Introduction

Welcome to Worldcraft, a graphical level editor for id Software's, Quake. With Worldcraft, you can make your own Quake maps quickly and easily! Worldcraft is written by DOOM Construction Kit author, Ben Morris.

Worldcraft's web site

The most up-to-date releases and information can be found at the Worldcraft web site:

<http://www.acdsystems.com/worldcraft/>

Ordering Information

You can order via Phone, FAX, or Online using your VISA or Mastercard. You can also order via Mail - please print and fill out this form and send it to one of the addresses below (NOTE: Please make cheques/money orders out to "ACD Systems"):

USA	Canada
ACD Systems, Inc.	ACD Systems, Ltd.
177 Telegraph Rd.	#591 PO Box 730
Bellingham, WA USA	Victoria, BC Canada
98226	V8W 2P9

To order by phone (24 hours a day, 7 days a week):

USA: 1-800-579-5309 (US Funds)
Canada: 1-800-563-7138 (Canadian Funds)
International: 1-250-382-5828

If you can't reach an 800 number from your area, please use the International number.

To order by FAX:

North America: 1-800-819-2207
International: 1-250-382-7099

Include your name, daytime phone number and address. Make sure the credit card information includes the holder's name, and the card's expiry date.

To order online (really fast!):

Visit Worldcraft's homepage - online ordering information is available there through our secure server at:

<http://www.acdsystems.com/worldcraft>

When you register Worldcraft, you get:

- A CD in the mail!
- Additional features not available in the Shareware version. Check the webpage for an up-to-date list of these features - the list will grow as Worldcraft becomes more sophisticated.
- Free minor updates available for download on the Internet. As more games are supported by Worldcraft, upgrade fees will be applicable: prices have yet to be determined.
- Limited support via e-mail.

Quake map specs

An excellent source of Quake editing information can be found at:

<http://www.infi.net/~nichd/qmapspec.html>

Note: Microsoft's DirectX3 must be installed to run Worldcraft. DirectX3 drivers can be found at either the Worldcraft web site or any Microsoft source.

Introduction to editing

Editing maps with Worldcraft

Quake level editing is based on a concept completely different to usual 3D editing and so while it is surprisingly simple, the immediate hurdle is realizing that it truly is as simple as it looks. Indeed, the hardest aspect of creating a level is coming up with the design itself.

Building blocks

Worldcraft uses a technique called Constructive Solid Geometry (CSG) to create maps. CSG is based on the simple idea of using building blocks - cubes, cylinders and wedges - to create more complex shapes such as a six-walled room. In Worldcraft, these building blocks are called solids.

If you ever did any DOOM editing, you'll remember that everything was made up of lines. In Quake level editing, there are no isolated lines - each object must be a three-dimensional object with volume. A six-walled room, then, is made up of six cubic solids - one for each of the four side walls, and two for the ceiling and floor. This concept is simple, but vital.

To view an example of a Quake room, load Worldcraft and Open the file ROOM.MAP. This map contains two areas: a sealed room, and a collection of blocks used to make the sealed room. The blocks are moved into touching positions - in fact, they can freely intersect - and the resulting enclosed space is what's seen by the players in Quake.

Carving a volume out of solids

In Worldcraft, any solid can be used to carve a volume out of other solids. For example, you can place a solid within the room's wall and tell Worldcraft to subtract the solid from the wall - effectively punching a hole right through the wall! This feature is not limited to using cubic shapes as a carving tool: any solid - cylinders, cubes and wedges - can be used to carve other solids.

And of course, you can place all your favorite Quake monsters, items, weapons and other entities in your new maps with Worldcraft.

Learning the ropes

The fastest way to become familiar with Worldcraft and creating Quake levels is to follow through the Tutorials that are included in these help topics. Or, read through the User's Guide, starting with the section entitled Overview of levels. As you are working with Worldcraft, you can use the Reference section for help with specific dialog boxes, menus, tools and utilities.

Overview of levels

What are levels made of?

Quake level editing is based on a concept completely different to usual 3D editing and so while it is surprisingly simple, the immediate hurdle is realising that it truly is as simple as it looks.

Levels are made from two types of objects: [solids](#) and [entities](#). These two object types are used in completely different ways, with solid usage being exceedingly simple, and entity usage being somewhat more involved. Together, solids and entities make a powerful editing system, yet, after a little practice with them, they are surprisingly easy to use.

Solids: your building blocks

A solid is a fully enclosed convex object which is used to create the level itself along with things such as moving platforms and doors. Worldcraft has four standard types of solids - block, wedge, cylinder and spike - but it really doesn't matter what shape the solid is, so long as it is fully enclosed and has no concave elements.

Often, solids will be grouped together to form a more complex object than the 'convex only' rule allows. When using the 'carve' tool on a solid, you will often find it has been sliced up into multiple solids automatically (all grouped) to avoid concave sections.

Solids can overlap each other without a problem and have no restrictions on size, position and orientation. This freedom is what allows Quake levels to have a much more interesting design than those in Doom, but keep in mind that the number of solids determines how long the level will take to QBSP and VIS, and how fast it will play in Quake.

Entities: your level's features

An entity is anything that isn't a solid, or is a solid that does something special. Entities range from monsters, doors, trains, weapons, switches, wind plus a multitude of other functions. They are used to make the levels more interesting than simply a walk from the start to the end.

Entities generally have their own default behavior, but many can be changed by editing or creating "keys" or by altering "flags".

These two object types are used in completely different ways with solid usage being exceedingly simple, and entity usage being somewhat more involved. But as with everything, once you've done it a few times it becomes second nature.

The necessities

A map really only needs two things to be playable in Quake; an area enclosed by solids, and a player start point. Anything after that is really just a bonus.

Lights are important in making a level look good, and as with everything else, once the concept is understood they are very powerful. There are quite a few light_entity types, covering fluorescent, strobing, normal and even some wall torches complete with prepackaged wall attachments.

To get anything approaching real daylight, you'll be using a LOT of lights. This will slow down LIGHT calculating (see [Compiling](#)) but that is nothing to fear. Most Quake levels tend to stick with fairly dark lighting anyway.

If you're making the level for deathmatch or co-op play, be sure to place plenty of deathmatch and co-op start points in appropriate places. One point to watch, for deathmatch in particular, is to avoid placing start points in areas where there will be a lot of action - telefragging is generally considered annoying.

Editing in three dimensions

Viewing your level

Worldcraft uses a fairly standard way to display your level: three 2-dimensional views and one 3-dimensional camera view. You'll do most of your editing in the 2D views, and the camera view is useful for getting a good view of your map before you test it in Quake.

The 2D views each offer a different perspective on your map: a Top (bird's eye) view, a Side view, and a Front view. Since each view offers a different representation of your map, you can shape objects in all three dimensions.

Navigating in the 2D views

Each 2D view has two scrollbars that can be used to move the area you're looking at. You can also use the arrow keys to scroll the Active view.

To change the Zoom factor for the Active view, use the gray + and - keys on the right side of your keyboard, or use the Magnification tool (the magnifying glass icon on the left-hand side of the screen) - click the left button to zoom in, and the right button to zoom out.

The 2D views will also display a grid - you can change the size of the grid with the [and] keys (European users can use the A and S keys.) By default, objects that you move and make are snapped to the grid - a common feature among CAD programs that makes alignment much easier. You can turn off this feature with the P key, or by using Map|Snap to Grid. You can also turn the grid off with Map|Show Grid.

Navigating in the 3D view

To navigate in the 3D view, select the camera tool.

- To move the camera without changing its angle, hold the right mouse button (**RMB**) in the 3D view while moving the mouse.
- To rotate the view and to look up and down, hold the left mouse button (**LMB**) in the 3D view while moving the mouse.
- To move the camera forward and backward, hold **Shift+RMB** and move the mouse up and down, or use the **D** and **C** keys.

Tip: The camera tool can also be positioned in the 2D views to place a precise viewpoint.

Tip: You can change the type of image displayed in the 3D window - wireframe, solid, and textured - by pressing one of the 3d view buttons at the top of the screen.

Note: The textured view may take a long time to load, depending on the speed of your computer and the size of the map you're working on.

- [Overview of levels](#)

Selecting and manipulating objects

Selecting solids and entities

To select an object:

1. Choose the [selection tool](#).
2. Click on one of the object's lines in the 2D views. Or, if you have a clear view of the object in the 3D view, click on one of its faces.
3. To select multiple objects, hold down the Ctrl key while selecting each object.

The selected object will be highlighted in red in the 3D view, and a selection rectangle - a box with [handles](#) - will surround the object in the 2D views. When multiple objects are selected, your editing will apply to all the selected objects.

Tip: To clear the selection - to deselect all objects - press C or use [Edit|Clear Selection](#).

Switching between scaling, rotation, and shearing modes

There are three selection modes: scaling, rotating, and shearing. Clicking the left mouse button repeatedly on the selection rectangle will toggle between these three modes. Using the selection rectangle, you can scale/move, rotate, and shear (slant) the selected objects:

- When you first select an object, it is in [scaling](#) mode, and has [nine handles](#).
- Click on the selection a second time to enter [rotation](#) mode. It now has handles on the [corners only](#).
- Click on the selection a third time to enter [shearing](#) mode. It now has handles on the [edges only](#).

For additional discussion of these selection modes, see [Overview of object manipulation](#).

Scaling and moving

To scale the object(s), move the cursor over one of the handles and click and hold the left mouse button. Then, drag the box to resize it to the desired proportions and release the left mouse button. The 2D and 3D views will be updated to reflect the change in size.

To move the object(s), move the mouse [inside](#) the selection rectangle (but not on the handles!) and click and hold the left mouse button. Drag the objects to the desired location and release the mouse button.

Tip: Hold down the Alt button to temporarily disable the snap-to-grid feature while you're moving or scaling the objects.

Rotation

To rotate the objects, click and hold the left button on one of the four corner handles. Drag your mouse around to rotate the object, and release the left button when you've rotated it to the desired angle.

Tip: Hold down the Shift key to constrain the rotation angle to multiples of 15 degrees.

Shearing

To shear the objects, click and hold the left button on one of the four side handles. Drag the mouse left/right or up/down to shear the object, and release the left button when you've sheared it to the desired angle.

Copying, Cutting, Pasting and Deleting selected objects

These standard features are available through the [Edit menu](#).

Tip: You can cut and paste objects into different maps!

Grouping and filtering objects

Collecting objects into groups

It can become very confusing to try to manipulate numerous objects at the same time. To alleviate this, Worldcraft allows you to group objects together so that they can be manipulated as a single object. Grouped objects will move, scale, rotate, and shear together as a single object.

- To group the objects you have selected, press the Group button.
- To ungroup the selected object, choose the UnGroup button.

Note: The feature described above, Grouping of objects, is unrelated to Worldcraft's "visible groups" feature, which is described below.

Organizing objects into VisGroups

Furthermore, you can collect your objects into "VisGroups", or "visible groups". You can then specify which VisGroups are visible in Worldcraft's edit windows. This allows you to ignore extraneous areas of the map and focus on the objects that you are currently working on. The filter control window shows a list of all VisGroups that have been defined.

To create a new VisGroup:

1. Press the "Edit Groups" button in the filter control window.
2. In the filter control window, press the "New Group" button.
3. Provide a name for the new VisGroup and choose its color.

To add objects to one or more VisGroups:

1. Select the objects that you want to be added.
2. Open the Object Properties window.
3. On the VisGroups page, choose which VisGroups these objects should belong to.

Choosing which VisGroups are visible

To enable filtering by VisGroups, put a checkmark beside Filter by VisGroups and then click the Apply button.

With filtering enabled, any VisGroups that are not checkmarked will be made invisible in the 2D and 3D views. You can toggle a VisGroup's status at any time; to view the results, click on the Apply button.

Note: Filtering is merely a convenience for editing purposes, and does not affect the actual level seen in Quake. Objects that are hidden by filtering will remain present in the compiled level.

Compiling the level

Running the map

Editing Quake levels is done in a standard known as .MAP. Quake, however, requires that the level be compiled into .BSP format.

All Quake editing tools are able to read and write the .MAP format. Worldcraft is no exception, although it also has an additional file type known as .RMF which is used to save additional information that isn't part of the .map standard (such as VisGroup information). See the [File menu](#) section for details on these formats and their usage.

To build your map into a playable BSP file, press the **F9** key, or choose File|Run Map in Quake. The [Run Map dialog box](#) will be displayed, allowing each of the following programs to be run at your discretion.

QBSP

The .MAP file describes all the solids, entities and textures that comprise the level. It is compiled into a .BSP file by the program called QBSP. A .BSP file can then be loaded into Quake and played without further ado. There are, however, two further - optional - steps you can take you make your level better: VIS and LIGHT.

VIS

If you run a .bsp file after QBSP'ing it, you'll find it generally slow and flickering, especially in larger levels (in fact, entire areas could be gray). This is because Quake is rendering every face which is in it's view, even if that face might be halfway across a level behind ten solid walls.

VIS optimizes a level by making it so that Quake only renders what it can see from any point in the map, thus making the level run a lot smoother. The trade off for having speed in the level is that VIS takes a LONG time to process the file, especially on a large level.

On a slow PC and a large level, you may well be looking at days for VIS to complete. For this reason, VIS is usually used only when the level is considered finished and ready to be released, unless you have access to a fast machine and wish to check it out at full frame rate more often.

Note: Whereas QBSP will work even if the level has leaks (see above for a description of leaks), even if it does spit up some error messages, VIS requires that the level be completely sealed from the poisonous gas of the gray void.

LIGHT

Finally, you can run LIGHT which will calculate shading and shadows for the entire level. If LIGHT is not run, all textures will be fully bright, so LIGHT's main use is to give the level atmosphere.

Manually compiling the level

Although the Run Map dialog box is convenient, it's still handy to know how to do it manually in a DOS window to see error messages and such. On a computer with little memory, you may prefer this approach.

Related Topics

- [Manually compiling the level](#)
- [Frequently asked questions](#)

Manually compiling the level

Running the map without Worldcraft

The Run Map feature might not work on all computers, since QBSP (the included program that turns MAP files into BSP files) requires a lot of memory. If you find that the feature does not work, here's how you can do it yourself:

1. Choose File|Export to Quake MAP. This will save your level as a Quake MAP file instead of a Worldcraft RMF (Rich map format) file.
2. Exit Worldcraft, and bring up an MS-DOS Window (use the Windows 95 Start menu, choose Programs, then MS-DOS Prompt.)
3. Change into your Worldcraft directory (for example, type `cd\worldcraft.`)
4. Run RUNMAP.EXE with your map file. RUNMAP takes two parameters: one, the name of your map file, and two, your quake directory. For example, if you were working with a file named mymap and your copy of Quake was located in `d:\quake`, you'd type:

```
c:\worldcraft> runmap mymap d:\quake
```

Running the utilities manually

If you prefer to run each utility separately, then you must invoke them yourself on the command line. Although the level can be used at any time after QBSP has created the .BSP file, the utilities should be executed in the following order. Their usages are as follows:

1. QBSP `c:/location/name.map c:/location/name`

Note: The second parameter doesn't require .bsp to be added to the name, and you can also make it's location aim directly to `/quake/id1/maps` if you wish (making it very easy to load into Quake with 'map name').

2. VIS `[-fast] c:/location/name.bsp`

Note: The -fast parameter is optional. It will VIS the level a lot faster, but isn't as optimal as a full VIS. Good for testing.

3. LIGHT `c:/location/name.bsp`

Overview of solids

What are solids?

A solid is a fully enclosed convex object which is used to create the level itself along with things such as moving platforms and doors. Worldcraft has four standard types of solids - block, wedge, cylinder and spike - but it really doesn't matter what shape the solid is, so long as it is fully enclosed and has no concave elements.

Often, solids will be grouped together to form a more complex object than the 'convex only' rule allows. When using the 'carve' tool on a solid, you will often find it has been sliced up into multiple solids automatically (all grouped) to avoid concave sections.

Solids can overlap each other without a problem and have no restrictions on size, position and orientation. This freedom is what allows Quake levels to have a much more interesting design than those in Doom, but keep in mind that the number of solids determines how long the level will take to QBSP and VIS, and how fast it will play in Quake.

Building the level with solids

Solids are used to construct the physical world that Quake is played in, so the way to treat solids is as you would treat a piece of wood or some bricks.

The advantage of this concept is that it allows solids to intersect each other without causing any slowdown once in Quake. This is because QBSP cuts away all intersecting sections, leaving just the polygons that will actually be seen in the game.

This freedom to intersect removes the necessity to make every wall and point of contact match up perfectly. In fact, it's often considered a good idea to deliberately overlap solids because it will save problems later.

For instructions on creating solids, see [Creating solids](#).

The entire level must be completely self contained, with no gaps - no matter how small - reaching into the gray void of outside. QBSP will probably still work on a level with a leak, but it will not produce a .ptr file and therefore the level cannot be processed by VIS.

Texturing the level

Texturing plays a large part in giving a level the quality appeal as those found in Quake. Texturing turns out to be an equally simple task, especially with Worldcraft.

Quake episodes are combined into .PAK files which are located in the /quake/id1 directory. Inside these PAK files is another file called a WAD2 file which holds all the textures for the episode. These WAD2 file can be extracted from the Quake PAK files, or downloaded from various Internet locations such as Worldcraft's WWW site.

Quake has four such WAD2 files, one for each episode. You can also add in your own textures, or remove some just as easily (you'll need a program to do this). Worldcraft lets you use multiple WAD2 files to texture your level, although to use this ability (which is not part of the Quake standard) you will need to use the special version of QBSP supplied with Worldcraft. If you only plan to edit using one WAD2 file, then you can use any version of QBSP that you wish.

When QBSP compiles the level, it will extract the textures you have used in your level from the WAD2 file and add just those to the resulting .BSP file (which can then be played in Quake).

Worldcraft makes texture placement quite simple. Every face of a solid can have its own texture, with accompanying X/Y scaling values, X/Y offset values and a rotation value. For details, see [Applying textures to solids](#).

Note: Mentioned previously was the ability to have a different texture on each face of a solid. It should be made clear that you cannot do this if any face is to be a liquid such as water or lava - those cases EVERY face of the enclosed solid must be the same texture, otherwise the level will not compile.

Creating solids

Overview

1. Select the [block tool](#).
2. In any 2D view, hold the left mouse button and drag out a bounding box. The box is reflected in the other 2D views.
3. Using the three 2D views, adjust the bounding box's width, depth, and height until it is the desired shape.
4. Choose the type of solid you want to create using the [object toolbar](#), and choose its texture using the [texture bar](#).
5. Press Enter to create the solid.

Creating a bounding box for the solid

To create a solid, you must first make the box that the solid will be contained in. This allows you to specify the size and position of the solid before it is created.

Create the initial box in any of the 2D views by holding down the left mouse button and dragging the mouse pointer. After you release the left button, a box will appear in the three 2D views. The box will have [handles](#) at each corner and on each side.

Adjusting the shape of the bounding box

Because you have not yet specified its third dimension, the box will initially have default thickness. You can adjust the box as many times as you like using the handles in the three views.

To adjust the size of the bounding box:

1. Place the mouse pointer over top of one of the handles. The pointer changes to a +.
2. While holding the left mouse button, drag the handle to the desired position for that edge or corner.

When you are satisfied with the bounding box, press **ENTER**, or click the right mouse button and choose **Create Object**. The cube will appear in the 3D view. Try moving around in the 3D view (see [Editing maps in 3D](#)) to view the cube from all sides.

Choosing a basic shape

This version of Worldcraft can create four types of solids: blocks, wedges, cylinders, and cones. Use the [Object Toolbar](#) to select a type of solid before you press **ENTER** to create the object. If the type of solid you've selected can have a variable number of faces, then the rightmost field will allow you to specify the number of faces you want to create.

Tip: Use the [Texture Bar](#) to specify which texture will be applied to the surfaces of the next object you create. To change the texture of an existing solid, or to specify the texture of individual faces of a solid, see [Applying textures to solids](#).

Related Topics

- [Selecting and manipulating items](#)
- [Editing existing items](#)
- [Applying textures to solids](#)

Applying textures to solids

What are textures?

Textures create the look of quake. Basically they are the pictures that are stuck on the wall to make them look like brick, wood, metal etc. The textures are divided into different themes. You can get them all from the Worldcraft web page. Put the files into your Worldcraft directory and then add them to Worldcraft's texture collection via the [Tools|Options](#) window.

Choosing a single texture for an entire solid

To specify a texture for every face of an object:

1. [Select](#) the solids you want to re-texture.
2. Use the [texture bar](#) to choose the new texture for these solids.
3. Click the [paintbrush tool](#).

Textures chosen in this manner will be applied to every face of the solid. For greater control over the textures on each face of an object, you must use the texture application tool.

Choosing a different texture for each face of a solid

To apply a different texture to each face of an object, you must use the texture application mode. To activate this mode, choose the [texture application tool](#) from the toolbar, or select Texture Application from the Tools menu. You can then select individual faces of objects directly in the 3D view.

To apply a texture to an individual face:

1. Select the [texture application tool](#).
2. Select the desired faces by choosing them in the 3D view.
3. Use the [Face Properties](#) window to choose the desired texture for these faces.
4. Press the **Apply** button.

Note: The texture application mode should not be confused with the normal editing mode. Most commands are not available while the face properties window is visible. You should leave texture application mode when you are done adjusting textures.

Tip: You can still move the viewpoint with the [camera tool](#) when you're in texture application mode.

Scaling a texture

The [Scale controls](#) on the [Face Properties](#) dialog box allow you to stretch or compress the texture bitmap in each axis on the face of the solid. You can specify the scale factor for each of the X and Y axes separately. Scale factors less than 1 reduce the size of the texture bitmap; larger scale factors increase its size.

Note: The X-Y scaling axes are oriented at the rotation angle that you specify. Therefore, if you rotate the texture (or the solid) after you have scaled the texture, additional adjustments to the texture scaling may be required.

Shifting a texture

The [Shift controls](#) can be found on the [Face Properties](#) dialog box. In these two fields, you can specify the number of pixels to offset the texture.

Note: Texture offsets are measured with respect to the gridlines, not the edges of your object. Therefore, if you move the object after it has been created, the texture offset may no longer be as desired, and may require further adjusting.

Rotating a texture

The [Rotation control](#) on the [Face Properties](#) dialog box allows you to specify the angle of rotation.

Note: If you rotate the object after it has been created, the texture will NOT rotate with it; therefore, additional adjustments to the texture's rotation may be required.

Carving sections from objects

What is carving?

Worldcraft has a powerful feature called carving. Carving is the act of deleting the shape of one solid from another. It's somewhat akin to using a cookie cutter to shape solids. Using subtraction you can create all sorts of other complex solids.

Consider that you've made a six-walled room and want to connect a hallway to it - you can't simply stick the hallway onto a side of the room, because the room's walls are solid; there's no way for the player to pass through the wall into the hallway. This is where carving comes in: you can place a solid within the room's wall and tell Worldcraft to subtract it of the wall - effectively punching a hole right through it!

Carving other objects using the selected object

Any solid can be used to carve a volume out of other solids - cubes, cylinders, spikes and wedges. To carve using an object:

1. Select the object that you want to use to carve other objects.
2. Position the object so that it intersects the other objects.
3. Click the carve tool, or choose Tools|Carve from the pulldown menus.

Note: Worldcraft will split a solid into multiple objects if the carving would produce a concave shape. The multiple objects are automatically joined into a single group.

- [Overview of object manipulation](#)

Overview of entities

What are entities?

An entity is anything that isn't a solid, or is a solid that does something special. Entities range from monsters, doors, trains, weapons, switches, wind plus a multitude of other functions. They are used to make the levels more interesting than simply a walk from the start to the end.

All entities are QuakeC functions which are mostly organized into categories such as "trigger" and "func" (although some, such as "path_corner", belong to no obvious group). While entities are QuakeC functions, you don't need to have any knowledge of QuakeC to use entities.

Entities generally have their own default behavior, but many can be changed by editing or creating "keys" or by altering "flags". For details, see [Overview of keys](#)

Entities are somewhat more involved than solids since they cover a much wider range of features. Entities can be created in two ways which give two distinct results, but unfortunately the only sure way to know which type to use is through experience and common sense.

Standalone entities

These are entities that have no solids attached to them. Examples of these are monster_entities, player start points and path_corners (which define the path of a func_train, i.e. a moving platform).

If these types of entities are created with attached solids (see below), the results can be unpredictable; in some cases it won't make a difference, and other times they simply won't work.

For instructions on creating standalone entities, see [Creating standalone entities](#).

Entities with attached solids

These are entities that use part of the physical level (i.e. one or more solids) as part of their functioning. Examples of these entities are func_door, func_plat, trigger_multiple etc. The attached solids will not always be visible once attached to an entity also, such as with any of the trigger_ functions.

These entities are actually created by taking a solid (or more commonly in the case of doors, a 'group') and using the 'toEntity' button or the 'Tie to entity' tool in the menus. This will create an entity and attach the selected solid/group to it, at which point an entity type can be selected.

Some entity types will use the shape of the solid for some purpose, but in many cases, the solid itself will appear invisible once played in Quake. The trigger_entities are example of this (although there is one type of trigger in the func_types which does leave the trigger visible) as is the entity that creates the exit portal.

For instructions on creating solid entities, see [Creating solid entities](#).

Entity keys

Entities have additional properties, called 'Keys' or 'Keyvalues'. Keys accept many different value types depending on the entity used and the particular key. For more information on keys, see [Overview of entity keys](#).

Related Topics

- [Properties dialog box](#)

Overview of entity keys

Entity keys

There are quite a few keys that are consistent across many of the entity types such as 'target', 'targetname', 'wait' and 'sound', although their purpose can change slightly from entity to entity.

You are strongly encouraged to read the 'Quake Map Specs' file located at:

<http://www.infi.net/~nichd/qmapspec.html>. This file is the best guide to knowing which keys can be used with what entities (although it shouldn't be taken as 100% correct).

Some of the more common (and important) key types follow:

targetname

This key is used if you wish to make the entity activate via some other event. A good example is a func_door that you wish to be opened by a switch instead of by proximity (its default). Do not give this key a value if you want the entity to work of its own accord. The 'targetname' key is very closely related to the 'target' key (see below).

The accepted values for a targetname key is any piece of text you wish to identify it by (not starting with a number). id's Quake maps use very simple targetnames like 't1' or 't12' whereas you might find it more helpful to use descriptive names such as 'door1' etc.

You can give several entities the same targetname, meaning that when the trigger happens (whatever it may be) they all activate at once.

target

Use this key if you wish to make this entity trigger another entity. Continuing the example from above, this entity could be a trigger_multiple which, when triggered, makes the func_door open. The value of the key should be exactly the same as the 'triggername' used in the entity you wish to trigger. You can give several entities the same target value, so for example you could have several switches open the same door.

Triggering is fully automatic in Quake, so once one entity has a target name, and another entity has the corresponding target, it will all work. The type of entity used as the trigger (or to be triggered for that matter) can be almost anything. You can make a door opening turn on a light for example. This targetname/target relationship is the real power behind Quake's level editing.

wait

This key can be used in many of the entity types to tell it to stay open (or whatever) for a certain number of seconds. The value can be anything starting at 0.01.

delay

Similar to wait, except it generally creates the pause at the beginning of the action. So we may have our trigger opening the door, except by giving the func_door a 'delay' key the door can be made to not open for a certain amount of time.

speed

The speed at which the entity moves.

angle

This is the direction in which the entity acts. The usage varies greatly across the entities, with it being the direction a monster_ starts facing and the direction a func_door opens. Possible values range from 0 (right) through to 360, with special values of -1 (vertically up) and -2 (down). Quake doesn't currently support up/down movement at angles except with func_train entities.

Note that Worldcraft doesn't use 'angle' as a key; instead, it has a little graphical representation at the top-right of the properties window.

lip

Lip is one of those bizarre multipurpose keys that turns out to be quite useful. A value of -1 (default) on a door, for example, will open the door (in the direction of the angle) by a distance of exactly the solids width in that direction. A positive value will make it open up less than its width, and large negative values will open it more than its width.

There are many other key types, so it's worth reading the 'Quake Map Specs' as mentioned above. Many entity types also have switches which, for example, tell that entity to only show up in deathmatch play etc. These switches are set in the second folder of an entities properties window.

See the section entitled [Properties](#) to learn how Worldcraft handles entity properties.

Creating point entities

You create a monster or other entity (herein called items) in much the same way as you create a solid - the difference is that an item requires you to specify just one 3D point. Items also have properties, such as facing direction, which can be adjusted later.

To create an item:

1. Select the [Entity Tool](#).
2. Use the [Object Toolbar](#) to choose the type of item that you want to create.
3. In any 2D view, click on the desired location for the item. The item's volume is reflected in all of the 2D views. Use the three 2D views to adjust the location of the item.
4. Press Enter to create the item.
5. Press Alt+Enter or choose Edit|Properties to access the item's [properties](#).

The list of entities is long, and includes ambient effects (light and sound sources), spawn and teleport locations, monsters, weapons and other powerups. Each type of entity fills a different volume of space; the entity appears in the 2D and 3D views as a cube of that volume.

For a description of entities and their keys, see [Overview of entities](#).

Tip: Items appear as purple boxes in the views.

Tip: When the level is run, items will fall to the nearest floor beneath them. Therefore, it's important not to bury the entity inside a floor or wall. Use the snap-to-grid feature to place items adjacent to, but not within, the floor and walls of your level.

Creating solid entities

Making a solid move

Moving solids are actually entities that use one or more solids as part of their functioning. These entities are actually created by taking a solid (or more commonly in the case of doors, a 'group') and using the 'toEntity' button or the 'Tie to entity' tool in the menus. This is just one example of creating a solid entity.

Creating a solid entity

Some entity types will use the shape of the solid for some purpose, but the solid itself will not always be visible in Quake. The trigger_ functions are examples of such entities. Other examples of solid entities are func_door, func_plat, trigger_multiple, and so on.

To make a solid entity:

1. Select the solid or solids that you want to be moveable.
2. Click the **toEntity** button at the toolbar, or use Tools|Tie to Entity.
3. Choose an entity type.

This will create an entity and attach the selected solid/group to it, at which point an entity type can be selected. The solid(s) are now all part of the entity, and when you select one, all of them are highlighted.

Tip: You can break the association between an entity and its solids by using Tools|Move to World.

Editing an entity's properties

Editing an entity's properties

Once you've placed an Item, you can edit its properties - you might want a Monster to appear only on the most difficult skill level, for example.

1. Select the item you want to edit.
2. Press Alt+Enter or choose Edit|Properties to edit its attributes.

The Object Properties dialog box will be displayed. Using this dialog box, you can change the item's type (its class), the angle it faces, and various attributes called keyvalues. Some classes don't require any keyvalues at all; others have several.

Using the SmartEdit view

For those items that do require keyvalues, Worldcraft has a feature called SmartEdit that allows you to edit the values without remembering the required keys. When SmartEdit is enabled, the Keyvalues listbox changes to a list of Attributes that are valid for the item's class.

To activate the SmartEdit view, press the SmartEdit button on the Object Properties dialog box. Compare the SmartEdit view to the default view.

Note: Why not permanently enable SmartEdit? The answer is expandability: advanced users might create their own Items using Quake's built-in programming language, and Worldcraft can't know about them without some customization to its configuration files. Therefore, it makes sense to allow people to edit the raw keyvalues during the development of these items.

- [Overview of entities](#)
- [Overview of entity keys](#)

Setting flags for an entity

Some entities allow you to specify a set of flags, each of which is either on or off. A typical entity's Flags tab looks like [this](#).

To access an item's flags:

1. [Select](#) the item you want to edit.
2. Press Alt+Enter or choose Edit|Properties. The [Object Properties](#) dialog box is displayed.
3. Choose the [Flags](#) page.

Each type of item has its own set of flags with unique meanings. For example, the flags for the item monster_army (the shotgun trooper in Quake) have the following meanings:

[Ambush](#), when checked, means that the Monster will only start to attack you after it sees you. When it's not checked, the Monster will try to attack you as soon as it hears your gunshots.

[Not in Easy](#), when checked, means that the Monster won't appear in the Easy skill level. This setting, combined with the other skill flags - [Not in Normal](#) and [Not in Hard](#) - allows you to make your maps more difficult for people who think they can take it!

[Not in Deathmatch](#) means that the Monster won't appear in Deathmatch games.

Note: The Not in... flags apply to many objects besides monsters - for example, health packs and shotgun shell packs could be made more abundant in the easier skill levels.

Tutorial: A simple room

Creating a new map

This tutorial will show the minimum steps needed to create a new map for Quake. This will be the most descriptive of all tutorials with the others requiring this one to be working.

1. First we must create an enclosed area from which to sculpt a level. From the Object Bar on the left of layout, select the Block Tool.
2. In the top view (default position is top right), click and hold the LMB somewhere in it, then drag the mouse down/right until you have a box of around 6x6 grid lines. Let go of the LMB.

Note: if your top/front/side views seem mixed around, it doesn't really matter since the level will still work even side-on.

3. Now look at either the front or side views (bottom/right and bottom/left respectively with default windows). You will probably see a 1-grid-thickness box with solid black squares at it's corners and along each side. If you can't see the entire box, scroll around the view using the scroll bar to the right of the window, or use the cursor keys on your keyboard.
4. Click the LMB on either the top-middle black square (when the cursor is over a square, it will change to show what type of move you can do - you want it to become a little vertical line with arrows top and bottom). With the LMB held, move the mouse upward until your side view box is around 5 grid lines high.

Note: This process of first creating a square in one view, then going to another view to scale it in that direction, is how all solids are created.

5. Currently there is only the guidelines of a box in the modeling views - no solid has been created yet. Before we create the box, you may want to reposition the guide-box by clicking and holding the LMB inside the box and moving around (it will snap to the grids). Try to center it around the center of the two dark black lines that run through each view (ie. the origin of the map). This isn't essential by any means - you can put stuff wherever you like - but it might keep things neat for the purpose of these tutorials.

Note: Clicking inside the selected objects bounding box is not only a way to move the object around (by holding the button) but also changes the edit mode (clicking once). So if you find you can't move it around, keep single clicking LMB inside the box until there are black squares at each corner and midway along each edge.

6. Just before we actually create the box, we should think about what texture we want to create it with. Textures can be easily changed at any time, but note that every solid MUST have a texture or the level will not work. So click LMB on the word 'Browse' in the texture window on the bottom right of screen. This will open a window of all available textures - pick one that might make a good room texture (i.e. not a liquid).

Note: If you find that the texture window contains no textures, that is because you haven't set up the Worldcraft options correctly. You'll need at least one WAD2 file (which has textures) located in your Worldcraft directory, and in the Tools|Options menu this WAD should be listed in the path area at the bottom.

7. One more thing to check before creating the solid; make sure the 'solid type' selector on the Object Bar says 'Block'. If it doesn't, click once on the text and select Block. Once you're happy with the size, shape, position and texture of your box, press Enter on your keyboard. This will create the solid.
8. This solid is actually our room, but the block is solid so we need to cut out an area inside it to make a room. Click on the Selection Tool and then in one of the windows click on/close to an edge of our newly created solid. If you've done this correctly, a bounding box will be drawn around our solid - looking much like the original guide-box - indicating that it is selected.

Note: With the solid selected, you can, if you wish, do some more resizing and repositioning at this point.

9. Open the Tool menu at the top of the screen and from there select 'Make Hollow' (you could also hit RMB over the selected object). This will open a window asking how thick to make the walls; 32 is default which is fine, so hit OK. You'll now find that what was once one solid is now six - one for each wall 32 units thick (the default grid size is 64 units which is almost exactly the height of your character).

Note: the reason the solid was chopped up was because Quake does not allow concave objects.

10. There is only one more thing required before you can actually check out your room in Quake - a player

start point. Click on the [Entity Tool](#) button. In the [Object Bar](#), you should see "player_start_point" which is the default entity type to create. If it shows another entity type, click once on the text then find and select "player_start_point". Now in the top view, click LMB somewhere inside our room. Then go to a side/front view and make sure the green guide is inside the room from that view also - if it is not, hold the LMB on the green box and move it around until it's inside the room. You can place it near the floor if you want, although be sure not to place him IN the floor or you won't be able to move once you start Quake.

11. Hit Enter to create the entity.

12. Your level is now ready to play (although in it's current form interest is likely to be short lived). Hit 'F9' (this is Worldcraft's [Run Map](#) feature) and you will find the compilation window. Select 'Full QBSP' and 'Full VIS' but make sure you have LIGHT turned off. Then hit go.

QBSP will compile the level, then VIS will optimize the level (hardly necessary with a level this size, but it'll be fast with only 6 solids) and then load up Quake with your level in it.

If the compiling stage didn't work, either you messed up the level somehow, or maybe the executables - qbsp.exe and vis.exe - aren't located in your Worldcraft directory as they need to be. If you're stuck, check the [Frequently asked questions](#) section.

If it compiled with no errors (the errors would flash by pretty quick - if you want to examine them in more detail you'll need to manually compile the level: see [Overview of compiling](#) for details), but Quake doesn't load up, then check that the path to Quake that you put in the Tools|Options menu is correct.

If it all went well and loaded into Quake, it might just be worth checking if you started in the level at the position you think you placed the start point entity. If not, you probably have your top/front/side views mixed around. Experiment a little. Actually, experiment a lot.

- [Next step: Adding some features](#)

Tutorial: Adding some features

Viewing the level in the 3D view

We haven't used the 3D window at all yet, so perhaps now is a good time to make use of it:

1. Select the Camera Tool button which is third down on the button-menu to the left.
2. Click and hold the LMB where the player entity is top view, then drag the mouse to the center of the pillar and let go.
3. You'll see a dark line in all three views now (you may need to scroll around a little in some windows) with a solid black dot at one end. You will also have noticed that the view in the 3D window has changed; the black dot represents the camera position and the other end of the line shows what the camera is looking at.
4. On the top horizontal button-menu in Worldcraft are the 3d view buttons which determine how the 3D view is rendered. The first is wireframe (which you are seeing already), the second is solid and the third is textured. It'll be hard to resist pressing 'texture' now so you may as well do it.
5. With Windows 95 set to a 16-bit display, you'll now see the 3D view showing an accurate representation of how the level will look in Quake. Play with Tools|Options|Texture Brightness if the 3D view looks too dark/bright. With Windows 95 set to 256 colours, the 3D view may be corrupted (this is a DirectX issue and not the fault of Worldcraft).
6. With the 3D view operating, and with the Camera Tool still selected, you can click and hold the LMB on either end of the camera line and move it around to change the 3D view. There more immediate way to move the camera around is by the use of the mouse buttons inside the 3D window itself (along with the 'Shift' key for zooming in/out). See Camera Tool for details on its usage.

Note: This 3D view doesn't relate to anything in Quake, it's only to help edit the level and align textures.

Selecting objects in the 3D view

Selecting objects has been covered thoroughly for 2D view, but once a map becomes cluttered the 3D view can actually be best for selecting. Try selecting some of the objects like:

1. Turn on solid rendering for the 3D window by pressing the gray block button from the MapView bar. The 3D view will now show solid colours.
2. Select the Camera Tool. Now move the camera view around until you are looking at the object you want to pick (see the section describing the Maptool Bar for full details on camera manipulation). Once you've played with the camera a bit, it'll become quite simple to use.
3. Now go to the Selection Tool and simply click on the object you wish to pick. It will turn red. Continue to hold the LMB if you wish to cycle through all objects currently under the cursor (very handy Worldcraft feature).

Adding more objects

As cool as our room is, it can be made a lot cooler. Adding in extra solids is as easy as it was to make the original room:

1. Select the Block Tool from the button-menu to the left.
2. From the Object Bar (just above the views area) you can now select another type. Choose a cylinder.
3. In the top view, draw out a 2x2 box, then from a side/front view, pull it's mid-top and mid-bottom squares up/down so that the bottom on the box sits on the ground, and the top touches the roof. Position it in the room, but don't place it where your player entity is.

Note: Our grid size is 64, and so because we made our walls 32 thick (when we did the Hollow), the guide-box won't snap exactly where you want it. You can either hold down Alt while you move (remove snapping altogether), or hit the '[' key on the keyboard which will actually halve the grid size to 32 making the snap work easily.

4. Before making the solid, go into the texture window again (bottom right of screen) and select another good pillar texture (rock or something).
5. Create the solid by pressing Enter.

6. Press F9 to check out the new map.

You'll now find a whopping great pillar in the middle of the room. This demonstrates how simple it is to add extra details to the map.

Adding some lights

At this point, when you run the level it will still be looking fully bright with no shading or shadows. Basically it looks like crap, so perhaps a few well placed lights will bring in some much needed atmosphere.

1. Select the Entity Tool from the button menu to the left of screen.
2. In the Object Bar, click once with the LMB then scroll down and select 'light_fluoro'.
3. Place the light entity around where you have your player start entity. Perhaps just a little above where the player one is (remember you'll need to manipulate it's position in more than one view to line it up correctly).
4. Press F9, but now in the compilation window select 'Full LIGHT'. Without this setting, any light entities in the map would still have no effect. Then press OK.

This will produce a very dark level except around the start position which will be subtly lit. It's easy to see that a lot of lights will be required to get nice even lighting around a large level. The alternative is to just boost up the amount of light produced by the one entity.

1. Select the light entity, then click the RMB with the mouse in the center of it's bounding box and select 'Properties' at the bottom.
2. The properties window is where you alter entities. Turn off 'SmartEdit' and click on the 'light' key. This value is default at 200, so make it 600 (three times as bright).
3. Close the properties window and hit F9 to run the level.

Continue the tutorial

- Next step: Enhancing the room

Tutorial: Enhancing the room

Modifying the textures

Now lets see an interesting effect of certain textures:

1. Choose the Selection Tool then select the pillar solid by clicking LMB on/close to one of its lines. If you accidentally highlight the room solid, then just click somewhere there are no solids to deselect everything (or press Alt+C).
2. With the pillar solid highlighted, click LMB on the texture window again. Now select the water01 texture or similar.
3. Changing the current texture to water hasn't automatically changed the texture of our selected object. Press the Paintbrush tool to apply the texture to our object.
4. Press F9 to run the level.

The pillar now has the animating water texture wrapped around it which looks kind of odd free-standing in thin air. In Quake, try running into the pillar to see what happens.

Making objects overlap

So far we've been basically aligning objects neatly by the grid, but Quake's style of level editing means that this isn't necessary. Just as an example:

1. Deselect any objects that might be selected, then select the pillar solid.
2. In the top view, move the pillar object so that it's center right on top of a wall. This will mean part of the pillar is inside the room, and part is outside.
3. Press F9 to run the level.

If the pillar is still water, you'll be able to see from this test that Quake has nicely clipped away that part of the pillar you don't see.

Rotating and shearing

Now let's apply rotation and shearing to some of the solids:

1. With the pillar still selected (or select it again if it isn't already selected), click LMB once inside it's bounding box.
2. The bounding box should now have solid circles at each corner which indicates that it's now in 'rotate' mode. Press and hold the LMB on one of the black dots and move the mouse around.
3. The pillar will be rotating around. Release the LMB once you've seen how it works.
4. Click once with the LMB again in the center of the bounding box.
5. The bounding box will have changed again to show solid black squares halfway long each edge (with none at the corners) which shows that it is in 'shear' mode. Press and hold the LMB on a square and move the mouse around.
6. This will shear the object. Release the mouse button when you've seen how it works.
7. Click once inside the bounding box again to return to move/ resize mode.

That demonstrates one way to produce solid shapes that aren't part of the predefined set. The other way is to use 'carve' to use one solid to slice away part of another.

Carving a volume out of solids

1. Create a new solid. We're after a 'block' type solid, located so that it half sits inside the pillar, and half sits outside (in the room). Press Enter when it's in the desired position (texture isn't important).
2. Now select the room object

Note: The room is composed of 6 solids, but since they are all grouped, selecting one of them will select them all.

3. Select Tools|Ungroup from the menu (or from the button-menu, or even the floating menu you get if you click the RMB over the selected object).

Note: The Carve Tool carves any object that it is touching based on whether their bounding boxes are

touching. Since the room group is surrounding everything, its bounding box is also touching everything else meaning that if we did a carve with those 6 solids grouped, the walls would become fragmented (try it if you want to see the effect). By ungrouping them they each get their own, smaller, bounding box which gets around the problem. You could just as easily move the room group well out of the way to do the carve, then move the room back once carving was complete. See [Tools|Carve](#) for further information.

4. Now deselect anything currently selected, and select that new block you created that was sticking into the pillar.
5. Select the Carve tool to carve a block out of the pillar in the shape of the cube.
6. With the cube still selected, use Edit|Delete to remove the block from the map (it was only used for carving, which is why texture wasn't important).

Note: Making this carve (which is actually a Boolean subtraction) will have made the pillar solid contain a concave section. Since concave shapes are not allowed, Worldcraft will have automatically sliced the pillar into several pieces and grouped them together.

7. Press F9 to run the map.

If you walk over to the pillar (wherever it is in your map at this point) you should see the shape of the block cut neatly into the side of the pillar.

Continue the tutorial

- [Next step: Joining two rooms](#)

Tutorial: Joining two rooms

Creating a hallway by carving

For this tutorial, we need two rooms that are not yet joined. Making two rooms is simply a case of following the [first tutorial](#) twice. However, do NOT create two player start point entities. With two hollow rooms created, connecting them is achieved by cutting out doors from each room, and either lining them up so that the two doors touch each other, or creating a hollow connection between them.

We'll assume with this tutorial that the rooms are a few grid lines away from each other, and at the same height. Due to the openness of this particular task, the tutorial may be hard to follow.

It's worth noting that there are many ways to achieve the result we're after, and this tutorial will only cover one such technique. Once you become competent with Worldcraft, these sorts of problems will be easily solved.

1. Select the [Block Tool](#) again, and create a 'block' type solid connecting the two rooms to each other. The solid should be placed where you want the doors to connect, and it should meet the outer wall of each room. Overlapping it into the walls of each room is fine; however, it should not extend into the interior of either room.

Note: Keep in mind that the room walls can be any thickness - it makes no difference in the compiled level. The only important rule is that the level must have no gaps (or "leaks") to the outside void when it comes time to run [VIS](#).

2. Once the solid is created (with an appropriate [texture](#)) it can still be [manipulated](#) into position via the various move, resize, rotate and shear functions covered in the previous tutorial.
3. Now create another solid - the texture of this one is unimportant - and place it inside the solid you just created. It must be visibly thinner than the first solid in height and width; however, it should be longer than the first solid, extending into the interior of each room at the ends. This latest solid will be used to cut a hole through the wall of room 1, through the larger solid placed between both walls, and through the wall of room 2.
4. Because carving is based on bounding boxes, we should ungroup the solids making up each room if they are grouped. To check, select one of the solids making up the walls of a room, and choose Tools|Ungroup. Do this for each room.
5. Select the thinner solid that we created last.
6. Select the [Tools|Carve](#) menu item (or choose the [carve button](#)).
7. Delete the thin solid (press the Del key, or choose [Edit|Delete](#)).

If the second solid was thinner and longer than the first solid, then you should find that an open walkway now exists between each room. As long as the interior of the hallway remains completely sealed from the outside void, the level will work.

If both rooms actually share a common wall, then one simple [Carve](#) operation is all that is required. If the rooms aren't neatly aligned with each other, it might be simpler to first carve door holes in each room, then construct the corridor by hand - first a floor, then each wall, then a roof - with several solids and the 'shear' operation.

Continue the tutorial

- [Next step: VisGroups](#)

Tutorial: VisGroups

Classifying objects into VisGroups

VisGroups are a unique feature of Worldcraft that makes editing large cluttered levels much easier, so they are worthy of our attention in this tutorial. When you start to work on large levels, VisGroups will be your best friend.

The idea is that you create a whole bunch of “VisGroups” which relate to particular areas you might want to selectively turn on/off all in one go. An example VisGroup list for a simple two room level might be:

```
room1
room2
doorstuff
furniture
furnitureroom1
furnitureroom2
```

Note that some of the groups listed might seem to overlap. This is one of the useful functions of VisGroups: any item can be in any number of groups.

Setting up VisGroups

Let's setup the above VisGroups ready to be used (this is just a demo of setting up VisGroups, but if you happen to have such a room ready it can be applied easily):

1. On the right side of the Worldcraft window at the top is the Filter Bar. At top/right of it is a button labelled 'Edit groups' which will invoke the VisGroups editor. Press it.
2. Now select 'New Group' - a new group is created.
3. With that group selected, you can edit the name of the group by typing in the text box top/right. Type in 'room1'.
4. Follow steps B and C for all the VisGroups listed above.

Note: By selecting each VisGroup you can also change the colour used to display that group in the editing windows.

5. With the VisGroups created, you are free to begin assigning objects to them. Select an entity, solid or group then open it's properties window via the Edit->Properties menu (or by clicking the RMB over the selected objects and selecting the bottom tool).
6. Go to the 'VisGroups' folder which for an entity will be the 3rd folder, and for solids it will be the only folder.
7. Here you choose which groups you want this object to be associated with. These groups have nothing to do with Quake, they are simply to make editing easier. If the chosen object is a chair in the first room, for example, you'd probably place a 'tick' next to; room1 furniture furnitureroom1
8. Place each item of the two rooms into appropriate groups.

Note: You can do multiple objects in one go. If you have several objects selected then open the properties->VisGroups window/folder and some of the objects have different groups already selected from others picked, there will be a “greyed out” pick placed into the appropriate box.

Our VisGroups are now ready for use. As you create new objects you should add them to the appropriate VisGroups or create new VisGroups where needed.

Enabling VisGroup filtering

In the Filter Control window, you will see a list of all the VisGroups along with tickboxes indicating which groups are visible. By default, Worldcraft doesn't have VisGrouping enabled, so no matter what groups are ticked you will not see any difference.

1. Tick some VisGroups you wish to work on. Perhaps you are planning to add something new to room 1, so having anything from room2 in the editing windows would just slow things down and make it hard to see whats going on. For now, tick just the 'room1' group which should at this point have anything associated with room1 placed in this group.
2. Place a tick in the 'Use groups' box located just below the list of groups. This will tell WC that you wish to use VisGroups although you won't see any changes yet.
3. Click 'Apply'.

After clicking on Apply, Worldcraft will look at all the settings in the VisGroups menu and then apply them to the editing window. This means that any objects that haven't been set to belong in the 'room1' VisGroup will be turned invisible making editing of room1 a lot easier.

Changing which VisGroups are visible

After editing the new object for a while you might decide that having all the other furniture in the room is making it still too cluttered, so:

1. In the Filter Control window (over the right of view), turn off 'room1' and turn on 'roomsurrounds1' with maybe 'doorstuff' if it'll be helpful for editing the new object.
2. The 'Use VisGroups' toggle should still be active from before, but if not turn it back on.
3. Hit Apply.

The furniture will disappear from view.

Finally, when the new object is completed and you want to view the whole level again:

1. On the Filter Control window, deselect the 'Use VisGroups' option.
2. Hit 'Apply' to make the change happen.

Note: To make use of VisGroups, you must save your maps in the .RMF file format. Only the .RMF format retains VisGroup information. See the description of the File menu for details on file formats.

Note: You don't need to make everything visible again to run it in Quake. If you hit F9 and examine the compilation options, you'll find a toggle which tells it whether to compile invisible objects or not.

Continue the tutorial

- Next step: A moving door

Tutorial: A moving door

Creating a door

The func_door entity is one of the more versatile functions available for level editing. The following example shows how to use it to create a basic door that opens up when you walk close enough to it.

1. Load in or create the simple room as described in [tutorial number one](#).
2. Now create a block type solid positioned in the room where you want the door (for test purposes it would probably be easiest to just place it in the center of the room) and at the size you want. Don't worry about fancy door trimmings just yet, this example will be free standing.

Note: The player is a fraction under 64 units high and roughly 32 units wide, so your door should be at least that size.

3. Select your door solid, and then select the 'toEntity' tool on the Object bar (or use 'Tie to entity' from the menu or the RMB-menu).
4. The door solid is now attached to an entity and it's the entity we wish to manipulate to become a door. After selecting 'toEntity' the properties window would have come up automatically. Change the entity type to 'func_door'.
5. In the 'angle' settings top/right of the properties window, make it -1.

Note: -1 is a special angle in Quake which means **up** and -2 means **down**.

6. Close the properties window and press F9 to run the map.

Running the map, you will find the door sitting where you created it, and the door will open vertically upward if you walk close to it.

Adjusting the door's movement

By default, a func_door (or func_plat etc.) will open a distance of exactly its width in the direction of its angle. To make it open twice as far:

1. You'll need to remember how tall you made your door. Lets assume you made it 80 units high.
2. With the door solid/entity selected, click the RMB inside the bounding box (which will open a menu) and select the bottom option which is 'properties'.
3. One of the keys is called 'Lip' which does different offset related things depending on the entity type. With a func_door it can be used to alter the amount the door will move; a positive value will make the door open less than it's full length, and a negative value will make it open more. Put in a value -2 x the height of the door (in our example case, that will be -160).

Note: The default value is -1. Negative values that turn out to be less than the doors length will make no difference, so for example, a value of -75 would still make it open 80 units. You'd need a value of '5' to make it open less than it's length.

4. Press F9 to run the map.

And there is a door that opens twice its actual height.

Connecting the door to a trigger

As with almost all entity type in Quake, func_door can do much more than simply opening when you walk close enough. Triggering the door to open by a switch is a common adaptation that Quake levels use a lot:

1. Select the door solid/entity and open its properties window.
2. Turn off 'SmartEdit' and click on 'add' to add a new key.
3. Make the key name 'targetname' and give it a useful value such as door1.

Note: 'targetname' is one of the most used key types. By giving an entity (almost any entity) a targetname key, you are making that entity activated by some other trigger (and a trigger can be almost anything). If you ran the map now, you'd find the door wouldn't open, since the door now requires a trigger of some sort.

4. Create a new solid making it about 16 units cubed. This will be our trigger so place it somewhere obvious and at a height such that the player can run into it. Use an appropriate texture that identifies it as a trigger

(i.e. lava wouldn't be that useful).

5. Select the new solid and press toEntity and make the entity type 'func_button'.

Note: There are numerous trigger types, and the func_button one we used is the only one that keeps the solid visible - that is, all the trigger_entity types will use the solid shape only as a detection box to tell if the trigger has been set off, and the solid itself will be invisible (which is why func_button isn't part of the trigger_group).

Continue the tutorial

- Next step: A teleporter

Tutorial: A teleporter

Creating a teleporter

A teleporter consists of two entities; one has a solid attached to it which is the part you step into, and the other is a standalone entity that marks where you teleport to.

1. Start by creating a tall solid - about big enough for a player to walk into.
2. Select this solid and from the menu select Edit|Copy (or from either the button or RMB menus).
3. Select Edit|Paste, then select the newly pasted solid and move it well out of the way (for now).

Note: Remember, from the Door tutorial, that the trigger_entity types are actually invisible once in Quake? 'trigger_teleport' is no different, so by making a copy of the entity solid we can later put it in exactly the same position as the trigger and make it appear visible.

4. Select the original teleport solid (make sure it's at a good position in your room) and press toEntity, then make the entity type a 'trigger_teleport'.
5. Turn off SmartEdit and add/edit a key called 'target' and give it a value something like "tele1".
6. Now create an entity and place it where you want the teleporter to throw you. The entity type should be an "info_teleport_destination".

Note: This second entity is NOT a solid attached to an entity via the 'toEntity' button which we've used before. This destination point must be a standalone entity created by the Entity Tool which is located just below the tool used to make solids.

7. Select the newly created entity and open its properties window.
8. If the entity type isn't already info_teleport_destination, make it so right now.
9. Change the angle parameter (top right of the properties window) to the direction you want the player to be facing when they pop out.
10. Turn off SmartEdit, then add/edit a key called 'targetname' and makes its value equal to the 'target' value you gave the trigger_teleport (tele1).
11. Both entities are now set up correctly and will work. But the teleporter will be invisible, so select the copied solid you made back at step 2.
12. Open the texture Browse window and find that wobbly black-with-white-dots one that we all recognise to be the teleport texture.
13. Hit the Paintbrush tool to apply this texture to the selected solid.
14. Move the solid so that it sits at exactly the same position as the teleporter solid entity.
15. Press F9 to run the map.

You'll see that the teleporter has its characteristic wobbly texture, and by running into it you'll be transported to the location given by the destination entity, and oriented in the direction given by the angle parameter.

Continue the tutorial

- Next step: A train

Tutorial: A train

Creating a train

Trains function a lot like teleporters in that they have a solid attached to an entity as the main section (the train itself) and 2 or more standalone entities to give a path to the train. This example will create basic train moving between three stop points.

1. Create a thin solid to use as the train itself (the train can be more complex by using multiple solids and then grouping them together into one object). Give it an appropriate texture.

Note: It makes no difference where you place the train solid, since trains will always snap themselves to the first stop point.

2. Select the solid and press toEntity. Make the entity type a 'func_train'.
3. Turn off SmartEdit and add/edit a key called 'target' and give it a value of something like "stop1".
4. The train is complete, but now we must tell it where to go. Create a standalone entity (use the Entity Tool) and place it where you want the train to start. The entity should be created as a 'path_corner' type although it can be changed in the properties window at any time.

Note: path_corner entities work relative to the bottom/left hand corner of the train solid/group bounding box. That is, if you select the train solid/group, the path_corner entity should be placed in the bottom/left hand corner of the bounding box. Currently there's no simple way to line everything up perfectly apart from careful placement.

5. With the first stop created, select it and open its properties window.
6. Create/edit a key called 'targetname' and give it a value equal to the target value you gave the train itself (stop1).
7. Create/edit a key called 'target' and give it a value of 'stop2'.
8. Close the properties window and now create another entity of the path_corner variety. Place it where you want the train's second stop to be (keeping in mind the bottom/left rule).
9. Select the entity then open the properties window. Edit/create a key called 'targetname' and give it a value of 'stop2'.
10. Edit/create a key called 'target' and give it a value of 'stop3' (are you beginning to see a pattern?).
11. Close the properties window and now create yet another entity of the path_corner variety. Place it where you want the train's last stop to be (keeping in mind the bottom/left rule).
12. Select the entity then open the properties window. Edit/create a key called 'targetname' and give it a value of 'stop3'.
13. Edit/create a key called 'target' and this time give it a value of 'stop1' (ie. this will make a train loop back to it's start position again).
14. Exit the properties window and press F9 to run the map.

When you enter the level, the train will be sitting waiting at the first stop point. Run up to it and jump on. A sound will play, followed by a pause (alter the 'delay' key value to change the pause length) and then it will travel to the second stop point. At the second stop point it will pause briefly again (length is set by the 'wait' key, although it seems to be impossible to remove the "stop" altogether) and then move on to the next stop.

And then from the third stop point it will move back to the first stop point again. Once it's reached where it started, by default it will just do the circuit again, but if you give any of the path_corner entities a 'wait' key of value '-1' the train will remain at that corner.

Trains aren't as flexible as they first seem; the requirement that they **MUST** stop - no matter how briefly - at each path_corner means that continuous motion isn't possible, and you cannot give rotation of any type to your train. This makes things like Duke Nukem's trains and swinging doors impossible to achieve without getting into QuakeC. (Hexen 2 and Quake 2 are expected to address this shortcoming.)

Frequently Asked Questions

Q: How can I run maps that I've made in Quake?

A: Worldcraft includes a feature that will build your map into a playable BSP file, and run Quake. You can activate this feature with the **F9** key, or use File|Run Map in Quake. This feature might not work on all computers, though, since QBSP (the included program that turns MAP files into BSP files) requires a lot of memory. If you find that the feature does not work, here's how you can do it yourself:

1. Choose File|Export to Quake MAP. This will save your level as a Quake MAP file instead of a Worldcraft RMF (Rich map format) file.
2. Exit Worldcraft, and bring up an MS-DOS Window (use the Windows 95 Start menu, choose Programs, then MS-DOS Prompt.)
3. Change into your Worldcraft directory (for example, type `cd\worldcraft.`)
4. Run RUNMAP.EXE with your map file. RUNMAP takes two parameters: one, the name of your map file, and two, your quake directory. For example, if you were working with a file named `mymap` and your copy of Quake was located in `D:\Quake`, you'd type:

```
c:\worldcraft> runmap mymap d:\quake
```

Q: What's the scale of maps in the editor to how they're displayed in Quake?

A: You get a feel for this over time, as you've edited some maps and tried them out in the game. A measurement that might help in the meantime is that the size of the player is about 25 units wide and 60 units high.

Q: When I start up Worldcraft, I don't see anything in the 3D views. What's wrong?

A: Make sure that you've loaded a MAP file or created something to be displayed. Remember, solids aren't created until you press the ENTER key after drawing them!

Note: Matrox Millennium cards have real problems with Microsoft's Direct3D, which is what Worldcraft uses to display your maps. If you have a Matrox card, try to get new drivers from Matrox or Microsoft - these drivers weren't available at the time this was written, but might be available by now.

Note: More topics to be added to this FAQ.

Interface

The Worldcraft interface has been designed to maximize ease of use. The help is divided into 3 basic categories; menus, buttons and windows.

Many of Worldcraft's features can be accessed by various different means; for example, 'Ungroup' can be selected from either the menu, the onscreen button, by pressing the right mouse button (RMB) over the selected object or by using the Ctrl+U hotkey. This should allow everyone to find a particular workflow method suited to their style of editing.

Likewise, the arrangement of buttons and windows can be customized to your particular taste. Most users will find the default arrangement quite suitable and it's recommended to at least become familiar with the program before thinking of customization.

Menus

Menus in Worldcraft stick to the standard style laid down by Windows 95. To open a menu, you can either click with the left mouse button (LMB) on the required menu title (at the top of the Worldcraft window), or use the Alt+{underlined letter} hotkeys.

By clicking once with the LMB on a menu title, it's selection menu will open and stay open until you do another LMB click (whether it be inside the menu or anywhere else). This method allows you to browse through each menu by moving the mouse around, and to select an item by clicking on it with the LMB. The other method is to click the LMB on the desired menu title, but continue to hold the button. An item is selected by positioning the mouse over it and releasing the button.

For further information on menu selection and menus in general, refer to Windows 95 documentation.

Related Topics

- [View menu](#)
- [Tools menu](#)
- [Window menu](#)

File Menu

New (Ctrl+N)

Opens a blank map. Used when you wish to create a new level from scratch. This will not destroy any level currently loaded in Worldcraft, it will just bring up another set of windows. This ability to open multiple levels allows cutting and pasting between maps. See the MENU|WINDOW:' for further information on using multiple maps.

Open (Ctrl+O)

Presents the standard Windows 95 Open File dialog box which allows you to select an existing quake map to load in. As with New, this will not destroy any currently loaded map.

The selector at the bottom of the file dialog box allows you to filter files between .MAP and .RMF. The .MAP file is the standard Quake editing format and is used by the QBSP program to create the actual Quake .bsp file (a .bsp file can be loaded into Quake and played). A .MAP file is compatible with all other Quake editing tools available.

The .RMF format is Worldcraft's own special format ,which allows extra information to be saved which is not part of the .map standard (such as 'VisGroup' information). It's recommended to use the .RMF format for general editing (since you can easily save them out in .map format if you wish) although if you don't intend to use any of Worldcraft's special features there is no harm in saving as .MAP.

Note that if you use Worldcraft's 'Run Map' feature, it will automatically save a .MAP file.

Close

This will close the currently selected level that you are editing (if there are multiple maps loaded, the current one is the one which has a blue top border). This function is the same as pressing the LMB on the 'X' icon on the top right of the editing area. If any changes were made to the current level since the last save it will ask you if you wish to save before closing.

Save (Ctrl+S)

If the current map already has a name, this will simply save the level with that name. If it is a new map which hasn't yet been saved, it will prompt you with a file dialog box to give the project a name. See Open for details on .map and .rmf formats.

Save As

This command will present a file dialog box even if the current map already has a name. Handy if you wish to save the map but don't wish to save over the top of the previous copy.

Export To Quake MAP

This command will save your level in an editor-neutral MAP format. This is the format used by QBSP, and is suitable for converting your level. This format is also created by the Run Now command.

Run Map in Quake (F9)

This does many things, but the end result is that by pressing this button you can play your level in Quake with no further fuss. Many factors determine whether it will be successful; these are discussed in the description of [Run Maps dialog box](#). When you run this feature, Worldcraft will automatically save your script.

Exit

This will exit Worldcraft. Any loaded levels which have been modified since their last save will give a request to save. Exit is the same as pressing LMB on the 'X' at the very top right of the Worldcraft window.

Edit Menu

The Edit menu presents the usual commands for editing, along with some Worldcraft specific commands.

Undo (Ctrl+Z)

Will undo the previous command. Worldcraft will remember consecutive commands and allow you to undo several of them at once; the number of undo steps is limited by the setting in the Options menu.

Redo (Ctrl+Y)

Will redo the command that was undone using the Undo command.

Cut (Ctrl+X)

This will delete the currently selected solid(s)/entity(s) and keep a copy in the clipboard buffer.

Copy (Ctrl+C)

This will copy the currently selected solid(s)/entity(s) into the clipboard buffer.

Paste (Ctrl+V)

This will paste whatever is in the clipboard buffer to the current map. The pasted object is centered in the two previously selected windows.

Paste Special...

See the section [Paste Special](#) for details.

Delete (Del)

This will remove the selected solid(s)/entity(s) from the map, and will not keep a copy in the clipboard buffer. A deleted item is lost forever.

Clear selection (Alt+C)

Will clear all selections.

Select all

Will select everything in the level being edited.

Properties

This command is where all the serious level creating and editing stuff happens. See the [Properties window](#) for full details.

Related Topics

- [Paste Special window](#)

Map menu

The map menu contains various options and menus relating to the map.

Snap to grid (P)

Moving objects around will snap them to the grid. This is on by default, and allows objects to be lined up more easily.

The grid snapping can be overridden at any time by holding down 'Alt' while moving. Doing this will ignore the current Worldcraft grid settings and instead snap to the smallest units that Quake can recognize.

Where the object chooses to snap to on the grid is determined by where you clicked on the selected object to move it around. If you clicked on it near the upper lefthand corner, then the object will snap to the inner top/left corners of the grid. Likewise, selecting the object towards the bottom/right will snap to the grids inner bottom/right corner.

Show grid (G)

The grid is by default turned on. Here you can turn it off if you don't wish to snap to the grid and it's cluttering the view.

Grid settings ([and])

These two sub-options will make the grid smaller or larger by a factor of two. Note that there are two sets of hotkeys available for grid setting.

Map properties

This contains information about the map which Quake will use. This is related to object properties and is also covered in the [Properties window](#) section.

Show Information

Shows basic statistics on your level. Solids are simple solids, PointEntities are lone entities, SolidEntities are entities which have one or more solids attached to them, and Faces is the number of polygons making up the scene.

To learn about solids and entities, see the Overview of Levels.

Check for problems

This is a useful command which will analyze your map for common errors. A full list of the problems that Worldcraft can detect will be added to this documentation in a later release.

Related Topics

- [Navigating maps in three dimensions](#)

View Menu

The view menu contains all Worldcraft viewing related commands.

This allows you to determine what elements are present on the Worldcraft layout. Details and descriptions of the particular elements can be found in the [overview of toolbars](#). The following can be selectively turned on and off (descriptions relative to default Worldcraft layout):

Object Bar: Thin horizontal bar located second row from the top.

MapTools Bar: Thin vertical bar located on the left of the layout.

MapOperations Bar: Thin horizontal bar located on the top row to the right.

MapView Bar: Thin horizontal bar located on the top row to the left.

Filter Control: Large box window on the right of layout to the top.

Texture Bar: Large box window on the right of layout to the bottom.

Status Bar: Thin horizontal bar located at the bottom of the layout.

2D X/Y Y/Z X/Z

The tick indicates which view the currently selected editing window is showing. Each editing window can be changed to another view at any point (so it's possible to have multiple windows looking at the level from the same direction) by changing the selected item.

3D

There are three render modes for the 3D view window:

wireframe: Views all solids in wireframe mode, and views entities as boxes. The size and colour of entities are determined by the type of the entity. Solids are shown in blue unless they belong to a VisGroup which have their own colours. The currently select items are shown in red.

filled polygons: Solids are viewed in solid form with entities rendered as solid boxes. Colours are determined by the same rules as with the 'wireframe' render method. Some basic lighting is applied to give the objects some shape.

textured polygons: This mode uses Microsoft's 'DirectX' to render the level with texturemaps applied. This view presents basically a 1:1 view of how the level will look inside Quake (with the exception of lighting) and is very useful for aligning textures.

Note: There is a limitation with DirectX while using 256 colours. The symptom is corruption of either the 3D view, the texture menu, or both. To avoid this if it causes problems, set your system to at least a 16bit display via Windows 95: Start|Settings|Control Panel|Display (and then Settings).

Autosize 4 views (Ctrl+A)

Will resize all four windows to equal sizes. Further window sizing details can be found in the WINDOWS topic.

Maximize/Restore active view (Z)

This command will be implemented in a future release of Worldcraft.

Hide Items

Selecting this will hide all entities from the view. By default this is off.

Center views on selection (Ctrl+E)

Center the X/Y/Z window views around the currently selected items.

Hide selected objects

This command will make the selected objects invisible. This visual control is not related to the VisGroups feature, and should not be confused with [VisGroup filtering](#).

Show hidden objects

This command will make the all hidden objects visible.

Related Topics

- [Navigating maps in three dimensions](#)

Tools Menu

The tools menu contains raw editing and manipulation commands.

Carve (Shift+Ctrl+C)

This command is very powerful and allows more complex shapes than the few default ones Worldcraft contains. The operation is a mathematical 'Boolean subtraction' which means that it subtracts one object from another.

To use Carve, place solids in an arrangement such that they overlap each other. Then select the solid you wish to cut with - the knife - and select the Carve option. The knife will remain unaltered, but the other solid(s) will have the shape of the knife solid removed from them.

Due to the way Quake levels are created, the solid that was carved up will most likely be now a combination of several smaller solids, in which case they will be grouped together.

Any solid whose bounding box is even partially in the 'knives' bounding box will be carved. This means that if you have a big environment around the solids you are carving, and all the solids making up the environment are grouped, the environment will get carved too. The solution is to do all carving outside of the main level area where it can't do any harm, or you can use a blank map for working in from which you can copy the results back to your level map.

For step-by-step instructions on how to carve an object, see [Carving volume out of solids](#).

Make Hollow (Ctrl+H)

This will hollow out the selected solid. The solid will be divided into a group of several smaller objects that make up the same shape but enclose a cavity. The thickness of the walls will be equal to the number of units that you specify.

If you specify a negative number for the wall thickness, then the walls will be constructed outward from the outer face of the solid, rather than inward. This allows you to build a solid (or group of solids) in the exact shape of the desired interior cavity, then construct walls around it using the Make Hollow command.

Group (Ctrl+G)

Group will join together all selected solids and entities into one unit. Selecting and deselecting any item contained in a group will select and deselect the WHOLE group. The only method to select an individual item contained within a group is to select the group and then select 'ungroup' (see below).

There are two useful purposes for grouping objects. Firstly, because it can make moving elements around much easier if it's to be done often (instead of having to select each element time and again). The other use is to easily create complex doors, platforms and trains that move as one unit.

Grouping will destroy any entity settings that a solid might contain.

For details on grouping, see [Grouping and filtering objects](#).

Ungroup

This will split a grouped unit into its individual solids and entities. Ungrouping will destroy any entity settings that the group may have had.

Tie to entity (Ctrl+E)

This will tie a particular solid, or group of solids to an entity. This is used to make everything from doors to trains and triggers. See the index for descriptions of solids and entities. Details on the entity window can be found in the section describing the [Properties window](#).

Move to world (Ctrl+W)

This is the reverse of 'Tie to entity'. It removes any entity settings the selected solid(s) have and reverts it/them to a normal solid.

Texture application (Shift+A)

Allows pixel-accurate placement of textures on any selected faces. Faces are the individual sides/facets of a solid and can be altered individually or as groups. If the current view mode for the 3D window is 'textured polygons' the changes made in the face will happen dynamically in the 3D view allowing textures to be lined up very accurately with little effort.

For details about using the texture application mode, see [Texture application window](#).

Align Objects

If several objects are selected, the align options will align all objects to the object that is the furthest in that

direction.

As an example, we have 4 objects we can see from the front view but they are all at different heights. If we select all 4 objects and then choose Tools|Align Objects|To Top, the three lowest objects will move up to align with the highest one.

Prefab Factory

This command allows you to access the Prefab Factory. The Prefab Factory is a set of libraries that contain useful objects that make building your level easier. You can also define your own libraries that contain objects you have created yourself. Each object must reside in its own .MAP or .RMF file. Libraries in the Prefab Factory also show up on the [Object bar](#).

Create Prefab

This command will create a new prefab using the selected object.

Window Menu

The window menu contains features relating to Worldcraft's layout.

New Window

Will create a new set of 4 windows for the current map and place them in front of the existing windows. Any change done in either set of windows will instantly update in the other set.

To change between sets, or to see behind the current working windows use the left-two icons on the top right of the work area (i.e. the second set down on the top right of the Worldcraft screen). The '_' button will minimize the current window and the icons that appears as two overlapping squares will shrink the current view.

Cascade

This will shrink all non-minimized windows and display them neatly cascaded in the work area starting at top left.

Tile

Will arrange all non-minimized windows so that they all have an equal amount of room on the work area, but do not overlap.

Arrange Icons

Will arrange all minimized window icons neatly along the bottom of the work area.

Messages

This command opens the Messages window, in which Worldcraft will report errors and other troubleshooting messages. Most users will have no need to use the Message window.

The bottom part of the Window menu contains the name of each map currently loaded. A tick is placed next to the currently active map, and by selecting any of the maps listed that map is made current. If the selected map is minimized it will be expanded.

Toolbar Buttons

Many of the often used commands found in the menus are also available as buttons in onscreen menus. These button-menus are divided into several sub-groups which can be individually moved around the Worldcraft screen, or even removed altogether.

To turn on/off any selected button-menu, use the toggle switches in the View|Screen Elements menu.

Moving button-menus around is achieved by clicking and holding the LMB inside the border of a menu (but not on an actual button), and then dragging it around the screen. Worldcraft will detect where a menu is currently being moved to, and change it's orientation accordingly.

Upon releasing the LMB, the menu will be dropped into position and Worldcraft will automatically rearrange all other windows and button-menus to accommodate the newly placed menu.

If dropped in a border section, the button-menu will become part of the border elements, but if dropped into the work area, it will become a standalone menu.

Note that any changes made in window/button-menu arrangement will be permanent and will be saved as default.

The following refer to default positioning.

MapView Bar

Contains three sets of buttons:

XY, YZ, XZ View

These refer to the three possible planar views. If a 2D view is currently selected, the button corresponding to that particular view will be highlighted.

You can make the currently selected window into a different view by selecting another button. Even the default 3D view located top left can be turned into a planar view, and you can have multiple showing the same planar view.

By default, the top right window is XY, the one below it is XZ and the bottom left window is YZ, with the top left window being the 3D view.

Wireframe, Polygonal, Textured View

These three buttons refer to the render method of the 3D view. See the [View Menu](#) topic for further descriptions of each render method.

Toggle Grid

Turns the grid on and off. See [Map|Show Grid](#) for further details.

MapOperations Bar

Contains five groups of icons relating to map editing and manipulation.

Carve

See Tools|Carve for details.

Group, Ungroup

See Tools|(Un)Group for details.

Align Left Right Top Bottom

See Tools|Align Objects for details.

Cut Copy Paste

See the [Edit menu](#) for details.

Run Map! (F9)

See the section on the [Run Map dialog](#) for details.

Object Bar

Contains four sections relating to object status and creation.

toWorld

Will remove any entity settings of the selected solid(s)/group. See Tools|Move To World for further details.

toEntity

This will attach the currently selected solid(s)/group to an entity. Entities are covered in the Properties topic. See Tools|Tie To Entity for further details.

Categories

When the [Entity Tool](#) is active, no categories are available. With [Block Tool](#) selected, there will be at least one category available: the "Primitives", which contain Worldcraft's four basic solid shapes: block, cylinder, spike, and wedge. If any Prefab libraries have been defined, then the library names will also be listed here.

Object

This list contains all objects that belong to the chosen category. For entities, the list contains all entity classes available. For solids, if the 'Primitives' category has been selected, then this list contains the four types of primitives. If a Prefab library has been selected, then this list contains all objects in the library.

Faces

This selector becomes active if the [Block Tool](#) is active, and either 'cylinder' or 'spike' is the current solid type. The value, which can be changed by either keyboard or clicking LMB on the little arrows), represents the number of side faces the cylinder/spike will be created with.

MapTools Bar

The main map creation button-menu contains 4 sections; viewing and selection, creation, textures and layers.

Selection tool (Shift+S)

Used to select object(s) thus making them current. Selecting objects can be done from both 2D and 3D windows by clicking the LMB on the required objects. Clicking on or near the lines of objects is the most sure way of selecting the correct object.

Selecting multiple objects can be achieved by holding down 'Ctrl' when selecting additional objects.

If selecting in a shaded or textured 3D view, by holding down the LMB in a selected area will cycle through all objects contained under the pointer.

A selected object is rendered as red in the 3D view, and is bordered by a red bounding box in the 2D windows. If several objects are selected, the bounding box expands to cover all objects.

To deselect all objects, click the LMB in an area of the 2D windows containing no objects, or use the Edit|Clear Selection tool (Alt+C).

For details on the use of selecting objects, see [Selecting and adjusting objects](#).

Magnify (Shift+G)

Used to zoom into and out of a 2D view. Clicking the LMB in a 2D view will zoom into the area under the pointer, and clicking RMB will zoom away from the area under the pointer. The same functions can be achieved by the '+' and '-' keys on the keypad.

Camera (Shift+C)

The camera tool is used to alter the 3D view and can be used in one of two ways.

If activated for the first time, you can draw a line in any of the 2D views; the start of the line, which is drawn as a solid black dot, will become the camera position, and the end of the line will be the place the camera looks at. Length of the line is not important. Once this line has been drawn once, it can be altered at any time by (with the camera tool selected) clicking LMB on either end of the line and dragging them around in the 2D views.

The second method is a little more intuitive as you are working directly in the 3D view. With the camera tool selected, you can use the LMB and the RMB with mouse movement to directly affect the view of the 3D window. Speed of update depends on map size and the current render method for that window.

The position and orientation of the camera is used only for editing and does not relate to anything in Quake. The default position for the camera is high above the level looking directly down at position 0,0,0.

For details on the use of the camera view, see [Navigating maps in three dimensions](#).

Block Tool (Shift+B)

Used to create solids in the map. Once selected, the 'Solid type' selector (second row from top) becomes active and allows you to specify the type of solid to be created.

See [Selecting and adjusting objects](#) for details on manipulating created solids.

See [Overview of Solids](#) for further information on solids.

Entity Tool (Shift+E)

Used to create standalone entities for the map (i.e. entities that have no solids attached to them). Once selected, the 'Entity type' selector (second row from top) becomes active and allows you to specify the type of entity to be created.

See the [Properties](#) topic for details on manipulating created entities.

See the [Overview of entities](#) for further information on entities.

Toggle texture application (Shift+A)

See [Tools|Texture Application](#) for details on the use of this command.

Apply current texture

Will apply the current texture to all selected solids. This tool works on the whole solid, so for individual faces the 'Toggle texture application' tool should be used.

Filter Control (VisGroups)

VisGroups is a powerful tool for limiting visible objects in the map. This allows for much easier editing on large levels but does require that you use the .rmf file type for saving your maps since the .map format doesn't include the VisGroup information.

The 'Filter Control' button-menu allows the filtering and creation of VisGroups. For this menu to be used, objects must be set up with VisGroup settings which is covered in the section describing the [Properties dialog box](#).

VisGroups

This large box at the top/left contains a list of all created VisGroups along with their on/off status (identified by a tick). You can individually turn on/off each group, although the changes don't take effect until you use 'Apply' (see below).

Filter by

With this tick box unticked, VisGroup filtering is totally turned off. With it ticked on, filtering is activated according to the settings in the VisGroups box. The change of this toggle only takes effect when you hit 'Apply' (see below).

Apply

This will re-filter everything according to the current settings of the VisGroups settings and the 'Filter by' toggle.

Edit Groups

Takes you into the VisGroup editor. This editor can also be accessed via the VisGroup folder in the properties window.

Groups

The large area to the left lists all VisGroups for the current map, along with their status (status is defined by a tick - on means the group will be visible if filtering is activated). There are no VisGroups by default, so to use them you must create some.

Selected group name

The name of the currently selected VisGroup. This can be edited by keyboard.

Color

The colour used to draw all objects of this VisGroup in the 2D and 3D windows. Selecting the 'Color' button opens the color selector window from which you can choose from a selection of predefined 'Basic colors' or create some customized ones to your liking.

Remove

Will delete the currently selected VisGroup from the list.

New group

Will create a new VisGroup in the list. By default this name will be 'new group' which should be edited to something more appropriate such as 'Room1' etc.

Related Topics

- [Grouping and filtering objects](#)
- [Selecting and adjusting objects](#)

Texture Bar

The texture bar selects the current texture. Any solids created are made using the current texture, and the 'Apply current texture' button in the 'MapTools Bar' will use the current texture to change the selected solid(s).

See [Tools|Texture Application](#) for details on its use.

Status Bar

The status bar is divided into 6 segments each giving various pieces of information depending on which window is selected and the current tool.

Help

Provides a description of menu commands and toolbar buttons.

Selection

Will give information on the current objects selections. If a single element is selected, it will give details information such as the entity type if it is an entity, or the number of faces if it is a solid. If multiple objects are selected, it will list how many.

Coordinates

Will list the current cursor coordinates for the window.

Bounding box/rotation/shear

When an object is selected, this area will display the bounding box size (i.e. the minimum sized box which can be drawn around the object(s)). The values are Width Length Height.

When you begin to do a move, resize, rotate or shear, the box will display information on the move.

If the type is 'move' (there will be solid black squares at each bounding box corner along with one halfway down each side and the cursor will be clicked inside the box) there will be no display.

If the type is 'resize' (bounding box will appear the same as for 'move' but the mouse will be clicked on one of the black squares) it will display the X/Y bounding box size for the current view.

If the type is 'rotate' (there will be solid black round dots at each bounding box corner) the area will display the rotation amount.

If the type is 'shear' (there will be solid black squares halfway along each side of the bounding box) it will display the amount of shearing.

Zoom

Shows the amount of zoom in the current 2D window.

Grid

Shows whether grid snapping is on or off, and the current size of the grid.

Paste Special

This menu allows multiple pasting of the clipboard contents with offsets and rotations. This relieves the work in creating something such as a picket fence where you can make one rail, then copy it multiple times with an offset for each new object.

Number of copies to paste

The number of new copies to paste.

Start at center of original

With this in its default position of on, offsets and rotations are relative to the location and rotation of the original item in the clipboard. With it off, the new objects will be created relative to the center of the two previously selected windows.

Group copies

Turning this on will group all resulting objects together. See Tools|Group and Tools|Ungroup for further details on grouping. The default is off.

Offset (accumulative)

The three boxes here allow offset values for X, Y and Z. With each additional paste, the next object will be offset from the previous one by these values which are given in Quake units.

The '<' buttons beside each box will automatically insert the current grid settings.

Rotation (accumulative)

These settings work in the same fashion as the Offset values, except that they apply rotation with each successive paste.

Run Map in Quake (F9)

By selecting this feature, and after giving the project a file name if one doesn't yet exist, another window is presented with various compilation options:

Additional Quake parameters

Here you can add extra Quake command line parameters such as `-listen` etc. which will be used when Quake is run.

Run QBSP

QBSP is the program which compiles a `.map` file into a `.bsp` file which can then be loaded into Quake and played. You have the options of not running QBSP (which is only useful if the `.bsp` file already exists and you only wish to do other things to it), 'Normal' which will compile the entire map into a new `.bsp`, or 'Entities only' which will also require that it has previously been QBSP'd with 'Normal', only this time it will compile just the entities.

Run VIS

VIS optimizes the level allowing it to run faster and smoother with no visible disappearing walls and textures. This is usually only done once a level is basically finished and ready for final testing since on a decent sized level it can take a LONG time (even days on very large levels and a slow PC).

The options are; no VIS, Fast (it's speedy, but isn't optimal) and Full which is generally only used for final release.

Run LIGHT

Light is another optional step in the compiling process. Without running Light, every texture in the level will be fully bright, meaning that there will be no shading or shadows. If you have any light entities in your level, running Light will give your level proper shading and shadows (if you run Light with no lights in your level, you will only see black).

The options are: no Light, Normal (is fast to calculate but shadows may be noticeably jagged edged) and Extra which will go a long way to removing jagged edges on shadows.

Don't run Quake

With this deselected, if the compilation is successful Quake will load up with your level ready for testing. Select this box if you don't wish Quake to load.

Save visible objects only

With this in its default off position, all objects in the level will be compiled, but with it selected on only visible objects will be compiled.

Note: Do not confuse the VIS utility with Worldcraft's [VisGroups](#) (visible groups) feature.

Related Topics

- [Compiling the level](#)
- [Manually compiling the level](#)
- [File menu](#)

Texture Application (Shift+A)

Allows pixel-accurate placement of textures on any selected faces. Faces are the individual sides/facets of a solid and can be alter individually or as groups.

If the current view mode for the 3D window is 'textured polygons' the changes made in the face will happen dynamically in the 3D view allowing textures to be lined up very accurately with little effort.

Scale X Y

Will stretch the texture of the selected face(s) in the X and Y directions by the desired factor.

Shift X Y

Will offset the texture by the selected number of pixels. The arrows to the right of each box can be used to offset with the mouse LMB. The longer you hold the button, the faster the stepping will become.

Rotation

The rotational orientation of the texture on the face(s). The mouse can again be used to change rotation via the arrows to the right of the input box.

Texture group

Worldcraft allows you to use multiple WAD files (a WAD the textures) and this selector lets you choose to browse ALL textures, or just those from a selected WAD.

Current texture

The text field contains the name of the currently selected texture. Clicking the LMB on the button to the right presents a thin window containing all the textures (based on the selection in 'Texture group') from which you can select a new current texture.

The currently selected face(s) will not gain this texture - use Apply to do this. All solids made are created with whatever is the 'current texture' at the time.

Revert

Worldcraft, up to a point, remembers the previously selected texture, and 'revert' will make it the 'current texture' again.

Apply

Changing the 'current texture' will not instantly change the selected face(s) to use that texture. Click LMB on Apply to give the selected face(s) this new texture.

Browse

Present a full screen view of the available textures (based on the selection in 'Texture group') for friendly texture browsing. Double click the LMB to select a new texture.

At the very bottom/left hand corner of the window is a selector which changes the viewing of the textures:

1:1	each texture is viewed at its full size
32x32	each texture is zoomed into a 32x32 box
64x64	each texture is zoomed into a 64x64 box
128x128	each texture is given a 128x128 box although no scaling is done

Related Topics

- [Tools menu](#)

Options

For setting up Worldcraft. All paths can be typed in by hand or by using the Browse option.

Quake Location

This should point to your \quake directory (it may be something like c:\quake or c:\games\quake). This is used by the Run Map (F9) command.

Maps location

Select the directory you wish to do your work in. This can be any directory you wish and doesn't necessarily need to be in the Worldcraft or Quake directories.

WAD files

WAD files contain the texture maps for Quake levels. Worldcraft allows multiple WAD files to be used although by using this feature means that you must use the QBSP program supplied with Worldcraft and cannot use any of the other versions around. Add will let you add a new WAD file and Remove will delete the selected WAD from the list.

Texture brightness

This slider determines how bright the textures will appear in the 3D view of Worldcraft. It has no effect on the appearance of textures in Quake.

Display a crosshair under the cursor

With this option enabled, Worldcraft will draw a crosshair under the mouse cursor in the 2D views.

Default to 15 degree rotations

When rotating a solid, having this option on will mean it will snap to 15 degree moves. This snapping can be overridden by holding down the 'Alt' key while rotating.

If this option is off, rotation can still be snapped to 15 degree movements by holding down 'Shift' while rotating.

Display scrollbars

Turning this option off will remove the scrollbars from the editing windows. Movement can still be achieved even with this off by either clicking and dragging or using the cursor keys.

Draw Vertices

By default every corner (vertex) of a solid is drawn as a little dot. Turning this option off will remove the dots.

Hardware Acceleration

Some buggy 3D accelerators, such as the Diamond Stealth 3D and the Millennium, can cause problems for Worldcraft. If you find Worldcraft crashing consistently, try disabling this setting.

- [Frequently asked questions](#)
- [Tools menu](#)

Windows

All editing is performed in the window views which may be either 2D or 3D. These windows can be arranged to your preference by using either the 2D and 3D options in the View pulldown menu, or the corresponding tools on the 'MapView bar'. See the [View Menu](#) for further details on configuration.

Traversing Windows

Resizing of the windows is achieved by clicking and holding the LMB on the cross bars separating each view; if selected in a vertical or horizontal section, movement is constrained to Y/X movements respectively. Selecting the bars in the very center where they cross over allows free movement.

To get the windows back to default size, use the View|Autosize 4 Views menu tool (Ctrl+A).

The currently selected window can be expanded to full size by pressing the 'z' hotkey. Pressing 'z' again will shrink it to the original size.

If scroll bars are turned on (Tools|Options|2D views), the 2D windows can be scrolled around by clicking the LMB on the arrows, on the slider bar (for interactive scrolling), or in the space above/ below the slider. The arrow keys on the keyboard also perform the same operation.

Further details can be found in the section describing the [MapTools Bar](#).

Related Topics

- [Editing maps in three dimensions](#)

Object Manipulation

Manipulating objects, whether they be solids or entities, is the whole purpose of the windows and is designed to be intuitive in the Worldcraft interface.

Object manipulating only occurs on selected objects/groups. See Maptools Bar|Selection Tool for details on selecting objects. Selected object(s)/groups have a bounding box drawn around them (red line) in the 2D windows and are rendered as red in the 3D view. By clicking the LMB in the center of a selected object, the manipulation type changes with the bounding box style changing accordingly. The order of type is; move/resize, rotate, shear. Note that point entities can not be resized, rotated or sheared.

Move/Resize

The bounding box will initially be drawn in 'move/resize' mode which has solid black squares drawn at each corner of the bounding box and halfway along each side.

To move the box to a new location, click and hold the LMB inside the bounding box, but not at the edges. Then drag to a new location and release the mouse button. If grid snapping is on, the movement will be snapped to the bounding box although this can be overridden by holding down Alt while moving.

See Map|Snap To Grid for further details on grid snapping.

Resizing is achieved by clicking and holding the LMB on any of the black squares. Then by moving the mouse, the objects is scaled in the direction of movement. The same grid snapping rules apply as for movement.

Rotate

The bounding box will be shown with solid black circles at each corner. Clicking and holding the LMB on a dot, then dragging the mouse around will rotate the selected objects around their common bounding box center.

If Tools|Options|2D Views has the 'Default to 15 degree rotations' set, then all rotations will be snapped to 15 degree steps. This can be overridden by holding down Alt while moving. If that option is set to off, 15 degree snapping can still be achieved by holding down Shift while moving.

Shear

The bounding box will be shown with solid black squares at the mid point along each edge. Clicking and holding the LMB on a square, then dragging the mouse around will shear the object in the direction of the move. Grid snapping rules apply as with Move.

Menu

Clicking the RMB inside a selected object opens up a menu which echoes many of the same commands available in the pull down menu and the various buttons menus.

Related Topics

- [Selecting and adjusting solids](#)

Properties

The properties window is the center of all Quake activity. While good looking levels are certainly essential, it's careful use of entities that makes a level interesting/challenging to play, and that's what properties are all about.

In the properties window there can be up to 3 folders available depending on the type of object selected.

Class Info

This folder will be available if the object is an entity, or a group of solids tied to an entity. Here you can choose on entity types and what keys will be used by that entity.

Class

Class refers to the type of entity used. The selector can be opened by clicking in the text area or on the arrow to the right.

Member of Groups

The large area to the left lists all VisGroups for the current map, along with their status (status is defined by a tick). There are no VisGroups by default, so to use them you must create some.

By placing a tick next to a VisGroup, you are placing the currently selected object(s) into that group. There are no limits to the number of groups you can place each object into, so for example, a group of solids could belong to a group called 'Room1' as well as belonging to a group called 'doors'.

Every solid/entity/group created in Worldcraft has its own VisGroup settings which can be edited by the VisGroups window of the object 'properties'. The window can be opened by one of many ways: Edit|Properties menu, Alt+Enter hotkey, or RMB on a selected object in the 2D views. An object must be selected to use this window.

Related Topics

- [Editing an entity's properties](#)

The texture bar allows you to choose a texture for the next object you create. You can also apply the chosen texture to an existing object using the **paintbrush tool**.

The face properties window appears when you activate the texture application tool. It allows you to apply a texture to individual faces of a solid. It also allows you to manipulate the angle, scale, and offset of the texture on each face. Most editing tasks are not available in texture application mode; therefore, this window should be closed when you are done adjusting textures.

The object bar allows you to choose the type of solid or entity to create. Solids will be created within the bounding box that you specify; if the solid is a cylinder or spike, then you can specify the number of faces to be created using the righthand field. If any prefab libraries are defined, then they are also accessible through the object bar. Each prefab library is listed as a solid category, and each prefab in the current library is listed under "Objects".

To create a solid, use the [block tool](#); to create an entity, use the [Entity Tool](#).

The paintbrush tool will apply the texture shown on the texture bar to all objects that are currently selected.

The block toolbar button allows you to create new solids. Use the object toolbar to choose the type of solid and number of faces, then drag a bounding box into the desired shape in the 2D views. Press ENTER to create the solid.

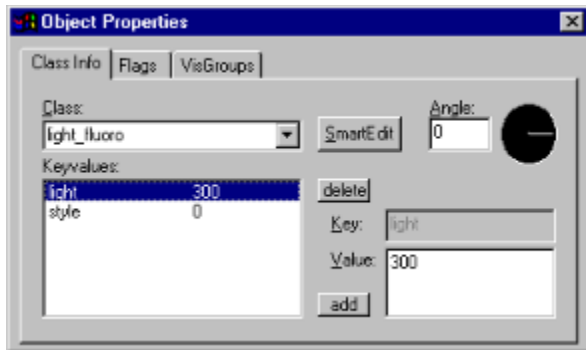

The camera toolbar button allows you to adjust the view seen in the 3D view window. Click and hold the right mouse button to move the camera's position left/right and up/down. Click and hold the left mouse button to rotate the view and to look up and down. Use the **D** and **C** keys to move the camera forward and backward. The camera's position can also be adjusted in the 2D views for a more precise viewpoint.

The texture application tool allows you to select individual faces of an object and specify the texture displayed on each face. The [face properties window](#) is visible whenever you are in texture application mode.

The selection tool allows you to [select](#) individual objects in any of the four views. To select more than one object, hold the Ctrl key down while selecting each object. Or, in the 2D views, drag out a bounding box that encloses all of the objects that you want to be selected.

Object Properties are accessed by selecting an object and then pressing Alt+Enter or choosing Edit|Properties. The first page contains the object's class, direction, and keyvalues; the second page contains the object's flags. Press the SmartEdit button for context-sensitive attribute fields. For further information, see Properties.

SmartEdit is enabled by clicking the SmartEdit button in the Object Properties dialog box. The default view presented each of the object's keyvalues in free-form fields; in the SmartEdit view, these attributes are instead presented in a context-sensitive interface which prohibits illegal values from being Entered.

The Flags page allows you to modify the flags for an object. It is located on the second page of the Object Properties dialog box.

A box in the 2D view is framed by nine **handles**. The handles allow you to adjust the size of the box in one or two directions at a time. Side handles allow the adjustment of a single edge; corner handles allow the adjustment of both edges that meet at that corner. Handles appear whenever an object has been [selected](#).

The Entity Tool allows you to create a new entity in your map. Types of entities include monsters, weapons, powerups, spawn points, sound and light sources. Creating an entity is similar to [creating a solid](#), but only one point needs to be specified. Once the entity has been created, you can modify its [properties](#) as desired.

The MapOperations bar gives you easy access to a number of object manipulation commands. From left to right, they are: carving, grouping/ungrouping, aligning, hiding/unhiding, cut/copy/paste, and Run Map.

The MapView bar allows you to adjust the way you view your map. The lefthand buttons allow you to choose which 2-dimensional view is shown in the active window. The center buttons allow you to choose what type of 3-dimensional view is visible. The rightmost button allows you to toggle the 2D gridlines on and off.

Face Properties

Scale:

X:

ties

Shift

X: 0

Y: 0

Rotation:

The Filter Control Window shows a list of all VisGroups that have been defined in this map. You can edit the VisGroup definitions (including adding and deleting VisGroups) by pressing the Edit Groups button. To enable VisGroup filtering, select the "Filter by VisGroups" checkbox.

VisGroups Filtering is enabled by selecting the "Filter by VisGroups" check box in the lower corner of the Filter Bar. When filtering is active, any VisGroups that are not checkmarked in the above list will be invisible. To change which VisGroups are visible, adjust the checkmarks as desired and then press the Apply button.

The carve button (leftmost button in this diagram) allows you to subtract the selected object from whatever objects it intersects. Essentially, the selected object acts as a cookie cutter, slicing the other objects with its surface. If the subtraction would produce a concave shape, then WC will replace the object with several smaller convex objects that produce the same shape. This is done because solids in Quake cannot be concave.

The Group and Ungroup buttons (center pair of buttons in this diagram) allow you to join the selected objects together so that they are manipulated as a single object, or to split apart the selected group of objects. A solid that is hollowed or carved may be split into several smaller objects that are grouped together.

The 3d view buttons allow you to choose what type of image will be seen in the 3D view. Choose the leftmost button for a **wireframe view**, in which only the edges of each object is drawn. Choose the center button for a **solid rendering view**, in which the faces of objects are rendered as flat surfaces. In these two views, objects will be colored according to the VisGroups that they belong to. Choose the rightmost button for **textured view**, in which the surfaces of objects are painted with the appropriate Quake textures. This view gives the most realistic view of the level, but may be slow to draw on some computers.

Worldcraft's 4 map views. Clockwise from top left: 3D view, top view, side view, front view.
