekend. I want to go to it, but not bad enough to risk my life.

(Bob Devine, I was waiting for your comment. Good show!)

Someone (sorry!) brought up the question of hot liquor pumps. I'm interested in this subject, too (I'm tired of lifting gallons of hot water). I don't need to pump my wort, only hot water for sparging, etc. so I'm not too concerned about sanitation. Any experience out there with dishwasher pumps or the like? As usual, I'm looking for something economical as well as useful.

Cheers,

This sounds like a rhetorical statement of wishfull thinking as it
apparently
is not possible without injecting pure oxygen.

>They use something called a fishtail which is basically a pipe
with a flattened end which they use to spray the wort into the
fermenters.

Great minds really do follow the same path. At the end of the hose
coming
from my wort pump is a short piece of 1/4" copper tubing, the end of
which is
flattened to spray the wort into the fermenter. However, I wasn't
clever
enough to call it a fishtail.

Mine is formed into a "U" shape so I can just hang it on the lip of the
fermenter (after sanitizing of course). It, like the airstone, creates
more
foam than there is room for so I occasionally un-hang it and use the
spray to
beat down the foam. This is far faster than waiting for it to collaps
by
itself.

This is what I do (for whatever it's worth): I design my labels on the
computer, copy as many of them as will fit onto a single page, and print
that page out. So now I have a single sheet with 'n' copies of my label
on it. I then photocopy this page to make as many copies as I need. I
cut
out the labels (not too difficult if you place them on the page wisely)
and
affix them to the bottles with a glue stick (I believe it is the same
stuff
we all used as 'paste' to make those wonderful cardboard creations in 1st
grade). Anyway, the labels fall off with just a quick soak in water (1
minute,
maybe two).

Subject: cylindrical coolers

In HBD 1212 David Hyde writes:

> 1. Would a 5 gal cooler make an adequate mash/lauter tun for
> 5 gal batches with an average amount of grain?

I use a 5 gal cylindrical cooler for 5 gal batches with good results. However, I only use it for decoction mashes. I use an enameled canning pot in the oven (5 gal) for infusion and temp. controlled. There are many equipment combinations that can be used and I'm sure you'll find your own odd ball favorite. I can mash 10 pounds of grain comfortably in the cooler, but obviously you can't use too thin a mash or too large a quantity of grain without exceeding its capacity. Basically, if I'm short of a strike temp. in the cooler, I can adjust the sizes of my decoctions, and in the pot just put it on the stove for a short period. If you intend to rely on boiling water infusions then you need to leave a little more headspace for temp. adjustments. Another use I have for the cylindrical cooler is to store my sparge water. Getting double duty out of equipment is a real advantage. I don't use it as a lauter tun, but I know people that do. Just be careful that you have an adequate false bottom or equivalent - the tap on my cooler plugs too easily for me to consider it.

> 2. If not, is there a relatively cheap source for large
> coolers?

The cheapest I've ever seen 10 gal cylindrical coolers new is \$38 which is close to but not quite cheap enough for me (it is more than I've paid for any other piece of equipment including an 8 gal brew pot or my grain mill). However, if I got seriously into high gravity beers or larger batch sizes I would get one in a second and make sure I could fit it out as a lauter tun (in other words, it's just a matter of time).

A method I'm going to try is rubber cement. The labels should peel right
off and any excess cement on the bottle can be removed with a wee bit of
rubbing. Haven't tried it yet though...give it a whirl.

Subject: Cl in H2O ?

Salutations!

I've just moved to Laramie, WY from Duluth, MN (Right on the shore of the largest easliy accessable source of fresh water). Anyway, I got a hold of the local water engineer, I guess a real chemist is not needed in their estimation, and he told me they add 1.5 g Cl to 1 L of H2O and that the time the water reaches town, 20 miles, the level is about .3 g of Cl per l of H2O. He was telling me about half life and that the use of Cl in the water was minimal. I asked if there were micro-organisms and he also said no. He's sending me a fact sheet.

One and a half grams of Chlorine per Liter of water seems like a lot to me, what about others? The city uses two sources of water, river and underground. Does anyone have anything to say about this?

I asked about water at the first homebrewer club meeting I attended and was told the water was usually on the alkaline side, but that was it. Our Club's name is Snowy Range Foamers, by the way.

Subject: regulator woes

I think my CO2 regulator is on the fritz. Where would I go to get it tested, and, possibly, serviced? Would it be cheaper to buy a new one?

Thanks

Subject: labels

Howdy--

In HBD #1212, Gretchen Brannaman wants suggestions for bottle lables.
Here's
my two cents.

I make small neck lables with a logo on them, instead of big labels that
go
on the body of the bottle (except for special "commemorative" batches).
The
advantages are:

- 1) Less paper. Instead of four labels from each sheet of paper, I can
get
around a dozen.
- 2) Easy identification. Since I have about five different kinds of
hombrew
in six-pack holders, I can easily indentify the beer by the neck
label
instead of lifting the bottles to see the labels on the body.
- 3) Less trash. Face it, they end up in the trash, & we need less of
that.

The ones I have now are rectangular. However, I plan to try curved ones,
about the shape of Celis' neck labels, the next time I make some. I have
a generic logo I use, & I ran off a master sheet. When I have a freshly
bottled batch, I make a copy of the master, write in the name of the
beer,
then xerox those. Next I just cut them out & use a "Uhu" glue stick to
stick
them on. The glue washes right off with the paper. Easy. The rectangle
shape
is easy to cut out, but fits on the neck funny. It depends on what you
want.

Enjoy,

Alan, Austin

SECTION II: YEAST PROFILES

PART 1: DRY ALE YEAST (*Saccharomyces cerevisiae*)

Coopers Ale Yeast

Good to very good reputation. The Coopers is quite fruity fermented at 65F. It's not phenolic at all and all the flavor is a very clean fruitiness.

Glenbrew Special Ale Yeast

Specially designed for use in "all malt" beers. Contains a special enzyme to obtain extremely low terminal gravities.

Doric Ale Yeast

Ok to very good reputation.

Edme Ale Yeast

Starts quick. Produces some fruity esters. Attenuative. Good reputation

Lallemand Nottingham Yeast

This yeast is remarkable for its high degree of flocculation. It settles out very quickly and firmly. Very good reputation. Quick fermentation at 62F. It's very clean and only very slightly fruity in the keg, but tastes/smells nutty in the bottled version. Nottingham appears to be relatively attenuative (more so than the Coopers).

Lallemand Windsor Yeast

Produces a beer which is clean and well balanced. This yeast produces an ale which is estery to both palate and nose with a slight fresh yeast flavor. Very good reputation. Not as quick as the Nottingham. Definite banana smell at racking.

Munton-Fison Ale Yeast

Starts quick. Produces some fruity esters. Attenuative. Fair to good reputation. It is reported that a phenolic taste is no longer a problem due to some strain changes.

Red Star Ale Yeast

This brand had a very bad reputation in the past, and for a while production was suspended. A different strain (AHY 43391) was selected by the company and is now being sold as Red Star Ale Yeast. The new strain is much improved! Reports from Dr. Fix, a brewer's yeast consultant, suggest that this is an excellent general purpose ale yeast with a clean taste. Apparent attenuation 76-78%.

Whitbread Ale Yeast

Fast starter. Distribution switched to Crosby and Baker with a change in the yeast. Very good reputation despite past quality problems.

PART 2: LIQUID ALE YEAST

BrewTek CL-10 American Microbrewery #1

A smooth, clean, strong fermenting ale yeast that works well down to 56F.

BrewTek CL-12 American Microbrewery #2

Produces an accentuated, rich and creamy malt profile with hints of diacetyl.

BrewTek CL-16 British Pale Ale #1

Produces a bold, woody and dry character which accentuates mineral and hop flavors.

BrewTek CL-18 British Pale Ale #2

A smooth, full flavored, well rounded ale yeast. Mildly estery, it is a strong fermenter.

BrewTek CL-26 British Draft Ale

Their (Brewteks) favorite Ale yeast, gives a full bodied, well rounded flavor with a buttery rich diacetyl.

BrewTek CL-28 Irish Dry Stout

A top fermenter, leaves a very recognizable character to Dry Stouts with roasted malts coming through well.

BrewTek CL-30 Belgian Ale #1

Produces a classic Belgian Ale flavor. Robust and estery with notes of clove and Plum.

BrewTek CL-32 Belgian Ale #2

Flanders style yeast. Makes a terrific strong brown and a good base brew for fruit flavored beers.

BrewTek CL-40 Old German Ale

For traditional Alt Biers, a strong fermenter which leaves a highly attenuated, mildly estery flavor.

Wyeast 1007 German Ale Yeast

Ferments dry and crisp leaving a complex yet mild flavor. Produces an extremely rocky head and ferments well down to 55 deg. F (12 deg. C). Flocculation is high and apparent attenuation is 73-77%. Optimum fermentation temperature: 62 deg. F (17 deg. C). A good balance of sweetness and tartness. A very pleasing yeast.

Wyeast 1024 Belgian Ale Yeast

Banana estery flavor. With both clove-like phenolics and alcohol spice, the Belgian will tell you right away that it's no ordinary yeast. Tartness often

develops over time. Ferment warm or with inadequate aeration and you're likely to get a bubblegum-like note. Intended for abbey beers, and works very well for that. And, depending on the wort composition, *lots* of banana notes.

Wyeast 1028 London Ale Yeast

Rich mineral profile, bold woody slight diacetyl production. Medium flocculation. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C). Complex, woody, tart, with strong mineral notes. It produces ales of marvelous complexity and sophistication. This yeast was used for the 1992 B.O.S.S. Challenge 1st place Barleywine, brewed by none other than Brian and Linda North.

Wyeast 1056 American/Chico Ale Yeast

Ferments dry, finishes soft, smooth and clean, and is very well balanced. Flocculation is low to medium. Apparent attenuation 73-77%. Optimum fermentation temperature: 68 deg. F (20 deg. C). The cleanest of the bunch, but mutation-prone. This is Sierra Nevada's yeast. Probably the best available all-around yeast, this strain can be used for anything, without embarrassment.

Wyeast 1084 Irish Ale Yeast

Slight residual diacetyl is great for stouts. It is clean smooth, soft and full bodied. Medium flocculation and apparent attenuation of 71-75%. Optimum fermentation temperature: 68 deg. F (20 deg. C). Soft, round, malty; the least attenuative of the Wyeast line. Very nice for any cold-weather ale, at its best in stouts and Scotch ales.

Wyeast 1098 British Ale Yeast

Ale yeast from Whitbread. Ferments dry and crisp, slightly tart and well balanced. Ferments well down to 55 deg. F (12 deg. C). Medium flocculation, apparent attenuation 73-75%. Optimum fermentation temperature: 70 deg. F (21 deg. C). Tart, crisp, clean. Great in pale ales and bitters, good in porters.

Wyeast 1338 European Ale Yeast

Ale yeast from Wissenschaftliche in Munich. A full bodied complex strain finishes very malty. Produces a dense rocky head during fermentation. High flocculation, apparent attenuation 67-71%. Optimum fermentation temperature: 70 deg. F (21 deg. C). It's clean and malty, especially well suited to Altbier.

Yeast Culture Kit A36

From Houffalize, Belgium. VSU: Belgian Ales.

Yeast Culture Kit A37

From Bavaria, Germany. VSU: Altbier, Kolsch.

Yeast Lab A01 Australian Ale Yeast

This all purpose strain produces a very complex woody and flavorful beer.

Australian origin. Medium attenuation, medium flocculation. Great for Brown Ales and Porters.

Yeast Lab A02 American Ale Yeast

This clean strain produces a very fruity aroma, with soft and smooth flavor

when fermented cool. Medium attenuation and low flocculation. This is an all

purpose ale yeast.

Yeast Lab A03 London Ale Yeast

Classic Pale Ale strain, very dry. A powdery yeast with a hint of diacetyl and rich mineral profile, crisp and clean. Medium attenuation and medium flocculation.

Yeast Lab A04 British Ale Yeast

This strain produces a great light bodied ale, excellent for Pale Ales and Brown Ales, with a complex estery flavor. Ferments dry with a sharp finish. Medium attenuation and medium flocculation.

Yeast Lab A05 Irish Ale Yeast

This top fermenting strain is ideal for Stouts and Porters. Slightly acidic, with a hint of butterscotch in the finish, soft and full bodied. Medium attenuation, high flocculation.

Yeast Lab A06 Dusseldorf Ale Yeast

German Altbier yeast strain finishes with full body, complex flavor and spicy sweetness. Medium attenuation, high flocculation.

Yeast Lab A07 Canadian Ale Yeast

This strain produces a light bodied, clean and flavorful beer, very fruity when fermented cool. High attenuation, medium flocculation. Good for light and cream ales.

Yeast Lab A08 Trappist Ale Yeast

This is a typical Trappist strain, producing a malty flavor with a balance of fruity, phenolic overtones when fermented warm. Alcohol tolerant, high attenuation and high flocculation.

PART 3: LAGER YEAST (SACCHAROMYCES UVARUM)

Dry Lager Yeast:(generally not recommended--tend to be inconsistent).

Liquid Lager Yeast: Much preferred over dry types!

BrewTek CL-60 Original Pilsner

Leaves a full bodied Lager with a sweet, underattenuated finish with a subdued diacetyl character.

BrewTek CL-62 American Megabrewery

A strong fermenter, leaves a light, crisp, almost dry finish to Lagers. Produces a good strong Lager.

BrewTek CL-64 Carlsbergensis

A Scandinavian Lager strain which leaves a full flavored, slightly sweet and malty profile.

BrewTek CL-66 N. German Lager

Exhibits a clean, crisp, traditional Lager character. A strong fermenting and forgiving Lager yeast.

BrewTek CL-68 East European Lager

Imparts a smooth, rich, almost creamy character, emphasizing a big malt flavor and clean finish.

BrewTek CL-86 California Esteem

Use to recreate "California common beers" leaves a slightly estery, well attenuated finish.

Wyeast 2007 Pilsen Lager Yeast

Our original Lager Yeast Strain. Specific for pilsner style beers. Ferments dry, crisp, clean and light. Medium flocculation. Apparent attenuation from 71-75%. Optimum fermentation temperature: 52 deg. F (11 deg. C). It is worth mentioning that this yeast strain is reportedly used quite a bit in St. Louis, if you know what I mean ;^).

Wyeast 2035 American Lager Yeast

Unlike American pilsner styles. It is bold, complex and woody. Produces slight diacetyl. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 50 deg. F (10 deg. C). This yeast allegedly is the one used by August Schell in New Ulm, MN.

Wyeast 2042 Danish Lager Yeast

Rich, yet crisp and dry. Soft, light profile which accentuates hop characteristics. Flocculation is low, apparent attenuation is 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

Wyeast 2112 California Lager Yeast

Warm fermenting bottom cropping strain, ferments well to 62 deg. F (17 deg. C) while keeping lager characteristics. Malty profile, highly flocculant, clears brilliantly. Apparent attenuation 72-76%. Allegedly, the Anchor steam yeast.

Wyeast 2124 Bohemian Lager Yeast

Ferments clean and malty, rich residual maltiness in high gravity pilsners, medium flocculation, apparent attenuation 69-73%. Optimum fermentation temperature: 48 deg. F (9 deg. C). Allegedly, one of the four (?) Pilsner Urquell yeasts.

Wyeast 2206 Bavarian Lager Yeast

Lager yeast strain used by many German breweries. Rich flavor, full bodied, malty and clean. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 48 deg. F (9 deg. C).

Wyeast 2308 Munich Lager Yeast

Lager yeast from Wissenschaftliche in Munich #308. One of the first pure yeast available to American home brewers. Sometimes unstable, but smooth soft

well rounded and full bodied. Medium flocculation, apparent attenuation 73-77%.

Optimum fermentation temperature: 50 deg. F (10 deg. C). One report of an intense off aroma (like home perm solution) with this yeast fermented at 45-50F, but it miraculously disappeared after four months aging in the bottle at 40F.

Yeast Culture Kit L09

From Bavaria, Germany. VSU: American Dark Lager, American Lager, Bavarian Dark, Doppelbock, Dortmund/Export, Eisbock, German Bock, German Lagers, German Schwarzbier, Hellesbock, Munich Helles, Marzen/Octoberfest, Pilsner. (Must be some yeast! :-)

Yeast Culture Kit L17

From Pilsen, Czechoslovakia. VSU: American Lagers, Bohemian Pilsner.

Date: Thu, 26 Aug 1993 16:24:40 -0500 (CDT)

From: WEIX@swmed.edu

Subject: yeast faq 5 of 8

Yeast Lab L31 Pilsner Lager Yeast

This classic strain produces a light lager in both flavor and body, fermenting dry and clean. High attenuation and medium flocculation.

Yeast Lab L32 Bavarian Lager Yeast

Use this classic strain for medium bodied lagers and bocks, as well as Vienna and Marzen styles, rich in flavor with a clean, malty sweetness. Medium attenuation and medium flocculation.

Yeast Lab L33 Munich Lager Yeast

Wissenschaftliche strain for medium bodied lagers and bocks, subtle and complex flavors, smooth and soft, a hint of sulfur when fresh. Medium attenuation and medium flocculation.

Yeast Lab L34 St. Louis Lager Yeast

This strain produces a round, very crisp and clean fruity flavor, with medium body. High attenuation and medium flocculation. Good for American style lagers.

Yeast Lab L35 California Lager Yeast

A California common beer strain, malty with a sweet woody flavor and subtle fruitiness. Medium attenuation and high flocculation.

PART 4: WEISSEN, LAMBIC, MEAD, AND BARLEYWINE STYLES.

BrewTek CL-90 Belgian Wheat

A top fermenting yeast which produces a soft, bread like flavor and leaves a sweet, mildly estery finish.

BrewTek CL-92 German Wheat

A true, top fermenting Weizenbier yeast. Spicy, clovy and estery. Highly attenuative.

BrewTek CL-94 American Wheat

Offers a smooth, slightly sweet wheat beer, with a full, clean, underattenuated malt flavor.

BrewTek CL-100 Brettanomyces Lambicus

Use to create Belgian Lambic beers. Added after primary fermentation with a regular ale yeast.

Wyeast 3056 Bavarian Weissen Yeast

A 50/50 blend of *S. cerevisiae* and *delbrueckii* to produce a south German style wheat beer with cloving sweetness when the beer is fresh. Medium flocculation, apparent attenuation 73-77%. Optimum fermentation temperature: 56 deg. F (13 deg. C). Problematic to get the right flavor, often just produces

relatively unattenuated beer, without the clove-like aroma/flavor.
Perhaps it's
the freshness of the Wyeast #3056 that makes the difference in whether
you get
the clove-like aroma/flavor or not.

Yeast Culture Kit M01

From Bavaria, Germany. VSU: American Wheat, Dunkel Weizen, German
Weizen,
Weizenbock.

Yeast Lab W51 Bavarian Weizen

This strain produces a classic German style wheat beer, with
moderately high,
spicy phenolic overtones reminiscent of cloves. Medium attenuation,
moderately
flocculant. Evidently much more consistent than Wyeast at producing a
true
Weizen flavor.

Mead Yeast

Yeast Lab M61 Dry Mead

Very alcohol tolerant, ferments dry, fruity and clean, yet leaves
noticeable
honey flavor and aroma.

Yeast Lab M62 Sweet Mead

This strain has reduced alcohol tolerance, therefore produces a very
fruity,
sweet mead with tremendous honey aromas.

Wine Yeast

Lallemand Lalvin Wine Yeast S. Bayanus. Good reputation.

Red Star Pasteur Champagne Yeast

Very attenuative. Good for mead. Good reputation. Popular yeast for
Imperial
Stouts and Barleywines due to it's high tolerance for alcohol. Some use
it by
itself, others pitch Pasteur after their chosen beer yeast poops out.

Wyeast 3021 Prise de mousse Champagne Yeast

Institute Pasteur champagne yeast race bayanus. Crisp and dry, ideal
for
sparkling and still red, white and fruit wines. Also can be used for
Barley
wines. Optimum fermentation temperature: 58 deg. F (14 deg. C).

Wyeast 3028 Wine Yeast

French wine yeast ideally suited for red and white wines which mature
rapidly. Enhances the fruity characteristics of most wines. Optimum
fermentation
temperature: 72 deg. F (22 deg. C).

Wyeast 4007 Wine Yeast

Malo-lactic culture blend isolated from western Oregon wineries.
Includes
strains Ey2d and Erla. Excellent for high acid wines and low pH. Softens
wines
by converting harsh malic acid to milder lactic acid. Can be added to
juice any

time after the onset of yeast fermentation when sulfur dioxide is less than 15 ppm.

Yeast Culture Kit M06

From Montreal, Canada. VSU: Barley Wine (Champagne).

=====
=====

SECTION III: YEAST MANAGEMENT

PART 1: HYDRATION PROCEDURE FOR DRY YEAST

a. Use 14 grams of dry yeast (usually 2 packets) per 5 gallons of brew. ***Rigorously*** sterilize everything used in the hydration procedure.

This

should include boiling and cooling the water for rehydration, so that chlorine is boiled off and the water is sanitized.

b. Add the dry yeast to 1/2 cup of water at 90F (32C). Leave for 15 mins.

c. Combine the hydrated yeast with 1-2 gallons of wort that is as close to the wort to be fermented as possible. You can take samples from the main wort at the end of the mash/sparge and rapidly boil and cool it.

d. Aerate the starter as much as possible under sanitary conditions.

e. Don't forget to properly oxygenate the main wort once it is *chilled*

(Shaking hot wort is dangerous, but even worse it can cause oxidation and give your beer funny flavors.)

f. Pitch the starter into the main wort once the latter has been chilled to the recommended fermentation temperature (65-68F or 18-20C). Yeast with good viability will result in minimal lags. (The longest experienced in test brews using the new Red Star Ale Yeast was 2 hrs.)

An alternative but slightly sub-optimal method is to cool the yeast-in-water mix from "b" to room temperature. Once the wort has been chilled and aerated (shaking the carboy works well), pitch the yeast. Stir or invert the carboy to disperse the yeast. Put in the blow-off tube or fermentation lock.

The two most essential things are to:

1. Sanitize everything in sight.
2. Aerate your wort to insure rapid initial yeast growth--your best defense against secondary infection.

Subject: yeast faq 7 of 8

D. Preparation of New Slants

Two steps are needed in the preparation of new slants. The first consists of adding the proper media to test tubes or petri dishes. Once prepared the slants will store well for a very long time when refrigerated, so many can be prepared at one time. The second step consists of inoculating the slants with yeast.

For the homebrewer who cannot afford several refrigerators: Please be advised that your refrigerator is a haven for bacteria, mold, and wild yeast. Anyone

wishing to store sterile slants in their refrigerator is advised to

1. Wipe down the slants before storage with ethanol or your favorite sanitizing solution.
2. Seal the slants with parafilm or electrical tape.
3. Keep the slants in a ziplock bag.
4. Wipe down the bag with ethanol or your favorite sanitizing solution before opening.

Preparation of Media:

(i) The media consists of dry malt extract and agar. As a general rule 4 tablespoons of malt extract and 1 tablespoon of agar per cup of water will yield 16-18 slants.

(ii) Bring the water to a boil, and then stir in the malt extract. Boil for 10 mins.

(iii) Remove from heat, and then start stirring in the agar. This will take some effort, but this usually indicates that a good solidification will ultimately be achieved. If your slants "sweat" too much, increase the amount of agar you use. Although commercial/scientific agar will vary little, I cannot answer for "food grade" supplies. Gelatin is easier to dissolve, but it sometimes does not always give a proper solidification.

(iv) When the agar is dissolved, the malt/agar solution should be added to the test tubes, filling each to approximately a third of their volume. Add the screw cap, but do not fully tighten.

(v) Autoclave the tubes at 15 psi for 15-20 mins.

(vi) Allow the tubes to cool. They can be left overnight in the autoclave/

pressure-cooker. Tighten the caps on the tubes, and place them at a 30 degree angle. Allow them to solidify at room temperature. Solidification should become apparent within a few hours. Tubes which are not solid after 24 hrs. should be discarded.

(vii) Refrigerate until needed, heeding storage precautions above.

Note: Plastic petri dishes can not be autoclaved, and so alternate procedures are needed for them. You may use the above techniques with *pyrex* petri dishes if you so desire. A common practice is to autoclave the malt/ agar solution in small jars or flasks. The agar solution is then poured into the petri dishes. Let the agar cool until the jars are hot but touchable. If the agar is too hot it will warp the plates. Swirl it gently to mix but avoid bubbles. It is a good idea to leave petri dishes prepared in this way at 25-30 C for 1-2 weeks to make sure bacteria or molds are not present. Let the poured plates dry overnight in a clean quiet room. Wipe them down, seal them, and bag them, but leave them at room temperature for 1 week. The bad bugs, if they are there, will be visually apparent at the end of that period and the contaminated plates discarded. While Petri dishes are more trouble than test tubes, they do offer the distinct advantage of having more surface area and being easier to store. After the trial period the dishes should be refrigerated.

Inoculation of Slants:

(i) Collection a small portion of the yeast to be added to the slants. It goes without saying that one should strictly follow the standard sterilization procedures of all items used to collect this yeast.

(ii) With one hand sterilize the inoculation loop (flame or alcohol solution). With the other hand open the cap of a slant.

(iii) Dip the loop into the yeast solution, and remove a small amount.

(iv) Slowly insert the loop into the tube avoiding contact with either the sides or neck of the tube. Streak the yeast over the solid. Only a thin layer is wanted, and one should try to use as much of the surface area as possible.

(v) Slowly remove the loop avoiding contact with tube walls or neck. Add the screw cap back on the tube and tighten.

(vi) When finished store the tubes at 25 C for one week. Visually inspect all

tubes at this time both for yeast growth, and also for any irregularities. Discard those which are not satisfactory.

(vii) Store the remainder at 2-8 C. After 3-4 mos. of storage, unused tubes should either be discarded or recultured; i.e., propagated by the procedures in Section III.2.c and then put on fresh slants. The best idea is to put production yeast on slants on a regular basis so that reculturing is not necessary.

Note: The larger surface area afforded by Petri dishes can be used to advantage in the above procedure. In particular, it useful to streak out yeast in parallel lines which make angles with each other. This allows for a better examination of growth patterns. Petri dishes should be sealed after the 1 week trial period with electrician's tape and refrigerated.

PART 3: YEAST WASHING FOR THE HOMEBREWER

Doug O'Brien forwarded the following to me. As it is a topic that pops up frequently on the HBD, I have included it in this FAQ.

Post follows:

The following notes were taken from a demonstration given to the Oregon Brew Crew by Dave Logsdon of WYeast Labs, on September 12th. According to Dave, it was important for healthy yeast to be washed free of trub and hop residue so that it could be stored for future use. Dave said that the problem with simply storing the mixed contents from a carboy after fermentation was that the unwanted particulates would suffocate the yeast over a period of time. Most breweries, Dave stressed, use an acid wash; the sterile water wash is much more practical for homebrewers.

Objective: To recover yeast from a finished batch of beer for repitching or storage for future brewing.

Materials: One primary fermenter after beer has been siphoned off or otherwise removed.

Three sanitized 1-quart Mason jars with lids, half full of sterile or boiled water. They should be cooled down, then chilled to refrigerator temperature (ca. 38°F).

Procedures:

- 1) Sanitize the opening of the carboy (flame or wipe with chlorine or alcohol)
- 2) Pour the water from one of the quart jars into the carboy. Swirl the water to agitate the yeast, hop residue and trub from the bottom.
- 3) Pour contents from the carboy back into the empty jar and replace the cover.
- 4) Agitate the jar to allow separation of the components. Continue to agitate periodically until obvious separation is noticeable.
- 5) While the viable yeast remains in suspension, pour off this portion into the second jar. Be careful to leave as much of the hops and trub behind as possible.
- 6) Agitate the second container to again get as much separation of yeast from particulate matter as possible. Allow contents to rest (about 1/2 hour to 1 hour) then pour off any excess water--and floating hop

particles--from the surface.

7) Pour off yeast fraction which suspends above the particulate into the third container.* Store this container up to 1 month refrigerated.

Pour
off liquid and add wort 2 days before brewing or repitch into a new
brew
straight away.

*It should be noted that in the actual demonstration, Dave eliminated the final step; the yeast in the second jar was essentially clean at this stage and seemingly fine for storage.

PART 4: PARALLEL YEAST CULTURES

Rick Cavasin sent me (PW) the following method of "parallel" culturing liquid yeasts. This should work with most packaged liquid yeasts, not just Wyeast. The advantages here for the beginner are that (in addition to saving money) it minimizes the problems of strain drift and contamination that can plague yeast ranchers. As for the savings, it makes liquid yeast almost as cheap as dry yeast!

Post follows:

Here's the (poor man's) method for stretching the Wyeast that I (Rick) have been using successfully. This method has worked for me with 4 different Wyeast ale strains (Whitbread, Irish, German, European). It's simple, and requires no special equipment. Also, it allows several brewers to swap yeasts with each brewer propagating one strain.

Briefly, my suggestion consists of converting the original Wyeast package into a number of 'copies' stored in beer bottles. ie. it is a parallel propagation rather than a serial propagation

Step 1: Prepare some starter wort (S.G. = 1.020), see Miller's book for recipe. Basically, you need about 1/2 gallon, but if you make more and can it in mason jars (using standard canning procedures), you will not have to prepare more at a later date. Note from PW--Most authorities now recommend using full strength (1.040), hopped wort for starters.

Step 2: Place 1/2 gallon or so of starter wort in a suitable container (1 gallon glass jug), pitch (inflated) Wyeast package at correct temp. and fit air lock. This is the 'master' starter.

Step 3: Allow to ferment to *completion*. When fermentation has ceased, agitate the 'beer' to suspend all sediment, and very carefully bottle it.

You will now have about 6 bottles of very thin beer with a good deal of viable yeast sediment in each bottle. Use each bottle as you would use a package of Wyeast - ie. prepare a starter culture a couple days before brewing. This is facilitated by canning wort when you prepare the master starter. All you need to in that case is pop open a mason jar of wort, dump it into a sanitized bottle/jug of appropriate size, pop open one of your bottle cultures, add it, agitate vigorously, and fit an air lock.

All yeast starters are of the same 'generation', ie. 'twice removed' from the original Wyeast package (as opposed to the usual 'once removed'). I've had the bottled cultures remain viable for more than 6 months.

Observe proper sanitation and wort aeration procedures throughout.

Equipment: 1 gallon jug (for 'master' starter)
1.5 litre wine bottle (for subsequent starters)
air lock
6 beer bottles, caps and capper

Optional equipment: mason jars and canning pot.

Cheers,
Rick C.

PART 2: PROPAGATION OF YEAST STRAINS

or

HOW TO HAVE YOUR VERY OWN YEAST RANCH!

A. General Comments

There is no single item as important as the selection of a yeast strain, or if appropriate strains, to be used in commercial brewing. The same applies to homebrewing. Sensory characteristics -- taste and smell -- will normally determine the type of yeast that is appropriate to any particular beer formulation. This section contains the necessary procedures for achieving self-sufficiency in pitching yeast. The part treated in this section is often called the Hansen pure culture system. The heart of this system is the so-called "yeast slant". It is a test tube containing a solidified media sloped at an angle. Often Petri dishes are used, but the media is level, and hence the term "slant" is not always appropriate. In any case, yeast cells are streaked on the surface of the solid media. When refrigerated, these slants will keep at least 3-4 months before they have to be recultured. Yeast are taken from the slants, and built up so there is enough to pitch a full batch. The system also contains procedures for doing the exact opposite, i.e., adding yeast to slants for storage and future use.

B. Equipment

The equipment needs for operating a pure culture system with slants are rather modest. The following are the major items.

1. Refrigerator. This is needed for slant and media storage.
2. Autoclave or pressure cooker. This will be needed to sterilize equipment and media for yeast work. A pressure cooker will do, but it should have a pressure gauge attached so that the conditions during sterilization can be controlled.
3. Media. The preferred media for slants is malt extract and agar. These can be obtained from any scientific outlet. Food grade agar is also available from some oriental markets. The flaked form is easier to work with.
4. Misc. A number of minor items will also be needed. These include inoculation loops, glassware, petri dishes, and test tubes.

C. Propagation of Yeast

This process consists of transferring some of the yeast on slants to a small flask or jar containing wort, then building this up until there is enough to pitch a full brew. the most delicate steps are the initial ones. Experience has shown that the best results are obtained by using full strength hopped wort for propagating yeast. The ideal situation is when the wort used in propagation is identical to the wort that will be used in brewing.
