Compendium Deluxe #1 Text Manipulation Menu

1.1   Text Manipulation

```
Filename           ComandsSizeDescription
ansicln1.lha          VX    6K Ansi Clean V1.0 by Hydra/LSD - AnsiClean
                                is an executeable that does the work and
                                CleanAnsi is a script that uses LIST to
                                create a list of files from the current
                                directory and all subdirs of all .TXT
                                files and then runs AnsiClean on each of
                                them.
bbsadd10.lha          VX    8K BBSADD 1.0 by S.K.Lindsay aka Linds - This
                                will add a text file to another text file,
                                such as a BBS advert onto a textfile
                                uploaded to your BBS.
code4.lha             VX   12K Code 4.0 by Jan Lindström - Code
                                transforms Amiga ascii text to PC ascii
                                text or PC  ascii text to Amiga ascii text.
conv201.lha           VX  167K CONVERT 2.01 by Rainer Koppler - This is a
                                powerful file conversion program. It
                                covers the application domain of any ASCII
                                file  conversion tool between Amiga and
                                any other computer system. In addition to
                                that  "Convert" is freely configurable, so
                                that it can be used for any conversion
                                problem.
cv.lha                VX   83K CV/CVT by Tobias Ferber - CV is a
                                character set conversion package. It
                                includes CVT,  the main conversion utility
                                which takes the conversion rules from
                                ASCII script files. There are currently 26
                                example  scripts  including Amiga<->DOS,
                                Amiga<->Mac, Amiga <->TeX and many more.
                                These script files can be generated by CSC
                                - the CharSet Compiler.
etm.lha               VX    1K ETM - Elite Text Maker v0.99 by Xypo - ETM
                                modifies ordinary textfiles into
                                "elitetext files". Maybe there are some
                                "elite" guys  out there that are in need
                                of just a program like this?
fdiff.lha             VX    3K FDiff 1.0 by Nicolas Dade - This compares
```

```
                        2 text files on a line-by-line basis,
                        outputing to STDOUT the lines which
                        differ, with a "+ <line number> "
                        precceding lines  from the NEWFILE, and a
                        "- <line number> " preceeding lines from
                        the OLDFILE. FDiff requires KS2.04.
figlet.lha          VX  42K Amiga Figlet by Glenn Chappell - This
                        creates large characters out of ordinary
                        screen characters. Figlet can create
                        characters in many different styles and
                        can "smush" these characters together in
                        various ways. Figlet output is generally
                        reminiscent of the sort of "signatures"
                        many people like to put at the end of
                        e-mail messages.
guidegen.lha        VX  32K GuideGen by Justin Miller - This will
                        generate AmigaGuide databases. It allows
                        you to add and remove nodes, edit each
                        node's text, arrange the node's order, and
                        create buttons and link them to other
                        nodes, potentially in other files.
Heddley.lha         VX  50K Heddley 1.0 by Edd Dumbill - Heddley is an
                        editor to help you create AmigaGuide
                        files.  It has a good-looking Intuition
                        interface and a powerful ARexx port - two
                        things which set it apart from any similar
                        tool.
ilbm2ascii14.lha    VX  44K ILBM2ASCII 1.4 by Tobias Ferber - Converts
                        IFF pictures into an ASCII
                        representation.  The program will
                        antialiase the text by selecting the best
                        characters to make the edge.  Characters
                        are also selected for their density when
                        shading.
lsd-wrap.lha        VX  11K ReWrap 1.0 by Shagratt of LSD - This is a
                        Text file reformatter. It rebuilds
                        paragraphs, removes margins, puts a space
                        after a comma, puts 2 spaces after a full
                        stop, puts a capital letter after a full
                        stop, If the entire file is in upper case,
                        it converts it to lower case, removes all
                        control codes, etc.
psnap22.lha         VX  47K PowerSnap 2.2 by Nico Francois - This
                        allows you to use the mouse to mark
                        characters  anywhere on the screen and
                        paste them  somewhere else, like in the
                        CLI or in a  string gadget. PowerSnap will
                        check what  font is used in the window you
                        snap from and will look for the position
                        of the characters automatically.
qman101.lha         VX   8K QMan V1.01 by Torgeir Hovden - QMan is a
                        man-page launcher, like MAN (1993 Kai
                        Iske/ Gunthersoft). Having used MAN for a
                        while, I was getting tired of having to
                        keep all my  helpfiles in specific
                        directories. Maybe  there is other
                        approach to this problem? The solution may
```

```
                           be QMan.
raline20.lha          VX   48K RandomLine 2.0 by J.Schmitz - This inserts
                           a randomly selected line of a list of text
                           lines into any given ascii file. it is
                           designed for a typical FIDO-Tosser. If you
                           write a mail and start RandomLine after
                           that a special text could be added.
snap164.lha           VX   99K Snap 1.63 by Mikael Karlsson - Snap is the
                           perfect tool for the lazy typer. Isn't it
                           irritating when you look at something on
                           the screen and think: "That is what I'm
                           going to type."? What if you could just
                           point at it  and get the computer to type
                           it for you?  That's what Snap does!
sort1_23.lha          VX   18K sort 1.23 by Rüdiger Werner - The program
                           was written for use in Shell only.  It is
                           started either by simply typing it's name
                           (of course it should be in the current
                           directory or in the path) or by giving
                           additionally switches and/or the name of
                           the file what should be sorted.
text2200.lha          VX   14K Text 2 Guide 2.0 by Stephan Sürken - This
                           converts plain ASCII text into Amiga
TEXT2SCP.lha          VX    8K TXT2SCP by Don Lester - This is a small
                           update to ascii2scp which wouldn't
                           properly handle escape codes in the source
                           file.  After reading complaints on
                           Internet from  some people who didn't like
                           doing an ASCII send to upload their
                           signature files, I  decided to crank out
                           this little program.
ttr_1-3.lha           VX    5K Tagline Ripper 1.3 by James W Savage - TTR
                           rips those amusing (or not) little
                           comments from the bottom of messages. It
                           then puts  them in a single, easy to
                           manage, file that you can then keep, edit,
                           or just throw away. This utility is fully
                           intuition driven and  uses the ASL file
                           requester for simple file  location. Needs
                           KS2.
txtcvt.lha            VX   10K TxtCvt 1.0 by Njål Fisketjøn - Converts a
                           document created with one of the
                           following  PC programs to pure
                           ASCII-format text; Word 5.5 for DOS, Word
                           1.x for Windows, Word 2.0 for Windows and
                           Windows Write 3.1.
```
