Objectives of Module 6

- Define Software Quality Assurance (SQA)
- Describe techniques, metrics, methods, and formal approaches to assuring software quality
- Describe methods for performing black box software testing
- Describe methods for performing white box software testing
- Describe strategies for testing software at the unit, subsystem, and system level

Software Quality Assurance

Conformance to explicitly stated functional and performance requirements, explicitly documented development standards, and implicit characteristics that are expected of all professionally developed software.

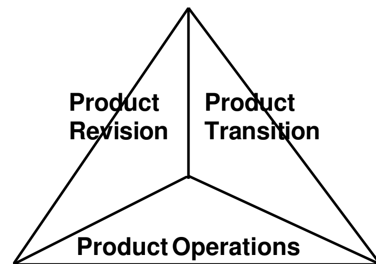
-- a definition of *Software Quality*, Pressman, Page 550

1. Quality is measured against software *requirements* .
2. Development *standards* guide the process of engineering software to increase the probability of high quality.
3. *Implied* requirements must be met as well and those requirements explicitly stated.

Software Quality Factors

- Directly Measured
  - Errors
  - Lines of Code
  - Execution Time of Unit
- Indirectly Measured
  - Usability
  - Maintenance

Software Quality Factors



McCall, J., P. Richards, and G. Walters, "Factors in Software Quality," three volumes, NTIS AD-A049-014, 015, 055, November 1977

Correctness. The extent to which a program satisfies its specification and fulfills the customer's mission objectives.

Reliability. The extent to which a program can be expected to perform its intended function with required precision.

Efficiency. The amount of computing resources and code required by a program to perform its function.

Integrity. The extent to which access to software or data by unauthorized persons can be controlled.

Usability. The effort required to learn, operate, prepare input, and interpret output of a program.

Maintainability. The effort required to locate and fix an error in a program.

Flexibility. The effort required to modify an operational program.

Testability. The effort required to test a program to ensure that it performs its intended function.

Portability. The effort required to transfer the program from one hardware and/or software system environment to another.

Reusability. The extent to which a program (or parts of a program) can be reused in other applications -- related to the packaging and scope of the functions that the program performs.

Interoperability. The effort required to couple one system to another.

Software Quality Checklists

Quality Factor	*Spec*	*Design*	*Impl*	*Test*	*Support*
Functionality					
Usability					
Reliability					
Performance					
Supportability					

Enter 0 (very poor) to 10 (outstanding) in each block to indentify quality

Grady, R.B., and D.L. Caswell, *Software Metrics: Establishing a Company-Wide Program*, Prentice-Hall, 1987

Functionality. Functionality is assessed by evaluating the feature set and capabilities of the program, the generality of the functions that are delivered, and the security of the overall system.

Usability. Usability is assessed by considering human factors, overall aesthetics, consistency, and documentation.

Reliability. Reliability is evaluated by measuring the frequency and severity of failure, the accuracy of output results, the mean time between feailure (MTBF), the ability to recover from failure, and the predictability of the program.

Performance. Performance is measured by evaluating processing speed, response time, resource consumption, throughput, and efficiency.

Supportability. Supportability combines the ability to extend the program (extensibility), adaptability, and serviceability (these three attributes represent a more common term -- maintainability), in addition to testability, compatibility, configurability (the ability to organize and control elements of the software configuration), the ease with which a system can be installed, and the ease with which problems can be localized.

Software Quality Assurance (SQA)

- **SQA is a "planned and systematic pattern of actions" to ensure quality in software.**
- **SQA is essential for any business which produces software products used by others.**
- **The SQA group serves as an in-house representative of the customers.**

SQA has the following major activities:

1. Application of technical methods to define, assess, and verify or validate software quality
2. Conduct of formal technical reviews
3. Software testing
4. Enforcement of standards
5. Control of change
6. Measurement
7. Record keeping and reporting

Software Reviews

Formal Technical Reviews (FTR)

- **Uncover errors in function, logic, and implementation for any representation of the software**
- **Verify that software meets specifications**
- **Ensure that software conforms to standards**
- **Ensure that software is developed in a uniform manner**
- **Ensure that the project is manageable**

Class of Reviews

- **Code Walkthroughs**
- **Code Inspections**
- **Round-Robin Reviews**
- **Others**

Formal Technical Review

Constraints

- **3-5 people in meeting -- developer, 2-3 reviewers, SQA representative, and recorder**
- **< 2 hours preparation time per person (pre-review before the meeting)**
- **< 2 hours for the meeting duration**

During the Meeting

- **Focus on a small, specific part of the software**
- **Review is initiated by SQA after the developer is done**
- **Developer talks through the product**
- **Recorder keeps notes on errors, issues, resolutions, and action items**
- **All attendees sign off on the team's findings**

Review Guidelines

- Review the product, not the developer
- Set an agenda and maintain it
- Limit debate and rebuttal
- Clarify the problem areas -- don't attempt to solve every problem
- Take written notes
- Limit the number of participants
- Insist upon advanced preparation
- Develop a checklist for each product to be reviewed
- Allocate resources and time schedule for the FTR
- Conduct meaningful training for all reviewers
- Review earlier reviews

Software Quality Metrics

- U.S. Air Force Systems Command Pamphlet 800-14: Design Structure Quality Index
- IEEE Standard 982.1-1988: Software Maturity Index
- Halstead's Software Science
- McCabe's Complexity Metric

AFSCP 800-14 Design Structure Quality Index (DSQI)

Three Steps:

1. **Obtain specific information about the program (S1-S7)**
2. **Determine intermediate values (D1-D6)**
3. **Compute DSQI:**

$$DSQI = \sum w_i D_i$$

wi is the relative weight of Di

DSQI is used by comparing it with previous DSQI's. If much lower than expected, there is a need to do more design and review.

Based on database and data flow items

S1: number of modules in program

S2: number of modules that input or output data (not control)

S3: number of modules that depend on prior processing

S4: number of database items (incl. data objects and all attributes that define objects)

S5: number of unique database items

S6: number of database sections (i.e., records or individual objects)

S7: number of modules with single entry and exit

D1: 1 if program is design with a formal process; 0 otherwise

D2: 1-S2/S1 (module independence)

D3: 1-S3/S1 (modules not dependent on prior processing)

D4: 1-S5/S4 (database size)

D5: 1-S6/S4 (database compart-mentalization)

D6: 1-S7/S1 (module entrance/exit characteristic)

IEEE Software Maturity Index (SMI)

M_T = # modules in current release
F_c = # modules in current release that have changed
F_a = # modules in current release that have been added
F_d = # modules from preceding release that were deleted in current release

$$SMI = \frac{M_T - (F_a + F_c + F_d)}{M_T}$$

As SMI approaches 1.0, the product is stabilizing.

Halstead Software Science

Given:

n_1 = # distinct operators in program
n_2 = # distinct operands in program
N_1 = # operator occurrences
N_2 = # operand occurrences

Program Length	$N = n_1 \log_2 n_1 + n_2 \log_2 n_2$	**statements**
Volume	$V = N \log_2 (n_1 + n_2)$	**bits to represent algorithm**
Volume Ratio	$L = \frac{2}{n_1} * \frac{n_2}{N_2}$	**min volume relative to actual volume possible**

- Based on operator/operand counts
- Lots of experimental work done
- Controversial
- Good agreement with reality
- N and V vary with the programming language

Example of Halstead's Metrics

Program

```
      SUBROUTINE  SORT  (X,  N)
      DIMENSION   X(N)
      IF  (N  .LT.  2)  RETURN
      DO  20  I=2,N
          DO  10  J=1,I
              IF  (X(I)  .GE.  X(J))  GOTO  10
              SAVE  =  X(I)
              X(I)  =  X(J)
              X(J)  =  SAVE
10        CONTINUE
20    CONTINUE
      RETURN
      END
```

Operators

Operator		*Count*
1	End of statement	7
2	Array subscript	6
3	=	5
4	IF ()	2
5	DO	2
6	,	2
7	End of program	1
8	.LT.	1
9	.GE.	1
10	GOTO 10	1

n1 = 10 N1 = 28

Example of Halstead's Metrics, Continued

Operands

Operand		*Count*
1	X	6
2	I	5
3	J	4
4	N	2
5	2	2
6	SAVE	2
7	1	1

n2 = 7 N2 = 22

Example of Halstead's Metrics, Continued

$$N = 10\log_2 10 + 7\log_2 7 = 52.871$$

$$V = \log_2(10+7) = 4.0875$$

$$L = \left(\frac{2}{10}\right)\left(\frac{7}{22}\right) = \frac{14}{220} = 0.06364$$

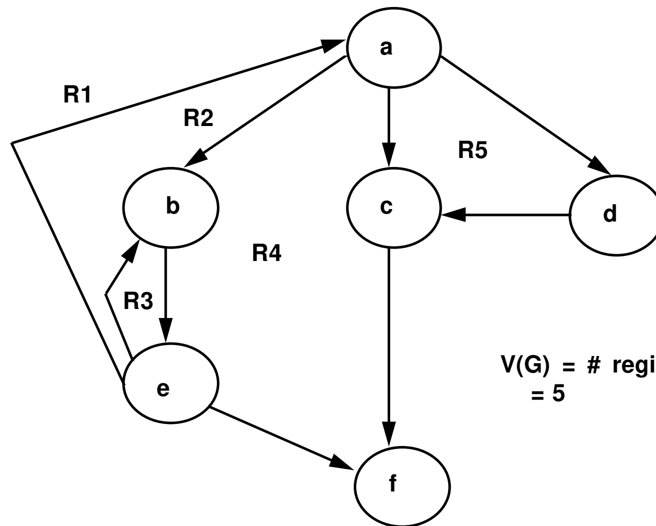
McCabe's Complexity Metric

- Create program graph, G
- Determine cyclomatic complexity, V(G)
- Useful for estimating testing difficulty

  V(G) > 10 indicates tough testing

- Based on control flow of program

Program Graph and V(G)

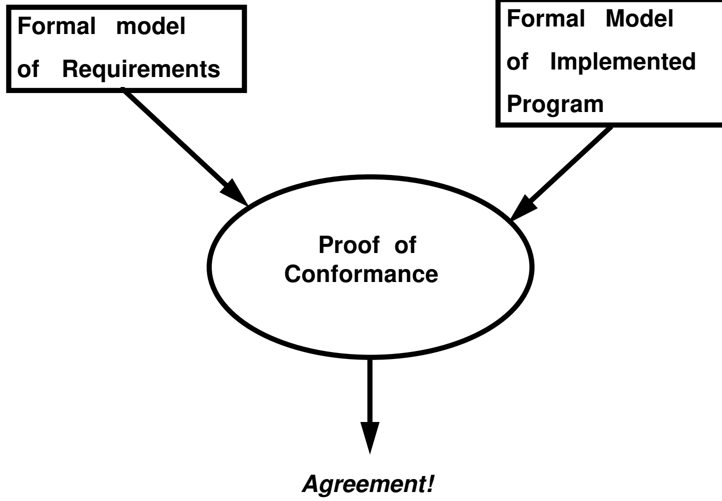


V(G) = # regions in planar graph
= 5

Formal Approaches to SQA

1. Proof of Correctness
2. Statistical Quality Assurance
3. Cleanroom Process

Proof of Correctness



Proof of Correctness

```
Stmt   Code
1      procedure RANDOM (SEED : in FLOAT) return FLOAT is
2      begin
3         assert (SEED > 0 and SEED < MAX.FLOAT)
...       ...
n-2       assert (RESULT > 0.0 and RESULT < 1.0)
n-1       return RESULT;
n      end RANDOM;
```

- To show that the program is correct, statements 3 to n-2 must unambiguously produce RESULT within the range from 0.0 to 1.0 given a SEED value.
- Tighter assertions provide more specific verification conditions.

Statistical Quality Assurance

1. Software defect information is collected.
2. Trace each defect to its cause.
3. Identify the 20% "vital few" defects.
4. Correct the "vital few" defects.

1. Statistical quality assurance is a growing trend in industry.
2. *Pareto Principle* - 80% of all defects can be traced to 20% of all possible causes.

Data Collection for Statistical SQA

Example:

Error	Total No.	Total %	Serious No.	Serious %	Moderate No.	Moderate %	Minor No.	Minor %
IES	205	22	34	27	68	18	103	24
MCC	156	17	12	9	68	18	76	17
IDS	48	5	1	1	24	6	23	5
VPS	25	3	0	0	15	4	10	2
EDR	130	14	26	20	68	18	36	8
IMI	58	6	9	7	18	5	31	7
EDL	45	5	14	11	12	3	19	4
IET	95	10	12	9	35	9	48	11
other	180	19	20	16	71	18	89	20
Totals	942		128		379		435	

IES, MCC, and EDR are the "vital few"

Definitions

IES - Incomplete or erroneous specification

MCC - Misinterpretation of customer communication

EDR - Error in data representation

IDS - Intentional deviation from specification

VPS - Violation of programming standards

IMI - Inconsistent module interface

EDL - Error in design logic

IET - Incomplete or erroneous testing

Defect Index

D_i = # defects uncovered in ith step of software engineering process
S_i = # serious defects
M_i = # moderate defects
T_i = # minor defects
PS = size of product (LOC, pages of doc, etc.)
W_j = weighting factor (j=1 for serious defect, 2 for moderate defect, 3 for minor defect)

$$PI_i = W_1\left(\frac{S_i}{D_i}\right) + W_2\left(\frac{M_i}{D_i}\right) + W_3\left(\frac{T_i}{D_i}\right)$$

$$DI = \frac{\Sigma(i * PI_i)}{PS} = \frac{PI_1 + 2PI_2 + 3PI_3 + \ldots}{PS}$$

- *Defect Index* can be used in conjunction with information collected in the prior chart to indicate the overall improvement in quality.
- Morale of story -- concentrate on the few things that really matter.

Cleanroom Software Engineering

- Software developed under statistical quality control
- Goal is defect prevention rather than defect removal
- Proof of correctness is used to prevent defects
- Statistical QA used to certify the quality of the software

- Cleanroom approach has been shown to remove 90% of all defects prior to first tests
- General use of method would require substantial changes in management and technical approaches in industry

Software Testing

1. Introduction
2. White Box Testing
3. Black Box Testing
4. Test Strategies

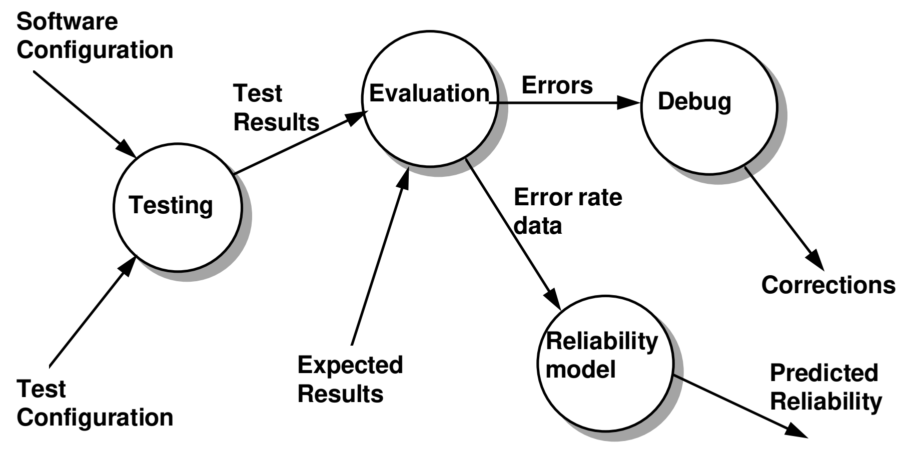
Software Fundamentals

Testing objectives

1. **We test to find errors**
2. **A good test case has a high probability of finding an as yet undiscovered error**
3. **A successful test uncovers an as yet undiscovered error**

Testing cannot show the absence of defects, it can only show that software defects are present.

Test Flow



White and Black Box Testing

<u>White Box Testing</u>

Uses the control structure of the procedural design to derive test cases

1. Basis Path Testing
2. Control Structure Testing

<u>Black Box Testing</u>

Uses functional requirements including input/output relations to derive tests.

1. Equivalence Partitioning
2. Boundary Value Analysis
3. Cause-Effect Graphing Techniques
4. Comparison Testing

White Box Testing

1. White box tests exercise all
   - independent paths with a module at least once
   - logical decisions on their true and false sides
   - loops at their boundaries and within their operational bounds
   - internal data structures to ensure their validity

2. Why test as white box rather than black box (which is easier)?
   - Logic errors and incorrect assumptions are inversely proportional to the probability that a program path will be executed.
   - We often believe that a logical path is not likely to be executed when, in fact, it may be executed on a regular basis.
   - Typographical errors are random.

Basis Path Testing

Test derived from a basis set of execution paths.

Cyclomatic number V(G) of the program graph is the upper bound of the size of the basis set.

The size of the basis set is the number of tests that must be designed and executed to guarantee coverage of all program statements.

Procedure:

1. Using the design or code as a foundation, draw a corresponding flow graph.
2. Determine the cyclomatic complexity of the resultant flow graph.
3. Determine a basis set of linearly independent paths
4. Prepare test cases that will force execution of each path in the basis set.

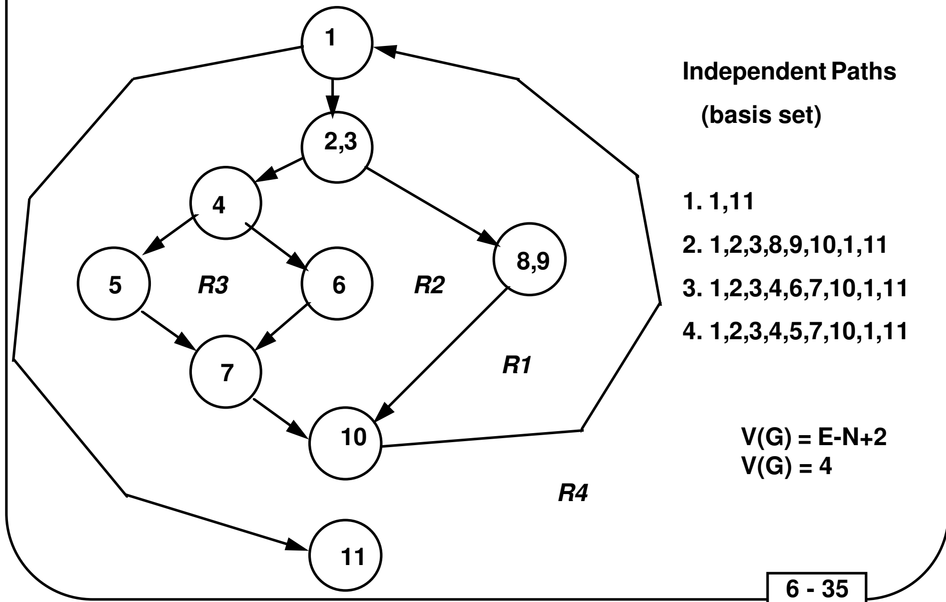
Deriving Independent Paths



Independent Paths
(basis set)

1. 1,11
2. 1,2,3,8,9,10,1,11
3. 1,2,3,4,6,7,10,1,11
4. 1,2,3,4,5,7,10,1,11

V(G) = E-N+2
V(G) = 4

Deriving Test Cases

Routine:

```
1   while x>0
2       y:=1
3       if x >10 then
4,5         if z then x:=-2
6                else x:=-3
7           end if
8       else y:=4
9              x:=-1
10      end if
    end loop
11 return
```

Tests:

Path 1,11

input: x < 1

output: unchanged x,y

Path 1,2,3,8,9,10,1,11

input: x > 0 and x < 10

output: y:=4, x:=-1

Path 1,2,3,4,6,7,10,1,11

input: x > 10 and z = false

output: y:=1, x:=-3

Path 1,2,3,4,5,7,10,1,11

input: x > 10 and z = true

output: y:=1, x:=-2

Control Structure Testing

The basis path testing technique previously described is one of a number of techniques for Control Structure Testing.

Basis path testing is simple and effective, but it is not sufficient in and of itself. Other variations on Control Structure Testing include:

- **Loop Testing**
- **Condition Testing**
- **Data Flow Testing**

Condition Testing

Condition Testing exercises the logical conditions contained in a program module.

A *simple condition* is a boolean variable or a relational expression, possibly preceded with one NOT operator.

A *relational expression* takes the form

E1 <relational-operator> E2

where E1 and E2 are arithmetic expressions and <relational-operator> is one of the following:

< <= = /= (inequality) > >=

A *compound condition* is composed of two or more simple conditions, boolean operators, and parentheses. It is assumed that boolean operators are used in a compound condition.

A *boolean expression* is a condition without relational expressions.

Data Flow Testing

Data Flow Testing **involves the selection of test paths of a program according to the locations of definitions and uses of variables in the program.**

With X representing a variable and S representing the number of a statement, we define:

DEF(S) = {X | statement S contains a definition of X}
USE(S) = {X | statement S contains a use of X}

A ***definition-use chain*** **(or DU chain) of variable X is of the form [X, S, S'], where S and S' are statement numbers, X is in DEF(S) and USE(S'), and the definition of X in statement S is live at statement S'.**

The ***DU testing strategy*** **requires that every DU chain be covered at least once.**

Loop Testing

Loop testing **is a white box testing technique that focuses exclusively on the validity of loop constructs. Four different classes of loops can be defined:**

- **Nested loops**
- **Concatenated loops**
- **Simple loops**
- **Unstructured loops**

Black Box Testing

Black box testing **methods focus on the functional requirements of the software. A set of input conditions is derived which fully exercises all functional requirements for a program or code fragment in black box testing.**

Black box testing attempts to find errors in the following categories:

- **incorrect or missing functions**
- **interface errors**
- **errors in data structures or external database access**
- **performance errors**
- **initialization and termination errors**

Black Box Testing Methods

- ***Equivalence Partitioning*** **- divides the input domain of a program into classes of data from which test cases can be derived**
- ***Boundary Value Analysis*** **- selects test cases that exercise bounding values**
- ***Cause-Effect Graphing Techniques*** **- provide concise representations of logical conditions and corresponding actions**
- ***Comparison Testing*** **- develop software redundantly, using separate software development teams for the same module, and compare the results generated by the independent modules**

Kinds of Automated Testing Tools
